Abstract

The Dakota (Design Analysis Kit for Optimization and Terascale Applications) toolkit provides a flexible and extensible interface between simulation codes and iterative analysis methods. Dakota contains algorithms for optimization with gradient and nongradient-based methods; uncertainty quantification with sampling, reliability, and stochastic expansion methods; parameter estimation with nonlinear least squares methods; and sensitivity/variance analysis with design of experiments and parameter study methods. These capabilities may be used on their own or as components within advanced strategies such as surrogate-based optimization, mixed integer nonlinear programming, or optimization under uncertainty. By employing object-oriented design to implement abstractions of the key components required for iterative systems analyses, the Dakota toolkit provides a flexible and extensible problem-solving environment for design and performance analysis of computational models on high performance computers.

This report serves as a reference manual for the commands specification for the Dakota software, providing input overviews, option descriptions, and example specifications.

Main Page

The Dakota (Design Analysis Kit for Optimization and Terascale Applications) toolkit provides a flexible, extensible interface between analysis codes and iteration methods.

Author

The Reference Manual documents all the input keywords that can appear in a Dakota input file to configure a Dakota study. Its organization closely mirrors the structure of dakota.input.summary. For more information see Dakota Input Specification. For information on software structure, refer to the Developers Manual [3], and for a tour of Dakota features and capabilities, including a tutorial, refer to the User’s Manual (Adams et al., 2010) [4].

1.1 How to Use this Manual

- To learn how to run Dakota from the command line, see Running Dakota
- To learn how to restart Dakota studies, see Restarting Dakota Studies
- To learn about the Dakota restart utility, see The Dakota Restart Utility

To find more information about a specific keyword

1. Use the search box at the top right (currently only finds keyword names)
2. Browse the Keywords tree on the left navigation pane
3. Look at the Dakota Input Specification
4. Navigate through the keyword pages, starting from the Keywords Area

To find more information about a Dakota related topic

1. Browse the Topics Area on the left navigation pane
2. Navigate through the topics pages, starting from the Topics Area

A small number of examples are included (see Sample Input Files) along with a description of the test problems (see Test Problems).

A bibliography for the Reference Manual is provided in Bibliographic References
Chapter 2

Running Dakota

The Dakota executable file is named dakota (dakota.exe on Windows) and is most commonly run from a terminal or command prompt.

2.1 Usage

If the dakota command is entered at the command prompt without any arguments, a usage message similar to the following appears:

```bash
usage: dakota [options and <args>]
  -help (Print this summary)
  -version (Print Dakota version number)
  -input <$val> (REQUIRED Dakota input file $val)
  -output <$val> (Redirect Dakota standard output to file $val)
  -error <$val> (Redirect Dakota standard error to file $val)
  -parser <$val> (Parsing technology: nidr[strict]:dumpfile)
  -no_input_echo (Do not echo Dakota input file)
  -check (Perform input checks)
  -pre_run [$val] (Perform pre-run (variables generation) phase)
  -run [$val] (Perform run (model evaluation) phase)
  -post_run [$val] (Perform post-run (final results) phase)
  -read_restart [$val] (Read an existing Dakota restart file $val)
  -stop_restart <$val> (Stop restart file processing at evaluation $val)
  -write_restart [$val] (Write a new Dakota restart file $val)
```

Of these command line options, only `input` is required, and the `-input` switch can be omitted if the input file name is the final item appearing on the command line (see Examples); all other command-line inputs are optional.

- `help` prints the usage message above.
- `version` prints version information for the executable.
- `check` invokes a dry-run mode in which the input file is processed and checked for errors, but the study is not performed.
- `input` provides the name of the Dakota input file.
- `output` and `error` options provide file names for redirection of the Dakota standard output (stdout) and standard error (stderr), respectively.
• The parser option is for debugging and will not be further described here.

• By default, Dakota will echo the input file to the output stream, but no_input_echo can override this behavior.

• read_restart and write_restart commands provide the names of restart databases to read from and write to, respectively.

• stop_restart command limits the number of function evaluations read from the restart database (the default is all the evaluations) for those cases in which some evaluations were erroneous or corrupted. Restart management is an important technique for retaining data from expensive engineering applications.

• -pre_run, -run, and -post_run instruct Dakota to run one or more execution phases, excluding others. The commands must be followed by filenames as described in Execution Phases.

Command line switches can be abbreviated so long as the abbreviation is unique, so the following are valid, unambiguous specifications: -h, -v, -c, -i, -o, -e, -s, -w, -re, -pr, -ru, and -po and can be used in place of the longer forms of the command line options.

For information on restarting Dakota, see Restarting Dakota Studies and The Dakota Restart Utility.

2.2 Examples

To run Dakota with a particular input file, the following syntax can be used:

    dakota -i dakota.in

or more simply

    dakota dakota.in

This will echo the standard output (stdout) and standard error (stderr) messages to the terminal. To redirect stdout and stderr to separate files, the -o and -e command line options may be used:

    dakota -i dakota.in -o dakota.out -e dakota.err

or

    dakota -o dakota.out -e dakota.err dakota.in

Alternatively, any of a variety of Unix redirection variants can be used. Refer to[?] for more information on Unix redirection. The simplest of these redirects stdout to another file:

    dakota dakota.in > dakota.out

2.3 Execution Phases

Dakota has three execution phases: pre-run, run, and post-run.

• pre-run can be used to generate variable sets

• run (core run) invokes the simulation to evaluate variables, producing responses

• post-run accepts variable/response sets and analyzes the results (for example, calculate correlations from a set of samples). Currently only two modes are supported and only for sampling, parameter study, and DACE methods:

  (1) pre-run only with optional tabular output of variables:

      dakota -i dakota.in -pre_run [::myvariables.dat]

  (2) post-run only with required tabular input of variables/responses:

      dakota -i dakota.in -post_run myvarsresponses.dat::
2.4 Restarting Dakota Studies

Dakota is often used to solve problems that require repeatedly running computationally expensive simulation codes. In some cases you may want to repeat an optimization study, but with a tighter final convergence tolerance. This would be costly if the entire optimization analysis had to be repeated. Interruptions imposed by computer usage policies, power outages, and system failures could also result in costly delays. However, Dakota automatically records the variable and response data from all function evaluations so that new executions of Dakota can pick up where previous executions left off. The Dakota restart file (dakota.rst by default) archives the tabulated interface evaluations in a binary format. The primary restart commands at the command line are -read_restart, -write_restart, and -stop_restart.

2.4.1 Writing Restart Files

To write a restart file using a particular name, the -write_restart command line input (may be abbreviated as -w) is used:

```
dakota -i dakota.in -write_restart my_restart_file
```

If no -write_restart specification is used, then Dakota will still write a restart file, but using the default name dakota.rst instead of a user-specified name.

To turn restart recording off, the user may use the restart_file keyword, in the interface block. This can increase execution speed and reduce disk storage requirements, but at the expense of a loss in the ability to recover and continue a run that terminates prematurely. This option is not recommended when function evaluations are costly or prone to failure. Please note that using the deactivate restart_file specification will result in a zero length restart file with the default name dakota.rst, which can overwrite an exiting file.

2.4.2 Using Restart Files

To restart Dakota from a restart file, the -read_restart command line input (may be abbreviated as -r) is used:

```
dakota -i dakota.in -read_restart my_restart_file
```

If no -read_restart specification is used, then Dakota will not read restart information from any file (i.e., the default is no restart processing).

To read in only a portion of a restart file, the -stop_restart control (may be abbreviated as -s) is used to specify the number of entries to be read from the database. Note that this integer value corresponds to the restart record processing counter (as can be seen when using the print utility (see The Dakota Restart Utility) which may differ from the evaluation numbers used in the previous run if, for example, any duplicates were detected (since these duplicates are not recorded in the restart file). In the case of a -stop_restart specification, it is usually desirable to specify a new restart file using -write_restart so as to remove the records of erroneous or corrupted function evaluations. For example, to read in the first 50 evaluations from dakota.rst:

```
dakota -i dakota.in -r dakota.rst -s 50 -w dakota_new.rst
```

The dakota_new.rst file will contain the 50 processed evaluations from dakota.rst as well as any new evaluations. All evaluations following the 50th in dakota.rst have been removed from the latest restart record.

2.4.3 Appending to a Restart File

If the -write_restart and -read_restart specifications identify the same file (including the case where -write_restart is not specified and -read_restart identifies dakota.rst), then new evaluations will be appended to the existing restart file.
2.4.4 Working with multiple Restart Files

If the \texttt{-write_restart} and \texttt{-read_restart} specifications identify different files, then the evaluations read from the file identified by \texttt{-read_restart} are first written to the \texttt{-write_restart} file. Any new evaluations are then appended to the \texttt{-write_restart} file. In this way, restart operations can be chained together indefinitely with the assurance that all of the relevant evaluations are present in the latest restart file.

2.4.5 How it Works

Dakota’s restart algorithm relies on its duplicate detection capabilities. Processing a restart file populates the list of function evaluations that have been performed. Then, when the study is restarted, it is started from the beginning (not a warm start) and many of the function evaluations requested by the iterator are intercepted by the duplicate detection code. This approach has the primary advantage of restoring the complete state of the iteration (including the ability to correctly detect subsequent duplicates) for all methods/iterators without the need for iterator-specific restart code. However, the possibility exists for numerical round-off error to cause a divergence between the evaluations performed in the previous and restarted studies. This has been rare in practice.

2.5 The Dakota Restart Utility

The Dakota restart utility program provides a variety of facilities for managing restart files from Dakota executions. The executable program name is \texttt{dakota_restart_util} and it has the following options, as shown by the usage message returned when executing the utility without any options:

```bash
Usage:
  dakota_restart_util command <arg1> [<arg2> <arg3> ...] --options
  dakota_restart_util print <restart_file>
  dakota_restart_util to_neutral <restart_file> <neutral_file>
  dakota_restart_util from_neutral <neutral_file> <restart_file>
  dakota_restart_util to_tabular <restart_file> <text_file> [--custom_annotated [header] [eval_id] [interface_id]]
  dakota_restart_util remove <double> <old_restart_file> <new_restart_file>
  dakota_restart_util remove_ids <int_1> ... <int_n> <old_restart_file> <new_restart_file>
  dakota_restart_util cat <restart_file_1> ... <restart_file_n> <new_restart_file>
```

Options:

--help: show dakota_restart_util help message
--custom_annotated arg tabular file options: header, eval_id, interface_id

Several of these functions involve format conversions. In particular, the binary format used for restart files can be converted to ASCII text and printed to the screen, converted to and from a neutral file format, or converted to a tabular format for importing into 3rd-party graphics programs. In addition, a restart file with corrupted data can be repaired by value or id, and multiple restart files can be combined to create a master database.

2.5.1 Print Command

The \texttt{print} option is useful to show contents of a restart file, since the binary format is not convenient for direct inspection. The restart data is printed in full precision, so that exact matching of points is possible for restarted runs or corrupted data removals. For example, the following command

```bash
dakota_restart_util print
dakota.rst
```

results in output similar to the following:

```
------------------------------------------
Restart record  1  (evaluation id  1):
------------------------------------------
Parameters:
    1.8000000000000000e+00 intake_dia
```

...<snip>...

Restart file processing completed: 11 evaluations retrieved.

### 2.5.2 Neutral File Format

A Dakota restart file can be converted to a neutral file format using a command like the following:

dakota_restart_util to_neutral dakota.rst dakota.neu

which results in a report similar to the following:

Writing neutral file dakota.neu
Restart file processing completed: 11 evaluations retrieved.

Similarly, a neutral file can be returned to binary format using a command like the following:

dakota_restart_util from_neutral dakota.neu dakota.rst

which results in a report similar to the following:

Reading neutral file dakota.neu
Writing new restart file dakota.rst
Neutral file processing completed: 11 evaluations retrieved.

The contents of the generated neutral file are similar to the following (from the first two records for the Cylinder example in [4]).

```
6 7 2 1.8000000000000000e+00 intake_dia 1.0000000000000000e+00 flatness 0 0 0 0
NULL 4 2 1 0 3 3 3 3 1 2 obj_fn nln_ineq_con_1 nln_ineq_con_2 nln_ineq_con_3
-2.4355973813420619e+00 -4.742848677140930e-01 -4.5000000000000001e+00
1.397114370299741e-01 -4.3644298963447897e-01 1.4999999999999999e-01
1.3855136437818300e-01 0.0000000000000000e+00 0.0000000000000000e+00
```
This format is not intended for direct viewing (print should be used for this purpose). Rather, the neutral file capability has been used in the past for managing portability of restart data across platforms (recent use of more portable binary formats has largely eliminated this need) or for advanced repair of restart records (in cases where the remove command was insufficient).

2.5.3 Tabular Format

Conversion of a binary restart file to a tabular format enables convenient import of this data into 3rd-party post-processing tools such as Matlab, TECplot, Excel, etc. This facility is nearly identical to the output activated by the tabular_data keyword in the Dakota input file specification, but with two important differences:

1. No function evaluations are suppressed as they are with tabular_data (i.e., any internal finite difference evaluations are included).
2. The conversion can be performed later, i.e., for Dakota runs executed previously.

An example command for converting a restart file to tabular format is:

dakota_restart_util to_tabular dakota.rst dakota.m

which results in a report similar to the following:

Writing tabular text file dakota.m
Restart file processing completed: 10 evaluations tabulated.

The contents of the generated tabular file are similar to the following (from the example in the Restart section of[4]). Note that while evaluations resulting from numerical derivative offsets would be reported (as described above), derivatives returned as part of the evaluations are not reported (since they do not readily fit within a compact tabular format):

%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 NO_ID 0.9 1.1 0.0002 0.26 0.76
2 NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 NO_ID 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
4 NO_ID 0.9 1.10011 0.0002004407265 0.259945 0.7602420121
...
2.5. THE DAKOTA RESTART UTILITY

For example, to recover Dakota 6.0 tabular format, which contained a header row, leading column with evaluation ID, but no interface ID:

```
dakota_restart_util to_tabular dakota.rst dakota.m --custom_annotated header eval_id
```

Resulting in

```
%eval_id   x1    x2    obj_fn   nln_ineq_con_1   nln_ineq_con_2
1        0.9    1.1    0.0002    0.26        0.76
2  0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3  0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...```

### 2.5.4 Concatenation of Multiple Restart Files

In some instances, it is useful to combine restart files into a single master function evaluation database. For example, when constructing a data fit surrogate model, data from previous studies can be pulled in and reused to create a combined data set for the surrogate fit. An example command for concatenating multiple restart files is:

```
dakota_restart_util cat dakota.rst.1 dakota.rst.2 dakota.rst.3 dakota.rst.all
```

which results in a report similar to the following:

```
Writing new restart file dakota.rst.all
dakota.rst.1 processing completed: 10 evaluations retrieved.
dakota.rst.2 processing completed: 110 evaluations retrieved.
dakota.rst.3 processing completed: 65 evaluations retrieved.
```

The `dakota.rst.all` database now contains 185 evaluations and can be read in for use in a subsequent Dakota study using the `-read_restart` option to the `dakota` executable.

### 2.5.5 Removal of Corrupted Data

On occasion, a simulation or computer system failure may cause a corruption of the Dakota restart file. For example, a simulation crash may result in failure of a post-processor to retrieve meaningful data. If 0’s (or other erroneous data) are returned from the user’s analysis driver, then this bad data will get recorded in the restart file. If there is a clear demarcation of where corruption initiated (typical in a process with feedback, such as gradient-based optimization), then use of the `-stop_restart` option for the `dakota` executable can be effective in continuing the study from the point immediately prior to the introduction of bad data. If, however, there are interspersed corruptions throughout the restart database (typical in a process without feedback, such as sampling), then the `remove` and `remove_ids` options of `dakota_restart_util` can be useful.

An example of the command syntax for the `remove` option is:

```
dakota_restart_util remove 2.e-04 dakota.rst dakota.rst.repaired
```

which results in a report similar to the following:

```
Writing new restart file dakota.rst.repaired
Restart repair completed: 65 evaluations retrieved, 2 removed, 63 saved.
```

where any evaluations in `dakota.rst` having an active response function value that matches `2.e-04` within machine precision are discarded when creating `dakota.rst.repaired`. An example of the command syntax for the `remove_ids` option is:

```
dakota_restart_util remove_ids 12 15 23 44 57 dakota.rst dakota.rst.repaired
```

which results in a report similar to the following:

```
Writing new restart file dakota.rst.repaired
Restart repair completed: 65 evaluations retrieved, 5 removed, 60 saved.
```
where evaluation ids 12, 15, 23, 44, and 57 have been discarded when creating \texttt{dakota.rst.repaired}. An important detail is that, unlike the \texttt{-stop_restart} option which operates on restart record numbers, the \texttt{remove_ids} option operates on evaluation ids. Thus, removal is not necessarily based on the order of appearance in the restart file. This distinction is important when removing restart records for a run that contained either asynchronous or duplicate evaluations, since the restart insertion order and evaluation ids may not correspond in these cases (asynchronous evaluations have ids assigned in the order of job creation but are inserted in the restart file in the order of job completion, and duplicate evaluations are not recorded which introduces offsets between evaluation id and record number). This can also be important if removing records from a concatenated restart file, since the same evaluation id could appear more than once. In this case, all evaluation records with ids matching the \texttt{remove_ids} list will be removed.

If neither of these removal options is sufficient to handle a particular restart repair need, then the fallback position is to resort to direct editing of a neutral file to perform the necessary modifications.
Chapter 3

Test Problems

This page contains additional information about two test problems that are used in Dakota examples throughout the Dakota manuals Textbook and Rosenbrock.

Many of these examples are also used as code verification tests. The examples are run periodically and the results are checked against known solutions. This ensures that the algorithms are correctly implemented.

Additional test problems are described in the User’s Manual.

3.1 Textbook

The two-variable version of the “textbook” test problem provides a nonlinearly constrained optimization test case. It is formulated as:

\[
\begin{align*}
\text{minimize} \quad & f = (x_1 - 1)^4 + (x_2 - 1)^4 \\
\text{subject to} \quad & g_1 = x_1^2 - \frac{x_2^2}{2} \leq 0 \\
& g_2 = x_2^2 - \frac{x_1^2}{2} \leq 0 \\
& 0.5 \leq x_1 \leq 5.8 \\
& -2.9 \leq x_2 \leq 2.9
\end{align*}
\]

Contours of this test problem are illustrated in the next two figures.
Figure 3.1: Contours of the textbook problem on the [-3,4] x [-3,4] domain. The feasible region lies at the intersection of the two constraints $g_1$ (solid) and $g_2$ (dashed).

Figure 3.2: Contours of the textbook problem zoomed into an area containing the constrained optimum point $(x_1, x_2) = (0.5, 0.5)$. The feasible region lies at the intersection of the two constraints $g_1$ (solid) and $g_2$ (dashed).

For the textbook test problem, the unconstrained minimum occurs at $(x_1, x_2) = (1, 1)$. However, the inclusion of the constraints moves the minimum to $(x_1, x_2) = (0.5, 0.5)$. Equation `textbookform` presents the 2-dimensional...
form of the textbook problem. An extended formulation is stated as

\[
\text{minimize } f = \sum_{i=1}^{n} (x_i - 1)^4 \\
\text{subject to } g_1 = x_1^2 - \frac{x_2}{2} \leq 0 \\
&g_2 = x_2^2 - \frac{x_1}{2} \leq 0 \\
&0.5 \leq x_1 \leq 5.8 \\
&-2.9 \leq x_2 \leq 2.9
\] (tbe)

where \(n\) is the number of design variables. The objective function is designed to accommodate an arbitrary number of design variables in order to allow flexible testing of a variety of data sets. Contour plots for the \(n = 2\) case have been shown previously.

For the optimization problem given in Equation tbe, the unconstrained solution (num\_nonlinear\_inequality\_constraints set to zero) for two design variables is:

\[
\begin{align*}
x_1 &= 1.0 \\
x_2 &= 1.0
\end{align*}
\]

with

\[
f^* = 0.0
\]

The solution for the optimization problem constrained by \(g_1\) (num\_nonlinear\_inequality\_constraints set to one) is:

\[
\begin{align*}
x_1 &= 0.763 \\
x_2 &= 1.16
\end{align*}
\]

with

\[
\begin{align*}
f^* &= 0.00388 \\
g_1^* &= 0.0 \text{ (active)}
\end{align*}
\]

The solution for the optimization problem constrained by \(g_1\) and \(g_2\) (num\_nonlinear\_inequality\_constraints set to two) is:

\[
\begin{align*}
x_1 &= 0.500 \\
x_2 &= 0.500
\end{align*}
\]

with

\[
\begin{align*}
f^* &= 0.125 \\
g_1^* &= 0.0 \text{ (active)} \\
g_2^* &= 0.0 \text{ (active)}
\end{align*}
\]

Note that as constraints are added, the design freedom is restricted (the additional constraints are active at the solution) and an increase in the optimal objective function is observed.
3.2 Rosenbrock

The Rosenbrock function\cite{34} is a well-known test problem for optimization algorithms. The standard formulation includes two design variables, and computes a single objective function. This problem can also be posed as a least-squares optimization problem with two residuals to be minimized because the objective function is the sum of squared terms.

**Standard Formulation**

The standard two-dimensional formulation can be stated as

\[
\text{minimize } f = 100(x_2 - x_1^2)^2 + (1 - x_1)^2 \tag{rosenstd}
\]

Surface and contour plots for this function are shown in the Dakota User’s Manual. The optimal solution is:

\[
x_1 = 1.0 \\
x_2 = 1.0
\]

with

\[
f^* = 0.0
\]

**A Least-Squares Optimization Formulation**

This test problem may also be used to exercise least-squares solution methods by recasting the standard problem formulation into:

\[
\text{minimize } f = (f_1)^2 + (f_2)^2 \tag{rosenls}
\]

where

\[
f_1 = 10(x_2 - x_1^2) \tag{rosenr1}
\]

and

\[
f_2 = 1 - x_1 \tag{rosenr2}
\]

are residual terms.

The included analysis driver can handle both formulations. In the Dakota/test directory, the rosengexecutable (compiled from Dakota_Source/test/rosenbrock.cpp) checks the number of response functions passed in the parameters file and returns either an objective function (as computed from Equation rosenstd) for use with optimization methods or two least squares terms (as computed from Equations rosenr1 -rosenr2 ) for use with least squares methods. Both cases support analytic gradients of the function set with respect to the design variables. See the User’s Manual for examples of both cases (search for Rosenbrock).
Chapter 4

Dakota Input Specification

4.1 Dakota NIDR

Valid Dakota input is dictated governed by the NIDR input specification file, dakota.input.nspec. This file is used by a code generator to create parsing system components that are compiled into Dakota. Therefore, dakota.input.nspec and its derived summary, dakota.input.summary, are the definitive source for input syntax, capability options, and optional and required capability sub-parameters for any given Dakota version.

Beginning users may find dakota.input.summary overwhelming or confusing and will likely derive more benefit from adapting example input files to a particular problem. Some examples can be found here: Sample Input Files. Advanced users can master the many input specification possibilities by understanding the structure of the input specification file.

4.2 Input Spec Overview

Refer to the dakota.input.summary file, in Input Spec Summary, for current input specifications.

- The summary describes every keyword including:
  - Whether it is required or optional
  - Whether it takes ARGUMENTS (always required) Additional notes about ARGUMENTS can be found here: Specifying Arguments.
  - Whether it has an ALIAS, or synonym
  - Which additional keywords can be specified to change its behavior
- Additional details and descriptions are described in Keywords Area
- For additional details on NIDR specification logic and rules, refer to[30] (Gay, 2008).

4.2.1 Common Specification Mistakes

Spelling mistakes and omission of required parameters are the most common errors. Some causes of errors are more obscure:

- Documentation of new capability sometimes lags its availability in source and executables, especially stable releases. When parsing errors occur that the documentation cannot explain, reference to the particular input specification used in building the executable, which is installed alongside the executable, will often resolve the errors.
If you want to compare results with those obtained using an earlier version of Dakota (prior to 4.1), your input file for the earlier version must use backslashes to indicate continuation lines for Dakota keywords. For example, rather than

```plaintext
# Comment about the following "responses" keyword...
responses,
  objective_functions = 1
# Comment within keyword "responses"
analytic_gradients
# Another comment within keyword "responses"
  no_hessians
```

you would need to write

```plaintext
# Comment about the following "responses" keyword...
responses, \ 
  objective_functions = 1 \ 
# Comment within keyword "responses" \ 
analytic_gradients \ 
# Another comment within keyword "responses" \ 
  no_hessians
```

with no white space (blanks or tabs) after the \ character.

In most cases, the NIDR system provides error messages that help the user isolate errors in Dakota input files.

### 4.2.2 Specifying Arguments

Some keywords, such as those providing bounds on variables, have an associated list of values or strings, referred to as arguments.

When the same value should be repeated several times in a row, you can use the notation \texttt{N*value} instead of repeating the value \texttt{N} times.

For example

```plaintext
lower_bounds -2.0 -2.0 -2.0
upper_bounds 2.0 2.0 2.0
```

could also be written

```plaintext
lower_bounds 3*-2.0
upper_bounds 3* 2.0
```

(with optional spaces around the *).

Another possible abbreviation is for sequences: \texttt{L:S:U} (with optional spaces around the : ) is expanded to \texttt{L:L+S:L+2*S ... U}, and \texttt{L:U} (with no second colon) is treated as \texttt{L:1:U}.

For example, in one of the test examples distributed with Dakota (test case 2 of \texttt{test/dakota_uq_textbook_sop_lhs.in}),

```plaintext
histogram_point = 2
  abscissas = 50. 60. 70. 80. 90.
  30. 40. 50. 60. 70.
  counts = 10 20 30 20 10
  10 20 30 20 10
```

could also be written

```plaintext
histogram_point = 2
  abscissas = 50 : 10 : 90
  30 : 10 : 70
  counts = 10:10:30 20 10
  10:10:30 20 10
```
4.3 SAMPLE INPUT FILES

Count and sequence abbreviations can be used together. For example

```
response_levels =
0.0  0.1  0.2  0.3  0.4  0.5  0.6  0.7  0.8  0.9  1.0
0.0  0.1  0.2  0.3  0.4  0.5  0.6  0.7  0.8  0.9  1.0
```
can be abbreviated

```
response_levels =
2*0.0:0.1:1.0
```

4.3 Sample Input Files

A Dakota input file is a collection of fields from the dakota.input.summary file that describe the problem to be solved by Dakota. Several examples follow.

Sample 1: Optimization

The following sample input file shows single-method optimization of the Textbook Example (see Textbook) using DOT’s modified method of feasible directions. A similar file is available as Dakota/examples/users/textbook_opt_conmin.in.

```plaintext
# Dakota Input File: textbook_opt_conmin.in
environment
  graphics
  tabular_data
    tabular_data_file = 'textbook_opt_conmin.dat'
method
  # dot_mmfd #DOT performs better but may not be available
  conmin_mfd
    max_iterations = 50
    convergence_tolerance = 1e-4
variables
  continuous_design = 2
  initial_point 0.9 1.1
  upper_bounds 5.8 2.9
  lower_bounds 0.5 -2.9
  descriptors 'x1' 'x2'
interface
direct
  analysis_driver = 'text_book'
responses
  objective_functions = 1
  nonlinear_inequality_constraints = 2
  numerical_gradients
    method_source dakota
    interval_type central
    fd_gradient_step_size = 1.e-4
  no_hessians
```

Sample 2: Least Squares (Calibration)

The following sample input file shows a nonlinear least squares (calibration) solution of the Rosenbrock Example (see Rosenbrock) using the NL2SOL method. A similar file is available as Dakota/examples/users/rosen_opt_nls.in

```plaintext
# Dakota Input File: rosen_opt_nls.in
environment
```
Sample 3: Nondeterministic Analysis

The following sample input file shows Latin Hypercube Monte Carlo sampling using the Textbook Example (see Textbook). A similar file is available as Dakota/test/dakota_uq_textbook_lhs.in.
4.3. SAMPLE INPUT FILES

counts = 1 1
descriptors = 'TF3h'

interface,
   fork asynch evaluation_concurrency = 5
   analysis_driver = 'text_book'

responses,
   response_functions = 3
   no_gradients
   no_hessians

Sample 4: Parameter Study
The following sample input file shows a 1-D vector parameter study using the Textbook Example (see Textbook). It makes use of the default environment and model specifications, so they can be omitted. A similar file is available in the test directory as Dakota/examples/users/rosen_ps_vector.in.

# Dakota Input File: rosen_ps_vector.in
environment
   graphics
      tabular_data
         tabular_data_file = 'rosen_ps_vector.dat'

method
   vector_parameter_study
      final_point = 1.1 1.3
      num_steps = 10

variables
   continuous_design = 2
      initial_point -0.3 0.2
      descriptors 'x1' "x2"

interface
   analysis_driver = 'rosenbrock'
      direct

responses
   objective_functions = 1
   no_gradients
   no_hessians

Sample 5: Hybrid Strategy
The following sample input file shows a hybrid environment using three methods. It employs a genetic algorithm, pattern search, and full Newton gradient-based optimization in succession to solve the Textbook Example (see Textbook). A similar file is available as Dakota/examples/users/textbook_hybrid_strat.in.

environment
   graphics
      hybrid sequential
         method_list = 'PS' 'PS2' 'NLP'

method
   id_method = 'PS'
   model_pointer = 'M1'
   coliny_pattern_search stochastic
      seed = 1234
      initial_delta = 0.1
      threshold_delta = 1.e-4
      solution_accuracy = 1.e-10

interface_pointer = 'I1'
responses_pointer = 'R2'

variables
id_variables = 'V1'
continuous_design = 2
initial_point 0.6 0.7
upper_bounds 5.8 2.9
lower_bounds 0.5 -2.9
descriptors 'x1' 'x2'

interface
id_interface = 'I1'
direct
analysis_driver = 'text_book'

responses
id_responses = 'R1'
objective_functions = 1
no_gradients
no_hessians

responses
id_responses = 'R2'
objective_functions = 1
analytic_gradients
analytic_hessians
Additional example input files, as well as the corresponding output and graphics, are provided in the Tutorial chapter of the Users Manual [4] (Adams et al., 2010).

4.4 Input Spec Summary

This file is derived automatically from dakota.input.nspec, which is used in the generation of parser system files that are compiled into the Dakota executable. Therefore, these files are the definitive source for input syntax, capability options, and associated data inputs. Refer to the Developers Manual information on how to modify the input specification and propagate the changes through the parsing system.

Key features of the input specification and the associated user input files include:

- In the input specification, required individual specifications simply appear, optional individual and group specifications are enclosed in [], required group specifications are enclosed in (), and either-or relationships are denoted by the | symbol. These symbols only appear in dakota.input.nspec; they must not appear in actual user input files.

- Keyword specifications (i.e., environment, method, model, variables, interface, and responses) begin with the keyword possibly preceded by white space (blanks, tabs, and newlines) both in the input specifications and in user input files. For readability, keyword specifications may be spread across several lines. Earlier versions of Dakota (prior to 4.1) required a backslash character (\) at the ends of intermediate lines of a keyword. While such backslashes are still accepted, they are no longer required.

- Some of the keyword components within the input specification indicate that the user must supply INTEGER, REAL, STRING, INTEGERLIST, REALLIST, or STRINGLIST data as part of the specification. In a user input file, the "=" is optional, data in a LIST can be separated by commas or whitespace, and the STRING data are enclosed in single or double quotes (e.g., 'text_book' or "text_book").

- In user input files, input is largely order-independent (except for entries in lists of data), case insensitive, and white-space insensitive. Although the order of input shown in the Sample Input Files generally follows the order of options in the input specification, this is not required.

- In user input files, specifications may be abbreviated so long as the abbreviation is unique. For example, the npsol_sqp specification within the method keyword could be abbreviated as npsol, but dot_sqp should not be abbreviated as dot since this would be ambiguous with other DOT method specifications.

- In both the input specification and user input files, comments are preceded by #.

- ALIAS refers to synonymous keywords, which often exist for backwards compatibility. Users are encouraged to use the most current keyword.

5.2 dakota_IO

Description
Keywords and Concepts relating inputs to Dakota and outputs from Dakota

Related Topics

• dakota_inputs
• dakota_output
• file_formats

Related Keywords

• error_file : Base filename for error redirection
• output_file : Base filename for output redirection
• input : Base filename for post-run mode data input
5.2. DAKOTA_INPUT

- output: Base filename for post-run mode data output
- input: Base filename for pre-run mode data input
- output: Base filename for pre-run mode data output
- read_restart: Base filename for restart file read
- stop_restart: Evaluation ID number at which to stop reading restart file
- input: Base filename for run mode data input
- output: Base filename for run mode data output
- write_restart: Base filename for restart file write

5.2.1 dakota_inputs

Description
empty

Related Topics
- block
- data_import_capabilities

Related Keywords

5.2.2 block

Description
A block is the highest level of keyword organization in Dakota. There are currently 6 blocks in the Dakota input spec:

Related Topics
- block_identifier
- block_pointer

Related Keywords
- environment: Top-level settings for Dakota execution
- interface: Specifies how function evaluations will be performed in order to map the variables into the responses.
- model: Specifies how variables are mapped into a set of responses
- responses: Description of the model output data returned to Dakota upon evaluation of an interface.
- variables: Specifies the parameter set to be iterated by a particular method.
**block_identifier**

**Description**

empty

**Related Topics**

**Related Keywords**

- **id_interface**: Name the interface block; helpful when there are multiple
- **id_method**: Name the method block; helpful when there are multiple
- **id_model**: Give the model block an identifying name, in case of multiple model blocks
- **id_responses**: Name the response block, helpful when there are multiple

**block_pointer**

**Description**

See **block_pointer** for details about pointers.

**Related Topics**

**Related Keywords**

- **top_method_pointer**: Identify which method leads the Dakota study
- **model_pointer**: Identifier for model block to be used by a method
- **model_pointer**: Identifier for model block to be used by a method
- **model_pointer**: Identifier for model block to be used by a method
- **model_pointer**: Identifier for model block to be used by a method
- **model_pointer**: Identifier for model block to be used by a method
- **model_pointer**: Identifier for model block to be used by a method
- **model_pointer**: Identifier for model block to be used by a method
- **model_pointer**: Identifier for model block to be used by a method
- **model_pointer**: Identifier for model block to be used by a method
- **model_pointer**: Identifier for model block to be used by a method
- **model_pointer**: Identifier for model block to be used by a method
5.2. DAKOTA_IO

- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer_list`: Associate models with method names
- `method_pointer_list`: Pointers to methods to execute sequentially or collaboratively
- `global_model_pointer`: Pointer to model used by global method
- `global_method_pointer`: Pointer to global method
- `local_model_pointer`: Pointer to model used by local method
- `local_method_pointer`: Pointer to local method
- `model_pointer_list`: Associate models with method names
- `method_pointer_list`: Pointers to methods to execute sequentially or collaboratively
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
• `model_pointer` : Identifier for model block to be used by a method
• `model_pointer` : Identifier for model block to be used by a method
• `model_pointer` : Identifier for model block to be used by a method
• `method_pointer` : Pointer to sub-method to run from each starting point
• `model_pointer` : Identifier for model block to be used by a method
• `model_pointer` : Identifier for model block to be used by a method
• `model_pointer` : Identifier for model block to be used by a method
• `model_pointer` : Identifier for model block to be used by a method
• `method_pointer` : Pointer to optimization or least-squares sub-method
• `model_pointer` : Identifier for model block to be used by a method
• `model_pointer` : Identifier for model block to be used by a method
• `model_pointer` : Identifier for model block to be used by a method
• `model_pointer` : Identifier for model block to be used by a method
• `model_pointer` : Pointer to sub-method to apply to surrogate
• `model_pointer` : Identifier for model block to be used by a method
• `method_pointer` : Pointer to sub-method to apply to surrogate
5.2. **DAKOTA_IO**

- **model_pointer** : Identifier for model block to be used by a method
- **model_pointer** : Identifier for model block to be used by a method
- **optional_interface_pointer** : Pointer to interface that provides non-nested responses
- **optional_interface_responses_pointer** : Pointer to responses block that defines non-nested responses
- **sub_method_pointer** : The `sub_method_pointer` specifies the method block for the sub-iterator
- **responses_pointer** : Specify which responses block will be used by this model block
- **interface_pointer** : Interface block pointer for the single model type
- **dace_method_pointer** : Specify a method to gather training data
- **high_fidelity_model_pointer** : Pointer to high fidelity model
- **low_fidelity_model_pointer** : Pointer to low fidelity model
- **actual_model_pointer** : Pointer to specify a "truth" model, from which to construct a surrogate
- **actual_model_pointer** : Pointer to specify a "truth" model, from which to construct a surrogate
- **variables_pointer** : Specify which variables block will be included with this model block
- **id_variables** : Name the variables block; helpful when there are multiple

### 5.2.3 data_import_capabilities

**Description**

empty

**Related Topics**

**Related Keywords**

### 5.2.4 dakota_output

**Description**

empty

**Related Topics**

**Related Keywords**

- **graphics** : Display a 2D graphics window of variables and responses
- **output_precision** : Control the output precision
- **results_output** : (Experimental) Write a summary file containing the final results
- **results_output_file** : The base file name of the results file
- **tabular_data** : Write a tabular results file with variable and response history
- **tabular_data_file** : File name for tabular data output
- **output** : Control how much method information is written to the screen and output file

### 5.2.5 file_formats

**Description**

See sections "Inputs to Dakota" and "Outputs from Dakota" in the Dakota User's Manual[4].

**Related Topics**

**Related Keywords**

- **annotated** : Selects annotated tabular file format
- **custom_annotated** : Selects custom-annotated tabular file format
- **freeform** : Selects freeform file format
- **annotated** : Selects annotated tabular file format
- **custom_annotated** : Selects custom-annotated tabular file format
- **freeform** : Selects freeform file format
- **annotated** : Selects annotated tabular file format
- **custom_annotated** : Selects custom-annotated tabular file format
- **freeform** : Selects freeform file format
- **aprepro** : Write parameters files in APREPRO syntax
- **aprepro** : Write parameters files in APREPRO syntax
- **annotated** : Selects annotated tabular file format
- **custom_annotated** : Selects custom-annotated tabular file format
- **freeform** : Selects freeform file format
- **active_only** : Import only active variables from tabular data file
- **annotated** : Selects annotated tabular file format
- **custom_annotated** : Selects custom-annotated tabular file format
- **freeform** : Selects freeform file format
- **annotated** : Selects annotated tabular file format
- **custom_annotated** : Selects custom-annotated tabular file format
- **freeform** : Selects freeform file format
- **active_only** : Import only active variables from tabular data file
• **annotated**: Selects annotated tabular file format
• **custom.annotated**: Selects custom-annotated tabular file format
• **freeform**: Selects freeform file format
• **annotated**: Selects annotated tabular file format
• **custom.annotated**: Selects custom-annotated tabular file format
• **freeform**: Selects freeform file format
• **active_only**: Import only active variables from tabular data file
• **annotated**: Selects annotated tabular file format
• **custom.annotated**: Selects custom-annotated tabular file format
• **freeform**: Selects freeform file format
• **active_only**: Import only active variables from tabular data file
• **annotated**: Selects annotated tabular file format
• **custom.annotated**: Selects custom-annotated tabular file format
• **freeform**: Selects freeform file format
• **active_only**: Import only active variables from tabular data file
• **annotated**: Selects annotated tabular file format
• **custom.annotated**: Selects custom-annotated tabular file format
• **freeform**: Selects freeform file format
• **active_only**: Import only active variables from tabular data file
• **annotated**: Selects annotated tabular file format
• **custom.annotated**: Selects custom-annotated tabular file format
• **freeform**: Selects freeform file format
• **active_only**: Import only active variables from tabular data file
• **annotated**: Selects annotated tabular file format
• **custom.annotated**: Selects custom-annotated tabular file format
• **freeform**: Selects freeform file format
• **active_only**: Import only active variables from tabular data file
• **annotated**: Selects annotated tabular file format
• **custom.annotated**: Selects custom-annotated tabular file format
• **freeform**: Selects freeform file format
• **active_only**: Import only active variables from tabular data file
• **annotated**: Selects annotated tabular file format
• **custom.annotated**: Selects custom-annotated tabular file format
• **freeform**: Selects freeform file format
• **active_only**: Import only active variables from tabular data file
• **annotated**: Selects annotated tabular file format
• **custom.annotated**: Selects custom-annotated tabular file format
• **freeform**: Selects freeform file format
• **freeform** : Selects freeform file format
• **annotated** : Selects annotated tabular file format
• **custom_annotated** : Selects custom-annotated tabular file format
• **freeform** : Selects freeform file format
• **active_only** : Import only active variables from tabular data file
• **annotated** : Selects annotated tabular file format
• **custom_annotated** : Selects custom-annotated tabular file format
• **freeform** : Selects freeform file format
• **annotated** : Selects annotated tabular file format
• **custom_annotated** : Selects custom-annotated tabular file format
• **freeform** : Selects freeform file format
• **active_only** : Import only active variables from tabular data file
• **annotated** : Selects annotated tabular file format
• **custom_annotated** : Selects custom-annotated tabular file format
• **freeform** : Selects freeform file format
• **annotated** : Selects annotated tabular file format
• **custom_annotated** : Selects custom-annotated tabular file format
• **freeform** : Selects freeform file format
• **active_only** : Import only active variables from tabular data file
• **annotated** : Selects annotated tabular file format
• **custom_annotated** : Selects custom-annotated tabular file format
• **freeform** : Selects freeform file format
5.2. DAKOTA_IO

- custom_annotated: Selects custom-annotated tabular file format
- freeform: Selects freeform file format
- active_only: Import only active variables from tabular data file
- annotated: Selects annotated tabular file format
- custom_annotated: Selects custom-annotated tabular file format
- freeform: Selects freeform file format
- active_only: Import only active variables from tabular data file
- annotated: Selects annotated tabular file format
- custom_annotated: Selects custom-annotated tabular file format
- freeform: Selects freeform file format
- annotated: Selects annotated tabular file format
- custom_annotated: Selects custom-annotated tabular file format
- freeform: Selects freeform file format
- active_only: Import only active variables from tabular data file
- annotated: Selects annotated tabular file format
- custom_annotated: Selects custom-annotated tabular file format
- freeform: Selects freeform file format
- annotated: Selects annotated tabular file format
- custom_annotated: Selects custom-annotated tabular file format
- freeform: Selects freeform file format
- active_only: Import only active variables from tabular data file
- annotated: Selects annotated tabular file format
- custom_annotated: Selects custom-annotated tabular file format
- freeform: Selects freeform file format
- annotated: Selects annotated tabular file format
- custom_annotated: Selects custom-annotated tabular file format
- freeform: Selects freeform file format
- active_only: Import only active variables from tabular data file
- annotated: Selects annotated tabular file format
- custom_annotated: Selects custom-annotated tabular file format
- freeform: Selects freeform file format
- annotated: Selects annotated tabular file format
- custom_annotated: Selects custom-annotated tabular file format
• freeform : Selects freeform file format
• active_only : Import only active variables from tabular data file
• annotated : Selects annotated tabular file format
• custom_annotated : Selects custom-annotated tabular file format
• freeform : Selects freeform file format
• annotated : Selects annotated tabular file format for experiment data
• custom_annotated : Selects custom-annotated tabular file format for experiment data
• freeform : Selects free-form tabular file format for experiment data
• annotated : Selects annotated tabular file format for experiment data
• custom_annotated : Selects custom-annotated tabular file format for experiment data

5.3  dakota_concepts

Description
Miscellaneous concepts related to Dakota operation

Related Topics
• method_independent_controls
• block
• strategies
• command_line_options
• restarts
• pointers

Related Keywords
5.3.1  method_independent_controls

Description
The <method_independent_controls> are those controls which are valid for a variety of methods. In some cases, these controls are abstractions which may have slightly different implementations from one method to the next. While each of these controls is not valid for every method, the controls are valid for enough methods that it was reasonable to consolidate the specifications.

Related Topics
• linear_constraints
5.3. **DAKOTA CONCEPTS**

**Related Keywords**
- `constraint_tolerance` : The maximum allowable value of constraint violation still considered to be feasible
- `convergence_tolerance` : Stopping criterion based on convergence of the objective function
- `final_solutions` : Number of designs returned as the best solutions
- `id_method` : Name the method block; helpful when there are multiple
- `max_function_evaluations` : Stopping criteria based on number of function evaluations
- `max_iterations` : Stopping criteria based on number of iterations
- `output` : Control how much method information is written to the screen and output file
- `scaling` : Turn on scaling for variables, responses, and constraints
- `speculative` : Compute speculative gradients

**5.3.2 linear constraints**

**Description**
Many methods use linear equality or inequality constraints.

**Related Topics**

**Related Keywords**
- `linear_equality_constraint_matrix` : Define coefficients of the linear equalities
- `linear_equality_scale_types` : Specify how each linear equality constraint is scaled
- `linear_equality_scales` : Define the characteristic values to scale linear equalities
- `linear_equality_targets` : Define target values for the linear equality constraints
- `linear_inequality_constraint_matrix` : Define coefficients of the linear inequality constraints
- `linear_inequality_lower_bounds` : Define lower bounds for the linear inequality constraint
- `linear_inequality_scale_types` : Specify how each linear inequality constraint is scaled
- `linear_inequality_scales` : Define the characteristic values to scale linear inequalities
- `linear_inequality_upper_bounds` : Define upper bounds for the linear inequality constraint
- `linear_equality_constraint_matrix` : Define coefficients of the linear equalities
- `linear_equality_scale_types` : Specify how each linear equality constraint is scaled
- `linear_equality_scales` : Define the characteristic values to scale linear equalities
- `linear_equality_targets` : Define target values for the linear equality constraints
- `linear_inequality_constraint_matrix` : Define coefficients of the linear inequality constraints
• **linear_inequality_lower_bounds**: Define lower bounds for the linear inequality constraint
• **linear_inequality_scale_types**: Specify how each linear inequality constraint is scaled
• **linear_inequality_scales**: Define the characteristic values to scale linear inequalities
• **linear_inequality_upper_bounds**: Define upper bounds for the linear inequality constraint
• **linear_equality_constraint_matrix**: Define coefficients of the linear equalities
• **linear_equality_scale_types**: Specify how each linear equality constraint is scaled
• **linear_equality_scales**: Define the characteristic values to scale linear equalities
• **linear_equality_targets**: Define target values for the linear equality constraints
• **linear_inequality_constraint_matrix**: Define coefficients of the linear inequality constraints
• **linear_inequality_lower_bounds**: Define lower bounds for the linear inequality constraint
• **linear_inequality_scale_types**: Specify how each linear inequality constraint is scaled
• **linear_inequality_scales**: Define the characteristic values to scale linear inequalities
• **linear_inequality_upper_bounds**: Define upper bounds for the linear inequality constraint
• **linear_equality_constraint_matrix**: Define coefficients of the linear equalities
• **linear_equality_scale_types**: Specify how each linear equality constraint is scaled
• **linear_equality_scales**: Define the characteristic values to scale linear equalities
• **linear_equality_targets**: Define target values for the linear equality constraints
5.3. DAKOTA_CONCEPTS

- linear_inequality_upper_bounds : Define upper bounds for the linear inequality constraint
- linear_equality_constraint_matrix : Define coefficients of the linear equalities
- linear_equality_scale_types : Specify how each linear equality constraint is scaled
- linear_equality_scales : Define the characteristic values to scale linear equalities
- linear_equality_targets : Define target values for the linear equality constraints
- linear_inequality_constraint_matrix : Define coefficients of the linear inequality constraints
- linear_inequality_lower_bounds : Define lower bounds for the linear inequality constraint
- linear_inequality_scale_types : Specify how each linear inequality constraint is scaled
- linear_inequality_scales : Define the characteristic values to scale linear inequalities
- linear_inequality_targets : Define target values for the linear inequality constraints
- linear_inequality_constraint_matrix : Define coefficients of the linear inequality constraints
- linear_inequality_lower_bounds : Define lower bounds for the linear inequality constraint
- linear_inequality_scale_types : Specify how each linear inequality constraint is scaled
- linear_inequality_scales : Define the characteristic values to scale linear inequalities
- linear_inequality_targets : Define target values for the linear inequality constraints
- linear_inequality_constraint_matrix : Define coefficients of the linear inequality constraints
- linear_inequality_lower_bounds : Define lower bounds for the linear inequality constraint
- linear_inequality_scale_types : Specify how each linear inequality constraint is scaled
- linear_inequality_scales : Define the characteristic values to scale linear inequalities
- linear_inequality_targets : Define target values for the linear inequality constraints
- linear_inequality_constraint_matrix : Define coefficients of the linear inequality constraints
- linear_inequality_lower_bounds : Define lower bounds for the linear inequality constraint
- linear_inequality_scale_types : Specify how each linear inequality constraint is scaled
- linear_inequality_scales : Define the characteristic values to scale linear inequalities
- linear_inequality_targets : Define target values for the linear inequality constraints
- linear_inequality_constraint_matrix : Define coefficients of the linear inequality constraints
- linear_inequality_lower_bounds : Define lower bounds for the linear inequality constraint
- linear_inequality_scale_types : Specify how each linear inequality constraint is scaled
- linear_inequality_scales : Define the characteristic values to scale linear inequalities
- linear_inequality_targets : Define target values for the linear inequality constraints
- linear_inequality_constraint_matrix : Define coefficients of the linear inequality constraints
- linear_inequality_lower_bounds : Define lower bounds for the linear inequality constraint
- linear_inequality_scale_types : Specify how each linear inequality constraint is scaled
- linear_inequality_scales : Define the characteristic values to scale linear inequalities
- linear_inequality_targets : Define target values for the linear inequality constraints
- linear_equation_scales : Define the characteristic values to scale linear equalities
- linear_equation_targets : Define target values for the linear equality constraints
- linear_inequality_constraint_matrix : Define coefficients of the linear inequality constraints
- linear_inequality_lower_bounds : Define lower bounds for the linear inequality constraint
- linear_inequality_scale_types : Specify how each linear inequality constraint is scaled
- linear_inequality_scales : Define the characteristic values to scale linear inequalities
- linear_inequality_upper_bounds : Define upper bounds for the linear inequality constraint
- linear_equation_constraint_matrix : Define coefficients of the linear equalities
- linear_equation_scale_types : Specify how each linear equality constraint is scaled
- linear_equation_scales : Define the characteristic values to scale linear equalities
- linear_equation_targets : Define target values for the linear equality constraints
- linear_inequality_constraint_matrix : Define coefficients of the linear inequality constraints
- linear_inequality_lower_bounds : Define lower bounds for the linear inequality constraint
- linear_inequality_scale_types : Specify how each linear inequality constraint is scaled
- linear_inequality_scales : Define the characteristic values to scale linear inequalities
- linear_inequality_upper_bounds : Define upper bounds for the linear inequality constraint
- linear_equation_constraint_matrix : Define coefficients of the linear equalities
- linear_equation_scale_types : Specify how each linear equality constraint is scaled
- linear_equation_scales : Define the characteristic values to scale linear equalities
- linear_equation_targets : Define target values for the linear equality constraints
- linear_inequality_constraint_matrix : Define coefficients of the linear inequality constraints
• **linear_inequality_lower_bounds** : Define lower bounds for the linear inequality constraint
• **linear_inequality_scale_types** : Specify how each linear inequality constraint is scaled
• **linear_inequality_scales** : Define the characteristic values to scale linear inequalities
• **linear_inequality_upper_bounds** : Define upper bounds for the linear inequality constraint
• **linear_equality_constraint_matrix** : Define coefficients of the linear equalities
• **linear_equality_scale_types** : Specify how each linear equality constraint is scaled
• **linear_equality_scales** : Define the characteristic values to scale linear equalities
• **linear_equality_targets** : Define target values for the linear equality constraints
• **linear_inequality_constraint_matrix** : Define coefficients of the linear inequality constraints
• **linear_inequality_lower_bounds** : Define lower bounds for the linear inequality constraint
• **linear_inequality_scale_types** : Specify how each linear inequality constraint is scaled
• **linear_inequality_scales** : Define the characteristic values to scale linear inequalities
• **linear_inequality_upper_bounds** : Define upper bounds for the linear inequality constraint
• **linear_equality_constraint_matrix** : Define coefficients of the linear equalities
• **linear_equality_scale_types** : Specify how each linear equality constraint is scaled
• **linear_equality_scales** : Define the characteristic values to scale linear equalities
• **linear_equality_targets** : Define target values for the linear equality constraints
• **linear_inequality_constraint_matrix** : Define coefficients of the linear inequality constraints
• **linear_inequality_lower_bounds** : Define lower bounds for the linear inequality constraint
• **linear_inequality_scale_types** : Specify how each linear inequality constraint is scaled
• **linear_inequality_scales** : Define the characteristic values to scale linear inequalities

5.3. \textit{DAKOTA} \textit{CONCEPTS}

- \texttt{linear\_equality\_scales} : Define the characteristic values to scale linear equalities
- \texttt{linear\_equality\_targets} : Define target values for the linear equality constraints
- \texttt{linear\_inequality\_constraint\_matrix} : Define coefficients of the linear inequality constraints
- \texttt{linear\_inequality\_lower\_bounds} : Define lower bounds for the linear inequality constraint
- \texttt{linear\_inequality\_scale\_types} : Specify how each linear inequality constraint is scaled
- \texttt{linear\_inequality\_scales} : Define the characteristic values to scale linear inequalities
- \texttt{linear\_inequality\_upper\_bounds} : Define upper bounds for the linear inequality constraint
- \texttt{linear\_equality\_constraint\_matrix} : Define coefficients of the linear equalities
- \texttt{linear\_equality\_scale\_types} : Specify how each linear equality constraint is scaled
- \texttt{linear\_equality\_scales} : Define the characteristic values to scale linear equalities
- \texttt{linear\_equality\_targets} : Define target values for the linear equality constraints
- \texttt{linear\_inequality\_constraint\_matrix} : Define coefficients of the linear inequality constraints
- \texttt{linear\_inequality\_lower\_bounds} : Define lower bounds for the linear inequality constraint
- \texttt{linear\_inequality\_scale\_types} : Specify how each linear inequality constraint is scaled
- \texttt{linear\_inequality\_scales} : Define the characteristic values to scale linear inequalities
- \texttt{linear\_inequality\_upper\_bounds} : Define upper bounds for the linear inequality constraint
- \texttt{linear\_equality\_constraint\_matrix} : Define coefficients of the linear equalities
- \texttt{linear\_equality\_scale\_types} : Specify how each linear equality constraint is scaled
- \texttt{linear\_equality\_scales} : Define the characteristic values to scale linear equalities
- \texttt{linear\_equality\_targets} : Define target values for the linear equality constraints
- \texttt{linear\_inequality\_constraint\_matrix} : Define coefficients of the linear inequality constraints
- \texttt{linear\_inequality\_lower\_bounds} : Define lower bounds for the linear inequality constraint
- \texttt{linear\_inequality\_scale\_types} : Specify how each linear inequality constraint is scaled
- \texttt{linear\_inequality\_scales} : Define the characteristic values to scale linear inequalities
- \texttt{linear\_inequality\_upper\_bounds} : Define upper bounds for the linear inequality constraint
- \texttt{linear\_equality\_constraint\_matrix} : Define coefficients of the linear equalities
- \texttt{linear\_equality\_scale\_types} : Specify how each linear equality constraint is scaled
- \texttt{linear\_equality\_scales} : Define the characteristic values to scale linear equalities
- \texttt{linear\_equality\_targets} : Define target values for the linear equality constraints
- \texttt{linear\_inequality\_constraint\_matrix} : Define coefficients of the linear inequality constraints
• **linear_inequality_lower_bounds**: Define lower bounds for the linear inequality constraint
• **linear_inequality_scale_types**: Specify how each linear inequality constraint is scaled
• **linear_inequality_scales**: Define the characteristic values to scale linear inequalities
• **linear_inequality_upper_bounds**: Define upper bounds for the linear inequality constraint
• **linear_inequality_constraint_matrix**: Define coefficients of the linear inequalities
• **linear_inequality_scale_types**: Specify how each linear inequality constraint is scaled
• **linear_inequality_scales**: Define the characteristic values to scale linear inequalities
• **linear_inequality_upper_bounds**: Define upper bounds for the linear inequality constraint
• **linear_inequality_constraint_matrix**: Define coefficients of the linear inequality constraints
• **linear_inequality_lower_bounds**: Define lower bounds for the linear inequality constraint
• **linear_inequality_scale_types**: Specify how each linear inequality constraint is scaled
• **linear_inequality_scales**: Define the characteristic values to scale linear inequalities
• **linear_inequality_upper_bounds**: Define upper bounds for the linear inequality constraint
• **linear_inequality_constraint_matrix**: Define coefficients of the linear inequalities
• **linear_inequality_scale_types**: Specify how each linear equality constraint is scaled
• **linear_inequality_scales**: Define the characteristic values to scale linear equalities
• **linear_inequality_targets**: Define target values for the linear equality constraints
• **linear_inequality_constraint_matrix**: Define coefficients of the linear inequality constraints
• **linear_inequality_lower_bounds**: Define lower bounds for the linear inequality constraint
• **linear_inequality_scale_types**: Specify how each linear inequality constraint is scaled
• **linear_inequality_scales**: Define the characteristic values to scale linear inequalities
• **linear_inequality_upper_bounds**: Define upper bounds for the linear inequality constraint

### 5.3.3 block

**Description**

A block is the highest level of keyword organization in Dakota. There are currently 6 blocks in the Dakota input spec:

**Related Topics**

- **block_identifier**
- **block_pointer**
5.3. DAKOTA_CONCEPTS

Related Keywords

- **environment**: Top-level settings for Dakota execution
- **interface**: Specifies how function evaluations will be performed in order to map the variables into the responses.
- **method**: Begins Dakota method selection and behavioral settings.
- **model**: Specifies how variables are mapped into a set of responses
- **responses**: Description of the model output data returned to Dakota upon evaluation of an interface.
- **variables**: Specifies the parameter set to be iterated by a particular method.

**block identifier**

**Description**

empty

**Related Topics**

**Related Keywords**

- **id interface**: Name the interface block; helpful when there are multiple
- **id method**: Name the method block; helpful when there are multiple
- **id model**: Give the model block an identifying name, in case of multiple model blocks
- **id responses**: Name the response block, helpful when there are multiple

**block pointer**

**Description**

See **block pointer** for details about pointers.

**Related Topics**

**Related Keywords**

- **top method pointer**: Identify which method leads the Dakota study
- **model pointer**: Identifier for model block to be used by a method
- **model pointer**: Identifier for model block to be used by a method
- **model pointer**: Identifier for model block to be used by a method
- **model pointer**: Identifier for model block to be used by a method
- **model pointer**: Identifier for model block to be used by a method
- **model pointer**: Identifier for model block to be used by a method
- **model pointer**: Identifier for model block to be used by a method
• **model\_pointer** : Identifier for model block to be used by a method
• **model\_pointer** : Identifier for model block to be used by a method
• **model\_pointer** : Identifier for model block to be used by a method
• **model\_pointer** : Identifier for model block to be used by a method
• **model\_pointer** : Identifier for model block to be used by a method
• **model\_pointer** : Identifier for model block to be used by a method
• **model\_pointer** : Identifier for model block to be used by a method

• **model\_pointer** : Identifier for model block to be used by a method
• **model\_pointer** : Identifier for model block to be used by a method

• **model\_pointer\_list** : Associate models with method names
• **method\_pointer\_list** : Pointers to methods to execute sequentially or collaboratively
• **global\_model\_pointer** : Pointer to model used by global method
• **global\_method\_pointer** : Pointer to global method
• **local\_model\_pointer** : Pointer to model used by local method
5.3. **DAKOTA_CONCEPTS**

- `local_method_pointer` : Pointer to local method
- `model_pointer_list` : Associate models with method names
- `method_pointer_list` : Pointers to methods to execute sequentially or collaboratively
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `method_pointer` : Pointer to sub-method to run from each starting point
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `method_pointer` : Pointer to optimization or least-squares sub-method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method

• **model_pointer**: Identifier for model block to be used by a method

• **model_pointer**: Identifier for model block to be used by a method

• **model_pointer**: Identifier for model block to be used by a method

• **model_pointer**: Identifier for model block to be used by a method

• **method_pointer**: Pointer to sub-method to apply to surrogate

• **model_pointer**: Identifier for model block to be used by a method

• **method_pointer**: Pointer to sub-method to apply to surrogate

• **model_pointer**: Identifier for model block to be used by a method

• **model_pointer**: Identifier for model block to be used by a method

• **optional_interface_pointer**: Pointer to interface that provides non-nested responses

• **optional_interface_responses_pointer**: Pointer to responses block that defines non-nested responses

• **sub_method_pointer**: The sub_method_pointer specifies the method block for the sub-iterator

• **responses_pointer**: Specify which responses block will be used by this model block

• **interface_pointer**: Interface block pointer for the single model type

• **dace_method_pointer**: Specify a method to gather training data

• **high_fidelity_model_pointer**: Pointer to high fidelity model

• **low_fidelity_model_pointer**: Pointer to low fidelity model

• **actual_model_pointer**: Pointer to specify a "truth" model, from which to construct a surrogate

• **actual_model_pointer**: Pointer to specify a "truth" model, from which to construct a surrogate

• **variables_pointer**: Specify which variables block will be included with this model block

• **id_variables**: Name the variables block; helpful when there are multiple

- **pre_run**: Invoke Dakota with pre-run mode active
- **read_restart**: Base filename for restart file read
- **run**: Invoke Dakota with run mode active
- **write_restart**: Base filename for restart file write

5.3.7 **restarts**

**Description**

empty

**Related Topics**

**Related Keywords**

5.3.8 **pointers**

**Description**

For all pointer specifications, if a pointer string is specified and no corresponding id string is available, Dakota will exit with an error message.

If the pointer is optional and no pointer string is specified, then the last specification parsed will be used.

It is appropriate to omit optional cross-referencing whenever the relationships are unambiguous due to the presence of only one specification.

- weibull_uncertain : Aleatory uncertain variable - Weibull

5.5.3 discrete_variables

Description
This page discusses discrete design, uncertain, and state variables (which have discrete in their keyword name) as they have similar specifications. These include:

1. Integer ranges
2. Sets of integers
3. Sets of reals
4. Sets of strings and each is described below.
In addition, some aleatory uncertain variables, e.g., `binomial_uncertain`, are discrete integer-valued random variables specified using parameters. These are described on their individual keyword pages.

**Sets**

Sets of integers, reals, and strings have similar specifications, though different value types. The variables are specified using three keywords:

- **Variable declaration keyword** - specifies the number of variables being defined
- **`elements_per_variable`** - a list of positive integers specifying how many set members each variable admits
  - Length = # of variables
- **`elements`** - a list of the permissible integer values in ALL sets, concatenated together.
  - Length = sum of `elements_per_variable`, or an integer multiple of number of variables
  - The order is very important here.
  - The list is partitioned according to the values of `elements_per_variable`, and each partition is assigned to a variable.

- The ordering of `elements_per_variable`, and the partitions of `elements` must match the strings from descriptors

For string variables, each string element value must be quoted and may contain alphanumeric, dash, underscore, and colon. White space, quote characters, and backslash/metacharacters are not permitted. Examples are given on the pages:

- discrete design set `integer`
- discrete design set `real`
- discrete design set `string`
- discrete uncertain set `integer`
- discrete uncertain set `real`
- discrete uncertain set `string`

**Range**

For discrete variables defined by range(s), the `lower_bounds` and `upper_bounds` restrict the permissible values. For design variables, this constrains the feasible design space and is frequently used to prevent nonphysical designs. This is a discrete interval variable that may take any integer value within bounds (e.g., `[1, 4]`, allowing values of 1, 2, 3, or 4). For some variable types, each variable is can be defined by multiple ranges.

Examples are given on the pages:

- `discrete_interval_uncertain`
5.5. VARIABLES

Related Topics

Related Keywords

- binomial_uncertain: Aleatory uncertain discrete variable - binomial
- discrete_design_range: Discrete design variables; each defined by an integer interval
- discrete_design_set: Set-valued discrete design variables
- integer: Integer-valued discrete design variables
- real: Real-valued discrete design variables
- string: String-valued discrete design set variables
- discrete_interval_uncertain: Epistemic uncertain variable - values from one or more discrete intervals
- discrete_state_range: Discrete state variables; each defined by an integer interval
- discrete_state_set: Set-valued discrete state variables

- real: Discrete state variables, each defined by a set of permissible real numbers
- string: String-valued discrete state set variables
- discrete_uncertain_set: Set-valued discrete uncertain variables
- integer: Discrete, epistemic uncertain variable - integers within a set
- real: Discrete, epistemic uncertain variable - real numbers within a set
- string: Discrete, epistemic uncertain variable - strings within a set
- geometric_uncertain: Aleatory uncertain discrete variable - geometric
- histogram_point_uncertain: Aleatory uncertain variable - discrete histogram
- hypergeometric_uncertain: Aleatory uncertain discrete variable - hypergeometric
- negative_binomial_uncertain: Aleatory uncertain discrete variable - negative binomial
- poisson_uncertain: Aleatory uncertain discrete variable - Poisson

5.5.4 variable_type

Description

Dakota variables can be grouped by their type, including all, design, uncertain, aleatory, epistemic, or state. There are certain situations where the user may want to explicitly control the subset of variables that is considered active for a certain Dakota method, and override the default alignments between methods and variable types. Refer to active for additional information.
Related Topics

- design_variables
- aleatory_uncertain_variables
- epistemic_uncertain_variables
- state_variables

Related Keywords

5.5.5 design_variables

Description

Design variables are those variables which are modified for the purposes of computing an optimal design.

The most common type of design variables encountered in engineering applications are of the continuous type. These variables may assume any real value within their bounds. All but a handful of the optimization algorithms in Dakota support continuous design variables exclusively.

Related Topics

Related Keywords

5.5.6 aleatory_uncertain_variables

Description

Aleatory uncertainty is also known as inherent variability, irreducible uncertainty, or randomness.

Aleatory uncertainty is predominantly characterized using probability theory. This is the only option implemented in Dakota.

Related Topics

Related Keywords

- beta_uncertain : Aleatory uncertain variable - beta
- binomial_uncertain : Aleatory uncertain discrete variable - binomial
- exponential_uncertain : Aleatory uncertain variable - exponential
5.5. VARIABLES

- frechet_uncertain : Aleatory uncertain variable - Frechet

- geometric_uncertain : Aleatory uncertain discrete variable - geometric
- gumbel_uncertain : Aleatory uncertain variable - gumbel
- histogram_bin_uncertain : Aleatory uncertain variable - continuous histogram
- histogram_point_uncertain : Aleatory uncertain variable - discrete histogram
- hypergeometric_uncertain : Aleatory uncertain discrete variable - hypergeometric
- lognormal_uncertain : Aleatory uncertain variable - lognormal
- loguniform_uncertain : Aleatory uncertain variable - loguniform
- negative_binomial_uncertain : Aleatory uncertain discrete variable - negative binomial
- normal_uncertain : Aleatory uncertain variable - normal (Gaussian)
- poisson_uncertain : Aleatory uncertain discrete variable - Poisson
- triangular_uncertain : Aleatory uncertain variable - triangular
- uniform_uncertain : Aleatory uncertain variable - uniform
- weibull_uncertain : Aleatory uncertain variable - Weibull

### 5.5.7 epistemic_uncertain_variables

**Description**

Epistemic uncertainty is uncertainty due to lack of knowledge.

In Dakota, epistemic uncertainty is characterized by interval analysis or the Dempster-Shafer theory of evidence.

Note that epistemic uncertainty can also be modeled with probability density functions - similarly to aleatory uncertainty Dakota does not support this capability.

**Related Topics**

**Related Keywords**

- continuous_interval_uncertain : Epistemic uncertain variable - values from one or more continuous intervals
- discrete_interval_uncertain : Epistemic uncertain variable - values from one or more discrete intervals
- discrete_uncertain_set : Set-valued discrete uncertain variables
- integer : Discrete, epistemic uncertain variable - integers within a set
- real : Discrete, epistemic uncertain variable - real numbers within a set
- string : Discrete, epistemic uncertain variable - strings within a set
5.5.8 state_variables

Description

State variables provide a convenient mechanism for managing additional model parameterizations such as mesh density, simulation convergence tolerances, and time step controls.

Only parameter studies and design of experiments methods will iterate on state variables. The initial_state is used as the only value for the state variable for all other methods, unless active_state is invoked.

If a method iterates on a state variable, the variable is treated as a design variable with the given bounds, or as a uniform uncertain variable with the given bounds.

If the state variable is defined only by its bounds, and the method does NOT iterate on state variables, then the initial_state must be inferred.

Related Topics

Related Keywords

- continuous_state : Continuous state variables
- discrete_state_range : Discrete state variables; each defined by an integer interval
- discrete_state_set : Set-valued discrete state variables
- integer : Discrete state variables, each defined by a set of permissible integers
- real : Discrete state variables, each defined by a set of permissible real numbers
- string : String-valued discrete state set variables

5.6 responses

Description

Keywords and concepts relating to the responses block

Related Topics

- response_types

Related Keywords

5.6.1 response_types

Description

The specification must be one of three types:

1. objective and constraint functions
2. calibration (least squares) terms and constraint functions
3. a generic response functions specification.
5.7. INTERFACE

These correspond to (a) optimization, (b) deterministic (least squares) or stochastic (Bayesian) inversion, and (c) general-purpose analyzer methods such as parameter studies, DACE, and UQ methods, respectively. Refer to responses for additional details and examples.

5.8.1 parameter_studies

Description

Parameter studies employ deterministic designs to explore the effect of parametric changes within simulation models, yielding one form of sensitivity analysis. They can help assess simulation characteristics such as smoothness, multi-modality, robustness, and nonlinearity, which affect the choice of algorithms and controls in follow-on optimization and UQ studies.

Dakota’s parameter study methods compute response data sets at a selection of points in the parameter space. These points may be specified as a vector, a list, a set of centered vectors, or a multi-dimensional grid. Capability overviews and examples of the different types of parameter studies are provided in the Users Manual [4].

With the exception of output verbosity (a setting of silent will suppress some parameter study diagnostic output), Dakota’s parameter study methods do not make use of the method independent controls. Therefore, the parameter study documentation which follows is limited to the method dependent controls for the vector, list, centered, and multidimensional parameter study methods.

5.8.4 sampling

Description

Sampling techniques are selected using the sampling method selection. This method generates sets of samples according to the probability distributions of the uncertain variables and maps them into corresponding sets of response functions, where the number of samples is specified by the samples integer specification. Means, standard deviations, coefficients of variation (COVs), and 95% confidence intervals are computed for the response functions. Probabilities and reliabilities may be computed for response_levels specifications, and response levels may be computed for either probability_levels or reliability_levels specifications (refer to the Method Commands chapter in the Dakota Reference Manual[5] for additional information).

Currently, traditional Monte Carlo (MC) and Latin hypercube sampling (LHS) are supported by Dakota and are chosen by specifying sample_type as random or lhs. In Monte Carlo sampling, the samples are selected randomly according to the user-specified probability distributions. Latin hypercube sampling is a stratified sampling technique for which the range of each uncertain variable is divided into $N_s$ segments of equal probability, where $N_s$ is the number of samples requested. The relative lengths of the segments are determined by the nature of the specified probability distribution (e.g., uniform has segments of equal width, normal has small segments near the mean and larger segments in the tails). For each of the uncertain variables, a sample is selected randomly from each of these equal probability segments. These $N_s$ values for each of the individual parameters are then combined in a shuffling operation to create a set of $N_s$ parameter vectors with a specified correlation structure. A feature of the resulting sample set is that every row and column in the hypercube of partitions has exactly one sample. Since the total number of samples is exactly equal to the number of partitions used for each uncertain variable, an arbitrary number of desired samples is easily accommodated (as compared to less flexible approaches in which the total number of samples is a product or exponential function of the number of intervals for each variable, i.e., many classical design of experiments methods).

Advantages of sampling-based methods include their relatively simple implementation and their independence from the scientific disciplines involved in the analysis. The main drawback of these techniques is the large number of function evaluations needed to generate converged statistics, which can render such an analysis computationally very expensive, if not intractable, for real-world engineering applications. LHS techniques, in general, require fewer samples than traditional Monte Carlo for the same accuracy in statistics, but they still can be prohibitively expensive. For further information on the method and its relationship to other sampling techniques, one is referred to the works by McKay, et al.[59], Iman and Shortencarier[53], and Helton and Davis[46]. Note that under certain separability conditions associated with the function to be sampled, Latin hypercube sampling provides a more accurate estimate of the mean value than does random sampling. That is, given an equal number of samples, the LHS estimate of the mean will have less variance than the mean value obtained through random sampling.

5.8.5 uncertainty quantification

Description

Dakota provides a variety of methods for propagating both aleatory and epistemic uncertainty.

At a high level, uncertainty quantification (UQ) or nondeterministic analysis is the process of characterizing input uncertainties, forward propagating these uncertainties through a computational model, and performing statistical or interval assessments on the resulting responses. This process determines the effect of uncertainties and assumptions on model outputs or results. In Dakota, uncertainty quantification methods specifically focus on the forward propagation part of the process, where probabilistic or interval information on parametric inputs are mapped through the computational model to assess statistics or intervals on outputs. For an overview of these approaches for engineering applications, consult[42].

UQ is related to sensitivity analysis in that the common goal is to gain an understanding of how variations in the parameters affect the response functions of the engineering design problem. However, for UQ, some or all of the components of the parameter vector, are considered to be uncertain as specified by particular probability distributions (e.g., normal, exponential, extreme value), or other uncertainty structures. By assigning specific distributional structure to the inputs, distributional structure for the outputs (i.e., response statistics) can be inferred. This migrates from an analysis that is more \{qualitative\} in nature, in the case of sensitivity analysis, to an analysis that is more rigorously \{quantitative\}.

UQ methods are often distinguished by their ability to propagate aleatory or epistemic input uncertainty characterizations, where aleatory uncertainties are irreducible variabilities inherent in nature and epistemic uncertainties are reducible uncertainties resulting from a lack of knowledge. Since sufficient data is generally available for aleatory uncertainties, probabilistic methods are commonly used for computing response distribution statistics based on input probability distribution specifications. Conversely, for epistemic uncertainties, any use of probability distributions is based on subjective knowledge rather than objective data, and we may alternatively explore nonprobabilistic methods based on interval specifications.

Dakota contains capabilities for performing nondeterministic analysis with both types of input uncertainty. These UQ methods have been developed by Sandia Labs, in conjunction with collaborators in academia[31],[32],[21],[79].

The aleatory UQ methods in Dakota include various sampling-based approaches (e.g., Monte Carlo and Latin Hypercube sampling), local and global reliability methods, and stochastic expansion (polynomial chaos expansions and stochastic collocation) approaches. The epistemic UQ methods include local and global interval analysis and Dempster-Shafer evidence theory. These are summarized below and then described in more depth in subsequent sections of this chapter. Dakota additionally supports mixed aleatory/epistemic UQ via interval-valued probability, second-order probability, and Dempster-Shafer theory of evidence. These involve advanced model recursions and are described in Section.

reliability_methods

Description

Reliability methods provide an alternative approach to uncertainty quantification which can be less computationally demanding than sampling techniques. Reliability methods for uncertainty quantification are based on probabilistic approaches that compute approximate response function distribution statistics based on specified uncertain variable distributions. These response statistics include response mean, response standard deviation, and cumulative or complementary cumulative distribution functions (CDF/CCDF). These methods are often more efficient at computing statistics in the tails of the response distributions (events with low probability) than sampling based approaches since the number of samples required to resolve a low probability can be prohibitive.

The methods all answer the fundamental question: “Given a set of uncertain input variables, $X$, and a scalar response function, $g$, what is the probability that the response function is below or above a certain level, $\bar{z}$?” The former can be written as $P[g(X) \leq \bar{z}] = F_{g}(\bar{z})$ where $F_{g}(\bar{z})$ is the cumulative distribution function (CDF) of the uncertain response $g(X)$ over a set of response levels. The latter can be written as $P[g(X) > \bar{z}]$ and defines the complementary cumulative distribution function (CCDF).

This probability calculation involves a multi-dimensional integral over an irregularly shaped domain of interest, $D$, where $g(X) < z$ as displayed in Figure figUQ05 for the case of two variables. The reliability methods all involve the transformation of the user-specified uncertain variables, $X$, with probability density function, $p(x_1, x_2)$, which can be non-normal and correlated, to a space of independent Gaussian random variables, $u$, possessing a mean value of zero and unit variance (i.e., standard normal variables). The region of interest, $D$, is also mapped to the transformed space to yield, $D_u$, where $g(U) < z$ as shown in Figure figUQ06. The Nataf transformation[17], which is identical to the Rosenblatt transformation[72] in the case of independent random variables, is used in Dakota to accomplish this mapping. This transformation is performed to make the probability calculation more tractable. In the transformed space, probability contours are circular in nature as shown in Figure figUQ06 unlike in the original uncertain variable space, Figure figUQ05. Also, the multi-dimensional integrals can be approximated by simple functions of a single parameter, $\beta$, called the reliability index. $\beta$ is the minimum Euclidean distance from the origin in the transformed space to the response surface. This point is also known as the most probable point (MPP) of failure. Note, however, the methodology is equally applicable for generic functions, not simply those corresponding to failure criteria; this nomenclature is due to the origin of these methods within the disciplines of structural safety and reliability. Note that there are local and global reliability methods. The majority of the methods available are local, meaning that a local optimization formulation is used to locate one MPP. In contrast, global methods can find multiple MPPs if they exist.

**stochastic_expansion_methods**

**Description**

The development of these techniques mirrors that of deterministic finite element analysis utilizing the notions of projection, orthogonality, and weak convergence[31],[32]. Rather than estimating point probabilities, they form an approximation to the functional relationship between response functions and their random inputs, which provides a more complete uncertainty representation for use in multi-code simulations. Expansion methods include polynomial chaos expansions (PCE), which employ multivariate orthogonal polynomials that are tailored to representing particular input probability distributions, and stochastic collocation (SC), which employs multivariate interpolation polynomials. For PCE, expansion coefficients may be evaluated using a spectral projection approach (based on sampling, tensor-product quadrature, Smolyak sparse grid, or cubature methods for numerical integration) or a regression approach (least squares or compressive sensing). For SC, interpolants are formed over tensor-product or sparse grids and may be local or global, value-based or gradient-enhanced, and nodal or hierarchical. In global value-based cases (Lagrange polynomials), the barycentric formulation is used[10],[56],[49] to improve numerical efficiency and stability. Both sets of methods provide analytic response moments and variance-based metrics; however, CDF/CCDF probabilities are evaluated numerically by sampling on the expansion.

5.8.7 **epistemic_uncertainty_quantification_methods**

**Description**

Epistemic uncertainty is uncertainty due to lack of knowledge.

In Dakota, epistemic uncertainty analysis is performed using interval analysis or Dempster-Shafer theory of evidence.

Note that epistemic uncertainty can also be modeled probabilistically. It would be more accurate to call this class of method, non-probabilistic uncertainty quantification, but the name persists for historical reasons.

\textbf{interval estimation}

\textbf{Description}

In interval analysis, one assumes that nothing is known about an epistemic uncertain variable except that its value lies somewhere within an interval. In this situation, it is NOT assumed that the value has a uniform probability of occuring within the interval. Instead, the interpretation is that any value within the interval is a possible value or a potential realization of that variable. In interval analysis, the uncertainty quantification problem is one of determining the resulting bounds on the output (defining the output interval) given interval bounds on the inputs. Again, any output response that falls within the output interval is a possible output with no frequency information assigned to it.

We have the capability to perform interval analysis using either \textit{global.interval.est} or \textit{local.interval.est}. In the global approach, one uses either a global optimization method or a sampling method to assess the bounds. \textit{global.interval.est} allows the user to specify either \textit{lhs}, which performs Latin Hypercube Sampling and takes the minimum and maximum of the samples as the bounds (no optimization is performed) or \textit{ego}. In the case of \textit{ego}, the efficient global optimization method is used to calculate bounds. The \textit{ego} method is described in Section . If the problem is amenable to local optimization methods (e.g. can provide derivatives or use finite difference method to calculate derivatives), then one can use local methods to calculate these bounds. \textit{local.interval.est} allows the user to specify either \textit{sqp} which is sequential quadratic programming, or \textit{nip} which is a nonlinear interior point method.

Note that when performing interval analysis, it is necessary to define interval uncertain variables as described in Section . For interval analysis, one must define only one interval per input variable, in contrast with Dempster-Shafer evidence theory, where an input can have several possible intervals. Interval analysis can be considered a special case of Dempster-Shafer evidence theory where each input is defined by one input interval with a basic probability assignment of one. In Dakota, however, the methods are separate and semantic differences exist in the output presentation. If you are performing a pure interval analysis, we recommend using either \textit{global.interval.est} or \textit{local.interval.est} instead of \textit{global.evidence} or \textit{local.evidence}, for reasons of simplicity. An example of interval estimation is found in the Dakota/examples/users/cantilever_uq.global_interval.in, and also in Section .

Note that we have kept separate implementations of interval analysis and Dempster-Shafer evidence theory because our users often want to couple interval analysis on an outer loop” with an aleatory, probabilistic analysis on an inner loop” for nested, second-order probability calculations. See Section for additional details on these nested approaches. These interval methods can also be used as the outer loop within an interval-valued probability analysis for propagating mixed aleatory and epistemic uncertainty – refer to Section for additional details.
Interval analysis is often used to model epistemic uncertainty. In interval analysis, the uncertainty quantification problem is one of determining the resulting bounds on the output (defining the output interval) given interval bounds on the inputs.

We can do interval analysis using either %global_interval_est or local_interval_est. In the global approach, one uses either a global optimization method or a sampling method to assess the bounds, whereas the local method uses gradient information in a derivative-based optimization approach.

An example of interval estimation is shown in Figure , with example results in Figure . This example is a demonstration of calculating interval bounds for three outputs of the cantilever beam problem. The cantilever beam problem is described in detail in Section . Given input intervals of [1,10] on beam width and beam thickness, we can see that the interval estimate of beam weight is approximately [1,100].

Min and Max estimated values for each response function:
weight: Min = 1.0000169352e+00 Max = 9.9999491948e+01
stress: Min = -9.7749994284e-01 Max = 2.1499428450e+01
displ: Min = -9.9315672724e-01 Max = 6.7429714485e+01

evidence_theory

Description

This section discusses Dempster-Shafer evidence theory. In this approach, one does not assign a probability distribution to each uncertain input variable. Rather, one divides each uncertain input variable into one or more intervals. The input parameters are only known to occur within intervals: nothing more is assumed.

Each interval is defined by its upper and lower bounds, and a Basic Probability Assignment (BPA) associated with that interval. The BPA represents a probability of that uncertain variable being located within that interval.

The intervals and BPAs are used to construct uncertainty measures on the outputs called “belief” and “plausibility.” Belief represents the smallest possible probability that is consistent with the evidence, while plausibility represents the largest possible probability that is consistent with the evidence. For more information about the Dempster-Shafer theory of evidence, see [66] and[47].

Similar to the interval approaches, one may use global or local methods to determine plausibility and belief measures for the outputs.

Usage Notes

Note that to calculate the plausibility and belief cumulative distribution functions, one has to look at all combinations of intervals for the uncertain variables. Within each interval cell combination, the minimum and maximum value of the objective function determine the belief and plausibility, respectively. In terms of implementation, global methods use LHS sampling or global optimization to calculate the minimum and maximum values of the objective function within each interval cell, while local methods use gradient-based optimization methods to calculate these minima and maxima.

Finally, note that many non-deterministic keywords apply to the evidence methods, but one needs to be careful about the interpretation and translate probabilistic measures to epistemic ones. For example, if the user specifies distribution of type complementary, a complementary plausibility and belief function will be generated for the
5.8. METHODS

Evidence methods (as opposed to a complementary distribution function in the sampling case). If the user specifies a set of responses levels, both the belief and plausibility will be calculated for each response level. Likewise, if the user specifies a probability level, the probability level will be interpreted both as a belief and plausibility, and response levels corresponding to the belief and plausibility levels will be calculated. Finally, if generalized reliability levels are specified, either as inputs (\texttt{gen\_reliability\_levels}) or outputs (\texttt{response\_levels} with \texttt{compute gen\_reliabilities}), then these are directly converted to/from probability levels and the same probability-based mappings described above are performed.

5.8.8 \hspace{1pt} variable\_support

Description

Different nondeterministic methods have differing support for uncertain variable distributions. Tables 5.37, 5.38, and 5.39 summarize the uncertain variables that are available for use by the different methods, where a "-" indicates that the distribution is not supported by the method, a "U" means the uncertain input variables of this type must be uncorrelated, a "C" denotes that correlations are supported involving uncertain input variables of this type, and an "A" means the appropriate variables must be specified as active in the variables specification block. For example, if one wants to support sampling or a stochastic expansion method over both continuous uncertain and continuous state variables, the specification \texttt{active all} must be listed in the variables specification block. Additional notes include:

- we have four variants for stochastic expansions (SE), listed as Wiener, Askey, Extended, and Piecewise which draw from different sets of basis polynomials. The term stochastic expansion indicates polynomial chaos and stochastic collocation collectively, although the Piecewise option is only currently supported for stochastic collocation. Refer to \texttt{polynomial\_chaos} and \texttt{stoch\_collocation} for additional information on these three options.

- methods supporting the epistemic interval distributions have differing approaches: \texttt{sampling} and the \texttt{lhs} option of \texttt{global\_interval\_est} model the interval basic probability assignments (BPAs) as continuous histogram bin distributions for purposes of generating samples; \texttt{local\_interval\_est} and the \texttt{ego} option of \texttt{global\_interval\_est} ignore the BPA details and models these variables as simple bounded regions defined by the cell extremes; and \texttt{local\_evidence} and \texttt{global\_evidence} model the interval specifications as true BPAs.

5.8.9 \hspace{1pt} optimization\_and\_calibration

Description

Optimization algorithms work to minimize (or maximize) an objective function, typically calculated by the user simulation code, subject to constraints on design variables and responses. Available approaches in Dakota include
well-tested, proven gradient-based, derivative-free local, and global methods for use in science and engineering design applications. Dakota also offers more advanced algorithms, e.g., to manage multi-objective optimization or perform surrogate-based minimization. This chapter summarizes optimization problem formulation, standard algorithms available in Dakota (mostly through included third-party libraries, see Section 6.5 of [4]), some advanced capabilities, and offers usage guidelines.

Optimization Formulations

This section provides a basic introduction to the mathematical formulation of optimization problems. The primary goal of this section is to introduce terms relating to these topics, and is not intended to be a description of theory or numerical algorithms. For further details, consult [8], [34], [41], [65], and [84].

A general optimization problem is formulated as follows:

\[
\begin{align*}
\text{minimize:} & \quad f(x) \\
\text{subject to:} & \quad g_L \leq g(x) \leq g_U \\
& \quad h(x) = h_t \\
& \quad a_L \leq A_c x \leq a_U \\
& \quad A_e x = a_t \\
& \quad x_L \leq x \leq x_U
\end{align*}
\]

where vector and matrix terms are marked in bold typeface. In this formulation, \( x = [x_1, x_2, \ldots, x_n] \) is an \( n \)-dimensional vector of real-valued design variables or design parameters. The \( n \)-dimensional vectors, \( x_L \) and \( x_U \), are the lower and upper bounds, respectively, on the design parameters. These bounds define the allowable values for the elements of \( x \), and the set of all allowable values is termed the design space or the parameter space. A design point or a sample point is a particular set of values within the parameter space.

The optimization goal is to minimize the objective function, \( f(x) \), while satisfying the constraints. Constraints can be categorized as either linear or nonlinear and as either inequality or equality. The nonlinear inequality constraints, \( g(x) \), are “2-sided,” in that they have both lower and upper bounds, \( g_L \) and \( g_U \), respectively. The nonlinear equality constraints, \( h(x) \), have target values specified by \( h_t \). The linear inequality constraints create a linear system \( A_c x \), where \( A_c \) is the coefficient matrix for the linear system. These constraints are also 2-sided as they have lower and upper bounds, \( a_L \) and \( a_U \), respectively. The linear equality constraints create a linear system \( A_e x \), where \( A_e \) is the coefficient matrix for the linear system and \( a_t \) are the target values. The constraints partition the parameter space into feasible and infeasible regions. A design point is said to be feasible if and only if it satisfies all of the constraints. Correspondingly, a design point is said to be infeasible if it violates one or more of the constraints.

Many different methods exist to solve the optimization problem given in Section 6.1 of [4], all of which iterate on \( x \) in some manner. That is, an initial value for each parameter in \( x \) is chosen, the response quantities, \( f(x) \), \( g(x) \), and \( h(x) \), are computed, often by running a simulation, and some algorithm is applied to generate a new \( x \) that will either reduce the objective function, reduce the amount of infeasibility, or both. To facilitate a general presentation of these methods, three criteria will be used in the following discussion to differentiate them: optimization problem type, search goal, and search method.

The optimization problem type can be characterized both by the types of constraints present in the problem and by the linearity or nonlinearity of the objective and constraint functions. For constraint categorization, a hierarchy of complexity exists for optimization algorithms, ranging from simple bound constraints, through linear constraints, to full nonlinear constraints. By the nature of this increasing complexity, optimization problem categorizations are inclusive of all constraint types up to a particular level of complexity. That is, an unconstrained...
5.8. METHODS

problem has no constraints, a bound-constrained problem has only lower and upper bounds on the design parameters, a linearly-constrained problem has both linear and bound constraints, and a nonlinearly-constrained problem may contain the full range of nonlinear, linear, and bound constraints. If all of the linear and nonlinear constraints are equality constraints, then this is referred to as an equality-constrained problem, and if all of the linear and nonlinear constraints are inequality constraints, then this is referred to as an inequality-constrained problem. Further categorizations can be made based on the linearity of the objective and constraint functions. A problem where the objective function and all constraints are linear is called a linear programming (LP) problem. These types of problems commonly arise in scheduling, logistics, and resource allocation applications. Likewise, a problem where at least some of the objective and constraint functions are nonlinear is called a nonlinear programming (NLP) problem. These NLP problems predominate in engineering applications and are the primary focus of Dakota.

The search goal refers to the ultimate objective of the optimization algorithm, i.e., either global or local optimization. In global optimization, the goal is to find the design point that gives the lowest feasible objective function value over the entire parameter space. In contrast, in local optimization, the goal is to find a design point that is lowest relative to a “nearby” region of the parameter space. In almost all cases, global optimization will be more computationally expensive than local optimization. Thus, the user must choose an optimization algorithm with an appropriate search scope that best fits the problem goals and the computational budget.

The search method refers to the approach taken in the optimization algorithm to locate a new design point that has a lower objective function value or is more feasible than the current design point. The search method can be classified as either gradient-based or nongradient-based. In a gradient-based algorithm, gradients of the response functions are computed to find the direction of improvement. Gradient-based optimization is the search method that underlies many efficient local optimization methods. However, a drawback to this approach is that gradients can be computationally expensive, inaccurate, or even nonexistent. In such situations, nongradient-based search methods may be useful. There are numerous approaches to nongradient-based optimization. Some of the more well known of these include pattern search methods (nongradient-based local techniques) and genetic algorithms (nongradient-based global techniques).

Because of the computational cost of running simulation models, surrogate-based optimization (SBO) methods are often used to reduce the number of actual simulation runs. In SBO, a surrogate or approximate model is constructed based on a limited number of simulation runs. The optimization is then performed on the surrogate model. Dakota has an extensive framework for managing a variety of local, multipoint, global, and hierarchical surrogates for use in optimization. Finally, sometimes there are multiple objectives that one may want to optimize simultaneously instead of a single scalar objective. In this case, one may employ multi-objective methods that are described in Section 6.3.1 of[4].

This overview of optimization approaches underscores that no single optimization method or algorithm works best for all types of optimization problems. Section 6.4 of[4] offers guidelines for choosing a Dakota optimization algorithm best matched to your specific optimization problem.

Constraint Considerations Dakota’s input commands permit the user to specify two-sided nonlinear inequality constraints of the form \( g_L \leq g_i(x) \leq g_U \), as well as nonlinear equality constraints of the form \( h_j(x) = h_I \). Some optimizers (e.g., npsol, optpp, soga, and moga methods) can handle these constraint forms directly, whereas other optimizers (e.g., asynch_pattern_search, dot, and conmin, mesh_adaptive_search) require Dakota to perform an internal conversion of all constraints to one-sided inequality constraints of the form \( g_i(x) \leq 0 \). In the latter case, the two-sided inequality constraints are treated as \( g_i(x) - g_U \leq 0 \) and \( g_L - g_i(x) \leq 0 \) and the equality constraints are treated as \( h_j(x) - h_I \leq 0 \) and \( h_I - h_j(x) \leq 0 \). The situation is similar for linear constraints: asynch_pattern_search, npsol, optpp, soga, and moga methods support them directly, whereas dot and conmin methods do not. For linear inequalities of the form \( a_Lx \leq a_U \) and linear equalities of the form \( a^T x = a_I \), the nonlinear constraint arrays in dot and conmin methods are further augmented to include \( a^T x - a_U \leq 0 \) and \( a_L - a^T x \leq 0 \) in the inequality case and \( a^T x - a_U \leq 0 \) and \( a_I - a^T x \leq 0 \) in the equality case. Awareness of these constraint augmenta-
tion procedures can be important for understanding the diagnostic data returned from the dot and conmin methods. Other optimizers fall somewhere in between. nlpql methods support nonlinear equality constraints \( h_j(x) = 0 \) and nonlinear one-sided inequalities \( g_i(x) \geq 0 \), but does not natively support linear constraints. Constraint mappings are used with NLPQL for both linear and nonlinear cases. Most coliny methods now support two-sided nonlinear inequality constraints and nonlinear constraints with targets, but do not natively support linear constraints.

When gradient and Hessian information is used in the optimization, derivative components are most commonly computed with respect to the active continuous variables, which in this case are the continuous design variables. This differs from parameter study methods (for which all continuous variables are active) and from nondeterministic analysis methods (for which the uncertain variables are active). Refer to Chapter 11 of [4] for additional information on derivative components and active continuous variables.

### Optimizing with Dakota: Choosing a Method

This section summarizes the optimization methods available in Dakota. We group them according to search method and search goal and establish their relevance to types of problems. For a summary of this discussion, see Section 6.4 of [4].

**Gradient-Based Local Methods**  Gradient-based optimizers are best suited for efficient navigation to a local minimum in the vicinity of the initial point. They are not intended to find global optima in nonconvex design spaces. For global optimization methods, see Section 6.2.3 of [4]. Gradient-based optimization methods are highly efficient, with the best convergence rates of all of the local optimization methods, and are the methods of choice when the problem is smooth, unimodal, and well-behaved. However, these methods can be among the least robust when a problem exhibits nonsmooth, discontinuous, or multimodal behavior. The derivative-free methods described in Section 6.2.2 of [4] are more appropriate for problems with these characteristics.

Gradient accuracy is a critical factor for gradient-based optimizers, as inaccurate derivatives will often lead to failures in the search or pre-mature termination of the method. Analytic gradients and Hessians are ideal but often unavailable. If analytic gradient and Hessian information can be provided by an application code, a full Newton method will achieve quadratic convergence rates near the solution. If only gradient information is available and the Hessian information is approximated from an accumulation of gradient data, the superlinear convergence rates can be obtained. It is most often the case for engineering applications, however, that a finite difference method will be used by the optimization algorithm to estimate gradient values. Dakota allows the user to select the step size for these calculations, as well as choose between forward-difference and central-difference algorithms. The finite difference step size should be selected as small as possible, to allow for local accuracy and convergence, but not so small that the steps are “in the noise.” This requires an assessment of the local smoothness of the response functions using, for example, a parameter study method. Central differencing will generally produce more reliable gradients than forward differencing but at roughly twice the expense.

Gradient-based methods for nonlinear optimization problems can be described as iterative processes in which a sequence of subproblems, usually which involve an approximation to the full nonlinear problem, are solved until the solution converges to a local optimum of the full problem. The optimization methods available in Dakota fall into several categories, each of which is characterized by the nature of the subproblems solved at each iteration.

**sequential_quadratic_programming**

**Description**
Sequential Quadratic Programming (SQP) algorithms are a class of mathematical programming problems used to solve nonlinear optimization problems with nonliner constraints. These methods are a generalization of Newton’s method: each iteration involves minimizing a quadratic model of the problem. These subproblems are formulated as minimizing a quadratic approximation of the Lagrangian subject to linearized constraints. Only gradient information is required; Hessians are approximated by low-rank updates defined by the step taken at each iteration. It is important to note that while the solution found by an SQP method will respect the constraints, the intermediate iterates may not. SQP methods available in Dakota are dot_sqp, nlpql_sqp, nlssol_sqp, and npsol_sqp. The particular implementation in nlpql_sqp uses a variant with distributed and non-monotone line search. Thus, this variant is designed to be more robust in the presence of inaccurate or noisy gradients common in many engineering applications.

5.8.13 nonlinear_least_squares

Description

Dakota’s least squares branch currently contains three methods for solving nonlinear least squares problems:

- NL2SOL, a trust-region method that adaptively chooses between two Hessian approximations (Gauss-Newton and Gauss-Newton plus a quasi-Newton approximation to the rest of the Hessian)
- NLSSOL, a sequential quadratic programming (SQP) approach that is from the same algorithm family as NPSOL
- Gauss-Newton, which supplies the Gauss-Newton Hessian approximation to the full-Newton optimizers from OPT++.

The important difference of these algorithms from general-purpose optimization methods is that the response set is defined by calibration terms (e.g. separate terms for each residual), rather than an objective function. Thus, a finer granularity of data is used by least squares solvers as compared to that used by optimizers. This allows the exploitation of the special structure provided by a sum of squares objective function.

5.10.1 package.coliny

Description
SCOLIB (formerly known as COLINY) is a collection of nongradient-based optimizers that support the Common Optimization Library INterface (COLIN). SCOLIB optimizers currently include coliny_cobyla, coliny_direct, coliny_ea, coliny_pattern_search and coliny_solis_wets. (Yes, the input spec still has "coliny" prepended to the method name.) Additional SCOLIB information is available from https://software.sandia.gov/trac/acro.
SCOLIB solvers now support bound constraints and general nonlinear constraints. Supported nonlinear constraints include both equality and two-sided inequality constraints. SCOLIB solvers do not yet support linear constraints. Most SCOLIB optimizers treat constraints with a simple penalty scheme that adds $\text{constraint\_penalty}$ times the sum of squares of the constraint violations to the objective function. Specific exceptions to this method for handling constraint violations are noted below. (The default value of $\text{constraint\_penalty}$ is 1000.0, except for methods that dynamically adapt their constraint penalty, for which the default value is 1.0.)

The method independent controls for $\text{max\_iterations}$ and $\text{max\_function\_evaluations}$ limit the number of major iterations and the number of function evaluations that can be performed during a SCOLIB optimization, respectively. The $\text{convergence\_tolerance}$ control defines the threshold value on relative change in the objective function that indicates convergence. The output verbosity specification controls the amount of information generated by SCOLIB: the silent, quiet, and normal settings correspond to minimal reporting from SCOLIB, whereas the verbose setting corresponds to a higher level of information, and debug outputs method initialization and a variety of internal SCOLIB diagnostics. The majority of SCOLIB’s methods perform independent function evaluations that can directly take advantage of Dakota’s parallel capabilities. Only $\text{coliny\_solis\_wets}$, $\text{coliny\_cobyla}$, and certain configurations of $\text{coliny\_pattern\_search}$ are inherently serial. The parallel methods automatically utilize parallel logic when the Dakota configuration supports parallelism. Lastly, neither speculative gradients nor linear constraints are currently supported with SCOLIB.

Some SCOLIB methods exploit parallelism through the use of Dakota’s concurrent function evaluations. The nature of the algorithms, however, limits the amount of concurrency that can be exploited. The maximum amount of evaluation concurrency that can be leveraged by the various methods is as follows:

- COBYLA: one
- DIRECT: twice the number of variables
- Evolutionary Algorithms: size of the population
- Pattern Search: size of the search pattern
- Solis-Wets: one

All SCOLIB methods support the $\text{show\_misc\_options}$ optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The $\text{misc\_options}$ optional specification provides a means for inputting additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

Each of the SCOLIB methods supports the $\text{solution\_target}$ control, which defines a convergence criterion in which the optimizer will terminate if it finds an objective function value lower than the specified target.

5.10.3 package_ddace

**Description**

The Distributed Design and Analysis of Computer Experiments (DDACE) library provides the following DA-CE techniques: grid sampling (grid), pure random sampling (random), orthogonal array sampling (oas), latin hypercube sampling (lhs), orthogonal array latin hypercube sampling (oa_lhs), Box-Behnken (box-behnken), and central composite design (central_composite).

It is worth noting that there is some overlap in sampling techniques with those available from the nondeterministic branch. The current distinction is that the nondeterministic branch methods are designed to sample within a variety of probability distributions for uncertain variables, whereas the design of experiments methods treat all variables as having uniform distributions. As such, the design of experiments methods are well-suited for performing parametric studies and for generating data sets used in building global approximations, but are not currently suited for assessing the effect of uncertainties characterized with probability distribution. If a design of experiments over both design/state variables (treated as uniform) and uncertain variables (with probability distributions) is desired, then **sampling** can support this with **active all** specified in the Variables specification block.

- `soga`: Single-objective Genetic Algorithm (a.k.a Evolutionary Algorithm)

5.10.8 package_nlpql

**Description**

The NLPQL library is a commercially-licensed library containing a sequential quadratic programming (SQP) optimizer, specified as Dakota’s `nlpql_sqp` method, for constrained optimization. The particular implementation used is NLPQLP [74], a variant with distributed and non-monotone line search.

**Related Topics**

**Related Keywords**

- `nlpql_sqp`: Sequential Quadratic Program
CHAPTER 5. TOPICS AREA

5.10.9 package_npsol

Description
The NPSOL library[33] contains a sequential quadratic programming (SQP) implementation (the npsol_sqp method). SQP is a nonlinear programming optimizer for constrained minimization.

Related Topics

Related Keywords
- npsol_sqp: Sequential Quadratic Program

5.10.10 package_optpp

Description
The OPT++ library[60] contains primarily gradient-based nonlinear programming optimizers for unconstrained, bound-constrained, and nonlinearly constrained minimization: Polak-Ribiere conjugate gradient (Dakota’s optpp_cg method), quasi-Newton (Dakota’s optpp_q_newton method), finite difference Newton (Dakota’s optpp_fd_newton method), and full Newton (Dakota’s optpp_newton method).

The conjugate gradient method is strictly unconstrained, and each of the Newton-based methods are automatically bound to the appropriate OPT++ algorithm based on the user constraint specification (unconstrained, bound-constrained, or generally-constrained). In the generally-constrained case, the Newton methods use a non-linear interior-point approach to manage the constraints. The library also contains a direct search algorithm, PDS (parallel direct search, Dakota’s optpp_pds method), which supports bound constraints.

Method Independent Controls
- These are specified directly under the method block.
  1. max_iterations
  2. max_function_evaluations
  3. convergence_tolerance
  4. output
  5. speculative

Concurrency
OPT++’s gradient-based methods are not parallel algorithms and cannot directly take advantage of concurrent function evaluations. However, if numerical_gradients with method_source dakota is specified, a parallel Dakota configuration can utilize concurrent evaluations for the finite difference gradient computations.

Constraints
- Linear constraint specifications are supported by each of the Newton methods (optpp_newton, optpp_q_newton, optpp_fd_newton, and optpp_g_newton)
  - optpp_cg must be unconstrained
  - optpp_pds can be, at most, bound-constrained.

**Description**

SCOLIB (formerly known as COLINY) is a collection of nongradient-based optimizers that support the Common Optimization Library INterface (COLIN). SCOLIB optimizers currently include coliny_cobyla, coliny_direct, coliny_ea, coliny_pattern_search and coliny_solis_wets. (Yes, the input spec still has "coliny" prepended to the method name.) Additional SCOLIB information is available from https://software.sandia.gov/trac/acro.

SCOLIB solvers now support bound constraints and general nonlinear constraints. Supported nonlinear constraints include both equality and two-sided inequality constraints. SCOLIB solvers do not yet support linear constraints. Most SCOLIB optimizers treat constraints with a simple penalty scheme that adds constraint_penalty times the sum of squares of the constraint violations to the objective function. Specific exceptions to this method for handling constraint violations are noted below. (The default value of constraint_penalty is 1000.0, except for methods that dynamically adapt their constraint penalty, for which the default value is 1.0.)

The method independent controls for max_iterations and max_function_evaluations limit the number of major iterations and the number of function evaluations that can be performed during a SCOLIB optimization, respectively. The convergence_tolerance control defines the threshold value on relative change in the objective function that indicates convergence. The output verbosity specification controls the amount of information generated by SCOLIB: the silent, quiet, and normal settings correspond to minimal reporting from SCOLIB, whereas the verbose setting corresponds to a higher level of information, and debug outputs method initialization and a variety of internal SCOLIB diagnostics. The majority of SCOLIB’s methods perform independent function evaluations that can directly take advantage of Dakota’s parallel capabilities. Only coliny_solis_wets, coliny_cobyla, and certain configurations of coliny_pattern_search are inherently serial. The parallel methods automatically utilize parallel logic when the Dakota configuration supports parallelism. Lastly, neither speculative gradients nor linear constraints are currently supported with SCOLIB.

Some SCOLIB methods exploit parallelism through the use of Dakota’s concurrent function evaluations. The nature of the algorithms, however, limits the amount of concurrency that can be exploited. The maximum amount of evaluation concurrency that can be leveraged by the various methods is as follows:

- COBYLA: one
- DIRECT: twice the number of variables
- Evolutionary Algorithms: size of the population
- Pattern Search: size of the search pattern
- Solis-Wets: one

All SCOLIB methods support the show_misc_options optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The misc_options optional specification provides a means for inputting additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

Each of the SCOLIB methods supports the solution_target control, which defines a convergence criterion in which the optimizer will terminate if it finds an objective function value lower than the specified target.

Table 5.3: Summary of Distribution Types supported by Nondeterministic Methods, Part III (Epistemic, Design, and State Types)
Chapter 6

Keywords Area

This page lists the six blocks. From here, you can navigate to every keyword.

- environment
- method
- model
- variables
- interface
- responses

Introduction to Dakota Keywords

In Dakota, the environment manages execution modes and I/O streams and defines the top-level iterator. Generally speaking, an iterator contains a model and a model contains a set of variables, an interface, and a set of responses. An iterator repeatedly operates on the model to map the variables into responses using the interface. Each of these six components (environment, method, model, variables, interface, and responses) are separate specifications in the user’s input file, and as a whole, determine the study to be performed during an execution of the Dakota software.

A Dakota execution is limited to a single environment, but may involve multiple methods and multiple models. In particular, advanced iterators (i.e., meta- and component-based iterators) and advanced models (i.e., nested and surrogate models) may specialize to include recursions with additional sub-iterators and sub-models. Since each model may contain its own variables, interface, and responses, there may be multiple specifications of the method, model, variables, interface, and responses sections.

Keyword Pages

Every Dakota keyword has its own page in this manual. The page describes:

- Whether the keyword takes ARGUMENTS, and the data type Additional notes about ARGUMENTS can be found here: Specifying Arguments.

- Whether it has an ALIAS

- Which additional keywords can be specified to change its behavior

- Which of these additional keywords are required or optional

- Additional information about how to use the keyword in an input file

</tbody>
</table>
### Description

The environment section in a Dakota input file is optional. It specifies the top-level solution environment, optionally including run modes, output controls, and identification of the primary iterative method (`top_method_pointer`). The output-related keywords address graphics, generation of tabular and results data, and precision of numerical output.

#### Run Mode Defaults

Dakota run phases include `check`, `pre_run`, `run`, and `post_run`. The default behavior is to `pre_run`, `run`, and `post_run`, though any or all of these may be specified to select specific run phases. Specifying `check` will cause Dakota to exit before any selected run modes.

### 6.1.1 check

- **Keywords Area**
  - `environment`
  - `check`

  Invoke Dakota in input check mode

### Topics

This keyword is related to the topics:

- `command_line_options`
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none
Argument(s): none
Default: no check; proceed to run

Description

When specified, Dakota input will be parsed and the problem instantiated. Dakota will exit reporting whether any errors were found.

6.1.2 output_file

- Keywords Area
- environment
- output_file

Base filename for output redirection

Topics

This keyword is related to the topics:

- dakota_IO
- command_line_options

Specification

Alias: none
Argument(s): STRING
Default: output to console, not file

Description

Specify a base filename to which Dakota output will be directed. Output will (necessarily) be redirected after the input file is parsed. This option is overridden by any command-line -output option.

Default Behavior
Output to console (screen).

6.1.3 error_file

- Keywords Area
- environment
- error_file

Base filename for error redirection
6.1. ENVIRONMENT

Topics
This keyword is related to the topics:

- dakota_IO
- command_line_options

Specification
Alias: none
Argument(s): STRING
Default: errors to console, not file

Description
Specify a base filename to which Dakota errors will be directed. Errors will (necessarily) be redirected after the input file is parsed. This option is overridden by any command-line -error option.

Default Behavior
Errors to console (screen).

6.1.4 read_restart

- Keywords Area
- environment
- read_restart

Base filename for restart file read

Topics
This keyword is related to the topics:

- dakota_IO
- command_line_options

Specification
Alias: none
Argument(s): STRING
Default: no restart read

<table>
<thead>
<tr>
<th>Required/-Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>stop_restart</td>
<td>Evaluation ID number at which to stop reading restart file</td>
</tr>
</tbody>
</table>
CHAPTER 6. KEYWORDS AREA

Description
Specify a base filename for the restart file Dakota should read. This option is overridden by any command-line -read_restart option.

Default Behavior
No restart file is read.

stop_restart
- Keywords Area
- environment
- read_restart
- stop_restart

Evaluation ID number at which to stop reading restart file

Topics
This keyword is related to the topics:
- dakota_IO

Specification
Alias: none
Argument(s): INTEGER
Default: read all records

Description
This option is overridden by any command-line -stop_restart option.

6.1.5 write_restart
- Keywords Area
- environment
- write_restart

Base filename for restart file write

Topics
This keyword is related to the topics:
- dakota_IO
- command_line_options
6.1. ENVIRONMENT

**Specification**

**Alias:** none

**Argument(s):** STRING

**Default:** dakota.rst

**Description**

Specify a base filename for the restart file Dakota should write. This option is overridden by any command-line -write_restart option.

### 6.1.6 pre_run

- **Keywords Area**

- environment

- pre_run

Invoke Dakota with pre-run mode active

**Topics**

This keyword is related to the topics:

- command_line_options

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** pre-run, run, post-run all executed

| Required/- | Description of Group | Dakot a Keyword input | Dakot a Keyword Description |
| Optional   |                      | output                |
|            | Base filename for pre-run mode data input |
| Optional   |                      | output                |
|            | Base filename for pre-run mode data output |

**Description**

When specified, Dakota execution will include the pre-run mode, which sets up methods and often generates parameter sets to evaluate. This mode is currently useful for parameter study, DACE, and Monte Carlo sampling methods.

**Default Behavior**

When no run modes are specified, Dakota will perform pre-run, run, and post-run phases.
CHAPTER 6. KEYWORDS AREA

input

- Keywords Area
- environment
- pre_run
- input

Base filename for pre-run mode data input

Topics
This keyword is related to the topics:

- dakota_IO

Specification
Alias: none
Argument(s): STRING
Default: no pre-run specific input read

Description
(For future expansion; not currently used by any methods.) Specify a base filename from which Dakota will read any pre-run input data. This option is overridden by any command-line -pre_run arguments.

output

- Keywords Area
- environment
- pre_run
- output

Base filename for pre-run mode data output

Topics
This keyword is related to the topics:

- dakota_IO

Specification
Alias: none
Argument(s): STRING
Default: no pre-run specific output written
### Description

Specify a base filename to which Dakota will write any pre-run output data (typically parameter sets to be evaluated). This option is overridden by any command-line -pre_run arguments.

#### Usage Tips

Dakota exports tabular data in one of three formats:

- annotated (default)
- custom_annotated
- freeform

**annotated**

- **Keywords Area**
- environment
- pre_run
- output
- annotated

Selects annotated tabular file format

**Topics**

This keyword is related to the topics:

- file_formats

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** annotated format
CHAPTER 6. KEYWORDS AREA

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The `annotated` keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify `custom_annotated header eval_id`
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
  annotated

Resulting tabular file:

```plaintext
%eval_id interface  x1   x2   obj_fn nln_ineq_con_1 nln_ineq_con_2
1  NO_ID     0.9  1.1   0.0002   0.26 0.76
2  NO_ID     0.90009  1.1 0.0001996404857 0.2601620081 0.759955
3  NO_ID     0.89991  1.1 0.0002003604863 0.2598380081 0.760045
...```

`custom_annotated`

- Keywords Area
- environment
- `pre_run`
- output
- `custom_annotated`

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- `file_formats`
6.1. ENVIRONMENT

Specification

Alias: none
Argument(s): none
Default: annotated format

| Required/- | Description of | Dakota Keyword | Dakota Keyword |
| Optional   | Group          |               | Description   |
| Optional   |                | header        | Enable header row in custom-annotated tabular file |
| Optional   |                | eval_id       | Enable evaluation ID column in custom-annotated tabular file |
| Optional   |                | interface_id  | Enable interface ID column in custom-annotated tabular file |

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```plaintext
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
custom_annotated header eval_id
```

Resulting tabular file:
### Specification

**Alias:** none  
**Argument(s):** none  
**Default:** no header

#### Description

See description of parent `custom_annotated`

**eval_id**

- **Keywords Area**
- **environment**
- **pre_run**
- **output**
- **custom_annotated**
- **eval_id**

Enable evaluation ID column in custom-annotated tabular file

### Specification

**Alias:** none  
**Argument(s):** none  
**Default:** no eval_id column
6.1. ENVIRONMENT

Description
See description of parent custom.annotated

interface_id
- Keywords Area
- environment
- pre_run
- output
- custom.annotated
- interface_id
Enable interface ID column in custom-annotated tabular file

Specification
Alias: none
Argument(s): none
Default: no interface_id column

Description
See description of parent custom.annotated

freeform
- Keywords Area
- environment
- pre_run
- output
- freeform
Selects freeform file format

Topics
This keyword is related to the topics:
- file_formats

Specification
Alias: none
Argument(s): none
Default: annotated format
CHAPTER 6. KEYWORDS AREA

Description
A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior
The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips
- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples
Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```plaintext
environment
tabular_data
  tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

```
0.9 1.1 0.0002 0.26 0.76
0.90009 1.1 0.0001996404857 0.2601620081 0.759955
0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...```

6.1.7 run

- Keywords Area
- environment
- run

Invoke Dakota with run mode active

Topics
This keyword is related to the topics:
- command_line_options

Specification
Alias: none
Argument(s): none
Default: pre-run, run, post-run all executed
6.1. ENVIRONMENT

<table>

<td></td>
<td>input</td>
<td>Base filename for run mode data input</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>output</td>
<td>Base filename for run mode data output</td>
</tr>
</tbody>
</table>

**Description**

When specified, Dakota execution will include the run mode, which invokes interfaces to map parameters to responses.

**Default Behavior**

When no run modes are specified, Dakota will perform pre-run, run, and post-run phases.

**input**

- Keywords Area
- environment
- run
- input

Base filename for run mode data input

**Topics**

This keyword is related to the topics:

- dakota.IO

**Specification**

Alias: none

Argument(s): STRING

Default: no run specific input read

**Description**

(For future expansion; not currently used by any methods.) Specify a base filename from which Dakota will read any run input data, such as parameter sets to evaluate. This option is overridden by any command-line -run arguments.
output

- Keywords Area
- environment
- run
- output

Base filename for run mode data output

Topics

This keyword is related to the topics:

- dakota_IO

Specification

Alias: none
Argument(s): STRING
Default: no run specific output written

Description

(For future expansion; not currently used by any methods.) Specify a base filename to which Dakota will write any run output data (typically parameter, response pairs). This option is overridden by any command-line -run arguments.

6.1.8 post_run

- Keywords Area
- environment
- post_run

Invoke Dakota with post-run mode active

Topics

This keyword is related to the topics:

- command_line_options

Specification

Alias: none
Argument(s): none
Default: pre-run, run, post-run all executed
### Description

When specified, Dakota execution will include the post-run mode, which analyzes parameter/response data sets and computes final results. This mode is currently useful for parameter study, DACE, and Monte Carlo sampling methods.

**Default Behavior**

When no run modes are specified, Dakota will perform pre-run, run, and post-run phases.

#### input

- **Keywords Area**
- `environment`
- `post_run`
- `input`

Base filename for post-run mode data input

Selects annotated tabular file format

**Topics**

This keyword is related to the topics:

- **file_formats**

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** annotated format
6.1. ENVIRONMENT

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated
```

Resulting tabular file:

</tr>
</tbody>
</table>

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval id column, and interface id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval.id (no interface-id), and data for variables and responses. Input file fragment:

```plaintext
environment
tagular_data
tagular_data_file = ‘dakota_summary.dat’
custom_annotated header eval_id
```

Resulting tabular file:
### 6.1. ENVIRONMENT

6.1. ENVIRONMENT

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```plaintext
environment
tabular_data
    tabular_data_file = 'dakota_summary.dat'
freeform
```

Resulting tabular file:

```
0.9  1.1  0.0002  0.26  0.76

CHAPTER 6. KEYWORDS AREA

**Specification**

**Alias:** none

**Argument(s):** STRING

**Default:** no post-run specific output written

**Description**

(For future expansion; not currently used by any methods.) Specify a base filename to which Dakota will write any post-run output data. This option is overridden by any command-line -post_run arguments.

### 6.1.9 graphics

- **Keywords Area**
- **environment**
- **graphics**

Display a 2D graphics window of variables and responses

**Topics**

This keyword is related to the topics:

- **dakota_output**

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** graphics off

**Description**

For most studies, the *graphics* flag activates a 2D graphics window containing history plots for the variables and response functions in the study. This window is updated in an event loop with approximately a 2 second cycle time. Some study types such as surrogate-based optimization or local reliability specialize the use of the graphics window.

There is no dependence between the *graphics* flag and the *tabular_data* flag; they may be used independently or concurrently.

**See Also**

These keywords may also be of interest:

- **tabular_data**
6.1.10  tabular_data

This keyword is related to the topics:

- dakota_output

Specification

**Alias:** tabular_graphics_data

**Argument(s):** none

**Default:** no tabular data output

<table>

<td></td>
<td>custom_annotated</td>
<td>Selects custom-annotated tabular file format</td>
</tr>
<tr>
<td></td>
<td></td>
<td>freeform</td>
<td>Selects freeform file format</td>
</tr>
</tbody>
</table>

**Description**

Specifying the **tabular_data** flag writes to a data file the same variable and response function history data plotted when using the **graphics** flag. Within the generated data file, the variables and response functions appear as columns and each function evaluation provides a new table row. This capability is most useful for post-processing of Dakota results with third-party graphics tools such as MatLab, Excel, Tecplot, etc.

There is no dependence between the **graphics** flag and the **tabular_data** flag; they may be used independently or concurrently.

Dakota exports tabular data in one of three formats:

- annotated (default)
- custom_annotated
- freeform

- annotated

Selects annotated tabular file format

Topics
This keyword is related to the topics:

- file_formats
6.1. ENVIRONMENT

Specification

Alias: none
Argument(s): none
Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom.annotated header eval_id
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```dakota
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
annotated
```

Resulting tabular file:

```plaintext
%eval_id interface x1  x2   obj_fn nln_ineq_con_1 nln_ineq_con_2
1   NO_ID   0.9 1.1   0.0002 0.26    0.76
2   NO_ID   0.90009 1.1 0.0001996404857 0.2601620081 0.759955

</tbody>
</table>

Description
A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior
The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

Usage Tips
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>results_output_file</td>
<td>results_output</td>
<td>The base file name of the results file</td>
</tr>
</tbody>
</table>

**Description**

Final results from a Dakota study can be output to `dakota_results.txt` by specifying `results_output` (optionally specifying an alternate file name with `results_output_filename`). The current experimental text file format is hierarchical and a precursor to planned output to structured text formats such as XML or YAML, and binary formats such as HDF5. The contents, organization, and format of results files are all under active development and are subject to change.

6.1.13 top_method_pointer

- Keywords Area
- environment
- top_method_pointer

Identify which method leads the Dakota study

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: method_pointer

Argument(s): STRING

Default: see discussion
CHAPTER 6. KEYWORDS AREA

Description

An optional \texttt{top\_method\_pointer} specification may be used to point to a particular method specification that will lead the Dakota analysis. The associated string must be a method identifier specified via \texttt{id\_method}. If \texttt{top\_method\_pointer} is not used, then it will be inferred as described below (no \texttt{top\_method\_pointer} within an environment specification is treated the same as no environment specification).

Default Behavior

The \texttt{top\_method\_pointer} keyword is typically used in Dakota studies consisting of more than one \texttt{method} block to clearly indicate which is the leading method. This method provides the starting point for the iteration. The corresponding method specification may recurse with additional sub-method pointers in the case of "meta-iteration" (see \texttt{method}) or may specify a single method without recursion. Either case will ultimately result in identification of one or more model specifications using \texttt{model\_pointer}, which again may or may not involve further recursion (see \texttt{nested} and \texttt{surrogate} for recursion cases). Each of the model specifications identify the variables and responses specifications (using \texttt{variables\_pointer} and \texttt{responses\_pointer}) that are used to build the model, and depending on the type of model, may also identify an interface specification (for example, using \texttt{interface\_pointer}). If one of these specifications does not provide an optional pointer, then that component will be constructed using the last specification parsed.

When the environment block is omitted, the top level method will be inferred as follows: When a single method is specified, there is no ambiguity and the sole method will be the top method. When multiple methods are specified, the top level method will be deduced from the hierarchical relationships implied by method pointers. If this inference is not well defined (e.g., there are multiple method specifications without any pointer relationship), then the default behavior is to employ the last method specification parsed.

Examples

Specify that the optimization method is the outermost method in an optimization under uncertainty study

\begin{verbatim}
environment
  top_method_pointer 'OPTIMIZATION_METHOD'
method
  id_method 'UQ_METHOD'
  ...
method
  id_method 'OPTIMIZATION_METHOD'
  ...
\end{verbatim}

### Method Block Requirements
At least one `method` block must appear in the Dakota input file. Multiple `method` blocks may be needed to fully define advanced analysis approaches.

Each `method` block must specify one method and, optionally, any associated keywords that govern the behavior of the method.

### The Methods
Each `method` block must select one method.

Starting with Dakota v6.0, the methods are grouped into two types: standard methods and multi-component methods.

The standard methods are stand-alone and self-contained in the sense that they only require a model to perform a study. They do not call other methods. While methods such as `polynomial_chaos` and `efficient_global` internally utilize multiple iterator and surrogate model components, these components are generally hidden from user control due to restrictions on modularity; thus, these methods are stand-alone.

The multi-component group of methods provides a higher level "meta-algorithm" that points to other methods and models that support sub-iteration. For example, in a sequential hybrid method, the `hybrid` method specification must identify a list of subordinate methods, and the "meta-algorithm" executes these methods in sequence and transfers information between them. Surrogate-based minimizers provide another example in that they point both to other methods (e.g. what optimization method is used to solve the approximate subproblem) as well as to models (e.g. what type of surrogate model is employed). Multi-component methods generally provide some level of "plug and play" modularity, through their flexible support of a variety of method and model selections.

### Component-Based Iterator Commands
Component-based iterator specifications include hybrid, multi-start, pareto set, surrogate-based local, surrogate-based global, and branch and bound methods. Whereas a standard iterator specification only needs an optional model pointer string (specified with `model_pointer`), component-based iterator specifications can include

<table>
<thead>

</tr>
</tbody>
</table>
method pointer, method name, and model pointer specifications in order to define the components employed in
the "meta-iteration." In particular, these specifications identify one or more methods (by pointer or by name) to
specify the subordinate iterators that will be used in the top-level algorithm. Identifying a sub-iterator by name
instead of by pointer is a lightweight option that relaxes the need for a separate method specification for the sub-
iterator; however, a model pointer may be required in this case to provide the specification connectivity normally
supported by the method pointer. Refer to these individual method descriptions for specific requirements for these
advanced methods.

**Method Independent Controls**

In addition to the method, there are 10 optional keywords, which are referred to as method independent
controls. These controls are valid for enough methods that it was reasonable to pull them out of the method
dependent blocks and consolidate the specifications, however, they are NOT universally respected by all methods.

**Examples**

Several examples follow. The first example shows a minimal specification for an optimization method.

```plaintext
method
dot_sqp
```

This example uses all of the defaults for this method.

A more sophisticated example would be

```plaintext
method,
id_method = 'NLP1'
dot_sqp
  max_iterations = 50
  convergence_tolerance = 1e-4
  output verbose
  model_pointer = 'M1'
```

This example demonstrates the use of identifiers and pointers as well as some method independent and method
dependent controls for the sequential quadratic programming (SQP) algorithm from the DOT library. The `max_iterations`, `convergence_tolerance`, and `output` settings are method independent controls, in that
they are defined for a variety of methods (see `dot` for usage of these controls).

The next example shows a specification for a least squares method.

```plaintext
method
optpp_g_newton
  max_iterations = 10
  convergence_tolerance = 1.e-8
  search_method trust_region
  gradient_tolerance = 1.e-6
```

Some of the same method independent controls are present along with several method dependent controls (`search_method` and `gradient_tolerance`) which are only meaningful for OPT++ methods (see `package_optpp`).

The next example shows a specification for a nondeterministic method with several method dependent controls
(refer to `sampling`).

```plaintext
method
sampling
  samples = 100
  seed = 12345
  sample_type lhs
  response_levels = 1000. 500.
```

The last example shows a specification for a parameter study method where, again, each of the controls are
method dependent (refer to `vector_parameter_study`).

```plaintext
method
vector_parameter_study
  step_vector = 1. 1. 1.
  num_steps = 10
```
6.2. METHOD

6.2.1 id_method

- Keywords Area
- method
- id_method

Name the method block; helpful when there are multiple

Topics

This keyword is related to the topics:

- block_identifier
- method_identifier
- method_independent_controls

Specification

Alias: none

Argument(s): STRING

Default: strategy use of last method parsed

Description

The method identifier string is supplied with id_method and is used to provide a unique identifier string for use with environment or meta-iterator specifications (refer to environment). It is appropriate to omit a method identifier string if only one method is included in the input file, since the single method to use is unambiguous in this case.

6.2.2 output

- Keywords Area
- method
- output

Control how much method information is written to the screen and output file

Topics

This keyword is related to the topics:

- dakota_output
- method_independent_controls

Specification

Alias: none

Argument(s): none

Default: normal
### Description

Choose from a total of five output levels during the course of a Dakota study. If there is no user specification for output verbosity, then the default setting is `normal`.

Specific mappings are as follows:

- **silent** (i.e., really quiet): silent iterators, silent model, silent interface, quiet approximation, quiet file operations
- **quiet**: quiet iterators, quiet model, quiet interface, quiet approximation, quiet file operations
- **normal**: normal iterators, normal model, normal interface, quiet approximation, quiet file operations
- **verbose**: verbose iterators, normal model, verbose interface, verbose approximation, verbose file operations
- **debug** (i.e., really verbose): debug iterators, normal model, debug interface, verbose approximation, verbose file operations

Note that iterators and interfaces utilize the full granularity in verbosity, whereas models, approximations, and file operations do not. With respect to iterator verbosity, different iterators implement this control in slightly different ways (as described below in the method independent controls descriptions for each iterator), however the meaning is consistent.

For models, interfaces, approximations, and file operations, **quiet** suppresses parameter and response set reporting and **silent** further suppresses function evaluation headers and scheduling output. Similarly, **verbose** adds file management, approximation evaluation, and global approximation coefficient details, and **debug** further adds diagnostics from nonblocking schedulers.

6.2.5 speculative

- Keywords Area
- method
- speculative

Compute speculative gradients

Topics
This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): none

Default: no speculation

Description
When performing gradient-based optimization in parallel, speculative gradients can be selected to address the load imbalance that can occur between gradient evaluation and line search phases. In a typical gradient-based optimization, the line search phase consists primarily of evaluating the objective function and any constraints at a trial point, and then testing the trial point for a sufficient decrease in the objective function value and/or constraint violation. If a sufficient decrease is not observed, then one or more additional trial points may be attempted sequentially. However, if the trial point is accepted then the line search phase is complete and the gradient evaluation phase begins. By speculating that the gradient information associated with a given line search trial point will be used later, additional coarse grained parallelism can be introduced by computing the gradient information (either by finite difference or analytically) in parallel, at the same time as the line search phase trial-point function values. This balances the total amount of computation to be performed at each design point and allows for efficient utilization of multiple processors. While the total amount of work performed will generally increase (since some speculative gradients will not be used when a trial point is rejected in the line search phase), the run time will usually decrease (since gradient evaluations needed at the start of each new optimization cycle were already performed in parallel during the line search phase). Refer to [14] for additional details. The speculative specification is implemented for the gradient-based optimizers in the DOT, CONMIN, and OPT++ libraries, and it can be used with dakota numerical or analytic gradient selections in the responses specification (refer to responses gradient section for information on these specifications). It should not be selected with vendor numerical gradients since vendor internal finite difference algorithms have not been modified for this purpose. In full-Newton approaches, the Hessian is also computed speculatively. NPSOL and NLSSOL do not support speculative gradients, as their gradient-based line search in user-supplied gradient mode (dakota numerical or analytic gradients) is a superior approach for load-balanced parallel execution.
The speculative specification enables speculative computation of gradient and/or Hessian information, where applicable, for parallel optimization studies. By speculating that the derivative information at the current point will be used later, the complete data set (all available gradient/Hessian information) can be computed on every function evaluation. While some of these computations will be wasted, the positive effects are a consistent parallel load balance and usually shorter wall clock time. The speculative specification is applicable only when parallelism in the gradient calculations can be exploited by Dakota (it will be ignored for vendor numerical gradients).

### 6.2.6 convergence_tolerance

- **Keywords Area**
  - method
  - convergence_tolerance

  Stopping criterion based on convergence of the objective function

**Topics**

This keyword is related to the topics:
- method_independent_controls

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 1.e-4

**Description**

The convergence_tolerance specification provides a real value for controlling the termination of iteration. It is a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by convergence_tolerance, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

**Behavior Varies by Package/Library**

This control is used with optimization and least squares iterators (DOT, CONMIN, NPSOL, NLSSOL, OPT++, and SCOLIB) and is not used within the uncertainty quantification, design of experiments, or parameter study iterator branches.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

**Notes on each library:**

- DOT: must be satisfied for two consecutive iterations
- NPSOL: defines an internal optimality tolerance which is used in evaluating if an iterate satisfies the first-order Kuhn-Tucker conditions for a minimum. The magnitude of convergence_tolerance approximately specifies the number of significant digits of accuracy desired in the final objective function (e.g., convergence_tolerance = 1.e-6 will result in approximately six digits of accuracy in the final objective function).
• NL2SOL: See nl2sol

6.2.7 constraint_tolerance

• Keywords Area
• method
• constraint_tolerance

The maximum allowable value of constraint violation still considered to be feasible

Topics
This keyword is related to the topics:
• method_independent_controls

Specification

Alias: none
  Argument(s): REAL
  Default: Library default

Description
The constraint_tolerance specification determines the maximum allowable value of infeasibility that any constraint in an optimization problem may possess and still be considered to be satisfied.

If a constraint function is greater than this value then it is considered to be violated by the optimization algorithm. This specification gives some control over how tightly the constraints will be satisfied at convergence of the algorithm. However, if the value is set too small the algorithm may terminate with one or more constraints being violated.

This specification is currently meaningful for the NPSOL, NLSSOL, DOT and CONMIN constrained optimizers.

Defaults
Defaults can vary depending on the method.

• DOT constrained optimizers: 0.003

• NPSOL: dependent upon the machine precision, typically on the order of $1.e^{-8}$ for double precision computations

6.2.8 scaling

• Keywords Area
• method
• scaling

Turn on scaling for variables, responses, and constraints
6.2. METHOD

Topics
This keyword is related to the topics:
- method\_independent\_controls

Specification
Alias: none
- Argument(s): none
- Default: no scaling

Description
Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by by providing the scaling keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the method, variables, and responses blocks. When the scaling keyword is omitted, all \_scale\_types and *scales specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.
- a *scales keyword, which gives characteristic values
- a *scale\_type keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types
There are four scale types:
1. none (default) - no scaling, value of *scales keyword is ignored
2. value - multiplicative scaling
3. auto - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:
- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].
4. **log** - logarithmic scaling
   
   First, any characteristic values from the optional *scales* specification are applied. Then logarithm base 10 scaling is applied.
   
   Logarithmic scaling is not available for linear constraints.
   
   When continuous design variables are log scaled, linear constraints are not allowed.

**Scales**

The *scales* keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding *scale_type*, as described above. Depending on the scale type, the characteristic values may be required or optional.

- **none, auto, log** - optional
- **value** - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0\times10^{-10}$*. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

**Examples**

The two examples below are equivalent:

```plaintext
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100

responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

**6.2.9 final_solutions**

- **Keywords Area**
- **method**
- **final_solutions**

  Number of designs returned as the best solutions

**Topics**

This keyword is related to the topics:

- **method_independent_controls**

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 1
6.2. METHOD

Description

The `final_solutions` controls the number of final solutions returned by the iterator as the best solutions. For most optimizers, this is one, but some optimizers can produce multiple solutions (e.g., genetic algorithms). When using a `hybrid` strategy, the number of final solutions dictates how many solutions are passed from one method to another.

Examples

In the case of sampling methods, if one specifies 100 samples (for example) but also specifies `final_solutions = 5`, the five best solutions (in order of lowest response function value) are returned.

6.2.10 `hybrid`

- **Keywords**
  - Area
  - method
  - hybrid

Strategy in which a set of methods synergistically seek an optimal design.

Specification

Alias: none  
Argument(s): none

</tr>
</tbody>
</table>
Description

In a hybrid minimization method (hybrid), a set of methods synergistically seek an optimal design. The relationships among the methods are categorized as:

- collaborative
- embedded
- sequential

The goal in each case is to exploit the strengths of different optimization and nonlinear least squares algorithms at different stages of the minimization process. Global + local hybrids (e.g., genetic algorithms combined with nonlinear programming) are a common example in which the desire for identification of a global optimum is balanced with the need for efficient navigation to a local optimum.

sequential

<td>List of Dakota methods to sequentially or collaboratively run</td>
</tr>
</tbody>
</table>
6.2. METHOD

Description

In the **sequential** approach, methods are run one at a time, in sequence. The best solutions from one method are used to initialize the next method.

The sequence of methods (i.e. iterators) to run are specified using either a `method_pointer_list` or a `method_name_list` (with optional `model_pointer_list`). Any number of iterators may be specified.

Method switching is managed through the separate convergence controls of each method. The number of solutions transferred between methods is specified by the particular method through its `final_solutions` method control.

For example, if one sets up a two-level study with a first method that generates multiple solutions such as a genetic algorithm, followed by a second method that is initialized only at a single point such as a gradient-based algorithm, it is possible to take the multiple solutions generated by the first method and create several instances of the second method, each one with a different initial starting point.

The logic governing the transfer of multiple solutions between methods is as follows:

- if one solution is returned from method A, then one solution is transferred to method B.

- If multiple solutions are returned from method A, and method B can accept multiple solutions as input (for example, as a genetic algorithm population), then one instance of method B is initialized with multiple solutions.

- If multiple solutions are returned from method A but method B only can accept one initial starting point, then method B is run several times, each one with a separate starting point from the results of method A.

CHAPTER 6. KEYWORDS AREA

### Description

In the *embedded* approach, a tightly-coupled hybrid is employed in which a subordinate local method provides periodic refinements to a top-level global method.

Global and local method strings supplied with the `global_method_pointer` and `local_method_pointer` specifications identify the two methods to be used. Alternatively, Dakota method names (e.g. 'soga') can be supplied using the `global_method_name` and `local_method_name` keywords, which each have optional model pointer specifications. The `local_search_probability` setting is an optional specification for supplying the probability (between 0.0 and 1.0) of employing local search to improve estimates within the global search.

**global_method_name**

- **Keywords Area**
- **method**
- **hybrid**
- **embedded**

Specify the global method by Dakota name

**Specification**

6.2. METHOD

- embedded
- global_method_name
- global_model_pointer

Pointer to model used by global method

Topics
This keyword is related to the topics:
- block_pointer

Specification
Alias: none
Argument(s): STRING

Description
global_model_pointer can be used to specify a model for use with the Dakota method named by the global_method_name specification. The argument is a string that refers to the id_model label of the desired model.

global_method_pointer
- Keywords Area
- method
- hybrid
- embedded
- global_method_pointer

Pointer to global method

Topics
This keyword is related to the topics:
- block_pointer

Specification
Alias: none
Argument(s): STRING

Description
The global_method_pointer identifies the method block to use as the global method in a hybrid embedded optimization using its id_method label.
local_method_name

- Keywords Area
- method
- hybrid
- embedded
- local_method_name

Specify the local method by Dakota name

Pointer to model used by local method

**Topics**

This keyword is related to the topics:

- block_pointer

**Specification**

Alias: none
Argument(s): STRING
6.2. METHOD

Description

`local_model_pointer` can be used to specify a model for use with the Dakota method named by the `local_method_name` specification. The argument is a string that refers to the `id_model` label of the desired model.

`local_method_pointer`

- **Keywords Area**
- **method**
- **hybrid**
- **embedded**
- **local_method_pointer**

  Pointer to local method

Topics

This keyword is related to the topics:

- **block_pointer**

Specification

**Alias:** none

**Argument(s):** STRING

Description

The `local_method_pointer` identifies the method block to use as the local method in a hybrid embedded optimization using its `id_method`.

`local_search_probability`

- **Keywords Area**
- **method**
- **hybrid**
- **embedded**
- **local_search_probability**

  Probability of executing local searches

Specification

**Alias:** none

**Argument(s):** REAL
Description

The `local_search_probability` setting is an optional specification for supplying the probability (between 0.0 and 1.0) of employing local search to improve estimates within the global search. Its default value is 0.1.

**collaborative**

- Keywords Area
- method
- hybrid
- collaborative

Multiple methods run concurrently and share information

### Specification

**Alias:** none  
**Argument(s):** none

<table>
<thead>
<tr>
<th>Required/- Optional Required <em>(Choose One)</em></th>
<th>Description of Group 1</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>method_name_list</td>
<td>List of Dakota methods to sequentially or collaboratively run</td>
</tr>
<tr>
<td></td>
<td></td>
<td>method_pointer_list</td>
<td>Pointers to methods to execute sequentially or collaboratively</td>
</tr>
</tbody>
</table>

### Description

In the collaborative approach, multiple methods work together and share solutions while executing concurrently. A list of method strings specifies the pool of iterators to be used. Any number of iterators may be specified. The method collaboration logic follows that of either the Agent-Based Optimization or HOPSPACK codes and is currently under development and not available at this time.

**method_name_list**

- Keywords Area
- method
- hybrid
- collaborative
- method_name_list

List of Dakota methods to sequentially or collaboratively run
6.2. METHOD

Specification

Alias: none
  Argument(s): STRINGLIST
\begin{table}
\begin{tabular}{|l|c|c|c|}
\hline
\textbf{Required/-} & \textbf{Description of} & \textbf{Dakota Keyword} & \textbf{Dakota Keyword} \\
\textbf{Optional} & \textbf{Group} & \textbf{model\_pointer\_list} & \textbf{Description} \\
\hline
\textbf{Optional} & & & Associate models with method names \\
\hline
\end{tabular}
\end{table}

\textbf{Description}

\texttt{method\_name\_list} specifies a list of Dakota methods (e.g. \texttt{soga, conmin\_freg}) that will be run by a hybrid sequential or hybrid collaborative method. The methods are executed with default options. The optional \texttt{model\_pointer\_list} may be used to associate a model with each method.

- \texttt{model\_pointer\_list}
- \texttt{Keywords Area}
- \texttt{method}
- \texttt{hybrid}
- \texttt{collaborative}
- \texttt{method\_name\_list}
- \texttt{model\_pointer\_list}

Associate models with method names

\textbf{Topics}

This keyword is related to the topics:

- \texttt{block\_pointer}

\textbf{Specification}

Alias: none

Argument(s): STRING

\textbf{Description}

Using the optional keyword \texttt{model\_pointer\_list}, models can be assigned to methods specified in the \texttt{method\_name\_list}. Models are referred to by name (i.e. by their \texttt{id\_model} labels). The length of the \texttt{model\_pointer\_list} must be either 1 or match the length of the \texttt{method\_name\_list}. If the former, the same model will be used for all methods, and if the latter, methods and models will be paired in the order that they appear in the two lists.
6.2. METHOD

method_pointer_list

- Keywords Area
- method
- hybrid
- collaborative
- method_pointer_list

Pointers to methods to execute sequentially or collaboratively

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none
Argument(s): STRINGLIST

Description

method_pointer_list specifies by name the methods that are to be executed by a hybrid sequential or hybrid collaborative method. Its argument is a list of strings that refer to method blocks by name (i.e. to their id_method labels).

iterator_servers

- Keywords Area
- method
- hybrid
- iterator_servers

Specify the number of iterator servers when Dakota is run in parallel

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none
Argument(s): INTEGER
**Description**

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional `iterator_servers` specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, `hybrid`, `multi_start`, and `pareto_set` component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [4] for additional information.

**iterator_scheduling**

- Keywords Area
- method
- hybrid
- `iterator_scheduling`

Specify the scheduling of concurrent iterators when Dakota is run in parallel

**Topics**

This keyword is related to the topics:

- concurrency_and_parallelism

**Specification**

Alias: none

**Argument(s):** none

<table>
<thead>

<th>Dakota Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>Group</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>master</code></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Description**

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional `iterator_scheduling` specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, `hybrid`, `multi_start`, and `pareto_set` component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [4] for additional information.
6.2. METHOD

master
- Keywords Area
- method
- hybrid
- iterator_scheduling
- master

Specify a dedicated master partition for parallel iterator scheduling

Topics
This keyword is related to the topics:
- concurrency_and_parallelism

Specification
Alias: none
Argument(s): none

Description
This option overrides the Dakota parallel automatic configuration, forcing the use of a dedicated master partition. In a dedicated master partition, one processor (the "master") dynamically schedules work on the iterator servers. This reduces the number of processors available to create servers by 1.

peer
- Keywords Area
- method
- hybrid
- iterator_scheduling
- peer

Specify a peer partition for parallel iterator scheduling

Topics
This keyword is related to the topics:
- concurrency_and_parallelism

Specification
Alias: none
Argument(s): none
CHAPTER 6. KEYWORDS AREA

Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a peer partition. In a peer partition, all processors are available to be assigned to iterator servers. Note that unlike the case of evaluation scheduling, it is not possible to specify static or dynamic.

processors_per_iterator

- Keywords Area
- method
- hybrid
- processors_per_iterator

Specify the number of processors per iterator server when Dakota is run in parallel

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none
Argument(s): INTEGER

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional processors_per_iterator specification supports user override of the automatic parallel configuration for the number of processors in each iterator server. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired server size at the iterator parallelism level. Currently, hybrid, multi_start, and pareto_set component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual[4] for additional information.

6.2.11 multi_start

- Keywords Area
- method
- multi_start

Multi-Start Optimization Method

Specification

Alias: none
Argument(s): none
### Description

In the multi-start iteration method (multi_start), a series of iterator runs are performed for different values of parameters in the model. A common use is for multi-start optimization (i.e., different local optimization runs from different starting points for the design variables), but the concept and the code are more general. Multi-start iteration is implemented within the MetaIterator branch of the Iterator hierarchy within the ConcurrentMeta-Iterator class. Additional information on the multi-start algorithm is available in the Users Manual[4].

The multi_start meta-iterator must specify a sub-iterator using either a method_pointer or a method_name plus optional model_pointer. This iterator is responsible for completing a series of iterative analyses from a set of different starting points. These starting points can be specified as follows: (1) using random_starts, for which the specified number of starting points are selected randomly within the variable bounds, (2) using starting_points, in which the starting values are provided in a list, or (3) using both random_starts and starting_points, for which the combined set of points will be used. In aggregate, at least one starting point must be specified. The most common example of a multi-start algorithm is multi-start optimization, in which a series of optimizations are performed from different starting values for the design variables. This can be an effective approach for problems with multiple minima.

<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>model_pointer</td>
<td>Identifier for model block to be used by a method</td>
</tr>
</tbody>
</table>

**Description**

The `method_name` keyword is used to specify a sub-method by Dakota method name (e.g. 'npsol_sqp') rather than block pointer. The method will be executed using its default settings. The optional `model_pointer` specification can be used to associate a model block with the method.

**model_pointer**

- Keywords Area
- method
- multi_start
- method_name
- model_pointer

Identifier for model block to be used by a method

**Topics**

This keyword is related to the topics:

- block_pointer

**Specification**

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)
6.2. METHOD

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.

See block_pointer for details about pointers.

Examples

```
environment
  tabular_graphics_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SIRR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
    0.1 0.2 0.6
    0.1 0.2 0.6
  sample_type lhs
  distribution cumulative

6.2. METHOD

<table>
<thead>
<tr>
<th>Optional</th>
<th>seed</th>
<th>Seed of the random number generator</th>
</tr>
</thead>
</table>

**Description**

The `multi_start` meta-iterator must specify a sub-iterator using either a `method_pointer` or a `method_name` plus optional `model_pointer`. This iterator is responsible for completing a series of iterative analyses from a set of different starting points. These starting points can be specified as follows: (1) using `random_starts`, for which the specified number of starting points are selected randomly within the variable bounds, (2) using `starting_points`, in which the starting values are provided in a list, or (3) using both `random_starts` and `starting_points`, for which the combined set of points will be used.

**seed**

- **Keywords Area**
- **method**
- **multi_start**
- **random_starts**
- **seed**

Seed of the random number generator

**Specification**

**Alias:** none

- **Argument(s):** INTEGER
- **Default:** system-generated (non-repeatable)

**Description**

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

**Default Behavior**
If not specified, the seed is randomly generated.

**Expected Output**
If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

**Usage Tips**
If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

**Examples**

```dakota
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```
starting_points
  • Keywords Area
  • method
  • multi_start
  • starting_points

List of user-specified starting points

Specification
Alias: none
  Argument(s): REALLIST

Description
The multi_start meta-iterator must specify a sub-iterator using either a method_pointer or a method_name plus optional model_pointer. This iterator is responsible for completing a series of iterative analyses from a set of different starting points. These starting points can be specified as follows: (1) using random_starts, for which the specified number of starting points are selected randomly within the variable bounds, (2) using starting_points, in which the starting values are provided in a list, or (3) using both random_starts and starting_points, for which the combined set of points will be used.

Specify the number of processors per iterator server when Dakota is run in parallel

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none

Argument(s): INTEGER

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional processors_per_iterator specification supports user override of the automatic parallel configuration for the number of processors in each iterator server. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired server size at the iterator parallelism level. Currently, hybrid, multi_start, and pareto_set component-based iterators support concurrency in their sub-iterations. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual[4] for additional information.

6.2.12 pareto_set

- Keywords Area
- method
- pareto_set

Pareto set optimization

Specification

Alias: none

Argument(s): none
## Description

In the pareto set minimization method (pareto_set), a series of optimization or least squares calibration runs are performed for different weightings applied to multiple objective functions. This set of optimal solutions defines a "Pareto set," which is useful for investigating design trade-offs between competing objectives. The code is similar enough to the multi_start technique that both algorithms are implemented in the same Concurrent-MetaIterator class.

The pareto_set specification must identify an optimization or least squares calibration method using either a method_pointer or a method_name plus optional model_pointer. This minimizer is responsible for computing a set of optimal solutions from a set of response weightings (multi-objective weights or least squares term weights). These weightings can be specified as follows: (1) using random_weight_sets, in which case weightings are selected randomly within [0,1] bounds, (2) using weight_sets, in which the weighting sets are specified in a list, or (3) using both random_weight_sets and weight_sets, for which the combined set of weights will be used. In aggregate, at least one set of weights must be specified. The set of optimal solutions is called the "pareto set," which can provide valuable design trade-off information when there are competing objectives.

**Keywords Area**

| Optional | seed | Seed of the random number generator |

**Description**

The `pareto_set` specification must identify an optimization or least squares calibration method using either a `method_pointer` or a `method_name` plus optional `model_pointer`. This minimizer is responsible for computing a set of optimal solutions from a set of response weightings (multi-objective weights or least squares term weights). These weightings can be specified as follows: (1) using `random_weight_sets`, in which case weightings are selected randomly within [0,1] bounds, (2) using `weight_sets`, in which the weighting sets are specified in a list, or (3) using both `random_weight_sets` and `weight_sets`, for which the combined set of weights will be used. In aggregate, at least one set of weights must be specified. The set of optimal solutions is called the "pareto set," which can provide valuable design trade-off information when there are competing objectives.

**seed**

- Keywords Area
- method
- `pareto_set`
- `random_weight_sets`
- `seed`

Seed of the random number generator

**Specification**

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)

**Description**

The random `seed` control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

weight_sets
  • Keywords Area
  • method
  • pareto_set
  • weight_sets

List of user-specified weighting sets

Specification

Alias: multi_objective_weight_sets
  Argument(s): REALLIST

Description

The pareto_set specification must identify an optimization or least squares calibration method using either a method_pointer or a method_name plus optional model_pointer. This minimizer is responsible for computing a set of optimal solutions from a set of response weightings (multi-objective weights or least squares term weights). These weightings can be specified as follows: (1) using random_weight_sets, in which case weightings are selected randomly within [0,1] bounds, (2) using weight_sets, in which the weighting sets are specified in a list, or (3) using both random_weight_sets and weight_sets, for which the combined set of weights will be used. In aggregate, at least one set of weights must be specified. The set of optimal solutions is called the "pareto set," which can provide valuable design trade-off information when there are competing objectives.

iterator_servers
  • Keywords Area
  • method
  • pareto_set
  • iterator_servers

Specify the number of iterator servers when Dakota is run in parallel

Topics

This keyword is related to the topics:
  • concurrency_and_parallelism
 Exactly feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional iterator_servers specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, hybrid, multi_start, and pareto_set component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [4] for additional information.

**iterator_scheduling**

- Keywords Area
- method
- pareto_set
- iterator_scheduling

Specify the scheduling of concurrent iterators when Dakota is run in parallel

**Topics**

This keyword is related to the topics:

- concurrency_and_parallelism

</tbody>
</table>
Description
An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional iterator_scheduling specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, hybrid, multi_start, and pareto_set component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [4] for additional information.

master
- Keywords Area
- method
- pareto_set
- iterator_scheduling
- master

Specify a dedicated master partition for parallel iterator scheduling

Topics
This keyword is related to the topics:
- concurrency_and_parallelism

Specification
Alias: none
Argument(s): none

Description
This option overrides the Dakota parallel automatic configuration, forcing the use of a dedicated master partition. In a dedicated master partition, one processor (the "master") dynamically schedules work on the iterator servers. This reduces the number of processors available to create servers by 1.

peer
- Keywords Area
- method
- pareto_set
- iterator_scheduling
- peer

Specify a peer partition for parallel iterator scheduling
Topics
This keyword is related to the topics:

- concurrency_and_parallelism

Specification
Alias: none
Argument(s): none

Description
This option overrides the Dakota parallel automatic configuration, forcing the use of a peer partition. In a peer partition, all processors are available to be assigned to iterator servers. Note that unlike the case of evaluation_scheduling, it is not possible to specify static or dynamic.

processors_per_iterator

- Keywords Area
- method
- pareto_set
- processors_per_iterator

Specify the number of processors per iterator server when Dakota is run in parallel

Topics
This keyword is related to the topics:

- concurrency_and_parallelism

Specification
Alias: none
Argument(s): INTEGER

Description
An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional processors_per_iterator specification supports user override of the automatic parallel configuration for the number of processors in each iterator server. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired server size at the iterator parallelism level. Currently, hybrid, multi_start, and pareto_set component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual[4] for additional information.

### Description

In surrogate-based optimization (SBO) and surrogate-based nonlinear least squares (SBNLS), minimization occurs using a set of one or more approximations, defined from a surrogate model, that are built and periodically updated using data from a “truth” model. The surrogate model can be a global data fit (e.g., regression or interpolation of data generated from a design of computer experiments), a multipoint approximation, a local Taylor Series expansion, or a model hierarchy approximation (e.g., a low-fidelity simulation model), whereas the truth model involves a high-fidelity simulation model. The goals of surrogate-based methods are to reduce the total number of truth model simulations and, in the case of global data fit surrogates, to smooth noisy data with an easily navigated analytic function.

In the surrogate-based local method, a trust region approach is used to manage the minimization process to maintain acceptable accuracy between the surrogate model and the truth model (by limiting the range over which the surrogate model is trusted). The process involves a sequence of minimizations performed on the surrogate model and bounded by the trust region. At the end of each approximate minimization, the candidate optimum point is validated using the truth model. If sufficient decrease has been obtained in the truth model, the trust region is re-centered around the candidate optimum point and the trust region will either shrink, expand, or remain the same size depending on the accuracy with which the surrogate model predicted the truth model decrease. If sufficient decrease has not been attained, the trust region center is not updated and the entire trust region shrinks by a user-specified factor. The cycle then repeats with the construction of a new surrogate model, a minimization, and another test for sufficient decrease in the truth model. This cycle continues until convergence is attained.

### Theory

For surrogate-based local problems with nonlinear constraints, a number of algorithm formulations exist as described in[23] and as summarized in the Advanced Examples section of the Models chapter of the Users Manual[4].

Pointer to sub-method to apply to surrogate
6.2. **METHOD**

**Topics**

This keyword is related to the topics:

- block_pointer

**Specification**

**Alias:** approx_method_pointer

**Argument(s):** STRING

**Description**

The `method_pointer` keyword is used to specify a pointer to an optimization or least-squares sub-method to apply to the surrogate model.

Any `model_pointer` identified in the sub-method specification is ignored. Instead, the parent method is responsible for selecting a surrogate model using its `model_pointer`.

**method_name**

- Keywords Area
- method
- surrogate_based_local
- method_name

Specify sub-method by name

**Specification**

**Alias:** approx_method_name

**Argument(s):** STRING

**Description**

The `method_name` keyword is used to specify a sub-method by Dakota method name (e.g. ‘npsol_sqp’) rather than block pointer. The method will be executed using its default settings. The optional `model_pointer` specification can be used to associate a model block with the method.

**model_pointer**

- Keywords Area
- method
- surrogate_based_local
- model_pointer

Identifier for model block to be used by a method
CHAPTER 6. KEYWORDS AREA

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: approx_model_pointer

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.

See block_pointer for details about pointers.

Examples

```plaintext
environment
  tabular_graphics_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'

- trust_region
- expand_threshold

  Expand trust region if trust region ratio is above this value

**Specification**

**Alias:** none  
**Argument(s):** REAL  
**Default:** 0.75

**Description**

The trust_region optional group specification can be used to specify the initial size of the trust region (using initial_size) relative to the total variable bounds, the minimum size of the trust region (using minimum_size), the contraction factor for the trust region size (using contraction_factor) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using expansion_factor) used when the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using contract_threshold) and the trust region size expansion threshold (using expand_threshold). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command contract_threshold sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command expand_threshold determines the trust region value above which the trust region will expand for the next SBL iteration.

**contraction_factor**

- Keywords Area
- method
- surrogate_based_local
- trust_region
- contraction_factor

  Amount by which step length is rescaled
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none
  Argument(s): REAL
  Default: 0.25

Description

For pattern search methods, contraction_factor specifies the amount by which step length is rescaled after unsuccessful iterates, must be strictly between 0 and 1.

For methods that can expand the step length, the expansion is 1/contraction_factor

expansion_factor

- Keywords Area
- method
- surrogate_based_local
- trust_region
- expansion_factor

Trust region expansion factor

Specification

Alias: none
  Argument(s): REAL
  Default: 2.0

Description

The trust_region optional group specification can be used to specify the initial size of the trust region (using initial_size) relative to the total variable bounds, the minimum size of the trust region (using minimum_size), the contraction factor for the trust region size (using contraction_factor) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using expansion_factor) used when the the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using contract_threshold) and the trust region size expansion threshold (using expand_threshold). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command contract_threshold sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command expand_threshold determines the trust region value above which the trust region will expand for the next SBL iteration.

**Description**

Following optimization of the approximate subproblem, the candidate iterate is evaluated using a merit function, which can be selected to be a simple penalty function with penalty ramped by surrogate_based_local iteration number (penalty_merit), an adaptive penalty function where the penalty ramping may be accelerated in order to avoid rejecting good iterates which decrease the constraint violation (adaptive_penalty_merit), a Lagrangian merit function which employs first-order Lagrange multiplier updates (lagrangian_merit), or an augmented Lagrangian merit function which employs both a penalty parameter and zeroth-order Lagrange multiplier updates (augmented_lagrangian_merit). When an augmented Lagrangian is selected for either the subproblem objective or the merit function (or both), updating of penalties and multipliers follows the approach described in [16].

Description

Following calculation of the merit function for the new iterate, the iterate is accepted or rejected and the trust region size is adjusted for the next surrogate_based_local iteration. Iterate acceptance is governed either by a trust region ratio (tr_ratio) formed from the merit function values or by a filter method (filter); however, trust region resizing logic is currently based only on the trust region ratio. For infeasible iterates, constraint relaxation can be used for balancing constraint satisfaction and progress made toward an optimum.

6.2. METHOD

Description

The `surrogate_based_global` specification must identify:

- a sub-method, using either `method_pointer` or `method_name`
- `model_pointer` must be used to identify a surrogate model

`surrogate_based_global` works in an iterative scheme where optimization is performed on a global surrogate using the same bounds during each iteration.

- In one iteration, the optimal solutions of the surrogate model are found, and then a selected set of these optimal surrogate solutions are passed to the next iteration.
- At the next iteration, these surrogate points are evaluated with the "truth" model, and then these points are added back to the set of points upon which the next surrogate is constructed.

In this way, the optimization acts on a more accurate surrogate during each iteration, presumably driving to optimality quickly.

Method Independent Controls

- `max_iterations` is used as a stopping criterion (see note below)

Notes

We have some cautionary notes before using the surrogate-based global method:

- **This approach has no guarantee of convergence.**
- One might first try a single minimization method coupled with a surrogate model prior to using the surrogate-based global method. This is essentially equivalent to setting `max_iterations` to 1 and will allow one to get a sense of what surrogate types are the most accurate to use for the problem.
- Also note that one can specify that surrogates be built for all primary functions and constraints or for only a subset of these functions and constraints. This allows one to use a "truth" model directly for some of the response functions, perhaps due to them being much less expensive than other functions.
- We initially recommend a small number of maximum iterations, such as 3-5, to get a sense of how the optimization is evolving as the surrogate gets updated. If it appears to be changing significantly, then a larger number (used in combination with restart) may be needed.

Theory

In surrogate-based optimization (SBO) and surrogate-based nonlinear least squares (SBNLS), minimization occurs using a set of one or more approximations, defined from a surrogate model, that are built and periodically updated using data from a "truth" model. The surrogate model can be a global data fit (e.g., regression or interpolation of data generated from a design of computer experiments), a multipoint approximation, a local Taylor Series expansion, or a model hierarchy approximation (e.g., a low-fidelity simulation model), whereas the truth model involves a high-fidelity simulation model. The goals of surrogate-based methods are to reduce the total number of truth model simulations and, in the case of global data fit surrogates, to smooth noisy data with an easily navigated analytic function.

It was originally designed for MOGA (a multi-objective genetic algorithm). Since genetic algorithms often need thousands or tens of thousands of points to produce optimal or near-optimal solutions, the use of surrogates can be helpful for reducing the truth model evaluations. Instead of creating one set of surrogates for the individual objectives and running the optimization algorithm on the surrogate once, the idea is to select points along the (surrogate) Pareto frontier, which can be used to supplement the existing points.

In this way, one does not need to use many points initially to get a very accurate surrogate. The surrogate becomes more accurate as the iterations progress.

method_pointer

- Keywords Area
- method
- surrogate_based_global
- method_pointer

Pointer to sub-method to apply to surrogate

Topics
This keyword is related to the topics:

- block_pointer

Specification
Alias: approx_method_pointer
Argument(s): STRING

Description
The method_pointer keyword is used to specify a pointer to an optimization or least-squares sub-method to apply to the surrogate model.

Any model_pointer identified in the sub-method specification is ignored. Instead, the parent method is responsible for selecting a surrogate model using its model_pointer.

method_name

- Keywords Area
- method
- surrogate_based_global
- method_name

Specify sub-method by name

Specification
Alias: approx_method_name
Argument(s): STRING
Description
The `method_name` keyword is used to specify a sub-method by Dakota method name (e.g. 'npsol_sqp') rather than block pointer. The method will be executed using its default settings. The optional `model_pointer` specification can be used to associate a model block with the method.

`model_pointer`
- Keywords Area
- method
- surrogate_based_global
- model_pointer

Identifier for model block to be used by a method

Topics
This keyword is related to the topics:
- block_pointer

Specification
Alias: approx_model_pointer
Argument(s): STRING
Default: method use of last model parsed (or use of default model if none parsed)

Description
The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior
If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips
When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.
See `block_pointer` for details about pointers.

Examples
```environment
tabular_graphics_data
method_pointer = 'UQ'
```
```method
id_method = 'UQ'
model_pointer = 'SURR'
sampling,
samples = 10
seed = 98765 rng rnum2```
Keywords Area

method

surrogate_based_global

replace_points

(Recommended) Replace points in the surrogate training set, instead of appending

Specification

Alias: none

Argument(s): none

Default: Points appended, not replaced
6.2. METHOD

Description
The user has the option of appending the optimal points from the surrogate model to the current set of truth points or using the optimal points from the surrogate model to replace the optimal set of points from the previous iteration. Although appending to the set is the default behavior, at this time we strongly recommend using the option `replace_points` because it appears to be more accurate and robust.

### Description

This is a duplicated keyword. Please use `dot` instead.

We here provide a caution regarding `dot.frcg`. In DOT Version 4.20, we have noticed inconsistent behavior of this algorithm across different versions of Linux. Our best assessment is that it is due to different treatments of uninitialized variables. As we do not know the intention of the code authors and maintaining DOT source code is outside of the Dakota project scope, we have not made nor are we recommending any code changes to address this. However, all users who use `dot.frcg` in DOT Version 4.20 should be aware that results may not be reliable.

### Specification

**Alias:** none

**Argument(s):** REALLIST

**Default:** no linear inequality constraints
6.2. METHOD

Description

In the inequality case, the constraint matrix $A$ provides coefficients for the variables in the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where the bounds are optionally specified by `linear_inequality_lower_bounds`, and `linear_inequality_upper_bounds`. The bounds, if not specified, will default to -infinity, and 0, respectively, resulting in one-sided inequalities of the form

$$Ax \leq 0$$

linear_inequality_lower_bounds

- Keywords Area
- method
- dot_frcg
- linear_inequality_lower_bounds

Define lower bounds for the linear inequality constraint

Topics

This keyword is related to the topics:
- linear_constraints

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = -infinity

Description

In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where $A$ is the constraining matrix of variable coefficients.

As with nonlinear inequality constraints (see `objective_functions`), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$Ax \leq 0$$

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than $+\text{bigRealBoundSize}$ ($1.e+30$, as defined in Minimizer) are treated as $+\text{infinity}$ and any lower bound values less than $-\text{bigRealBoundSize}$ are treated as $-\text{infinity}$.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since $-\text{DBL}\text{MAX} < -\text{bigRealBoundSize}$).
linear_inequality_upper_bounds

- Keywords Area
- method
- dot_frcg
- linear_inequality_upper_bounds

Define upper bounds for the linear inequality constraint

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = 0.

Description

In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where $A$ is the constrain matrix of variable coefficients. As with nonlinear inequality constraints (see objective_functions), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$Ax \leq 0.0$$

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than $+\text{bigRealBoundSize}$ ($1.e+30$, as defined in Minimizer) are treated as $+\infty$ and any lower bound values less than $-\text{bigRealBoundSize}$ are treated as $-\infty$.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since $-\text{DBL_MAX} < -\text{bigRealBoundSize}$).

linear_inequality_scale_types

- Keywords Area
- method
- dot_frcg
- linear_inequality_scale_types

Specify how each linear inequality constraint is scaled
6.2. METHOD

Topics
This keyword is related to the topics:

- linear_constraints

Specification
Alias: none
Argument(s): STRINGLIST
Default: vector values = 'none'

Description

linear_inequality_scale_types provide strings specifying the scaling type for each linear inequality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- 'none' - no scaling
- 'value' - characteristic value if this is chosen, then linear_inequality_scales must be specified
- 'auto' - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables $x$:

$$\tilde{x}^j = \frac{x^j - x_O^j}{x_M^j}$$

we have the following system for linear inequality constraints

$$a_L \leq A_i x \leq a_U$$

$$a_L \leq A_i (\text{diag}(x_M) \tilde{x} + x_O) \leq a_U$$

$$a_L - A_i x_O \leq A_i \text{diag}(x_M) \tilde{x} \leq a_U - A_i x_O$$

$$\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U$$

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

linear_inequality_scales

- Keywords Area
- method
- dot_frcg
- linear_inequality_scales

Define the characteristic values to scale linear inequalities
CHAPTER 6. KEYWORDS AREA

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = 1 . (no scaling)

Description

Each entry in linear_inequality_scales may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

Behavior depends on the choice of linear_inequality_scale_type:

- scale_type - behavior of linear_inequality_scales
- ‘none’ - ignored
- ‘value’ - required
- ‘auto’ - optional

If a single real value is specified it will apply to all components of the constraint.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables $x$:

$$\bar{x}^j = \frac{x^j - x_O^j}{x_M^j}$$

we have the following system for linear inequality constraints

$$a_L \leq A_i x \leq a_U$$
$$a_L \leq A_i (\text{diag}(x_M) \bar{x} + x_O) \leq a_U$$
$$a_L - A_i x_O \leq A_i \text{diag}(x_M) \bar{x} \leq a_U - A_i x_O$$
$$\tilde{a}_L \leq \tilde{A}_i \bar{x} \leq \tilde{a}_U$$

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

linear_equality_constraint_matrix

- Keywords Area
- method
- dot_frcg
- linear_equality_constraint_matrix

Define coefficients of the linear equalities
6.2. METHOD

Topics
This keyword is related to the topics:

- linear_constraints

Specification
Alias: none

Argument(s): REALLIST
Default: no linear equality constraints

Description
In the equality case, the constraint matrix $A$ provides coefficients for the variables on the left hand side of:

$$Ax = a_t$$

linear_equality_targets

- Keywords Area
- method
- dot_frcg
- linear_equality_targets

Define target values for the linear equality constraints

Topics
This keyword is related to the topics:

- linear_constraints

Specification
Alias: none

Argument(s): REALLIST
Default: vector values = 0.

Description
In the equality case, the targets $a_t$ provide the equality constraint right hand sides:

$$Ax = a_t$$

If this is not specified, the defaults for the equality constraint targets enforce a value of 0. for each constraint:

$$Ax = 0.0$$
linear_equali\_ty_scale\_types
• Keywords Area
• method
• dot\_fr\_\_c\_g
• linear_equali\_ty_scale\_types

Specify how each linear equality constraint is scaled

Topics
This keyword is related to the topics:
• linear\_constraints

Specification
Alias: none
Argument(s): STRINGLIST
Default: vector values = 'none'

Description
linear_equali\_ty_scale\_types provide strings specifying the scaling type for each linear equality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:
• 'none' - no scaling
• 'value' - characteristic value if this is chosen, then linear_equali\_ty_scales must be specified
• 'auto' - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling.
For example, for variable scaling on continuous design variables \( x \):

\[
\tilde{x}^j = \frac{x^j - x^j_O}{x^j_M}
\]

we have the following system for linear equality constraints

\[
a_L \leq A_i x \leq a_U
\]

\[
a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U
\]

\[
a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O
\]

\[
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to \([0,1]\).
6.2. METHOD

linearEqualityScales

- Keywords Area
- method
- dot_frcg
- linearEqualityScales

Define the characteristic values to scale linear equalities

Topics

This keyword is related to the topics:

- linearConstraints

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = 1. (no scaling)

Description

Each entry in `linearEqualityScales` may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

See the scaling page for details on how to use this keyword.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables $x$:

$$
\tilde{x} = \frac{x^j - x^j_O}{x^j_M}
$$

we have the following system for linear inequality constraints

$$
a_L \leq A_i x \leq a_U
$$

$$
a_L \leq A_i (\text{diag}(x_M) \tilde{x} + x_O) \leq a_U
$$

$$
a_L - A_i x_O \leq A_i \text{diag}(x_M) \tilde{x} \leq a_U - A_i x_O
$$

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to $[0,1]$. 
model_pointer

- Keywords Area
- method
- dot_frcg
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative. See block_pointer for details about pointers.

6.2. METHOD

- **linear_inequality_constraint_matrix**

  Define coefficients of the linear inequality constraints

**Topics**

This keyword is related to the topics:

- linear_constraints

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Default:** no linear inequality constraints

**Description**

In the inequality case, the constraint matrix $A$ provides coefficients for the variables in the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where the bounds are optionally specified by `linear_inequality_lower_bounds`, and `linear_inequality_upper_bounds`. The bounds, if not specified, will default to -infinity, and 0, respectively, resulting in one-sided inequalities of the form

$$Ax \leq 0.0$$

**linear_inequality_lower_bounds**

- **Keywords Area**
  - method
  - dot_mmfd
  - `linear_inequality_lower_bounds`

  Define lower bounds for the linear inequality constraint

**Topics**

This keyword is related to the topics:

- linear_constraints

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Default:** vector values = -infinity
**Description**

In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where $A$ is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see `objective_functions`), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$Ax \leq 0$$

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than $+\text{bigRealBoundSize}$ (1.e+30, as defined in Minimizer) are treated as $+\infty$ and any lower bound values less than $-\text{bigRealBoundSize}$ are treated as $-\infty$.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since $-\text{DBL\_MAX} < -\text{bigRealBoundSize}$).

**Specification**

_Clipboard copy_  

*Alias:* none  

*Argument(s):* REALLIST  

*Default:* vector values = 0 .

**Description**

In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where $A$ is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see `objective_functions`), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$Ax \leq 0.0$$
result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than +bigRealBoundSize (1.e+30, as defined in Minimizer) are treated as +infinity and any lower bound values less than -bigRealBoundSize are treated as -infinity.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since -DBL_MAX < -bigRealBoundSize).

**linear_inequality_scale_types**

- **Keywords Area**
- **method**
- **dot_mmfd**
- **linear_inequality_scale_types**

Specify how each linear inequality constraint is scaled

**Topics**

This keyword is related to the topics:

- **linear_constraints**

**Specification**

**Alias:** none

**Argument(s):** STRINGLIST

**Default:** vector values = 'none'

**Description**

`linear_inequality_scale_types` provide strings specifying the scaling type for each linear inequality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- `'none'` - no scaling
- `'value'` - characteristic value if this is chosen, then `linear_inequality_scales` must be specified
- `'auto'` - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables $x$:

$$
\tilde{x}^j = \frac{x^j - x^j_O}{x^j_M}
$$

we have the following system for linear inequality constraints

$$
a_L \leq A_i x \leq a_U
$$

$$
a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U
$$
a_L - A_i x_O \leq A_i \text{diag}(x_M) \tilde{x} \leq a_U - A_i x_O \\
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

**linear_inequality_scales**

- **Keywords Area**
- **method**
- **dot_mmfd**
- **linear_inequality_scales**

Define the characteristic values to scale linear inequalities

**Topics**

This keyword is related to the topics:

- **linear_constraints**

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Default:** vector values = 1 . (no scaling)

**Description**

Each entry in `linear_inequality_scales` may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

Behavior depends on the choice of `linear_inequality_scale_type`:

- **scale_type** - behavior of `linear_inequality_scales`
- **'none'** - ignored
- **'value'** - required
- **'auto'** - optional

If a single real value is specified it will apply to all components of the constraint.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables $x$:

$$
\tilde{x}^j = \frac{x^j - x_O^j}{x_M^j}
$$

we have the following system for linear inequality constraints

$$
a_L \leq A_i x \leq a_U
$$
6.2. METHOD

\[ a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U \]
\[ a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O \]
\[ \tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U \]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

CHAPTER 6. KEYWORDS AREA

Description

Each entry in `linear_equality_scales` may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

See the scaling page for details on how to use this keyword.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables \( x \):\[
\tilde{x}_j = \frac{x_j - x_O}{x_M}
\]

we have the following system for linear inequality constraints\[
a_L \leq A_i \tilde{x} \leq a_U
\]
\[
a_L \leq A_i (\text{diag}(x_M) \tilde{x} + x_O) \leq a_U
\]
\[
a_L - A_i x_O \leq A_i \text{diag}(x_M) \tilde{x} \leq a_U - A_i x_O
\]
\[
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to \([0,1]\).

model_pointer

- Keywords Area
- method
- dot_mmfd
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)
6.2. METHOD

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

Examples

```yaml
environment
  tabular_graphics_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SRR'
  sampling,
      samples = 10

CHAPTER 6. KEYWORDS AREA

Description

In the inequality case, the constraint matrix $A$ provides coefficients for the variables in the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where the bounds are optionally specified by `linear.inequality.lower.bounds`, and `linear.inequality.upper.bounds`. The bounds, if not specified, will default to $-\infty$, and 0, respectively, resulting in one-sided inequalities of the form

$$Ax \leq 0.0$$

linear.inequality.lower.bounds

- Keywords Area
- method
- dot.bfgs
- linear.inequality.lower.bounds

Define lower bounds for the linear inequality constraint

Topics

This keyword is related to the topics:

- linear.constraints

Specification

Alias: none

Argument(s): REALLIST

Default: vector values $= -\infty$

Description

In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where $A$ is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see `objective.functions`), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$Ax \leq 0.0$$

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than $+\text{bigRealBoundSize}$ ($1.e+30$, as defined in Minimizer) are treated as $+\infty$ and any lower bound values less than $-\text{bigRealBoundSize}$ are treated as $-\infty$.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since $-\text{DBL.MAX} < -\text{bigRealBoundSize}$).
6.2. METHOD

linear_inequality_upper_bounds

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model-pointer for each method is imperative.

See block_pointer for details about pointers.

• linear_inequality_constraint_matrix

Define coefficients of the linear inequality constraints

Topics
This keyword is related to the topics:

• linear_constraints

Specification
Alias: none
Argument(s): REALLIST
Default: no linear inequality constraints

Description
In the inequality case, the constraint matrix \( A \) provides coefficients for the variables in the two-sided formulation:

\[
a_l \leq Ax \leq a_u
\]

Where the bounds are optionally specified by linear_inequality_lower_bounds, and linear_inequality_upper_bounds. The bounds, if not specified, will default to -infinity, and 0, respectively, resulting in one-sided inequalities of the form

\[
Ax \leq 0.0
\]

linear_inequality_lower_bounds

• Keywords Area
• method
• dot_slp
• linear_inequality_lower_bounds

Define lower bounds for the linear inequality constraint

Topics
This keyword is related to the topics:

• linear_constraints

Specification
Alias: none
Argument(s): REALLIST
Default: vector values = -infinity
**Description**

In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where $A$ is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see `objective_functions`), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$Ax \leq 0.0$$

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than $+\text{bigRealBoundSize}$ ($1.e+30$, as defined in Minimizer) are treated as $+\infty$ and any lower bound values less than $-\text{bigRealBoundSize}$ are treated as $-\infty$.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since $-\text{DBLMAX} < -\text{bigRealBoundSize}$).

**linear_inequality_upper_bounds**

- Keywords Area
- method
- dot_slp
- linear_inequality_upper_bounds

Define upper bounds for the linear inequality constraint

**Topics**

This keyword is related to the topics:

- linear_constraints

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Default:** vector values = 0.

**Description**

In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where $A$ is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see `objective_functions`), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$Ax \leq 0.0$$
result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than \( +\text{bigRealBoundSize} \) (1.e+30, as defined in Minimizer) are treated as \(+\infty\) and any lower bound values less than \(-\text{bigRealBoundSize}\) are treated as \(-\infty\).

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since \(-\text{DBL}\text{MAX} < -\text{bigRealBoundSize}\)).

linear_inequality_scale_types

- Keywords Area
- method
- dot_slp
- linear_inequality_scale_types

Specify how each linear inequality constraint is scaled

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none
Argument(s): STRINGLIST
Default: vector values = 'none'

Description

linear_inequality_scale_types provide strings specifying the scaling type for each linear inequality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- 'none' - no scaling
- 'value' - characteristic value if this is chosen, then linear_inequality_scales must be specified
- 'auto' - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables \( x \):

\[
\tilde{x}^j = \frac{x^j - x^j_O}{x^j_M - x^j_O}
\]

we have the following system for linear inequality constraints

\[
a_L \leq A_i \tilde{x} \leq a_U
\]

\[
a_L \leq A_i (\text{diag}(x_M) \tilde{x} + x_O) \leq a_U
\]
6.2. METHOD

\[ a_L - A_i x_O \leq A_i \text{diag}(x_M) \hat{x} \leq a_U - A_i x_O \]
\[ \hat{a}_L \leq \hat{A}_i \hat{x} \leq \hat{a}_U \]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

**linear_inequality_scales**

- Keywords Area
- method
- dot_slp
- linear_inequality_scales

Define the characteristic values to scale linear inequalities

**Topics**

This keyword is related to the topics:

- linear_constraints

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Default:** vector values = 1. (no scaling)

**Description**

Each entry in `linear_inequality_scales` may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

Behavior depends on the choice of `linear_inequality_scale_type`:

- `scale_type` - behavior of `linear_inequality_scales`
  - ‘none’ - ignored
  - ‘value’ - required
  - ‘auto’ - optional

If a single real value is specified it will apply to all components of the constraint.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables x:

\[ \tilde{x}_i = \frac{x_i^j - x_i^O}{x_i^M} \]

we have the following system for linear inequality constraints

\[ a_L \leq A_i \tilde{x} \leq a_U \]
\[ a_L \leq A_i (\text{diag}(x_M) \bar{x} + x_O) \leq a_U \]
\[ a_L - A_i x_O \leq A_i \text{diag}(x_M) \bar{x} \leq a_U - A_i x_O \]
\[ \bar{a}_L \leq \bar{A}_i \bar{x} \leq \bar{a}_U \]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

- **block_pointer**

**Specification**

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)

**Description**

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

**Usage Tips**

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model-pointer` for each method is imperative.

See `block_pointer` for details about pointers.

**Examples**

```plaintext
environment
  tabular_graphics_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
  response_levels = 0.1 0.2 0.6
  sample_type lhs

**Description**

The DOT library [85] contains nonlinear programming optimizers, specifically the Broyden-Fletcher-Goldfarb-Shanno (Dakota’s dot_bfgs method) and Fletcher-Reeves conjugate gradient (Dakota’s dot_frcg method) methods for unconstrained optimization, and the modified method of feasible directions (Dakota’s dot_mmfd method), sequential linear programming (Dakota’s dot_slp method), and sequential quadratic programming (Dakota’s dot_sqp method) methods for constrained optimization.

Specialized handling of linear constraints is supported with DOT; linear constraint coefficients, bounds, and targets can be provided to DOT at start-up and tracked internally.

One of the five available methods in **Group 1** must be specified.

All these methods take the same **Optional Keywords**, dealing with linear equality and inequality constraints.

**Method Independent Controls - Stopping Critera**

Stopping criteria are set by:

- `max_iterations`
- `max_function_evaluations`
- `convergence_tolerance`
- `constraint_tolerance`

Note: The `convergence_tolerance` criterion must be satisfied for two consecutive iterations before DOT will terminate.

**Method Independent Controls - Output**

The output verbosity specification controls the amount of information generated by DOT: the **silent** and **quiet** settings result in header information, final results, and objective function, constraint, and parameter information on each iteration; whereas the **verbose** and **debug** settings add additional information on gradients, search direction, one-dimensional search results, and parameter scaling factors.

**Concurrency**

DOT contains no parallel algorithms which can directly take advantage of concurrent evaluations. However, if `numerical_gradients` with `method_source dakota` is specified, then the finite difference function evaluations can be performed concurrently (using any of the parallel modes described in the Users Manual[4]). In addition, if `speculative` is specified, then gradients (`dakota numerical` or `analytic` gradients) will be computed on each line search evaluation in order to balance the load and lower the total run time in parallel optimization studies.

**frcg**

- **Keywords Area**
- `method`
- `dot`
• frcg

A conjugate gradient optimization method

Topics
This keyword is related to the topics:

• package dot

Specification
Alias: none

Argument(s): none

Description
We here provide a caution regarding dot_frcg. In DOT Version 4.20, we have noticed inconsistent behavior of this algorithm across different versions of Linux. Our best assessment is that it is due to different treatments of uninitialized variables. As we do not know the intention of the code authors and maintaining DOT source code is outside of the Dakota project scope, we have not made nor are we recommending any code changes to address this. However, all users who use dot_frcg in DOT Version 4.20 should be aware that results may not be reliable.

See package dot for information related to all DOT methods.

CHAPTER 6. KEYWORDS AREA

Specification

Alias: none

Argument(s): REALLIST

Default: no linear inequality constraints

Description

In the inequality case, the constraint matrix $A$ provides coefficients for the variables in the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where the bounds are optionally specified by $\text{linear.inequality.lower.bounds}$, and $\text{linear.inequality.upper.bounds}$. The bounds, if not specified, will default to $-\infty$, and 0, respectively, resulting in one-sided inequalities of the form

$$Ax \leq 0.0$$

$\text{linear.inequality.lower.bounds}$

- Keywords Area
- method
- dot
- $\text{linear.inequality.lower.bounds}$

Define lower bounds for the linear inequality constraint

Topics

This keyword is related to the topics:

- $\text{linear.constraints}$

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = -infinity

Description

In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where $A$ is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see $\text{objective.functions}$), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$Ax \leq 0.0$$
result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than +bigRealBoundSize (1.e+30, as defined in Minimizer) are treated as +infinity and any lower bound values less than -bigRealBoundSize are treated as -infinity.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since -DBL_MAX < -bigRealBoundSize).

linear_inequality_upper_bounds

- Keywords Area
- method
- dot
- linear_inequality_upper_bounds

Define upper bounds for the linear inequality constraint

Topics

This keyword is related to the topics:
- linear_constraints

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = 0.

Description

In the inequality case, the lower \( a_l \) and upper \( a_u \) bounds provide constraint limits for the two-sided formulation:

\[
a_l \leq Ax \leq a_u
\]

Where \( A \) is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see objective_functions), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

\[
Ax \leq 0.0
\]

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than +bigRealBoundSize (1.e+30, as defined in Minimizer) are treated as +infinity and any lower bound values less than -bigRealBoundSize are treated as -infinity.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since -DBL_MAX < -bigRealBoundSize).
linear_inequality_scale_types

- Keywords Area
- method
- dot
- linear_inequality_scale_types

Specify how each linear inequality constraint is scaled

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): STRINGLIST

Default: vector values = ’none’

Description

linear_inequality_scale_types provide strings specifying the scaling type for each linear inequality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- ’none’ - no scaling
- ’value’ - characteristic value if this is chosen, then linear_inequality_scales must be specified
- ’auto’ - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables x:

\[
\hat{x}_j = \frac{x_j - x_O}{x_M}
\]

we have the following system for linear inequality constraints

\[
\begin{align*}
    a_L & \leq A_i x \leq a_U \\
    a_L & \leq A_i (\text{diag}(x_M)\hat{x} + x_O) \leq a_U \\
    a_L - A_i x_O & \leq A_i \text{diag}(x_M)\hat{x} \leq a_U - A_i x_O \\
    \bar{a}_L & \leq \bar{A}_i \hat{x} \leq \bar{a}_U
\end{align*}
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].
6.2. METHOD

linear_inequality_scales

- Keywords Area
- method
- dot
- linear_inequality_scales

Define the characteristic values to scale linear inequalities

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): REALIST

Default: vector values = 1. (no scaling)

Description

Each entry in linear_inequality_scales may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

Behavior depends on the choice of linear_inequality_scale_type:

- scale_type - behavior of linear_inequality_scales
- 'none' - ignored
- 'value' - required
- 'auto' - optional

If a single real value is specified it will apply to all components of the constraint.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables $x$:

$$ \tilde{x}^j = \frac{x^j - x_O^j}{x_M^j} $$

we have the following system for linear inequality constraints

$$ a_L \leq A_i x \leq a_U $$
$$ a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U $$
$$ a_L - A_i x_O \leq A_i (\text{diag}(x_M)\tilde{x}) \leq a_U - A_i x_O $$
$$ \tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U $$

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].
linearEqualityConstraintMatrix

- Keywords Area
- method
- dot
- linearEqualityConstraintMatrix

Define coefficients of the linear equalities

**Topics**

This keyword is related to the topics:

- linearConstraints

**Specification**

**Alias:** none

- **Argument(s):** REALLIST
- **Default:** no linear equality constraints

**Description**

In the equality case, the constraint matrix $A$ provides coefficients for the variables on the left hand side of:

$$Ax = a_t$$

linearEqualityTargets

- Keywords Area
- method
- dot
- linearEqualityTargets

Define target values for the linear equality constraints

**Topics**

This keyword is related to the topics:

- linearConstraints

**Specification**

**Alias:** none

- **Argument(s):** REALLIST
- **Default:** vector values $= 0$.
6.2. METHOD

Description

In the equality case, the targets \( a_t \) provide the equality constraint right hand sides:

\[ Ax = a_t \]

If this is not specified, the defaults for the equality constraint targets enforce a value of 0. for each constraint:

\[ Ax = 0.0 \]

linear.equality_scale_types

- **Keywords Area**
- **method**
- **dot**
- **linear.equality_scale_types**

Specify how each linear equality constraint is scaled

Topics

This keyword is related to the topics:

- **linear_constraints**

Specification

**Alias:** none

**Argument(s):** STRINGLIST

**Default:** vector values = 'none'

Description

linear.equality_scale_types provide strings specifying the scaling type for each linear equality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- **'none'** - no scaling
- **'value'** - characteristic value if this is chosen, then linear.equality.scales must be specified
- **'auto'** - automatic scaling If a single string is specified it will apply to all constraints.

 Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables \( x \):

\[ \bar{x}^j = \frac{x^j - x^j_D}{x^j_M} \]

we have the following system for linear equality constraints

\[ a_L \leq A_i x \leq a_U \]
and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

**linear_equalities**

- **Keywords Area**
- **method**
- **dot**
- **linear_equalities**

Define the characteristic values to scale linear equalities

**Topics**

This keyword is related to the topics:

- **linear_constraints**

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Default:** vector values = 1 . (no scaling)

**Description**

Each entry in *linear_equalities* may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

See the *scaling* page for details on how to use this keyword.

Scaling for linear constraints is applied *after* any continuous variable scaling.

For example, for variable scaling on continuous design variables *x*:

$$\tilde{x}^j = \frac{x^j - x_{O}^j}{x_{M}^j}$$

we have the following system for linear inequality constraints

$$a_L \leq A_i x \leq a_U$$

$$a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U$$

$$a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O$$

$$\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U$$

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].
6.2. METHOD

model_pointer

• Keywords Area
• method
• dot
• model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

• block_pointer

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model-pointer for each method is imperative.

See block_pointer for details about pointers.

**Argument(s):** REALLIST

**Default:** vector values = -infinity
6.2. METHOD

Description
In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where $A$ is the constraining matrix of variable coefficients.

As with nonlinear inequality constraints (see objective functions), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$Ax \leq 0.0$$

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than $+\text{bigRealBoundSize}$ (1.e+30, as defined in Minimizer) are treated as $+\infty$ and any lower bound values less than $-\text{bigRealBoundSize}$ are treated as $-\infty$.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since $-\text{DBLMAX} < -\text{bigRealBoundSize}$).

- linear_inequality_upper_bounds

Define upper bounds for the linear inequality constraint

Topics
This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = 0.

Description
In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where $A$ is the constraining matrix of variable coefficients.

As with nonlinear inequality constraints (see objective functions), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$Ax \leq 0.0$$
result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than +bigRealBoundSize (1.e+30, as defined in Minimizer) are treated as +infinity and any lower bound values less than -bigRealBoundSize are treated as -infinity.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since -DBL_MAX < -bigRealBoundSize).

linear_inequality_scale_types

- Keywords Area
- method
- conmin_frcg
- linear_inequality_scale_types

Specify how each linear inequality constraint is scaled

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): STRINGLIST

Default: vector values = 'none'

Description

linear_inequality_scale_types provide strings specifying the scaling type for each linear inequality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- 'none' - no scaling
- 'value' - characteristic value if this is chosen, then linear_inequality_scales must be specified
- 'auto' - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables x:

$$\tilde{x}^j = \frac{x^j - x_j^O}{x_j^M}$$

we have the following system for linear inequality constraints

$$a_L \leq A_i x \leq a_U$$

$$a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U$$
\[ a_L - A_i x_O \leq A_i \text{diag}(x_M) \tilde{x} \leq a_U - A_i x_O \]
\[ \tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U \]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

**linear_inequality_scales**

- **Keywords Area**

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Default:** vector values = 1. (no scaling)

**Description**

Each entry in **linear_inequality_scales** may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

Behavior depends on the choice of **linear_inequality_scale_type**:

- **scale_type** - behavior of **linear_inequality_scales**
  - **'none'** - ignored
  - **'value'** - required
  - **'auto'** - optional

If a single real value is specified it will apply to all components of the constraint.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables \( x \):

\[ \tilde{x}^j = \frac{x^j - x^j_O}{x^j_M} \]

we have the following system for linear inequality constraints

\[ a_L \leq A_i x \leq a_U \]
\[
\begin{align*}
a_L \leq A_i \left( \text{diag}(x_M) \bar{x} + x_O \right) & \leq a_U \\
a_L - A_i x_O & \leq A_i \text{diag}(x_M) \bar{x} \leq a_U - A_i x_O \\
\tilde{a}_L \leq \tilde{A}_i \tilde{x} & \leq \tilde{a}_U
\end{align*}
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

**linear_equality_constraint_matrix**

- Keywords Area
- method
- conmin_frcg
- linear_equality_constraint_matrix

Define coefficients of the linear equalities

**Topics**

This keyword is related to the topics:

- linear_constraints

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Default:** no linear equality constraints

**Description**

In the equality case, the constraint matrix \(A\) provides coefficients for the variables on the left hand side of:

\[
Ax = a_t
\]

**linear_equality_targets**

- Keywords Area
- method
- conmin_frcg
- linear_equality_targets

Define target values for the linear equality constraints
6.2. METHOD

Topics
This keyword is related to the topics:

- linear_constraints

Specification
Alias: none
Argument(s): REALLIST
Default: vector values = 0.

Description
In the equality case, the targets $a_t$ provide the equality constraint right hand sides:

$$Ax = a_t$$

If this is not specified, the defaults for the equality constraint targets enforce a value of 0. for each constraint:

$$Ax = 0.0$$

linearEqualityScaleTypes

- Keywords Area
- method
- conmin_frcg
- linearEqualityScaleTypes

Specify how each linear equality constraint is scaled

Topics
This keyword is related to the topics:

- linear_constraints

Specification
Alias: none
Argument(s): STRINGLIST
Default: vector values = 'none'
Description

`linear_equation_scale_types` provide strings specifying the scaling type for each linear equality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- `'none'` - no scaling
- `'value'` - characteristic value if this is chosen, then `linear_equation_scales` must be specified
- `'auto'` - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables $x$:

$$\tilde{x}^j = \frac{x^j - x^j_O}{x^j_M}$$

we have the following system for linear equality constraints

$$a_L \leq A_i x \leq a_U$$

$$a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U$$

$$a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O$$

$$\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U$$

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to $[0,1]$.

`linear_equation_scales`

- **Keywords Area**
- **method**
- **conmin_frcg**
- **linear_equation_scales**

Define the characteristic values to scale linear equalities

Topics

This keyword is related to the topics:

- **linear_constraints**

Specification

Alias: none

**Argument(s):** REALLIST

**Default:** vector values = 1. (no scaling)
6.2. METHOD

Description

Each entry in linear_equalities_scales may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

See the scaling page for details on how to use this keyword.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables x:

\[
\tilde{x}^i = \frac{x^i - x^i_O}{x^i_M}
\]

we have the following system for linear inequality constraints

\[
a_L \leq A_i x \leq a_U
\]

\[
a_L \leq A_i \left( \text{diag}(x_M)\tilde{x} + x_O \right) \leq a_U
\]

\[
a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O
\]

\[
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

model_pointer

- Keywords Area
- method
- conmin_frcg
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)
CHAPTER 6. KEYWORDS AREA

Description
The **model_pointer** is used to specify which **model** block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**
If not specified, a Dakota method will use the last model block parsed. If specified, there must be a **model** block in the Dakota input file that has a corresponding **id_model** with the same name.

**Usage Tips**
When doing advanced analyses that involve using multiple methods and multiple models, defining a **model-pointer** for each method is imperative.

See **block_pointer** for details about pointers.

**Examples**

```plaintext
environment
    tabular_graphics_data
    method_pointer = 'UQ'

method
    id_method = 'UQ'
    model_pointer = 'SURR'
    sampling,
        samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
        0.1 0.2 0.6
        0.1 0.2 0.6
    sample_type lhs
    distribution cumulative

model
    id_model = 'SURR'
    surrogate global,
    dace_method_pointer = 'DACE'
    polynomial quadratic

method
    id_method = 'DACE'
    model_pointer = 'DACE_M'
    sampling sample_type lhs
        samples = 121 seed = 5034 rng rnum2

model
    id_model = 'DACE_M'
    single
    interface_pointer = 'I1'

variables
    uniform_uncertain = 2
        lower_bounds = 0. 0.
        upper_bounds = 1. 1.
    descriptors = 'x1' 'x2'

interface
    id_interface = 'I1'
    system asynch evaluation_concurrency = 5
        analysis_driver = 'text_book'

responses
```

Optional

linear.equality_-scale_types

Specify how each linear equality constraint is scaled.

Optional

classic.equality_-scales

Define the characteristic values to scale linear equalities.

Optional

model_pointer

Identifier for model block to be used by a method.

Description

This is a duplicated keyword. Please use conmin instead.

See Also

These keywords may also be of interest:

- mfd

linear.inequality.constraint_matrix

- Keywords Area
- method
- conmin.mfd
- linear.inequality.constraint_matrix

Define coefficients of the linear inequality constraints.

Topics

This keyword is related to the topics:

- linear.constraints

Specification

Alias: none

Argument(s): REALLIST

Default: no linear inequality constraints
6.2. METHOD

Description

In the inequality case, the constraint matrix $A$ provides coefficients for the variables in the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where the bounds are optionally specified by `linear.inequality.lower.bounds`, and `linear.inequality.upper.bounds`. The bounds, if not specified, will default to -infinity, and 0, respectively, resulting in one-sided inequalities of the form

$$Ax \leq 0$$

`linear.inequality.lower.bounds`

- Keywords Area
- method
- conmin_mfd
- `linear.inequality.lower.bounds`

Define lower bounds for the linear inequality constraint

Topics

This keyword is related to the topics:

- `linear.constraints`

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = -infinity

Description

In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where $A$ is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see `objective.functions`), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$Ax \leq 0$$

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than `+bigRealBoundSize` (1.e+30, as defined in Minimizer) are treated as +infinity and any lower bound values less than `-bigRealBoundSize` are treated as -infinity.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since `-DBL_MAX < -bigRealBoundSize`).
linear_inequality_upper_bounds

- Keywords Area
- method
- conmin_mfd
- linear_inequality_upper_bounds

Define upper bounds for the linear inequality constraint

**Topics**

This keyword is related to the topics:

- linear_constraints

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Default:** vector values = 0.

**Description**

In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

\[ a_l \leq Ax \leq a_u \]

Where $A$ is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see objective functions), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

\[ Ax \leq 0.0 \]

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than $+\text{bigRealBoundSize}$ (1.e+30, as defined in Minimizer) are treated as $+\infty$ and any lower bound values less than $-\text{bigRealBoundSize}$ are treated as $-\infty$.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since $-\text{DBL\_MAX} < -\text{bigRealBoundSize}$).

linear_inequality_scale_types

- Keywords Area
- method
- conmin_mfd
- linear_inequality_scale_types

Specify how each linear inequality constraint is scaled
6.2. METHOD

Topics
This keyword is related to the topics:

- linear_constraints

Specification
Alias: none
Argument(s): STRINGLIST
Default: vector values = 'none'

Description
linear_inequality_scale_types provide strings specifying the scaling type for each linear inequality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- 'none' - no scaling
- 'value' - characteristic value if this is chosen, then linear_inequality_scales must be specified
- 'auto' - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables \( x \):

\[
\bar{x}^j = \frac{x^j - x^j_O}{x^j_M}
\]

we have the following system for linear inequality constraints

\[
a_L \leq A_i x \leq a_U
\]

\[
a_L \leq A_i (\text{diag}(x_M)\bar{x} + x_O) \leq a_U
\]

\[
a_L - A_i x_O \leq A_i (\text{diag}(x_M)\bar{x}) \leq a_U - A_i x_O
\]

\[
\bar{a}_L \leq \bar{A}_i \bar{x} \leq \bar{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

linear_inequality_scales

- Keywords Area
- method
- conmin_mfd
- linear_inequality_scales

Define the characteristic values to scale linear inequalities
Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = 1 . (no scaling)

Description

Each entry in `linear_inequality_scales` may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

Behavior depends on the choice of `linear_inequality_scale_type`:

- `scale_type` - behavior of `linear_inequality_scales`
- `'none'` - ignored
- `'value'` - required
- `'auto'` - optional

If a single real value is specified it will apply to all components of the constraint.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables $x$:

$$
\tilde{x}^j = \frac{x^j - x_O^j}{x_M^j}
$$

we have the following system for linear inequality constraints

$$
a_L \leq A_i x \leq a_U
$$

$$
a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U
$$

$$
a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O
$$

$$
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
$$

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0, 1].

`linear_equality_constraint_matrix`

### Description

The CONMIN library[83] is a public domain library of nonlinear programming optimizers, specifically the Fletcher-Reeves conjugate gradient (Dakota’s *conmin_frcg* method) method for unconstrained optimization, and the method of feasible directions (Dakota’s *conmin_mfd* method) for constrained optimization. As CONMIN was a predecessor to the DOT commercial library, the algorithm controls are very similar.
One of the two available methods in Group 1 must be specified. All these methods take the same Optional Keywords, dealing with linear equality and inequality constraints.

linear_inequality_constraint_matrix

- Keywords Area
- method
- conmin
- linear_inequality_constraint_matrix

Define coefficients of the linear inequality constraints

Topics
This keyword is related to the topics:

- linear_constraints

Specification
Alias: none
Argument(s): REALLIST
Default: no linear inequality constraints
Description

In the inequality case, the constraint matrix $A$ provides coefficients for the variables in the two-sided formulation:

\[ a_l \leq Ax \leq a_u \]

Where the bounds are optionally specified by `linear_inequality_lower_bounds`, and `linear_inequality_upper_bounds`. The bounds, if not specified, will default to -infinity, and 0, respectively, resulting in one-sided inequalities of the form

\[ Ax \leq 0.0 \]

linear_inequality_lower_bounds

- Keywords: Area
- method
- conmin
- linear_inequality_lower_bounds

Define lower bounds for the linear inequality constraint

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = -infinity

Description

In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

\[ a_l \leq Ax \leq a_u \]

Where $A$ is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see `objective_functions`), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

\[ Ax \leq 0.0 \]

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than `+bigRealBoundSize` (1.e+30, as defined in Minimizer) are treated as +infinity and any lower bound values less than `-bigRealBoundSize` are treated as -infinity.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since `-DBL_MAX < -bigRealBoundSize`).
linear_inequality_upper_bounds

- Keywords Area
- method
- conmin
- linear_inequality_upper_bounds

Define upper bounds for the linear inequality constraint

Topics

This keyword is related to the topics:
- linear_constraints

Specification

Alias: none
- Argument(s): REALLIST
- Default: vector values = 0.

Description

In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where $A$ is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see objective_functions), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$Ax \leq 0.0$$

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than $+\text{bigRealBoundSize}$ ($1.e+30$, as defined in Minimizer) are treated as $+\infty$ and any lower bound values less than $-\text{bigRealBoundSize}$ are treated as $-\infty$.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since $-\text{DBL_MAX} < -\text{bigRealBoundSize}$).

linear_inequality_scale_types

- Keywords Area
- method
- conmin
- linear_inequality_scale_types

Specify how each linear inequality constraint is scaled
6.2. METHOD

Topics
This keyword is related to the topics:

- linear_constraints

Specification
Alias: none
Argument(s): STRINGLIST
Default: vector values = 'none'

Description
linear_inequality_scale_types provide strings specifying the scaling type for each linear inequality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- 'none' - no scaling
- 'value' - characteristic value if this is chosen, then linear_inequality_scales must be specified
- 'auto' - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables \( x \):

\[
\tilde{x}_j = \frac{x_j^i - x_O^j}{x_M^j}
\]

we have the following system for linear inequality constraints

\[
a_L \leq A_i \tilde{x} \leq a_U
\]

\[
a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U
\]

\[
a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O
\]

\[
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to \([0,1]\).

linear_inequality_scales

- Keywords Area
- method
- conmin
- linear_inequality_scales

Define the characteristic values to scale linear inequalities
CHAPTER 6. KEYWORDS AREA

Topics
This keyword is related to the topics:

- linear_constraints

Specification
Alias: none
Argument(s): REALLIST
Default: vector values = 1 . (no scaling)

Description
Each entry in linear_inequality_scales may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

Behavior depends on the choice of linear_inequality_scale_type:

- scale_type - behavior of linear_inequality_scales
- ’none’ - ignored
- ’value’ - required
- ’auto’ - optional

If a single real value is specified it will apply to all components of the constraint.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables x:

\[ \tilde{x}^j = \frac{x^j - x^O}{x^M} \]

we have the following system for linear inequality constraints

\[ a_L \leq A_i x \leq a_U \]
\[ a_L \leq A_i (\text{diag}(x_M) \tilde{x} + x_O) \leq a_U \]
\[ a_L - A_i x_O \leq A_i \text{diag}(x_M) \tilde{x} \leq a_U - A_i x_O \]
\[ \tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U \]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

linear_equality_constraint_matrix

- Keywords Area
- method
- conmin
- linear_equality_constraint_matrix

Define coefficients of the linear equalities
6.2. METHOD

Topics
This keyword is related to the topics:
  - linear_constraints

Specification
Alias: none
  Argument(s): REALLIST
  Default: no linear equality constraints

Description
In the equality case, the constraint matrix $A$ provides coefficients for the variables on the left hand side of:

$$Ax = a_t$$

linear_equality_targets
  - Keywords Area
  - method
  - conmin
  - linear_equality_targets

Define target values for the linear equality constraints

Topics
This keyword is related to the topics:
  - linear_constraints

Specification
Alias: none
  Argument(s): REALLIST
  Default: vector values = 0.

Description
In the equality case, the targets $a_t$ provide the equality constraint right hand sides:

$$Ax = a_t$$

If this is not specified, the defaults for the equality constraint targets enforce a value of 0 for each constraint:

$$Ax = 0.0$$
linear_equity_scale_types

- Keywords Area
- method
- conmin
- linear_equity_scale_types

Specify how each linear equality constraint is scaled

Topics
This keyword is related to the topics:

- linear_constraints

Specification

Alias: none
Argument(s): STRINGLIST
Default: vector values = 'none'

Description

linear_equity_scale_types provide strings specifying the scaling type for each linear equality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- 'none' - no scaling
- 'value' - characteristic value if this is chosen, then linear_equity_scales must be specified
- 'auto' - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables $x$:

$$\tilde{x}^j = \frac{x^j - x^j_O}{x^j_M}$$

we have the following system for linear equality constraints

$$a_L \leq A_i x \leq a_U$$

$$a_L \leq A_i (\text{diag}(x_M) \tilde{x} + x_O) \leq a_U$$

$$a_L - A_i x_O \leq A_i \text{diag}(x_M) \tilde{x} \leq a_U - A_i x_O$$

$$\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U$$

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

6.2. METHOD

linear_equation_scales

- Keywords Area
- method
- conmin
- linear_equation_scales

Define the characteristic values to scale linear equalities

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = 1. (no scaling)

Description

Each entry in linear_equation_scales may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

See the scaling page for details on how to use this keyword.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables \( x \):

\[
\tilde{x}^j = \frac{x^j - x^j_O}{x^j_M}
\]

we have the following system for linear inequality constraints

\[
a_L \leq A_i x \leq a_U
\]

\[
a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U
\]

\[
a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O
\]

\[
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to \([0, 1]\).
**model_pointer**

- **Keywords Area**
- **method**
- **conmin**
- **model_pointer**

Identifier for model block to be used by a method

**Topics**

This keyword is related to the topics:

- **block_pointer**

**Specification**

**Alias**: none

**Argument(s)**: STRING

**Default**: method use of last model parsed (or use of default model if none parsed)

**Description**

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

**Usage Tips**

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

**Examples**

```plaintext

**linear_inequality_constraint_matrix**

- Keywords Area
- method
- dl_solver
6.2. METHOD

- **linear_inequality_constraint_matrix**

  Define coefficients of the linear inequality constraints

**Topics**

This keyword is related to the topics:

- **linear_constraints**

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Default:** no linear inequality constraints

**Description**

In the inequality case, the constraint matrix $A$ provides coefficients for the variables in the two-sided formulation:

$$ a_l \leq Ax \leq a_u $$

Where the bounds are optionally specified by `linear_inequality_lower_bounds`, and `linear_inequality_upper_bounds`. The bounds, if not specified, will default to -infinity, and 0, respectively, resulting in one-sided inequalities of the form

$$ Ax \leq 0.0 $$

**linear_inequality_lower_bounds**

- **Keywords Area**
  - method
  - dl_solver
  - linear_inequality_lower_bounds

  Define lower bounds for the linear inequality constraint

**Topics**

This keyword is related to the topics:

- **linear_constraints**

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Default:** vector values = -infinity
Description

In the inequality case, the lower \( a_l \) and upper \( a_u \) bounds provide constraint limits for the two-sided formulation:

\[
  a_l \leq Ax \leq a_u
\]

Where \( A \) is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see objective functions), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

\[
  Ax \leq 0.0
\]

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than \( +\text{bigRealBoundSize} \) (1.e+30, as defined in Minimizer) are treated as \( +\text{infinity} \) and any lower bound values less than \( -\text{bigRealBoundSize} \) are treated as \( -\text{infinity} \).

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since \( -\text{DBL}\text{MAX} < -\text{bigRealBoundSize} \)).

**linear_inequality_upper_bounds**

- Keywords Area
- method
- dl_solver
- linear_inequality_upper_bounds

Define upper bounds for the linear inequality constraint

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = 0.

Description

In the inequality case, the lower \( a_l \) and upper \( a_u \) bounds provide constraint limits for the two-sided formulation:

\[
  a_l \leq Ax \leq a_u
\]

Where \( A \) is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see objective functions), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

\[
  Ax \leq 0.0
\]
result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than \(+bigRealBoundSize\) (1.e+30, as defined in Minimizer) are treated as \(+\infty\) and any lower bound values less than \(-bigRealBoundSize\) are treated as \(-\infty\).

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since \(-DBLMAX<-bigRealBoundSize\)).

### linear_inequality_scale_types

- **Keywords Area**
- **method**
- **dl_solver**
- **linear_inequality_scale_types**

Specify how each linear inequality constraint is scaled

#### Topics

This keyword is related to the topics:

- **linear_constraints**

#### Specification

**Alias:** none

**Argument(s):** STRINGLIST

**Default:** vector values = 'none'

#### Description

**linear_inequality_scale_types** provide strings specifying the scaling type for each linear inequality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- **'none’** - no scaling
- **'value’** - characteristic value if this is chosen, then **linear_inequality_scales** must be specified
- **'auto’** - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables \(x\):

\[
\tilde{x}^j = \frac{x^j - x^j_O}{x^j_M}
\]

we have the following system for linear inequality constraints

\[
a_L \leq A_i \tilde{x} \leq a_U
\]

\[
a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U
\]
$a_L - A_i x_O \leq A_i \text{diag}(x_M) \tilde{x} \leq a_U - A_i x_O$

\[\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

**linear_inequality_scales**

- Keywords Area
- method
- dl_solver
- linear_inequality_scales

Define the characteristic values to scale linear inequalities

**Topics**

This keyword is related to the topics:

- linear_constraints

**Specification**

Alias: none

**Argument(s):** REALLIST

**Default:** vector values = 1 . (no scaling)

**Description**

Each entry in `linear_inequality_scales` may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

Behavior depends on the choice of `linear_inequality_scale_type`:

- `scale_type` - behavior of `linear_inequality_scales`
- `'none'` - ignored
- `'value'` - required
- `'auto'` - optional

If a single real value is specified it will apply to all components of the constraint.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables $x$:

\[
\tilde{x}^j = \frac{x^j - x^j_O}{x^j_M - x^j_O}
\]

we have the following system for linear inequality constraints

\[a_L \leq A_i x \leq a_U\]
\[ a_L \leq A_i (\text{diag}(x_M)\hat{x} + x_O) \leq a_U \]
\[ a_L - A_i x_O \leq A_i \text{diag}(x_M)\hat{x} \leq a_U - A_i x_O \]
\[ \hat{a}_L \leq \hat{A}_i \hat{x} \leq \hat{a}_U \]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to \([0,1]\).

### Description

NPSOL provides an implementation of sequential quadratic programming that can be accessed with `npsol_sqp`.  

**Stopping Criteria**

The method independent controls for `max_iterations` and `max_function_evaluations` limit the number of major SQP iterations and the number of function evaluations that can be performed during an NPSOL optimization. The `convergence_tolerance` control defines NPSOL’s internal optimality tolerance which is used in evaluating if an iterate satisfies the first-order Kuhn-Tucker conditions for a minimum. The magnitude of `convergence_tolerance` approximately specifies the number of significant digits of accuracy desired in the final objective function (e.g., `convergence_tolerance = 1.e-6` will result in approximately six digits of accuracy in the final objective function). The `constraint_tolerance` control defines how tightly the constraint functions are satisfied at convergence. The default value is dependent upon the machine precision.
of the platform in use, but is typically on the order of $1 \times 10^{-8}$ for double precision computations. Extremely small values for constraint tolerance may not be attainable. The output verbosity setting controls the amount of information generated at each major SQP iteration: the silent and quiet settings result in only one line of diagnostic output for each major iteration and print the final optimization solution, whereas the verbose and debug settings add additional information on the objective function, constraints, and variables at each major iteration.

Concurrence

NPSOL is not a parallel algorithm and cannot directly take advantage of concurrent evaluations. However, if numerical_gradients with method_source dakota is specified, then the finite difference function evaluations can be performed concurrently (using any of the parallel modes described in the Users Manual [4]).

An important related observation is the fact that NPSOL uses two different line searches depending on how gradients are computed. For either analytic_gradients or numerical_gradients with method_source dakota, NPSOL is placed in user-supplied gradient mode (NPSOL’s ”Derivative Level” is set to 3) and it uses a gradient-based line search (the assumption is that user-supplied gradients are inexpensive). On the other hand, if numerical_gradients are selected with method_source vendor, then NPSOL is computing finite differences internally and it will use a value-based line search (the assumption is that finite differencing on each line search evaluation is too expensive). The ramifications of this are: (1) performance will vary between method_source dakota and method_source vendor for numerical_gradients, and (2) gradient speculation is unnecessary when performing optimization in parallel since the gradient-based line search in user-supplied gradient mode is already load balanced for parallel execution. Therefore, a speculative specification will be ignored by NPSOL, and optimization with numerical gradients should select method_source dakota for load balanced parallel operation and method_source vendor for efficient serial operation.

Linear constraints

Lastly, NPSOL supports specialized handling of linear inequality and equality constraints. By specifying the coefficients and bounds of the linear inequality constraints and the coefficients and targets of the linear equality constraints, this information can be provided to NPSOL at initialization and tracked internally, removing the need for the user to provide the values of the linear constraints on every function evaluation.

**verify_level**

- **Keywords Area**
- **method**
- **npsol_sqp**
- **verify_level**

Verify the quality of analytic gradients

**Specification**

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** -1 (no gradient verification)

**Description**

**verify_level** instructs the NPSOL and NLSSOL algorithms to perform their own finite difference verification of the gradients provided by Dakota. Typically these are used to verify **analytic_gradients** produced by a
simulation code, though the option can be used with other Dakota-supplied gradient types including numerical or mixed.

Level 1 will verify the objective gradients, level 2, the nonlinear constraint gradients, and level 3, both. See the Optional Input Parameters section of the NPSOL manual[33] for additional information, including options to verify at the user-supplied initial point vs. first feasible point.

**function_precision**

- **Keywords Area**
- **method**
- **npsol_sqp**
- **function_precision**

Specify the maximum precision of the analysis code responses

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 1.0e-10

**Description**

The function_precision control provides the algorithm with an estimate of the accuracy to which the problem functions can be computed. This is used to prevent the algorithm from trying to distinguish between function values that differ by less than the inherent error in the calculation.

**linesearch_tolerance**

- **Keywords Area**
- **method**
- **npsol_sqp**
- **linesearch_tolerance**

Choose how accurately the algorithm will compute the minimum in a line search

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 0.9 (inaccurate line search)

**Description**

The linesearch_tolerance setting controls the accuracy of the line search. The smaller the value (between 0 and 1), the more accurately the algorithm will attempt to compute a precise minimum along the search direction.
linear_inequality_constraint_matrix

- Keywords Area
- method
- npsol_sqp
- linear_inequality_constraint_matrix

Define coefficients of the linear inequality constraints

**Topics**

This keyword is related to the topics:

- linear_constraints

**Specification**

**Alias:** none  
**Argument(s):** REALLIST  
**Default:** no linear inequality constraints

**Description**

In the inequality case, the constraint matrix $A$ provides coefficients for the variables in the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where the bounds are optionally specified by `linear_inequality_lower_bounds`, and `linear_inequality_upper_bounds`. The bounds, if not specified, will default to $-\infty$, and 0, respectively, resulting in one-sided inequalities of the form

$$Ax \leq 0.0$$

linear_inequality_lower_bounds

- Keywords Area
- method
- npsol_sqp
- linear_inequality_lower_bounds

Define lower bounds for the linear inequality constraint

**Topics**

This keyword is related to the topics:

- linear_constraints
6.2. METHOD

Specification

Alias: none
Argument(s): REALLIST
Default: vector values = -infinity

Description

In the inequality case, the lower \( a_l \) and upper \( a_u \) bounds provide constraint limits for the two-sided formulation:

\[
  a_l \leq Ax \leq a_u
\]

Where \( A \) is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see \texttt{objective_functions}), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

\[
  Ax \leq 0.0
\]

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than \(+\text{bigRealBoundSize}\) (1.e+30, as defined in Minimizer) are treated as \(+\infty\) and any lower bound values less than \(-\text{bigRealBoundSize}\) are treated as \(-\infty\).

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since \(-\text{DBL_MAX} < -\text{bigRealBoundSize}\)).

\texttt{linear\_inequality\_upper\_bounds}

- Keywords Area
- method
- npsol_sqp
- \texttt{linear\_inequality\_upper\_bounds}

Define upper bounds for the linear inequality constraint

Topics

This keyword is related to the topics:

- \texttt{linear\_constraints}

Specification

Alias: none
Argument(s): REALLIST
Default: vector values = 0.
Description

In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where $A$ is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see objective functions), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$Ax \leq 0.0$$

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than $+\text{bigRealBoundSize}$ (1.e+30, as defined in Minimizer) are treated as $+\text{infinity}$ and any lower bound values less than $-\text{bigRealBoundSize}$ are treated as $-\text{infinity}$.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since $-\text{DBL_MAX} < -\text{bigRealBoundSize}$).

linear_inequality_scale_types

- Keywords Area
- method
- npsol_sqp
- linear_inequality_scale_types

Specify how each linear inequality constraint is scaled

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): STRINGLIST

Default: vector values = 'none'

Description

linear_inequality_scale_types provide strings specifying the scaling type for each linear inequality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- 'none' - no scaling
- 'value' - characteristic value if this is chosen, then linear_inequality_scales must be specified
• ‘auto’ - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables \( x \):

\[
\tilde{x}^j = \frac{x^j - x_O^j}{x_M^j}
\]

we have the following system for linear inequality constraints

\[
a_L \leq A_i x \leq a_U
\]

\[
a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U
\]

\[
a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O
\]

\[
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to \([0,1]\).

**linear_inequality_scales**

- **Keywords** Area
- method
- npsol_sqp
- linear_inequality_scales

Define the characteristic values to scale linear inequalities

**Topics**

This keyword is related to the topics:

- linear_constraints

**Specification**

*Alias:* none

*Argument(s):* REALLIST

*Default:* vector values = 1. (no scaling)

**Description**

Each entry in `linear_inequality_scales` may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

Behavior depends on the choice of `linear_inequality_scale_type`:

- `scale_type` - behavior of `linear_inequality_scales`

- ‘none’ - ignored
• ‘value’ - required
• ‘auto’ - optional

If a single real value is specified it will apply to all components of the constraint.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables \( x \):

\[
\tilde{x}^j = \frac{x^j - x^j_O}{x^j_M - x^j_O}
\]

we have the following system for linear inequality constraints

\[
a_L \leq A_i x \leq a_U
\]

\[
a_L \leq A_i \left( \text{diag}(x_M) \tilde{x} + x_O \right) \leq a_U
\]

\[
a_L - A_i x_O \leq A_i \text{diag}(x_M) \tilde{x} \leq a_U - A_i x_O
\]

\[
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to \([0,1]\).

**linear.equality.constraint_matrix**

• Keywords Area
• method
• npsol_sqp
• linear.equality.constraint_matrix

Define coefficients of the linear equalities

**Topics**

This keyword is related to the topics:

• linear.constraints

**Specification**

Alias: none

Argument(s): REALLIST

Default: no linear equality constraints

**Description**

In the equality case, the constraint matrix \( A \) provides coefficients for the variables on the left hand side of:

\[
Ax = a_t
\]
6.2. METHOD

linear_equality_targets

- Keywords Area
- method
- npsol_sqp
- linear_equality_targets

Define target values for the linear equality constraints

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = 0.

Description

In the equality case, the targets \( a_t \) provide the equality constraint right hand sides:

\[
Ax = a_t
\]

If this is not specified, the defaults for the equality constraint targets enforce a value of 0. for each constraint: 

\[
Ax = 0.0
\]

linear_equality_scale_types

- Keywords Area
- method
- npsol_sqp
- linear_equality_scale_types

Specify how each linear equality constraint is scaled

Topics

This keyword is related to the topics:

- linear_constraints
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none
Argument(s): STRINGLIST
Default: vector values = 'none'

Description

linear_equalities are provided strings specifying the scaling type for each linear equality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- 'none' - no scaling
- 'value' - characteristic value if this is chosen, then linear_equalities must be specified
- 'auto' - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables \( x \):

\[
\tilde{x}^j = \frac{x^j - x_O^j}{x_M^j}
\]

we have the following system for linear equality constraints

\[
a_L \leq A_i x \leq a_U
\]

\[
a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U
\]

\[
a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O
\]

\[
\hat{a}_L \leq \hat{A}_i \tilde{x} \leq \hat{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to \([0,1]\).

linear_equalities

- Keywords Area
- method

- linear_equalities

Define the characteristic values to scale linear equalities

Topics

This keyword is related to the topics:

- linear_constraints
6.2. METHOD

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = 1 . (no scaling)

Description

Each entry in linear.equality.scales may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

See the scaling page for details on how to use this keyword.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables $x$:

$$
\tilde{x}^j = \frac{x^j - x^j_O}{x^j_M}
$$

we have the following system for linear inequality constraints

$$
a_L \leq A_i x \leq a_U \\
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
$$

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

model_pointer

- Keywords Area
- method
- npsol_sqp
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)
CHAPTER 6. KEYWORDS AREA

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.

See block_pointer for details about pointers.

Examples

```plaintext
environment
    tabular_graphics_data
method_pointer = 'UQ'

method
    id_method = 'UQ'
    model_pointer = 'SRR'
sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
    0.1 0.2 0.6
    0.1 0.2 0.6
    sample_type lhs
distribution cumulative

model
    id_model = 'SRR'
surrogate global,
dace_method_pointer = 'DACE'
polynomial quadratic

method
    id_method = 'DACE'
    model_pointer = 'DACE_M'
sampling sample_type lhs
    samples = 121 seed = 5034 rng rnum2

model
    id_model = 'DACE_M'
single
interface_pointer = 'I1'

variables
    uniform_uncertain = 2
    lower_bounds = 0. 0.
    upper_bounds = 1. 1.
    descriptors = 'x1' 'x2'

interface
    id_interface = 'I1'
system asynch evaluation_concurrency = 5
    analysis_driver = 'text_book'

responses
```
response_functions = 3

**Description**

NLSSOL is available as `nlssol_sqp` and supports unconstrained, bound-constrained, and generally-constrained problems. It exploits the structure of a least squares objective function through the periodic use of Gauss-Newton Hessian approximations to accelerate the SQP algorithm.

**Stopping Criteria**

The method independent controls for `max_iterations` and `max_function_evaluations` limit the number of major SQP iterations and the number of function evaluations that can be performed during an NPSOL optimization. The `convergence_tolerance` control defines NPSOL's internal optimality tolerance which is used in evaluating if an iterate satisfies the first-order Kuhn-Tucker conditions for a minimum. The magnitude of `convergence_tolerance` approximately specifies the number of significant digits of accuracy desired in the final objective function (e.g., `convergence_tolerance = 1.e-6` will result in approximately six digits.
6.2. METHOD

of accuracy in the final objective function). The constraint_tolerance control defines how tightly the constraint functions are satisfied at convergence. The default value is dependent upon the machine precision of the platform in use, but is typically on the order of $1.0 \times 10^{-8}$ for double precision computations. Extremely small values for constraint_tolerance may not be attainable.

These keywords may also be of interest:

- `npsol_sqp`
- `nl2sol`
- `optpp_g_newton`
- `field_calibration_terms`

`verify_level`

- Keywords Area
- method
- `nlssol_sqp`
- `verify_level`

Verify the quality of analytic gradients

Specification

Alias: none

Argument(s): INTEGER
Default: -1 (no gradient verification)

Description

verify_level instructs the NPSOL and NLSSOL algorithms to perform their own finite difference verification of the gradients provided by Dakota. Typically these are used to verify analytic_gradients produced by a simulation code, though the option can be used with other Dakota-supplied gradient types including numerical or mixed.

Level 1 will verify the objective gradients, level 2, the nonlinear constraint gradients, and level 3, both. See the Optional Input Parameters section of the NPSOL manual[33] for additional information, including options to verify at the user-supplied initial point vs. first feasible point.

function_precision

- Keywords Area
- method
- `nlssol_sqp`
- `function_precision`

Specify the maximum precision of the analysis code responses
CHAPTER 6. KEYWORDS AREA

Specification
Alias: none
Argument(s): REAL
Default: 1.0e-10

Description
The function precision control provides the algorithm with an estimate of the accuracy to which the problem functions can be computed. This is used to prevent the algorithm from trying to distinguish between function values that differ by less than the inherent error in the calculation.

linesearch_tolerance
- Keywords Area
- method
- nlssol_sqp
- linesearch_tolerance

Choose how accurately the algorithm will compute the minimum in a line search

Specification
Alias: none
Argument(s): REAL
Default: 0.9 (inaccurate line search)

Description
The linesearch_tolerance setting controls the accuracy of the line search. The smaller the value (between 0 and 1), the more accurately the algorithm will attempt to compute a precise minimum along the search direction.

linear_inequality_constraint_matrix
- Keywords Area
- method
- nlssol_sqp
- linear_inequality_constraint_matrix

Define coefficients of the linear inequality constraints

Topics
This keyword is related to the topics:
- linear_constraints
6.2. METHOD

Specification

Alias: none
Argument(s): REALLIST
Default: no linear inequality constraints

Description

In the inequality case, the constraint matrix $A$ provides coefficients for the variables in the two-sided formulation:

$$ a_l \leq Ax \leq a_u $$

Where the bounds are optionally specified by `linear_inequality_lower_bounds`, and `linear_inequality_upper_bounds`. The bounds, if not specified, will default to -infinity, and 0, respectively, resulting in one-sided inequalities of the form

$$ Ax \leq 0.0 $$

linear_inequality_lower_bounds

- Keywords Area
- method
- nlssol_sqp
- linear_inequality_lower_bounds

Define lower bounds for the linear inequality constraint

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none
Argument(s): REALLIST
Default: vector values = -infinity

Description

In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$ a_l \leq Ax \leq a_u $$

Where $A$ is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see `objective_functions`), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$ Ax \leq 0.0 $$
result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than \( +\text{bigRealBoundSize (1.e+30, as defined in Minimizer) are treated as +infinity and any lower bound values less than } -\text{bigRealBoundSize are treated as -infinity.} \)

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since \(-\text{DBL\_MAX < -bigRealBoundSize}\)).

**linear_inequality_upper_bounds**

- Keywords Area
- method
- nlssol_sqp
- linear_inequality_upper_bounds

Define upper bounds for the linear inequality constraint

**Topics**

This keyword is related to the topics:

- linear_constraints

**Specification**

Alias: none

*Argument(s):* REALLIST

*Default:* vector values = 0 .

**Description**

In the inequality case, the lower \( a_l \) and upper \( a_u \) bounds provide constraint limits for the two-sided formulation:

\[
a_l \leq Ax \leq a_u
\]

Where \( A \) is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see objective.functions), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

\[
Ax \leq 0.0
\]

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than \( +\text{bigRealBoundSize (1.e+30, as defined in Minimizer) are treated as +infinity and any lower bound values less than } -\text{bigRealBoundSize are treated as -infinity.} \)

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since \(-\text{DBL\_MAX < -bigRealBoundSize}\)).
6.2. METHOD

linear_inequality_scale_types

• Keywords Area
• method
• nlssol
• linear_inequality_scale_types

Specify how each linear inequality constraint is scaled

Topics

This keyword is related to the topics:

• linear_constraints

Specification

Alias: none
Argument(s): STRINGLIST
Default: vector values = ’none’

Description

linear_inequality_scale_types provide strings specifying the scaling type for each linear inequality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

• ’none’ - no scaling
• ’value’ - characteristic value if this is chosen, then linear_inequality_scale_types must be specified
• ’auto’ - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables x:

\[
\tilde{x}^j = \frac{x^j - x^j_O}{x^j_M} \]

we have the following system for linear inequality constraints

\[
a_L \leq A_i x \leq a_U
\]

\[
a_L \leq A_i (\text{diag}(x_M) \tilde{x} + x_O) \leq a_U
\]

\[
a_L - A_i x_O \leq A_i \text{diag}(x_M) \tilde{x} \leq a_U - A_i x_O
\]

\[
\hat{a}_L \leq \hat{A}_i \tilde{x} \leq \hat{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].
linear_inequality_scales

- Keywords Area
- method
- nlssol_sqp
- linear_inequality_scales

Define the characteristic values to scale linear inequalities

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): REALLIST
Default: vector values = 1 . (no scaling)

Description

Each entry in linear_inequality_scales may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

Behavior depends on the choice of linear_inequality_scale_type:

- scale_type - behavior of linear_inequality_scales
- 'none' - ignored
- 'value' - required
- 'auto' - optional

If a single real value is specified it will apply to all components of the constraint.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables x:

\[ \tilde{x}_j = \frac{x_j^O - x_j^O}{x_j^M} \]

we have the following system for linear inequality constraints:

\[ a_L \leq A_i \tilde{x} \leq a_U \]
\[ a_L \leq A_i (\text{diag}(x_M) \tilde{x} + x_O) \leq a_U \]
\[ a_L - A_i x_O \leq A_i \text{diag}(x_M) \tilde{x} \leq a_U - A_i x_O \]
\[ \tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U \]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].
6.2. METHOD

**linear\_equality\_constraint\_matrix**
- Keywords Area

- nlssol\_sqp
- linear\_equality\_constraint\_matrix

Define coefficients of the linear equalities

**Topics**
This keyword is related to the topics:
- linear\_constraints

**Specification**

**Alias:** none
- **Argument(s):** REALLIST
- **Default:** no linear equality constraints

**Description**
In the equality case, the constraint matrix $A$ provides coefficients for the variables on the left hand side of:

$$Ax = at$$

**linear\_equality\_targets**
- Keywords Area
- method
- nlssol\_sqp
- linear\_equality\_targets

Define target values for the linear equality constraints

**Topics**
This keyword is related to the topics:
- linear\_constraints

**Specification**

**Alias:** none
- **Argument(s):** REALLIST
- **Default:** vector values $= 0$. 
Description

In the equality case, the targets \( a_t \) provide the equality constraint right hand sides:

\[
Ax = a_t
\]

If this is not specified, the defaults for the equality constraint targets enforce a value of 0. for each constraint:

\[
Ax = 0
\]

linear_equation_scale_types

• Keywords Area
• method
• nlssol_sqp
• linear_equation_scale_types

Specify how each linear equality constraint is scaled

Topics

This keyword is related to the topics:

• linear_constraints

Specification

Alias: none

Argument(s): STRINGLIST

Default: vector values = 'none'

Description

linear_equation_scale_types provide strings specifying the scaling type for each linear equality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

• 'none' - no scaling

• 'value' - characteristic value if this is chosen, then linear_equation_scales must be specified

• 'auto' - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables \( x \):

\[
\tilde{x}^j = \frac{x^j - x^j_0}{x^j_M}
\]

we have the following system for linear equality constraints

\[
a_L \leq A_t x \leq a_U
\]
6.2. METHOD

\[ a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U \]
\[ a_L - A_i x_O \leq A_i (\text{diag}(x_M)\tilde{x}) \leq a_U - A_i x_O \]
\[ \tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U \]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

**linear_equality_scales**

- **Keywords** Area

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.

See block_pointer for details about pointers.

Examples

```plaintext
environment
    tabular_graphics_data
    method_pointer = 'UQ'

method
    id_method = 'UQ'
    model_pointer = 'SURR'
    sampling,
        samples = 10
        seed = 98765 rng rnum2
        response_levels = 0.1 0.2 0.6
        0.1 0.2 0.6
        0.1 0.2 0.6
        sample_type lhs
    distribution cumulative

model
    id_model = 'SURR'
```
surrogate global,
dace_method_pointer = 'DACE'
polynomial quadratic

method
id_method = 'DACE'
model_pointer = 'DACE_M'
sampling sample_type lhs
samples = 121 seed = 5034 rng rnum2

model
id_model = 'DACE_M'
single
interface_pointer = 'I1'

variables
uniform_uncertain = 2
lower_bounds = 0. 0.
upper_bounds = 1. 1.

verify_level

- Keywords Area
- method
- stanford
- verify_level

Verify the quality of analytic gradients

Specification

Alias: none
Argument(s): INTEGER
Default: -1 (no gradient verification)

Description

verify_level instructs the NPSOL and NLSSOL algorithms to perform their own finite difference verification of the gradients provided by Dakota. Typically these are used to verify analytic_gradients produced by a simulation code, though the option can be used with other Dakota-supplied gradient types including numerical or mixed.

Level 1 will verify the objective gradients, level 2, the nonlinear constraint gradients, and level 3, both. See the Optional Input Parameters section of the NPSOL manual[33] for additional information, including options to verify at the user-supplied initial point vs. first feasible point.

function_precision

- Keywords Area
- method
- stanford
- function_precision

Specify the maximum precision of the analysis code responses

Specification

Alias: none
Argument(s): REAL
Default: 1.0e-10

Description

The function_precision control provides the algorithm with an estimate of the accuracy to which the problem functions can be computed. This is used to prevent the algorithm from trying to distinguish between function values that differ by less than the inherent error in the calculation.
6.2. METHOD

linesearch_tolerance

- Keywords Area
- method
- stanford
- linesearch_tolerance

Choose how accurately the algorithm will compute the minimum in a line search

**Specification**

**Alias:** none
**Argument(s):** REAL
**Default:** 0.9 (inaccurate line search)

**Description**

The linesearch_tolerance setting controls the accuracy of the line search. The smaller the value (between 0 and 1), the more accurately the algorithm will attempt to compute a precise minimum along the search direction.

**linear_inequality_constraint_matrix**

- Keywords Area
- method
- stanford
- linear_inequality_constraint_matrix

Define coefficients of the linear inequality constraints

**Topics**

This keyword is related to the topics:

- linear_constraints

**Specification**

**Alias:** none
**Argument(s):** REALIST
**Default:** no linear inequality constraints
Description
In the inequality case, the constraint matrix $A$ provides coefficients for the variables in the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where the bounds are optionally specified by `linear.inequality.lower_bounds`, and `linear.inequality.upper_bounds`. The bounds, if not specified, will default to -infinity, and 0, respectively, resulting in one-sided inequalities of the form

$$Ax \leq 0.0$$

`linear.inequality.lower_bounds`

- Keywords Area
- method
- stanford
- `linear.inequality.lower_bounds`

Define lower bounds for the linear inequality constraint

Topics
This keyword is related to the topics:

- `linear.constraints`

Specification
Alias: none

Argument(s): REALLIST

Default: vector values = -infinity

Description
In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where $A$ is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see `objective.functions`), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$Ax \leq 0.0$$

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than +`bigRealBoundSize` (1.e+30, as defined in Minimizer) are treated as `+infinity` and any lower bound values less than -`bigRealBoundSize` are treated as `-infinity`.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since `-DBL_MAX < -bigRealBoundSize`).
6.2. METHOD

linear_inequality_upper_bounds

- Keywords Area
- method
- stanford
- linear_inequality_upper_bounds

Define upper bounds for the linear inequality constraint

Topics

This keyword is related to the topics:
- linear_constraints

Specification

Alias: none

**Argument(s):** REALLIST

**Default:** vector values = 0.

**Description**

In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$
al \leq Ax \leq au$$

Where $A$ is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see objective_functions), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$Ax \leq 0.0$$

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than $+\text{bigRealBoundSize}$ ($1.e+30$, as defined in Minimizer) are treated as $+\infty$ and any lower bound values less than $-\text{bigRealBoundSize}$ are treated as $-\infty$.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since $-\text{DBLMAX} < -\text{bigRealBoundSize}$).

linear_inequality_scale_types

- Keywords Area
- method
- stanford
- linear_inequality_scale_types

Specify how each linear inequality constraint is scaled
CHAPTER 6. KEYWORDS AREA

Topics
This keyword is related to the topics:

- linear_constraints

Specification
Alias: none
Argument(s): STRINGLIST
Default: vector values = 'none'

Description
linear_inequality_scale_types provide strings specifying the scaling type for each linear inequality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- 'none' - no scaling
- 'value' - characteristic value if this is chosen, then linear_inequality_scales must be specified
- 'auto' - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables \( x \):

\[
\tilde{x}^j = \frac{x^j - x_O^j}{x_M^j}
\]

we have the following system for linear inequality constraints

\[
a_L \leq A_i x \leq a_U
\]

\[
a_L \leq A_i (\text{diag}(x_M) \tilde{x} + x_O) \leq a_U
\]

\[
a_L - A_i x_O \leq A_i \text{diag}(x_M) \tilde{x} \leq a_U - A_i x_O
\]

\[
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to \([0,1]\).

linear_inequality_scales

- Keywords Area
- method
- stanford
- linear_inequality_scales

Define the characteristic values to scale linear inequalities
6.2. METHOD

Topics
This keyword is related to the topics:

- linear_constraints

Specification

Alias: none
Argument(s): REALLIST
Default: vector values = 1. (no scaling)

Description
Each entry in linear_inequality_scales may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

Behavior depends on the choice of linear_inequality_scale_type:

- scale_type - behavior of linear_inequality_scales
- 'none' - ignored
- 'value' - required
- 'auto' - optional

If a single real value is specified it will apply to all components of the constraint.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables \( x \):

\[
\tilde{x}_j = \frac{x_j - x_O}{x_M}
\]

we have the following system for linear inequality constraints

\[
a_L \leq A_i x \leq a_U
\]

\[
a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U
\]

\[
a_L - A_i x_O \leq A_i (\text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O
\]

\[
\tilde{a}_L \leq A_i \tilde{x} \leq \tilde{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

linear_equality_constraint_matrix

- Keywords Area
- method
- stanford
- linear_equality_constraint_matrix

Define coefficients of the linear equalities
CHAPTER 6. KEYWORDS AREA

Topics
This keyword is related to the topics:
  • linear_constraints

Specification
Alias: none
  Argument(s): REALLIST
  Default: no linear equality constraints

Description
In the equality case, the constraint matrix \( A \) provides coefficients for the variables on the left hand side of:

\[
Ax = a_t
\]

linear_equalities
  • Keywords Area
  • method
  • stanford
  • linear_equalities

Define target values for the linear equality constraints

Topics
This keyword is related to the topics:
  • linear_constraints

Specification
Alias: none
  Argument(s): REALLIST
  Default: vector values = 0.

Description
In the equality case, the targets \( a_t \) provide the equality constraint right hand sides:

\[
Ax = a_t
\]

If this is not specified, the defaults for the equality constraint targets enforce a value of 0. for each constraint:

\[
Ax = 0.0
\]
6.2. METHOD

linear_equality_scale_types

- Keywords Area
- method
- stanford
- linear_equality_scale_types

Specify how each linear equality constraint is scaled

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): STRINGLIST

Default: vector values = 'none'

Description

linear_equality_scale_types provide strings specifying the scaling type for each linear equality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- 'none' - no scaling
- 'value' - characteristic value if this is chosen, then linear.equality.scales must be specified
- 'auto' - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables \( x \):

\[
\tilde{x}^j = \frac{x^j - x^j_O}{x^j_M}
\]

we have the following system for linear equality constraints

\[
a_L \leq A_i x \leq a_U
\]
\[
a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U
\]
\[
a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O
\]
\[
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].
linear\_equality\_scales

- Keywords Area
- method
- stanford
- linear\_equality\_scales

Define the characteristic values to scale linear equalities

Topics

This keyword is related to the topics:

- linear\_constraints

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = 1. (no scaling)

Description

Each entry in linear\_equality\_scales may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

See the scaling page for details on how to use this keyword.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables \( x \):

\[
\tilde{x}^j = \frac{x^j - x_O^j}{x_M^j}
\]

we have the following system for linear inequality constraints

\[
a_L \leq A_i x \leq a_U
\]

\[
a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U
\]

\[
a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O
\]

\[
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to \([0,1]\).
6.2. METHOD

model_pointer

- Keywords Area
- method
- stanford
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.

See block_pointer for details about pointers.

Description

NLPQL provides an implementation of sequential quadratic programming through nlpq_sqp. The particular SQP implementation in nlpq_sqp uses a variant with distributed and non-monotone line search. Thus, this variant is designed to be more robust in the presence of inaccurate or noisy gradients common in many engineering applications.

The method independent controls for maximum iterations and output verbosity are mapped to NLPQL controls MAXIT and IPRINT, respectively. The maximum number of function evaluations is enforced within the NLPQLPOptimizer class.

linear_inequality_constraint_matrix

- Keywords Area
- method
- nlpq_sqp
- linear_inequality_constraint_matrix

Define coefficients of the linear inequality constraints

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): REALLIST

Default: no linear inequality constraints

Description

In the inequality case, the constraint matrix $A$ provides coefficients for the variables in the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where the bounds are optionally specified by linear_inequality_lower_bounds, and linear_inequality_upper_bounds. The bounds, if not specified, will default to -infinity, and 0, respectively, resulting in one-sided inequalities of the form

$$Ax \leq 0.0$$

6.2. METHOD

**linear_inequality_lower_bounds**

- Keywords Area
- method
- nlpql sqp
- linear_inequality_lower_bounds

Define lower bounds for the linear inequality constraint

**Topics**

This keyword is related to the topics:

- linear_constraints

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Default:** vector values = -infinity

**Description**

In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$ a_l \leq Ax \leq a_u $$

Where $A$ is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see objective_functions), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$ Ax \leq 0.0 $$

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than $+\text{bigRealBoundSize}$ (1.e+30, as defined in Minimizer) are treated as $+\text{infinity}$ and any lower bound values less than $-\text{bigRealBoundSize}$ are treated as $-\text{infinity}$.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since $-\text{DBLMAX} < -\text{bigRealBoundSize}$).

$$Ax = at$$

linear_equalirty_targets

- Keywords Area
- method
- nlpql_sqp
- linear_equalirty_targets

Define target values for the linear equality constraints

Topics
This keyword is related to the topics:

- linear_constraints

Specification
Alias: none

Argument(s): REALLIST
Default: vector values = 0.

Description
In the equality case, the targets $at$ provide the equality constraint right hand sides:

$$Ax = at$$

If this is not specified, the defaults for the equality constraint targets enforce a value of 0. for each constraint:

$$Ax = 0.0$$

linear_equalirty_scale_types

- Keywords Area
- method
- nlpql_sqp
- linear_equalirty_scale_types

Specify how each linear equality constraint is scaled
Topics
This keyword is related to the topics:

- linear_constraints

Specification
Alias: none
Argument(s): STRINGLIST
Default: vector values = 'none'

Description
linear_equation_scale_types provide strings specifying the scaling type for each linear equality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- 'none' - no scaling
- 'value' - characteristic value if this is chosen, then linear_equation_scales must be specified
- 'auto' - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables x:

\[ \tilde{x}^j = \frac{x^j - x^j_O}{x^j_M} \]

we have the following system for linear equality constraints

\[
\begin{align*}
a_L & \leq A_i x \leq a_U \\
a_L & \leq A_i (\text{diag}(x_M) \tilde{x} + x_O) \leq a_U \\
a_L - A_i x_O & \leq A_i \text{diag}(x_M) \tilde{x} \leq a_U - A_i x_O \\
\tilde{a}_L & \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U 
\end{align*}
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

linear_equation_scales
- Keywords Area
- method
- nlpql_sqp
- linear_equation_scales

Define the characteristic values to scale linear equalities
6.2. METHOD

Topics
This keyword is related to the topics:

- linearconstraints

Specification
Alias: none
Argument(s): REALIST
Default: vector values = 1. (no scaling)

Description
Each entry in linear_equality_scales may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

See the scaling page for details on how to use this keyword.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables \( x \):

\[
\tilde{x}^j = \frac{x^j - x_O^j}{x_M^j}
\]

we have the following system for linear inequality constraints

\[
a_L \leq A_i x \leq a_U
\]

\[
a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U
\]

\[
a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

model_pointer

- nlpl_sqp
- model_pointer

Identifier for model block to be used by a method

Topics
This keyword is related to the topics:

- block_pointer
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations
needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model
block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model-
_pointer for each method is imperative.

See block_pointer for details about pointers.

6.2. METHOD

max_step

- **Keywords Area**
- **method**
- **optpp_cg**
- **max_step**

Max change in design point

**Specification**

**Alias:** none  
**Argument(s):** REAL  
**Default:** 1000.

**Description**

The `max_step` control specifies the maximum step that can be taken when computing a change in the current design point (e.g., limiting the Newton step computed from current gradient and Hessian information). It is equivalent to a move limit or a maximum trust region size. The `gradient_tolerance` control defines the threshold value on the L2 norm of the objective function gradient that indicates convergence to an unconstrained minimum (no active constraints). The `gradient_tolerance` control is defined for all gradient-based optimizers.

gradient_tolerance

- **Keywords Area**
- **method**
- **optpp_cg**
- **gradient_tolerance**

Stopping criteria based on L2 norm of gradient

**Specification**

**Alias:** none  
**Argument(s):** REAL  
**Default:** 1.e-4

**Description**

The `gradient_tolerance` control defines the threshold value on the L2 norm of the objective function gradient that indicates convergence to an unconstrained minimum (no active constraints). The `gradient_tolerance` control is defined for all gradient-based optimizers.
linear_inequality_constraint_matrix

- **Keywords Area**

- **linear_inequality_constraint_matrix**

Define coefficients of the linear inequality constraints

**Topics**

This keyword is related to the topics:

- **linear_constraints**

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Default:** no linear inequality constraints

**Description**

In the inequality case, the constraint matrix $A$ provides coefficients for the variables in the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where the bounds are optionally specified by `linear_inequality_lower_bounds`, and `linear_inequality_upper_bounds`. The bounds, if not specified, will default to -$\infty$, and 0, respectively, resulting in one-sided inequalities of the form

$$Ax \leq 0.0$$

linear_inequality_lower_bounds

- **Keywords Area**
- **method**
- **optpp_cg**
- **linear_inequality_lower_bounds**

Define lower bounds for the linear inequality constraint

**Topics**

This keyword is related to the topics:

- **linear_constraints**
6.2. METHOD

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = -infinity

Description

In the inequality case, the lower \(a_l\) and upper \(a_u\) bounds provide constraint limits for the two-sided formulation:

\[ a_l \leq Ax \leq a_u \]

Where \(A\) is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see objective functions), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

\[ Ax \leq 0.0 \]

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than \(+\text{bigRealBoundSize}\) (1.e+30, as defined in Minimizer) are treated as \(+\infty\) and any lower bound values less than \(-\text{bigRealBoundSize}\) are treated as \(-\infty\).

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since \(-\text{DBL_MAX} < -\text{bigRealBoundSize}\)).

linear_inequality_upper_bounds

- Keywords Area
- method
- optpp_cg
- linear_inequality_upper_bounds

Define upper bounds for the linear inequality constraint

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = 0.
CHAPTER 6. KEYWORDS AREA

Description

In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where $A$ is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see objective_functions), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$Ax \leq 0.0$$

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than $+\text{bigRealBoundSize}$ (1.e+30, as defined in Minimizer) are treated as $+\text{infinity}$ and any lower bound values less than $-\text{bigRealBoundSize}$ are treated as $-\text{infinity}$.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since $-\text{DBL}_\text{MAX} < -\text{bigRealBoundSize}$).

linear_inequality_scale_types

- Keywords Area
- method
- optpp_cg
- linear_inequality_scale_types

Specify how each linear inequality constraint is scaled

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): STRINGLIST

Default: vector values = 'none'

Description

linear_inequality_scale_types provide strings specifying the scaling type for each linear inequality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- 'none' - no scaling
- 'value' - characteristic value if this is chosen, then linear_inequality_scales must be specified
• ‘auto’ - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables \( x \):

\[
\tilde{x}^j = \frac{x^j - x^j_O}{x^j_M - x^j_O}
\]

we have the following system for linear inequality constraints

\[
a_L \leq A_i x \leq a_U
\]

\[
a_L \leq A_i (\text{diag}(x_M) \tilde{x} + x_O) \leq a_U
\]

\[
a_L - A_i x_O \leq A_i \text{diag}(x_M) \tilde{x} \leq a_U - A_i x_O
\]

\[
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to \([0,1]\).

\textbf{linear_inequality_scales}

- Keywords Area
- method
- optpp_cg
- linear_inequality_scales

Define the characteristic values to scale linear inequalities

\textbf{Topics}

This keyword is related to the topics:

- linear_constraints

\textbf{Specification}

\textbf{Alias}: none

\textbf{Argument(s)}: REALLIST

\textbf{Default}: vector values = 1 . (no scaling)

\textbf{Description}

Each entry in \texttt{linear_inequality_scales} may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

Behavior depends on the choice of \texttt{linear_inequality_scale_type}:

- \texttt{scale_type} - behavior of \texttt{linear_inequality_scales}
- ‘none’ - ignored
• ‘value’ - required
• ‘auto’ - optional

If a single real value is specified it will apply to all components of the constraint.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables $x$:

$$\tilde{x}^j = \frac{x^j - x^j_O}{x^j_M}$$

we have the following system for linear inequality constraints

$$a_L \leq A_i x \leq a_U$$

$$a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U$$

$$a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O$$

we have the following system for linear inequality constraints

$$a_L \leq A_i x \leq a_U$$

$$a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U$$

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

6.2. **METHOD**

**Description**

This is a Newton method that expects a gradient and computes a low-rank approximation to the Hessian. Each of the Newton-based methods are automatically bound to the appropriate OPT++ algorithm based on the user constraint specification (unconstrained, bound-constrained, or generally-constrained). In the generally-constrained case, the Newton methods use a nonlinear interior-point approach to manage the constraints.

See package \texttt{optpp} for info related to all \texttt{optpp} methods.

</table>

**Description**

The \texttt{search\_method} control is defined for all Newton-based optimizers and is used to select between \texttt{trust\_region}, \texttt{gradient\_based\_line\_search}, and \texttt{value\_based\_line\_search} methods. The \texttt{gradient\_based\_line\_search} option uses the line search method proposed by[61]. This option satisfies sufficient decrease and curvature conditions; whereas, \texttt{value\_based\_line\_search} only satisfies the sufficient decrease condition. At each line search iteration, the \texttt{gradient\_based\_line\_search} method computes the function and gradient at the trial point. Consequently, given expensive function evaluations, the \texttt{value\_based\_line\_search} method is preferred to the \texttt{gradient\_based\_line\_search} method. Each of these Newton methods
additionally supports the `tr_pds` selection for unconstrained problems. This option performs a robust trust region search using pattern search techniques. Use of a line search is the default for bound-constrained and generally-constrained problems, and use of a `trust_region` search method is the default for unconstrained problems.

- **search_method**
- **gradient_based_line_search**

Set the search method to use the gradient
6.2. METHOD

Specification

Alias: none
Argument(s): none

Description

The search_method control is defined for all Newton-based optimizers and is used to select between trust_region, gradient_based_line_search, and value_based_line_search methods. The gradient_based_line_search option uses the line search method proposed by[61]. This option satisfies sufficient decrease and curvature conditions; whereas, value_based_line_search only satisfies the sufficient decrease condition. At each line search iteration, the gradient_based_line_search method computes the function and gradient at the trial point. Consequently, given expensive function evaluations, the value_based_line_search method is preferred to the gradient_based_line_search method. Each of these Newton methods additionally supports the tr_pds selection for unconstrained problems. This option performs a robust trust region search using pattern search techniques. Use of a line search is the default for bound-constrained and generally-constrained problems, and use of a trust_region search method is the default for unconstrained problems.

trust_region

- Keywords Area
- method
- optpp_q_newton
- search_method
- trust_region

Use trust region as the globalization strategy.

Specification

Alias: none
Argument(s): none

Description

The trust_region optional group specification can be used to specify the initial size of the trust region (using initial_size) relative to the total variable bounds, the minimum size of the trust region (using minimum_size), the contraction factor for the trust region size (using contraction_factor) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using expansion_factor) used when the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using contract_threshold) and the trust region size expansion threshold (using expand_threshold). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command contract_threshold sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command expand_threshold determines the trust region value above which the trust region will expand for the next SBL iteration.
tr_pds

- Keywords Area
- method
- optpp_q_newton
- search_method
- tr_pds

Use direct search as the local search in a trust region method

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The `search_method` control is defined for all Newton-based optimizers and is used to select between `trust_region`, `gradient_based_line_search`, and `value_based_line_search` methods. The `gradient_based_line_search` option uses the line search method proposed by[61]. This option satisfies sufficient decrease and curvature conditions; whereas, `value_based_line_search` only satisfies the sufficient decrease condition. At each line search iteration, the `gradient_based_line_search` method computes the function and gradient at the trial point. Consequently, given expensive function evaluations, the `value_based_line_search` method is preferred to the `gradient_based_line_search` method. Each of these Newton methods additionally supports the `tr_pds` selection for unconstrained problems. This option performs a robust trust region search using pattern search techniques. Use of a line search is the default for bound-constrained and generally-constrained problems, and use of a `trust_region` search method is the default for unconstrained problems.

merit_function

- Keywords Area
- method
- optpp_q_newton
- merit_function

Balance goals of reducing objective function and satisfying constraints

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** argaez_tapia
### Description

A *merit_function* is a function in constrained optimization that attempts to provide joint progress toward reducing the objective function and satisfying the constraints.

**el_bakry**
- **Keywords Area**
- **method**
- **optpp_q_newton**
- **merit_function**
- **el_bakry**

El-Bakry merit function

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The "el_bakry" merit function is the L2-norm of the first order optimality conditions for the nonlinear programming problem. The cost per linesearch iteration is $n+1$ function evaluations. For more information, see[20].

**argaez_tapia**
- **Keywords Area**
- **method**
- **optpp_q_newton**
- **merit_function**
- **argaez_tapia**

The merit function by Tapia and Argaez
CHAPTER 6. KEYWORDS AREA

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

The "argaez.tapia" merit function can be classified as a modified augmented Lagrangian function. The augmented Lagrangian is modified by adding to its penalty term a potential reduction function to handle the perturbed complementarity condition. The cost per linesearch iteration is one function evaluation. For more information, see [80]. If the function evaluation is expensive or noisy, set the `merit_function` to "argaez.tapia" or "van.shanno".

**van.shanno**

- Keywords Area
- method
- optpp_q_newton
- merit_function
- van.shanno

The merit function by Vanderbei and Shanno

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

The "van.shanno" merit function can be classified as a penalty function for the logarithmic barrier formulation of the nonlinear programming problem. The cost per linesearch iteration is one function evaluation. For more information see [82]. If the function evaluation is expensive or noisy, set the `merit_function` to "argaez.tapia" or "van.shanno".

**steplength_to_boundary**

- Keywords Area
- method
- optpp_q_newton
- steplength_to_boundary

Controls how close to the boundary of the feasible region the algorithm is allowed to move
6.2. METHOD

Specification

Alias: none
Argument(s): REAL
Default: Merit function dependent: 0.8 (el_bakry), 0.99995 (argaez_tapia), 0.95 (van_shanno)

Description

The steplength_to_boundary specification is a parameter (between 0 and 1) that controls how close to the boundary of the feasible region the algorithm is allowed to move. A value of 1 means that the algorithm is allowed to take steps that may reach the boundary of the feasible region. If the user wishes to maintain strict feasibility of the design parameters this value should be less than 1. Default values are .8, .99995, and .95 for the el_bakry, argaez_tapia, and van_shanno merit functions, respectively.

centering_parameter

- Keywords Area
- method
- optpp_q_newton
- centering_parameter

Controls how closely the algorithm should follow the "central path"

Specification

Alias: none
Argument(s): REAL
Default: Merit function dependent: 0.2 (el_bakry), 0.2 (argaez_tapia), 0.1 (van_shanno)

Description

The centering_parameter specification is a parameter (between 0 and 1) that controls how closely the algorithm should follow the "central path". See[88] for the definition of central path. The larger the value, the more closely the algorithm follows the central path, which results in small steps. A value of 0 indicates that the algorithm will take a pure Newton step. Default values are .2, .2, and .1 for the el_bakry, argaez_tapia, and van_shanno merit functions, respectively.

max_step

- Keywords Area
- method
- optpp_q_newton
- max_step

Max change in design point
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none
Argument(s): REAL
Default: 1000.

Description

The max_step control specifies the maximum step that can be taken when computing a change in the current design point (e.g., limiting the Newton step computed from current gradient and Hessian information). It is equivalent to a move limit or a maximum trust region size. The gradient_tolerance control defines the threshold value on the L2 norm of the objective function gradient that indicates convergence to an unconstrained minimum (no active constraints). The gradient_tolerance control is defined for all gradient-based optimizers.

gradient_tolerance

- Keywords Area
- method
- optpp_q_newton
- gradient_tolerance

Stopping criteria based on L2 norm of gradient

Specification

Alias: none
Argument(s): REAL
Default: 1.e-4

Description

The gradient_tolerance control defines the threshold value on the L2 norm of the objective function gradient that indicates convergence to an unconstrained minimum (no active constraints). The gradient_tolerance control is defined for all gradient-based optimizers.

linear_inequality_constraint_matrix

- Keywords Area
- method
- optpp_q_newton
- linear_inequality_constraint_matrix

Define coefficients of the linear inequality constraints

Topics

This keyword is related to the topics:

- linear_constraints
6.2. METHOD

Specification

Alias: none

Argument(s): REALLIST

Default: no linear inequality constraints

Description

In the inequality case, the constraint matrix $A$ provides coefficients for the variables in the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where the bounds are optionally specified by `linear_inequality_lower_bounds`, and `linear_inequality_upper_bounds`. The bounds, if not specified, will default to -infinity, and 0, respectively, resulting in one-sided inequalities of the form

$$Ax \leq 0.0$$

linear_inequality_lower_bounds

- Keywords Area
- method
- optpp_q_newton
- linear_inequality_lower_bounds

Define lower bounds for the linear inequality constraint

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = -infinity

Description

In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where $A$ is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see `objective_functions`), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$Ax \leq 0.0$$
result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than +bigRealBoundSize (1.e+30, as defined in Minimizer) are treated as +infinity and any lower bound values less than -bigRealBoundSize are treated as -infinity.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since -DBL_MAX < -bigRealBoundSize).

linear_inequality_upper_bounds

• Keywords Area
  • method
  • optpp_q_newton
  • linear_inequality_upper_bounds

Define upper bounds for the linear inequality constraint

Topics

This keyword is related to the topics:

• linear_constraints

Specification

Alias: none
  
  Argument(s): REALLIST
  
  Default: vector values = 0.

Description

In the inequality case, the lower \( a_l \) and upper \( a_u \) bounds provide constraint limits for the two-sided formulation:

\[
 a_l \leq Ax \leq a_u
\]

Where \( A \) is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see objective functions), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

\[
 Ax \leq 0.0
\]

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than +bigRealBoundSize (1.e+30, as defined in Minimizer) are treated as +infinity and any lower bound values less than -bigRealBoundSize are treated as -infinity.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since -DBL_MAX < -bigRealBoundSize).
specification

Alias: none
Argument(s): STRINGLIST
Default: vector values = ’none’

Description

linear.inequality_scale_types provide strings specifying the scaling type for each linear inequality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

• ’none’ - no scaling
• ’value’ - characteristic value if this is chosen, then linear.inequality.scales must be specified
• ’auto’ - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables x:

\[ \tilde{x}^j = \frac{x^j - x^j_O}{x^j_M} \]

we have the following system for linear inequality constraints

\[ a_L \leq A_i x \leq a_U \]
\[ a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U \]
\[ a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O \]
\[ \tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U \]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].
linear_inequality_scales

- Keywords Area
- method
- optpp_q_newton
- linear_inequality_scales

Define the characteristic values to scale linear inequalities.

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = 1 . (no scaling)

Description

Each entry in `linear_inequality_scales` may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

Behavior depends on the choice of `linear_inequality_scale_type`:

- `scale_type` - behavior of `linear_inequality_scales`
  - 'none' - ignored
  - 'value' - required
  - 'auto' - optional

If a single real value is specified it will apply to all components of the constraint.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables $x$:

$$
\tilde{x}^j = \frac{x^j - x^j_O}{x^j_M}
$$

we have the following system for linear inequality constraints

$$
a_L \leq A_i x \leq a_U
$$

$$
a_L \leq A_i (\text{diag}(x_M) \tilde{x} + x_O) \leq a_U
$$

$$
a_L - A_i x_O \leq A_i \text{diag}(x_M) \tilde{x} \leq a_U - A_i x_O
$$

$$
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
$$

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to $[0,1]$. 
6.2. METHOD

linear.equality.constraint_matrix

- Keywords Area
- method
- optpp.q.newton
- linear.equality.constraint_matrix

Define coefficients of the linear equalities

Topics
This keyword is related to the topics:

- linear.constraints

Specification
Alias: none
Argument(s): REALLIST
Default: no linear equality constraints

Description
In the equality case, the constraint matrix $A$ provides coefficients for the variables on the left hand side of:

$$Ax = a_t$$

linear.equality.targets

- Keywords Area
- method
- optpp.q.newton
- linear.equality.targets

Define target values for the linear equality constraints

Topics
This keyword is related to the topics:

- linear.constraints

Specification
Alias: none
Argument(s): REALLIST
Default: vector values $= 0$. 

CHAPTER 6. KEYWORDS AREA

Description
In the equality case, the targets \( a_t \) provide the equality constraint right hand sides:

\[ Ax = a_t \]

If this is not specified, the defaults for the equality constraint targets enforce a value of 0. for each constraint:

\[ Ax = 0.0 \]

linear_equality_scale_types

- Keywords Area
- method
- optpp_q_newton
- linear_equality_scale_types

Specify how each linear equality constraint is scaled

Topics
This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): STRINGLIST

Default: vector values = 'none'

Description

linear_equality_scale_types provide strings specifying the scaling type for each linear equality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- 'none' - no scaling
- 'value' - characteristic value if this is chosen, then linear_equality_scales must be specified
- 'auto' - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables \( x \):

\[ \tilde{x}^j = \frac{x^j - x_O^j}{x_M^j} \]

we have the following system for linear equality constraints

\[ a_L \leq A_t x \leq a_U \]
6.2. METHOD

\[
a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U \\
a_L - A_i x_O \leq A_i (\text{diag}(x_M)\tilde{x}) \leq a_U - A_i x_O \\
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

linear\_equality\_scales

- **Keywords** Area
- method
- optpp_nls_newton
- linear\_equality\_scales

Define the characteristic values to scale linear equalities

**Topics**

This keyword is related to the topics:

- linear\_constraints

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Default:** vector values = 1. (no scaling)

**Description**

Each entry in linear\_equality\_scales may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

See the scaling page for details on how to use this keyword.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables \(x\):

\[
\tilde{x}^j = \frac{x^j - x_O^j}{x_M^j}
\]

we have the following system for linear inequality constraints

\[
a_L \leq A_i x \leq a_U \\
a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U \\
a_L - A_i x_O \leq A_i (\text{diag}(x_M)\tilde{x}) \leq a_U - A_i x_O \\
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].
model_pointer

- **Keywords Area**
- **method**
- **optpp.q_newton**
- **model_pointer**

Identifier for model block to be used by a method

**Topics**

This keyword is related to the topics:

- **block_pointer**

**Specification**

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)

**Description**

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

**Usage Tips**

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

**Examples**

```plaintext
environment
    tabular_graphics_data
    method_pointer = 'UQ'

method
    id_method = 'UQ'
    model_pointer = 'SURR'

**Description**

This is a Newton method that expects a gradient and computes a finite-difference approximation to the Hessian. Each of the Newton-based methods are automatically bound to the appropriate OPT++ algorithm based on the user constraint specification (unconstrained, bound-constrained, or generally-constrained). In the generally-constrained case, the Newton methods use a nonlinear interior-point approach to manage the constraints.

See package optpp for info related to all optpp methods.

Description

The search_method control is defined for all Newton-based optimizers and is used to select between trust_region, gradient_based_line_search, and value_based_line_search methods. The gradient_based_line_search option uses the line search method proposed by[61]. This option satisfies sufficient decrease and curvature conditions; whereas, value_based_line_search only satisfies the sufficient decrease condition. At each line search iteration, the gradient_based_line_search method computes the function and gradient at the trial point. Consequently, given expensive function evaluations, the value_based_line_search method is preferred to the gradient_based_line_search method. Each of these Newton methods additionally supports the tr_pds selection for unconstrained problems. This option performs a robust trust region search using pattern search techniques. Use of a line search is the default for bound-constrained and generally-constrained problems, and use of a trust_region search method is the default for unconstrained problems.

Use of a line search is the default for bound-constrained and generally-constrained problems, and use of a `trust_region` search method is the default for unconstrained problems.

`trust_region`

- **Keywords Area**
- **method**
Use trust region as the globalization strategy.

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

The `trust_region` optional group specification can be used to specify the initial size of the trust region (using `initial_size`), the minimum size of the trust region (using `minimum_size`), the contraction factor for the trust region size (using `contraction_factor`) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using `expansion_factor`) used when the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using `contract_threshold`) and the trust region size expansion threshold (using `expand_threshold`). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command `contract_threshold` sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command `expand_threshold` determines the trust region value above which the trust region will expand for the next SBL iteration.

**Description**

The `search_method` control is defined for all Newton-based optimizers and is used to select between `trust_region`, `gradient_based_line_search`, and `value_based_line_search` methods. The `gradient_based_line_search` option uses the line search method proposed by [61]. This option satisfies sufficient decrease and curvature conditions; whereas, `value_based_line_search` only satisfies the sufficient decrease condition. At each line search iteration, the `gradient_based_line_search` method computes the function
and gradient at the trial point. Consequently, given expensive function evaluations, the value_based_line_search method is preferred to the gradient_based_line_search method. Each of these Newton methods additionally supports the tr_pds selection for unconstrained problems. This option performs a robust trust region search using pattern search techniques. Use of a line search is the default for bound-constrained and generally-constrained problems, and use of a trust_region search method is the default for unconstrained problems.

merit_function

- Keywords Area
- method
- optpp_fd_newton
- merit_function

Balance goals of reducing objective function and satisfying constraints

Specification

Alias: none
Argument(s): none
Default: argaez_tapia

| | | | by Tapia and |
| | | | Argaex |
| | | | The merit function |
| | | | by Vanderbei and |
| | | | Shanno |

Description

A merit_function is a function in constrained optimization that attempts to provide joint progress toward reducing the objective function and satisfying the constraints.

el_bakry

- Keywords Area
- method
- optpp_fd_newton
- merit_function
- el_bakry

El-Bakry merit function
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none
  Argument(s): none

Description

The "el_bakry" merit function is the L2-norm of the first order optimality conditions for the nonlinear programming problem. The cost per linesearch iteration is \( n+1 \) function evaluations. For more information, see [20].

```
argaez_tapia
```

- Keywords Area
- method
- optpp_fd_newton
- merit_function
- argaez_tapia

The merit function by Tapia and Argaez

Specification

Alias: none
  Argument(s): none

Description

The "argaez_tapia" merit function can be classified as a modified augmented Lagrangian function. The augmented Lagrangian is modified by adding to its penalty term a potential reduction function to handle the perturbed complementarity condition. The cost per linesearch iteration is one function evaluation. For more information, see [80].

If the function evaluation is expensive or noisy, set the merit_function to "argaez_tapia" or "van_shanno".

```
van_shanno
```

- Keywords Area
- method
- optpp_fd_newton
- merit_function
- van_shanno

The merit function by Vanderbei and Shanno
6.2. METHOD

Specification

Alias: none
  Argument(s): none

Description

The "van_shanno" merit function can be classified as a penalty function for the logarithmic barrier formulation of the nonlinear programming problem. The cost per linesearch iteration is one function evaluation. For more information see[82].

If the function evaluation is expensive or noisy, set the merit function to "argaez_tapia" or "van_shanno".

steplength_to_boundary

- Keywords Area
- method
- optpp_fd_newton
- steplength_to_boundary

Controls how close to the boundary of the feasible region the algorithm is allowed to move

Specification

Alias: none
  Argument(s): REAL
  Default: Merit function dependent: 0.8 (el_bakry), 0.99995 (argaez_tapia), 0.95 (van_shanno)

Description

The steplength_to_boundary specification is a parameter (between 0 and 1) that controls how close to the boundary of the feasible region the algorithm is allowed to move. A value of 1 means that the algorithm is allowed to take steps that may reach the boundary of the feasible region. If the user wishes to maintain strict feasibility of the design parameters this value should be less than 1. Default values are .8, .99995, and .95 for the el_bakry, argaez_tapia, and van_shanno merit functions, respectively.

centering_parameter

- Keywords Area
- method
- optpp_fd_newton
- centering_parameter

Controls how closely the algorithm should follow the "central path"
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none

Argument(s): REAL

Default: Merit function dependent: 0.2 (el_bakry), 0.2 (argaez_tapia), 0.1 (van_shanno)

Description

The centering parameter specification is a parameter (between 0 and 1) that controls how closely the algorithm should follow the "central path". See[88] for the definition of central path. The larger the value, the more closely the algorithm follows the central path, which results in small steps. A value of 0 indicates that the algorithm will take a pure Newton step. Default values are .2, .2, and .1 for the el_bakry, argaez_tapia, and van_shanno merit functions, respectively.

max_step

- Keywords Area
- method
- optpp_fd_newton
- max_step

Max change in design point

Specification

Alias: none

Argument(s): REAL

Default: 1000.

Description

The max_step control specifies the maximum step that can be taken when computing a change in the current design point (e.g., limiting the Newton step computed from current gradient and Hessian information). It is equivalent to a move limit or a maximum trust region size. The gradient_tolerance control defines the threshold value on the L2 norm of the objective function gradient that indicates convergence to an unconstrained minimum (no active constraints). The gradient_tolerance control is defined for all gradient-based optimizers.

gradient_tolerance

- Keywords Area
- method
- optpp_fd_newton
- gradient_tolerance

Stopping criteria based on L2 norm of gradient
6.2. METHOD

Specification
Alias: none
Argument(s): REAL
Default: 1.e-4

Description
The gradient_tolerance control defines the threshold value on the L2 norm of the objective function gradient that indicates convergence to an unconstrained minimum (no active constraints). The gradient-tolerance control is defined for all gradient-based optimizers.

linear_inequality_constraint_matrix
- Keywords Area
- method
- optpp_fd_newton
- linear_inequality_constraint_matrix

Define coefficients of the linear inequality constraints

Topics
This keyword is related to the topics:
- linear_constraints

Specification
Alias: none
Argument(s): REALLIST
Default: no linear inequality constraints

Description
In the inequality case, the constraint matrix $A$ provides coefficients for the variables in the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where the bounds are optionally specified by linear_inequality_lower_bounds, and linear_inequality_upper_bounds. The bounds, if not specified, will default to -infinity, and 0, respectively, resulting in one-sided inequalities of the form

$$Ax \leq 0.0$$
linear_inequality_lower_bounds

- Keywords Area
- method
- optpp_fd_newton
- linear_inequality_lower_bounds

Define lower bounds for the linear inequality constraint

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none
Argument(s): REALIST
Default: vector values = -infinity

Description

In the inequality case, the lower \( a_l \) and upper \( a_u \) bounds provide constraint limits for the two-sided formulation:

\[
a_l \leq Ax \leq a_u
\]

Where \( A \) is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see objective functions), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

\[
Ax \leq 0.0
\]

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than \(+\text{bigRealBoundSize}(1.0e+30, \text{as defined in Minimizer})\) are treated as \(+\infty\) and any lower bound values less than \(-\text{bigRealBoundSize}\) are treated as \(-\infty\).

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since \(-\text{DBL}_{\text{MAX}} < -\text{bigRealBoundSize}\)).

linear_inequality_upper_bounds

- Keywords Area
- method
- optpp_fd_newton
- linear_inequality_upper_bounds

Define upper bounds for the linear inequality constraint
6.2. METHOD

Topics
This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): REALLIST
Default: vector values = 0.

Description
In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where $A$ is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see objective_functions), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$Ax \leq 0.0$$

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than $+\text{bigRealBoundSize}$ (1.e+30, as defined in Minimizer) are treated as $+\infty$ and any lower bound values less than $-\text{bigRealBoundSize}$ are treated as $-\infty$.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since $-\text{DBL_MAX} < -\text{bigRealBoundSize}$).

linear_inequality_scale_types

- Keywords Area
- method
- optpp_fd_newton
- linear_inequality_scale_types

Specify how each linear inequality constraint is scaled

Topics
This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): STRINGLIST
Default: vector values = ‘none’
Description

*linear_inequality_scale_types* provide strings specifying the scaling type for each linear inequality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- ’none’ - no scaling
- ’value’ - characteristic value if this is chosen, then *linear_inequality_scales* must be specified
- ’auto’ - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied *after* any continuous variable scaling. For example, for variable scaling on continuous design variables \( x \):

\[
\tilde{x}^j = \frac{x^j - x^j_O}{x^j_M - x^j_O}
\]

we have the following system for linear inequality constraints

\[
a_L \leq A_i x \leq a_U
\]

\[
a_L \leq A_i (\text{diag}(x_M) \tilde{x} + x_O) \leq a_U
\]

\[
a_L - A_i x_O \leq A_i \text{diag}(x_M) \tilde{x} \leq a_U - A_i x_O
\]

\[
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to \([0,1]\).

*linear_inequality_scales*

- **Keywords Area**
- **method**
- **optpp_fd_newton**
- **linear_inequality_scales**

Define the characteristic values to scale linear inequalities

Topics

This keyword is related to the topics:

- **linear_constraints**

Specification

**Alias:** none

**Argument(s):** REALLIST

**Default:** vector values = 1. (no scaling)
6.2. METHOD

Description

Each entry in `linear_inequality_scales` may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

Behavior depends on the choice of `linear_inequality_scale_type`:

- `scale_type` - behavior of `linear_inequality_scales`
- `'none'` - ignored
- `'value'` - required
- `'auto'` - optional

If a single real value is specified it will apply to all components of the constraint.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables $x$:

$$
\tilde{x}^j = \frac{x^j - x^j_O}{x^j_M}
$$

we have the following system for linear inequality constraints

$$
a_L \leq A_i x \leq a_U
$$

$$
a_L \leq A_i \left( \text{diag}(x_M) \tilde{x} + x_O \right) \leq a_U
$$

$$
a_L - A_i x_O \leq A_i \text{diag}(x_M) \tilde{x} \leq a_U - A_i x_O
$$

$$
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
$$

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to $[0,1]$. 

`linear_equality_constraint_matrix`

- Keywords Area
- method
- optpp_fd_newton
- `linear_equality_constraint_matrix`

Define coefficients of the linear equalities

Topics

This keyword is related to the topics:

- `linear_constraints`

Specification

Alias: none

**Argument(s):** REALLIST

**Default:** no linear equality constraints
CHAPTER 6. KEYWORDS AREA

Description
In the equality case, the constraint matrix $A$ provides coefficients for the variables on the left hand side of:

$$Ax = at$$

linear.equality_targets
- Keywords Area
- method
- optpp_fd_newton
- linear.equality_targets

Define target values for the linear equality constraints

Topics
This keyword is related to the topics:
- linear_constraints

Specification
Alias: none
Argument(s): REALLIST
Default: vector values = 0.

Description
In the equality case, the targets $at$ provide the equality constraint right hand sides:

$$Ax = at$$

If this is not specified, the defaults for the equality constraint targets enforce a value of 0. for each constraint: $Ax = 0.0$

linear.equality.scale_types
- Keywords Area
- method
- optpp_fd_newton
- linear.equality.scale_types

Specify how each linear equality constraint is scaled
6.2. METHOD

Topics
This keyword is related to the topics:

- linear_constraints

Specification
Alias: none
Argument(s): STRINGLIST
Default: vector values = 'none'

Description
linear.equality_scale_types provide strings specifying the scaling type for each linear equality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- 'none' - no scaling
- 'value' - characteristic value if this is chosen, then linear.equality.scales must be specified
- 'auto' - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables $x$:

$$\tilde{x} = \frac{x - x_O}{x_M}$$

we have the following system for linear equality constraints

$$a_L \leq A_i \tilde{x} \leq a_U$$

$$a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U$$

$$a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O$$

$$\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U$$

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

linear.equality_scales

- Keywords Area
- method

Define the characteristic values to scale linear equalities
CHAPTER 6. KEYWORDS AREA

Topics
This keyword is related to the topics:

- linear_constraints

Specification
Alias: none
Argument(s): REALLIST
Default: vector values = 1 . (no scaling)

Description
Each entry in linear_equality_scales may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

See the scaling page for details on how to use this keyword.
Scaling for linear constraints is applied after any continuous variable scaling.
For example, for variable scaling on continuous design variables $x$:

$$
\tilde{x}^j = \frac{x^j - x^j_O}{x_M^j}
$$

we have the following system for linear inequality constraints

$$
a_L \leq A_i \tilde{x} \leq a_U
$$

$$
a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U
$$

$$
a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O
$$

$$
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
$$

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

model_pointer
- Keywords Area
- method
- optpp_fd_newton
- model_pointer

Identifier for model block to be used by a method

Topics
This keyword is related to the topics:

- block_pointer
6.2. METHOD

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

Examples

```plaintext
environment
tabular_graphics_data
method_pointer = 'UQ'

method
id_method = 'UQ'
model_pointer = 'SURR'
sampling,
samples = 10
seed = 98765 rng rnum2
response_levels = 0.1 0.2 0.6
0.1 0.2 0.6
0.1 0.2 0.6
sample_type lhs
distribution cumulative

model
id_model = 'SURR'
surrogate global,
daec_method_pointer = 'DACE'
polynomial quadratic

method
id_method = 'DACE'
model_pointer = 'DACE_M'
sampling sample_type lhs
samples = 121 seed = 5034 rng rnum2

model
id_model = 'DACE_M'
single
interface_pointer = 'I1'

variables
uniform_uncertain = 2
lower_bounds = 0. 0.
upper_bounds = 1. 1.
descriptors = 'x1' 'x2'
```
interface
  id_interface = 'I1'
  system asynch evaluation_concurrency = 5
  analysis_driver = 'text_book'

responses
  response_functions = 3
  no_gradients
  no_hessians

CHAPTER 6. KEYWORDS AREA

Description

The Gauss-Newton algorithm is available as `optpp_g_newton` and supports unconstrained, bound-constrained, and generally-constrained problems. When interfaced with the unconstrained, bound-constrained, and nonlinear interior point full-Newton optimizers from the OPT++ library, it provides a Gauss-Newton least squares capability which – on zero-residual test problems – can exhibit quadratic convergence rates near the solution. (Real problems almost never have zero residuals, i.e., perfect fits.)

See package `optpp` for info related to all `optpp` methods.

6.2. METHOD

Description

The search_method control is defined for all Newton-based optimizers and is used to select between trust_region, gradient_based_line_search, and value_based_line_search methods. The gradient_based_line_search option uses the line search method proposed by[61]. This option satisfies sufficient decrease and curvature conditions; whereas, value_base_line_search only satisfies the sufficient decrease condition. At each line search iteration, the gradient_based_line_search method computes the function and gradient at the trial point. Consequently, given expensive function evaluations, the value_based_line_search method is preferred to the gradient_based_line_search method. Each of these Newton methods additionally supports the tr_pds selection for unconstrained problems. This option performs a robust trust region search using pattern search techniques. Use of a line search is the default for bound-constrained and generally-constrained problems, and use of a trust_region search method is the default for unconstrained problems.

trust_region

- Keywords Area
- method
- optpp_g_newton
- search_method
- trust_region

Use trust region as the globalization strategy.

**Specification**

**Alias:** none  
**Argument(s):** none
6.2. METHOD

Description

The trust_region optional group specification can be used to specify the initial size of the trust region (using initial_size) relative to the total variable bounds, the minimum size of the trust region (using minimum_size), the contraction factor for the trust region size (using contraction_factor) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using expansion_factor) used when the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using contract_threshold) and the trust region size expansion threshold (using expand_threshold). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command contract_threshold sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command expand_threshold determines the trust region value above which the trust region will expand for the next SBL iteration.

tr_pds

- Keywords Area

**Description**

A merit function is a function in constrained optimization that attempts to provide joint progress toward reducing the objective function and satisfying the constraints.

**el_bakry**

- Keywords Area
- method
- optpp_g_newton
- merit_function
- el_bakry

El-Bakry merit function

**Specification**

Alias: none  
Argument(s): none

**Description**

The "el_bakry" merit function is the L2-norm of the first order optimality conditions for the nonlinear programming problem. The cost per linesearch iteration is n+1 function evaluations. For more information, see[20].
6.2. METHOD

argaez_tapia

- Keywords Area
- method
- optpp_g_newton
- merit_function
- argaez_tapia

The merit function by Tapia and Argaez

Specification

Alias: none
Argument(s): none

Description

The "argaez_tapia" merit function can be classified as a modified augmented Lagrangian function. The augmented Lagrangian is modified by adding to its penalty term a potential reduction function to handle the perturbed complementarity condition. The cost per linesearch iteration is one function evaluation. For more information, see [80].

If the function evaluation is expensive or noisy, set the merit_function to "argaez_tapia" or "van_shanno".

van_shanno

- Keywords Area
- method
- optpp_g_newton
- merit_function
- van_shanno

The merit function by Vanderbei and Shanno

Specification

Alias: none
Argument(s): none

Description

The "van_shanno" merit function can be classified as a penalty function for the logarithmic barrier formulation of the nonlinear programming problem. The cost per linesearch iteration is one function evaluation. For more information see [82].

If the function evaluation is expensive or noisy, set the merit_function to "argaez_tapia" or "van_shanno".
steplength_to_boundary

- Keywords Area
- method
- optpp.g.newton
- steplength_to_boundary

Controls how close to the boundary of the feasible region the algorithm is allowed to move

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** Merit function dependent: 0.8 (el_bakry), 0.99995 (argaez_tapia), 0.95 (van_shanno)

**Description**

The steplength_to_boundary specification is a parameter (between 0 and 1) that controls how close to the boundary of the feasible region the algorithm is allowed to move. A value of 1 means that the algorithm is allowed to take steps that may reach the boundary of the feasible region. If the user wishes to maintain strict feasibility of the design parameters this value should be less than 1. Default values are .8, .99995, and .95 for the el_bakry, argaez_tapia, and van_shanno merit functions, respectively.

centering_parameter

- Keywords Area
- method
- optpp.g.newton
- centering_parameter

Controls how closely the algorithm should follow the “central path”

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** Merit function dependent: 0.2 (el_bakry), 0.2 (argaez_tapia), 0.1 (van_shanno)

**Description**

The centering_parameter specification is a parameter (between 0 and 1) that controls how closely the algorithm should follow the “central path”. See[88] for the definition of central path. The larger the value, the more closely the algorithm follows the central path, which results in small steps. A value of 0 indicates that the algorithm will take a pure Newton step. Default values are .2, .2, and .1 for the el_bakry, argaez_tapia, and van_shanno merit functions, respectively.
6.2. METHOD

max_step
  • Keywords Area
  • method
  • optpp_g_newton
  • max_step

Max change in design point

Specification
Alias: none
  Argument(s): REAL
  Default: 1000.

Description
The max_step control specifies the maximum step that can be taken when computing a change in the current design point (e.g., limiting the Newton step computed from current gradient and Hessian information). It is equivalent to a move limit or a maximum trust region size. The gradient_tolerance control defines the threshold value on the L2 norm of the objective function gradient that indicates convergence to an unconstrained minimum (no active constraints). The gradient_tolerance control is defined for all gradient-based optimizers.

gradient_tolerance
  • Keywords Area
  • method
  • optpp_g_newton
  • gradient_tolerance

Stopping criteria based on L2 norm of gradient

Specification
Alias: none
  Argument(s): REAL
  Default: 1.e-4

Description
The gradient_tolerance control defines the threshold value on the L2 norm of the objective function gradient that indicates convergence to an unconstrained minimum (no active constraints). The gradient_tolerance control is defined for all gradient-based optimizers.
Keywords Area

method

optpp_g_newton

linear_inequality_constraint_matrix

Define coefficients of the linear inequality constraints

Topics
This keyword is related to the topics:

• linear_constraints

Specification
Alias: none
Argument(s): REALLIST
Default: no linear inequality constraints

Description
In the inequality case, the constraint matrix \( A \) provides coefficients for the variables in the two-sided formulation:

\[
a_l \leq Ax \leq a_u
\]

Where the bounds are optionally specified by linear_inequality_lower_bounds, and linear_inequality_upper_bounds. The bounds, if not specified, will default to \(-\infty\), and 0, respectively, resulting in one-sided inequalities of the form

\[
Ax \leq 0.0
\]

linear_inequality_lower_bounds

• Keywords Area

• method

• optpp_g_newton

• linear_inequality_lower_bounds

Define lower bounds for the linear inequality constraint

Topics
This keyword is related to the topics:

• linear_constraints
6.2. METHOD

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = -infinity

Description

In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where $A$ is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see objective functions), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$Ax \leq 0.0$$

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than $+\text{bigRealBoundSize}$ ($1.e+30$, as defined in Minimizer) are treated as $+\infty$ and any lower bound values less than $-\text{bigRealBoundSize}$ are treated as $-\infty$.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since $-\text{DBL_MAX} < -\text{bigRealBoundSize}$).

linear_inequality_upper_bounds

- Keywords Area
- method
- optpp_g_newton
- linear_inequality_upper_bounds

Define upper bounds for the linear inequality constraint

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = 0.
CHAPTER 6. KEYWORDS AREA

Description

In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$ a_l \leq Ax \leq a_u $$

Where $A$ is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see objective_functions), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$ Ax \leq 0.0 $$

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than $+\text{bigRealBoundSize}$ ($1.e+30$, as defined in Minimizer) are treated as $+\infty$ and any lower bound values less than $-\text{bigRealBoundSize}$ are treated as $-\infty$.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since $-\text{DBL_MAX} < -\text{bigRealBoundSize}$).

linear_inequality_scale_types

- Keywords Area
- method
- optpp_g_newton
- linear_inequality_scale_types

Specify how each linear inequality constraint is scaled

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): STRINGLIST

Default: vector values = 'none'

Description

linear_inequality_scale_types provide strings specifying the scaling type for each linear inequality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- 'none' - no scaling
- 'value' - characteristic value if this is chosen, then linear_inequality_scales must be specified
• ‘auto’ - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables \( x \):

\[
\tilde{x}^j = \frac{x^j - x^j_O}{x^j_M - x^j_O}
\]

we have the following system for linear inequality constraints

\[
a_L \leq A_i x \leq a_U
\]

\[
a_L \leq A_i (\text{diag}(x_M) \tilde{x} + x_O) \leq a_U
\]

\[
a_L - A_i x_O \leq A_i (\text{diag}(x_M) \tilde{x}) \leq a_U - A_i x_O
\]

\[
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to \([0,1]\).

**linear_inequality_scales**

- **Keywords Area**
- **method**
- **optpp_g_newton**
- **linear_inequality_scales**

Define the characteristic values to scale linear inequalities

**Topics**

This keyword is related to the topics:

- **linear_constraints**

**Specification**

**Alias:** none

**Argument(s):** REALIST

**Default:** vector values = 1. (no scaling)

**Description**

Each entry in **linear_inequality_scales** may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

Behavior depends on the choice of **linear_inequality_scale_type**:

- **scale_type** - behavior of **linear_inequality_scales**

  - ‘none’ - ignored
CHAPTER 6. KEYWORDS AREA

• 'value' - required
• 'auto' - optional

If a single real value is specified it will apply to all components of the constraint.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables \( x \):

\[
\tilde{x}^j = \frac{x^j - x^j_O}{x^j_M}
\]

we have the following system for linear inequality constraints

\[
a_L \leq A_i x \leq a_U
\]

\[
a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U
\]

\[
a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O
\]

\[
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to \([0,1]\).

linear_equality_constraint_matrix

• Keywords Area
• method
• optpp_g_newton
• linear_equality_constraint_matrix

Define coefficients of the linear equalities

Topics

This keyword is related to the topics:

• linear_constraints

Specification

Alias: none

Argument(s): REALLIST

Default: no linear equality constraints

Description

In the equality case, the constraint matrix \( A \) provides coefficients for the variables on the left hand side of:

\[
Ax = a_i
\]
6.2. METHOD

linear_equality_targets

- Keywords Area
- method
- optpp.g.newton
- linear_equality_targets

Define target values for the linear equality constraints

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = 0.

Description

In the equality case, the targets \( a_t \) provide the equality constraint right hand sides:

\[
Ax = a_t
\]

If this is not specified, the defaults for the equality constraint targets enforce a value of 0. for each constraint: \( Ax = 0.0 \)

linear_equality_scale_types

- Keywords Area
- method
- optpp.g.newton
- linear_equality_scale_types

Specify how each linear equality constraint is scaled

Topics

This keyword is related to the topics:

- linear_constraints
**Specification**

Alias: none  
**Argument(s):** STRINGLIST  
**Default:** vector values = 'none'

**Description**

`linear_equation_scale_types` provide strings specifying the scaling type for each linear equality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- 'none' - no scaling
- 'value' - characteristic value if this is chosen, then `linear_equation_scales` must be specified
- 'auto' - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables $x$:

$$\tilde{x}^j = \frac{x^j - x_O^j}{x_M^j}$$

we have the following system for linear equality constraints

$$a_L \leq A_i \tilde{x} \leq a_U$$

$$a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U$$

$$a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O$$

$$\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U$$

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

**linear_equation_scales**

- **Keywords Area**
- **method**
- **optpp_g_newton**
- **linear_equation_scales**

Define the characteristic values to scale linear equalities

**Topics**

This keyword is related to the topics:

- **linear_constraints**
6.2. METHOD

Specification

Alias: none
Argument(s): REALIST
Default: vector values = 1. (no scaling)

Description

Each entry in linear_equality_scales may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

See the scaling page for details on how to use this keyword.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables \( x \):

\[
\tilde{x}^j = \frac{x^j - x^O}{x^M}
\]

we have the following system for linear inequality constraints

\[
a_L \leq A_i x \leq a_U
\]

\[
a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U
\]

\[
a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O
\]

\[
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to \([0,1]\).

model_pointer

- Keywords Area
- method
- optpp_g_newton
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none
Argument(s): STRING
Default: method use of last model parsed (or use of default model if none parsed)
CHAPTER 6. KEYWORDS AREA

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model-pointer` for each method is imperative.

See `block_pointer` for details about pointers.

Examples

environment
   tabular_graphics_data
   method_pointer = 'UQ'

method
   id_method = 'UQ'
   model_pointer = 'SURR'
   sampling,
      samples = 10

**Description**

This is a full Newton method that expects a gradient and a Hessian. Each of the Newton-based methods are automatically bound to the appropriate OPT++ algorithm based on the user constraint specification (unconstrained, bound-constrained, or generally-constrained). In the generally-constrained case, the Newton methods use a non-linear interior-point approach to manage the constraints.

See `package_optpp` for info related to all `optpp` methods.

trust_region

• Keywords Area
  • method
  • optpp_newton
  • search_method
  • trust_region

  Use trust region as the globalization strategy.

Specification

Alias: none
  Argument(s): none

Description

The trust_region optional group specification can be used to specify the initial size of the trust region (using initial_size) relative to the total variable bounds, the minimum size of the trust region (using minimum_size), the contraction factor for the trust region size (using contraction_factor) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using expansion_factor) used when the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using contract_threshold) and the trust region size expansion threshold (using expand_threshold). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command contract_threshold sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command expand_threshold determines the trust region value above which the trust region will expand for the next SBL iteration.
Use direct search as the local search in a trust region method

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The search method control is defined for all Newton-based optimizers and is used to select between trust-region, gradient-based line search, and value-based line search methods. The gradient-based line search option uses the line search method proposed by[61]. This option satisfies sufficient decrease and curvature conditions; whereas, value-based line search only satisfies the sufficient decrease condition. At each line search iteration, the gradient-based line search method computes the function and gradient at the trial point. Consequently, given expensive function evaluations, the value-based line-search method is preferred to the gradient-based line search method. Each of these Newton methods additionally supports the tr_pds selection for unconstrained problems. This option performs a robust trust region search using pattern search techniques. Use of a line search is the default for bound-constrained and generally-constrained problems, and use of a trust-region search method is the default for unconstrained problems.

Argument(s): none

Description

The "van_shanno" merit function can be classified as a penalty function for the logarithmic barrier formulation of the nonlinear programming problem. The cost per linesearch iteration is one function evaluation. For more information see [82].

If the function evaluation is expensive or noisy, set the merit_function to "argaez_tapia" or "van_shanno".

steplength_to_boundary

- Keywords Area
- method
- optpp_newton
- steplength_to_boundary

Controls how close to the boundary of the feasible region the algorithm is allowed to move
6.2. METHOD

Specification

Alias: none

Argument(s): REAL

Default: Merit function dependent: 0.8 (el_bakry), 0.99995 (argaez_tapia), 0.95 (van_shanno)

Description

The `steplength_to_boundary` specification is a parameter (between 0 and 1) that controls how close to the boundary of the feasible region the algorithm is allowed to move. A value of 1 means that the algorithm is allowed to take steps that may reach the boundary of the feasible region. If the user wishes to maintain strict feasibility of the design parameters this value should be less than 1. Default values are .8, .99995, and .95 for the el_bakry, argaez_tapia, and van_shanno merit functions, respectively.

centering_parameter

- Keywords Area
- method
- optpp_newton
- centering_parameter

Controls how closely the algorithm should follow the "central path"

Specification

Alias: none

Argument(s): REAL

Default: Merit function dependent: 0.2 (el_bakry), 0.2 (argaez_tapia), 0.1 (van_shanno)

Description

The `centering_parameter` specification is a parameter (between 0 and 1) that controls how closely the algorithm should follow the "central path". See[88] for the definition of central path. The larger the value, the more closely the algorithm follows the central path, which results in small steps. A value of 0 indicates that the algorithm will take a pure Newton step. Default values are .2, .2, and .1 for the el_bakry, argaez_tapia, and van_shanno merit functions, respectively.

max_step

- Keywords Area
- method
- optpp_newton
- max_step

Max change in design point
CHAPTER 6. KEYWORDS AREA

Specification
Alias: none
Argument(s): REAL
Default: 1000.

Description
The `max_step` control specifies the maximum step that can be taken when computing a change in the current design point (e.g., limiting the Newton step computed from current gradient and Hessian information). It is equivalent to a move limit or a maximum trust region size. The `gradient_tolerance` control defines the threshold value on the L2 norm of the objective function gradient that indicates convergence to an unconstrained minimum (no active constraints). The `gradient_tolerance` control is defined for all gradient-based optimizers.

`gradient_tolerance`

- Keywords Area
- method
- optpp_newton
- gradient_tolerance

Stopping criteria based on L2 norm of gradient

Specification
Alias: none
Argument(s): REAL
Default: 1.e-4

Description
The `gradient_tolerance` control defines the threshold value on the L2 norm of the objective function gradient that indicates convergence to an unconstrained minimum (no active constraints). The `gradient_tolerance` control is defined for all gradient-based optimizers.

`linear_inequality_constraint_matrix`

- Keywords Area
- method
- optpp_newton
- `linear_inequality_constraint_matrix`

Define coefficients of the linear inequality constraints

Topics
This keyword is related to the topics:

- `linear_constraints`
6.2. METHOD

Specification

Alias: none
Argument(s): REALLIST
Default: no linear inequality constraints

Description

In the inequality case, the constraint matrix $A$ provides coefficients for the variables in the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where the bounds are optionally specified by linear_inequality_lower_bounds, and linear_inequality_upper_bounds. The bounds, if not specified, will default to -infinity, and 0, respectively, resulting in one-sided inequalities of the form

$$Ax \leq 0.0$$

linear_inequality_lower_bounds

- Keywords Area
- method
- optpp_newton
- linear_inequality_lower_bounds

Define lower bounds for the linear inequality constraint

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none
Argument(s): REALLIST
Default: vector values = -infinity

Description

In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where $A$ is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see objective_functions), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$Ax \leq 0.0$$
result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota
versions).

In a user bounds specification, any upper bound values greater than +\texttt{bigRealBoundSize} (1.e+30, as
defined in Minimizer) are treated as +\infty and any lower bound values less than \(-\texttt{bigRealBoundSize}\) are

treated as -\infty.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the
default lower bounds drop out since -DBL\_MAX < -\texttt{bigRealBoundSize}).

\texttt{linear\_inequality\_upper\_bounds}

- Keywords Area
- method
- optpp\_newton
- \texttt{linear\_inequality\_upper\_bounds}

Define upper bounds for the linear inequality constraint

\textbf{Topics}

This keyword is related to the topics:

- \texttt{linear\_constraints}

\textbf{Specification}

\textbf{Alias}: none

\textbf{Argument(s)}: REAL\_LIST

\textbf{Default}: vector values = 0.

\textbf{Description}

In the inequality case, the lower \(a_l\) and upper \(a_u\) bounds provide constraint limits for the two-sided formulation:

\[ a_l \leq Ax \leq a_u \]

Where \(A\) is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see \texttt{objective\_functions}), the default linear inequality constraint

bounds are selected so that one-sided inequalities of the form

\[ Ax \leq 0.0 \]

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota
versions).

In a user bounds specification, any upper bound values greater than \(+\texttt{bigRealBoundSize}\) (1.e+30, as
defined in Minimizer) are treated as +\infty and any lower bound values less than \(-\texttt{bigRealBoundSize}\) are

treated as -\infty.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the
default lower bounds drop out since -DBL\_MAX < -\texttt{bigRealBoundSize}).
6.2. **METHOD**

**linear_inequality_scale_types**

- Keywords Area
- method
- optpp_newton
- linear_inequality_scale_types

Specify how each linear inequality constraint is scaled

**Topics**

This keyword is related to the topics:

- linear_constraints

**Specification**

**Alias:** none

**Argument(s):** STRINGLIST

**Default:** vector values = ’none’

**Description**

`linear_inequality_scale_types` provide strings specifying the scaling type for each linear inequality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- ’none’ - no scaling
- ’value’ - characteristic value if this is chosen, then `linear_inequality_scales` must be specified
- ’auto’ - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables $x$:

$$\tilde{x}^j = \frac{x^j - x^j_O}{x^j_M}$$

we have the following system for linear inequality constraints

$$a_L \leq A_i x \leq a_U$$
$$a_L \leq A_i (\text{diag}(x_M) \tilde{x} + x_O) \leq a_U$$
$$a_L - A_i x_O \leq A_i \text{diag}(x_M) \tilde{x} \leq a_U - A_i x_O$$
$$\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U$$

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].
linear_inequality_scales

- Keywords Area
- method
- optpp_newton
- linear_inequality_scales

Define the characteristic values to scale linear inequalities

Topics

This keyword is related to the topics:
- linear_constraints

Specification

Alias: none

- Argument(s): REALLIST
- Default: vector values = 1 . (no scaling)

Description

Each entry in `linear_inequality_scales` may be a user-specified, nonzero characteristic value to be used in scaling each constraint. Behavior depends on the choice of `linear_inequality_scale_type`:

- `scale_type`: behavior of `linear_inequality_scales`
  - `'none'`: ignored
  - `'value'`: required
  - `'auto'`: optional

If a single real value is specified it will apply to all components of the constraint.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables $x$:

$$\tilde{x}^j = \frac{x^j - x_O^j}{x_M^j}$$

we have the following system for linear inequality constraints

$$a_L \leq A_i x \leq a_U$$
$$a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U$$
$$a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O$$
$$\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U$$

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to $[0,1]$. 
6.2. METHOD

**linear.equality.constraint_matrix**

- **Keywords Area**
- **method**
- **optpp.newton**
- **linear.equality.constraint_matrix**

Define coefficients of the linear equalities

**Topics**

This keyword is related to the topics:

- **linear.constraints**

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Default:** no linear equality constraints

**Description**

In the equality case, the constraint matrix $A$ provides coefficients for the variables on the left hand side of:

$$Ax = a_t$$

**linear.equality.targets**

- **Keywords Area**

**Argument(s):** REALLIST

**Default:** vector values $= 0$. 
CHAPTER 6. KEYWORDS AREA

Description

In the equality case, the targets $a_t$ provide the equality constraint right hand sides:

$$Ax = a_t$$

If this is not specified, the defaults for the equality constraint targets enforce a value of 0. for each constraint:

$$Ax = 0$$

linear_equation.scale_types

- Keywords Area
- method
- optpp.newton
- linear_equation.scale_types

Specify how each linear equality constraint is scaled

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): STRINGLIST

Default: vector values = 'none'

Description

linear_equation.scale_types provide strings specifying the scaling type for each linear equality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- 'none' - no scaling
- 'value' - characteristic value if this is chosen, then linear_equation.scales must be specified
- 'auto' - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables $x$:

$$\tilde{x}_j = \frac{x_j - x_{jO}}{x_{jM}}$$

we have the following system for linear equality constraints

$$a_L \leq A_i x \leq a_U$$
6.2. METHOD

\[ a_L \leq A_i \left( \text{diag}(x_M)\tilde{x} + x_O \right) \leq a_U \]
\[ a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O \]
\[ \tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U \]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

**linear_equality_scales**

- **Keywords Area**
- **method**

Define the characteristic values to scale linear equalities

**Topics**

This keyword is related to the topics:

- **linear_constraints**

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Default:** vector values = 1. (no scaling)

**Description**

Each entry in `linear_equality_scales` may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

See the `scaling` page for details on how to use this keyword.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables \( x \):

\[ \tilde{x}^i = \frac{x^i - x^i_O}{x^i_M} \]

we have the following system for linear inequality constraints

\[ a_L \leq A_i x \leq a_U \]
\[ a_L \leq A_i \left( \text{diag}(x_M)\tilde{x} + x_O \right) \leq a_U \]
\[ a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O \]
\[ \tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U \]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].
model_pointer

- Keywords Area
- method
- optpp_newton
- model_pointer

Identifier for model block to be used by a method

Topics
This keyword is related to the topics:
- block_pointer

Specification

Alias: none
- Argument(s): STRING
- Default: method use of last model parsed (or use of default model if none parsed)

Description
The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior
If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips
When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.

See block_pointer for details about pointers.

Examples

```python
environment
definition
method_pointer = 'UQ'

method
definition
id_method = 'UQ'
model_pointer = 'SURR'
sampling,
samples = 10
seed = 98765 rng rnum2
response_levels = 0.1 0.2 0.6
sample_type lhs
distribution cumulative

definition
id_model = 'SURR'
```
6.2. METHOD

surrogate global,
dace_method_pointer = 'DACE'
polynomial quadratic

method
id_method = 'DACE'
model_pointer = 'DACE_M'
sampling sample_type lhs
samples = 121 seed = 5034 rng rnum2

model
id_model = 'DACE_M'
single
interface_pointer = 'I1'

variables
uniform_uncertain = 2
lower_bounds = 0.0
upper_bounds = 1.1
descriptors = 'x1' 'x2'

interface
id_interface = 'I1'
system async evaluation_concurrency = 5
analysis_driver = 'text_book'

responses
response_functions = 3
no_gradients
no_hessians

\begin{align*}
  a_L & \leq A_i x \leq a_U \\
  a_L & \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U \\
  a_L - A_i x_O & \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O \\
  \tilde{a}_L & \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
\end{align*}

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].
6.2. METHOD

**model_pointer**

- **Keywords Area**
- **method**
- **optpp_pds**
- **model_pointer**

Identifier for model block to be used by a method

**Topics**

This keyword is related to the topics:

- **block_pointer**

**Specification**

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)

**Description**

The **model_pointer** is used to specify which **model** block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a **model** block in the Dakota input file that has a corresponding **id_model** with the same name.

**Usage Tips**

When doing advanced analyses that involve using multiple methods and multiple models, defining a **model_pointer** for each method is imperative.

See **block_pointer** for details about pointers.

**Examples**

```
environment
    tabular_graphics_data
    method_pointer = 'UQ'

method
    id_method = 'UQ'
    model_pointer = 'SURR'

**Description**

The asynchronous parallel pattern search (APPS) algorithm [37] is a fully asynchronous pattern search technique in that the search along each offset direction continues without waiting for searches along other directions to finish.

Currently, APPS only supports coordinate bases with a total of $2n$ function evaluations in the pattern, and these patterns may only contract.

**Concurrency**

APPS exploits parallelism through the use of Dakota’s concurrent function evaluations. The variant of the algorithm that is currently exposed, however, limits the amount of concurrency that can be exploited. In particular, APPS can leverage an evaluation concurrency level of at most twice the number of variables. More options that allow for greater evaluation concurrency may be exposed in future releases.

**Algorithm Behavior**

- `initial_delta`: the initial step length, must be positive
- `threshold_delta`: step length used to determine convergence, must be greater than or equal to $4.4e-16$
- `contraction_factor`: amount by which step length is rescaled after unsuccessful iterates, must be strictly between 0 and 1

**Merit Functions**

APPS solves nonlinearly constrained problems by solving a sequence of linearly constrained merit function-base subproblems. There are several exact and smoothed exact penalty functions that can be specified with the `merit_function` control. The options are as follows:

- `merit_max`: based on $\ell_\infty$ norm
- `merit_max_smooth`: based on smoothed $\ell_\infty$ norm
6.2. METHOD

- merit1: based on $\ell_1$ norm
- merit1_smooth: based on smoothed $\ell_1$ norm
- merit2: based on $\ell_2$ norm
- merit2_smooth: based on smoothed $\ell_2$ norm
- merit2_squared: based on $\ell_2^2$ norm

The user can also specify the following to affect the merit functions:

- constraint_penalty
- smoothing_parameter

Method Independent Controls

The only method independent controls that are currently mapped to APPS are:

- max_function_evaluations
- constraint_tolerance
- output

Note that while APPS treats the constraint tolerance separately for linear and nonlinear constraints, we apply the same value to both if the user specifies constraint_tolerance.

The APPS internal display level is mapped to the Dakota output settings as follows:

- debug: display final solution, all input parameters, variable and constraint info, trial points, search directions, and execution details
- verbose: display final solution, all input parameters, variable and constraint info, and trial points
- normal: display final solution, all input parameters, variable and constraint summaries, and new best points
- quiet: display final solution and all input parameters
- silent: display final solution

initial_delta

- Keywords Area
- method
- asynch_pattern_search
- initial_delta

Initial step size for non-gradient based optimizers

Specification

Alias: none

Argument(s): REAL
Default: 1.0
CHAPTER 6. KEYWORDS AREA

Description

If initial_delta is supplied by the user, it will be applied in an absolute sense in all coordinate directions. APPS documentation advocates choosing initial_delta to be the approximate distance from the initial point to the solution. If this is unknown, it is advisable to err on the side of choosing an initial_delta that is too large or to not specify it. In the latter case, APPS will take a full step to the boundary in each direction. Relative application of initial_delta is not available unless the user scales the problem accordingly.

contraction_factor

- Keywords Area
- method
- asynch_pattern_search
- contraction_factor

Amount by which step length is rescaled

Specification

Alias: none
Argument(s): REAL
Default: 0.5

Description

For pattern search methods, contraction_factor specifies the amount by which step length is rescaled after unsuccessful iterates, must be strictly between 0 and 1.

For methods that can expand the step length, the expansion is \(1 / \text{contraction factor}\)

threshold_delta

- Keywords Area
- method
- asynch_pattern_search
- threshold_delta

Stopping criteria based on step length or pattern size

Specification

Alias: none
Argument(s): REAL
Default: 0.01

Description

threshold_delta is the step length or pattern size used to determine convergence.
solution_target

- Keywords Area
- method
- asynch_pattern_search
- solution_target

Stopping criteria based on objective function value

**Specification**

**Alias:** solution_accuracy

**Argument(s):** REAL

**Default:** no target

**Description**

solution_target is a termination criterion. The algorithm will terminate when the function value falls below solution_target.

synchronization

- Keywords Area
- method
- asynch_pattern_search
- synchronization

Select how Dakota schedules function evaluations in a pattern search

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** nonblocking

<table>
<thead>

</table>

**Description**

The synchronization specification can be used to specify the use of either blocking or nonblocking schedulers.
CHAPTER 6. KEYWORDS AREA

blocking

- Keywords Area
- method
- asynch_pattern_search
- synchronization
- blocking

Evaluate all points in a pattern

**Specification**

Alias: none

Argument(s): none

**Description**

In the blocking case, all points in the pattern are evaluated (in parallel), and if the best of these trial points is an improving point, then it becomes the next iterate. These runs are reproducible, assuming use of the same seed in the stochastic case.

nonblocking

- Keywords Area
- method
- asynch_pattern_search
- synchronization
- nonblocking

Evaluate points in the pattern until an improving point is found

**Specification**

Alias: none

Argument(s): none

**Description**

In the nonblocking case, all points in the pattern may not be evaluated. The first improving point found becomes the next iterate. Since the algorithm steps will be subject to parallel timing variabilities, these runs will not generally be repeatable.
merit_function

- Keywords Area
- method
- asynch_pattern_search
- merit_function

Balance goals of reducing objective function and satisfying constraints

Specification

Alias: none
Argument(s): none
Default: merit2_squared

6.2. METHOD

constraint_penalty

- Keywords Area
- method
- asynch_pattern_search
- constraint_penalty

Multiplier for the penalty function

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 1.0

**Description**

Most SCOLIB optimizers treat constraints with a simple penalty scheme that adds `constraint_penalty` times the sum of squares of the constraint violations to the objective function. The default value of `constraint_penalty` is 1000.0, except for methods that dynamically adapt their constraint penalty, for which the default value is 1.0.

**smoothing_factor**

- Keywords Area
- method
- asynch_pattern_search
- smoothing_factor

Smoothing value for smoothed penalty functions

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 0.0

**Description**

- **smoothing_parameter:** initial smoothing value for smoothed penalty functions, must be between 0 and 1 (inclusive)
Define coefficients of the linear inequality constraints

Topics
This keyword is related to the topics:
* linear_constraints

Specification
Alias: none
Argument(s): REALLIST
Default: no linear inequality constraints

Description
In the inequality case, the constraint matrix $A$ provides coefficients for the variables in the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where the bounds are optionally specified by `linear_inequality_lower_bounds`, and `linear_inequality_upper_bounds`. The bounds, if not specified, will default to -infinity, and 0, respectively, resulting in one-sided inequalities of the form

$$Ax \leq 0.0$$

Define lower bounds for the linear inequality constraint

Topics
This keyword is related to the topics:
* linear_constraints
6.2. **METHOD**

### Specification

**Alias:** none

**Argument(s):** REALLIST

**Default:** vector values = -infinity

### Description

In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where $A$ is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see `objective_functions`), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$Ax \leq 0$$

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than `+bigRealBoundSize` ($1.e+30$, as defined in Minimizer) are treated as $+\infty$ and any lower bound values less than `-bigRealBoundSize` are treated as $-\infty$.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since $-\text{DBL}_\text{MAX} < -\text{bigRealBoundSize}$).

#### linear_inequality_upper_bounds

- **Keywords Area**
- **method**
- **asynch_pattern_search**
- **linear_inequality_upper_bounds**

Define upper bounds for the linear inequality constraint

### Topics

This keyword is related to the topics:

- **linear_constraints**

### Specification

**Alias:** none

**Argument(s):** REALLIST

**Default:** vector values = 0.
CHAPTER 6. KEYWORDS AREA

Description
In the inequality case, the lower \( a_l \) and upper \( a_u \) bounds provide constraint limits for the two-sided formulation:

\[
a_l \leq Ax \leq a_u
\]

Where \( A \) is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see objective_functions), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

\[
Ax \leq 0.0
\]

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than \(+\text{bigRealBoundSize} \) (1.e+30, as defined in Minimizer) are treated as +infinity and any lower bound values less than \(-\text{bigRealBoundSize} \) are treated as -infinity.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since \(-\text{DBL\_MAX} < -\text{bigRealBoundSize}\)).

**linear_inequality_scale_types**

- Keywords Area
- method
- asynch_pattern_search
- linear_inequality_scale_types

Specify how each linear inequality constraint is scaled

Topics
This keyword is related to the topics:

- linear_constraints

Specification
Alias: none

Argument(s): STRINGLIST

Default: vector values = 'none'

Description
**linear_inequality_scale_types** provide strings specifying the scaling type for each linear inequality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- 'none' - no scaling
- 'value' - characteristic value if this is chosen, then **linear_inequality_scales** must be specified
• ‘auto’ - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables $x$:

$$\tilde{x}_j = \frac{x_j - x_{j,O}}{x_{M}}$$

we have the following system for linear inequality constraints

$$a_L \leq A_i x \leq a_U$$

$$a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U$$

$$a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O$$

$$\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U$$

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

**linear_inequality_scales**

- Keywords Area
- method
- asynch_pattern_search
- linear_inequality_scales

Define the characteristic values to scale linear inequalities

**Topics**
This keyword is related to the topics:

- linear_constraints

**Specification**

Alias: none

Argument(s): REALIST

Default: vector values = 1. (no scaling)

**Description**

Each entry in `linear_inequality_scales` may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

Behavior depends on the choice of `linear_inequality_scale_type`:

- scale_type - behavior of `linear_inequality_scales`
- ‘none’ - ignored
• ’value’ - required
• ’auto’ - optional

If a single real value is specified it will apply to all components of the constraint.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables $x$:

$$\tilde{x}^j = \frac{x^j - x^j_O}{x^j_M}$$

we have the following system for linear inequality constraints

$$a_L \leq A_i x \leq a_U$$

$$a_L \leq A_i \left( \text{diag}(x_M)\tilde{x} + x_O \right) \leq a_U$$

$$a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O$$

$$\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U$$

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to $[0,1]$.

**linear_equality_constraint_matrix**

- Keywords Area
- method
- asynch_pattern_search
- linear_equality_constraint_matrix

Define coefficients of the linear equalities

**Topics**

This keyword is related to the topics:

- linear_constraints

**Specification**

Alias: none

- Argument(s): REALLIST
- Default: no linear equality constraints

**Description**

In the equality case, the constraint matrix $A$ provides coefficients for the variables on the left hand side of:

$$Ax = a_t$$
linear_equalit Targets

- Keywords Area
- method
- asynch_pattern_search
- linear_equalit Targets

Define target values for the linear equality constraints

Topics
This keyword is related to the topics:
- linear_constraints

Specification
Alias: none
- Argument(s): REALLIST
- Default: vector values = 0.

Description
In the equality case, the targets \(a_t\) provide the equality constraint right hand sides:

\[ Ax = a_t \]

If this is not specified, the defaults for the equality constraint targets enforce a value of 0. for each constraint: \(Ax = 0.0\)

linear_equalit_scale_Types

- Keywords Area
- method
- asynch_pattern_search
- linear_equalit_scale_Types

Specify how each linear equality constraint is scaled

Topics
This keyword is related to the topics:
- linear_constraints
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none
Argument(s): STRINGLIST
Default: vector values = 'none'

Description

linear.equality.scale_types provide strings specifying the scaling type for each linear equality constraint, in methods that support scaling.
An entry may be selected for each constraint. The options are:

- 'none' - no scaling
- 'value' - characteristic value if this is chosen, then linear.equality.scales must be specified
- 'auto' - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling.
For example, for variable scaling on continuous design variables x:

\[
\tilde{x}^j = \frac{x^j - x_O^j}{x_M^j}
\]

we have the following system for linear equality constraints

\[
a_L \leq A_i \tilde{x} \leq a_U
\]
\[
a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U
\]
\[
a_L \leq A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O
\]
\[
\tilde{a}_L \leq \hat{A}_i \tilde{x} \leq \tilde{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

linear.equality.scales

- Keywords Area
- method
- asynch_pattern_search
- linear.equality.scales

Define the characteristic values to scale linear equalities

Topics

This keyword is related to the topics:

- linear_constraints
6.2. **METHOD**

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Default:** vector values = 1. (no scaling)

**Description**

Each entry in `linear_equality_scales` may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

See the scaling page for details on how to use this keyword.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables $x$:

$$\tilde{x}^j = \frac{x^j - x^j_O}{x^j_M}$$

we have the following system for linear inequality constraints

$$a_L \leq A_i x \leq a_U$$

$$a_L \leq A_i (\text{diag}(x_M) \tilde{x} + x_O) \leq a_U$$

$$a_L - A_i x_O \leq A_i \text{diag}(x_M) \tilde{x} \leq a_U - A_i x_O$$

$$\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U$$

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0, 1].

**model_pointer**

- **Keywords Area**
- **method**
- **asynch_pattern_search**
- **model_pointer**

Identifier for model block to be used by a method

**Topics**

This keyword is related to the topics:

- **block_pointer**

**Specification**

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)
CHAPTER 6. KEYWORDS AREA

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

Examples

```plaintext
environment

6.2. METHOD

**Optional model pointer**

Identifier for model block to be used by a method.

### Description

The mesh adaptive direct search algorithm\[9\] is a derivative-free generalized pattern search in which the set of points evaluated becomes increasingly dense, leading to good convergence properties. It can handle unconstrained problems as well as those with bound constraints and general nonlinear constraints. Furthermore, it can handle continuous, discrete, and categorical variables.

#### Default Behavior

By default, `mesh_adaptive_search` operates on design variables. The types of variables can be expanded through the use of the `active` keyword in the `variables` block in the Dakota input file. Categorical variables, however, must be limited to design variables.

#### Expected Outputs

The best objective function value achieved and associated parameter and constraint values can be found at the end of the Dakota output. The method’s internally summarized iteration history will appear in the screen output. It also generates a history file containing a list of all function evaluations done.

#### Additional Discussion

The mesh adaptive direct search method is made available in Dakota through the NOMAD software\[2\], available to the public under the GNU LGPL from [http://www.gerad.ca/nomad](http://www.gerad.ca/nomad).

### Examples

The following is an example of a Dakota input file that makes use of `mesh_adaptive_search` to optimize the textbook function.

```plaintext
method,
    mesh_adaptive_search
    seed = 1234
variables,
    continuous_design = 3
    initial_point -1.0 1.5 2.0
    upper_bounds 10.0 10.0 10.0
    lower_bounds -10.0 -10.0 -10.0
    descriptors 'x1' 'x2' 'x3'
interface,
    direct
    analysis_driver = 'text_book'
responses,
    objective_functions = 1
    no_gradients
    no_hessians
end verbatim
```

The best function value and associated parameters are found at the end of the Dakota output.

```
<<<< Function evaluation summary: 674 total (674 new, 0 duplicate)
<<<< Best parameters
    1.000000000000e+00 x1
```
A NOMAD-generated iteration summary is also printed to the screen.

6.2. METHOD

blackbox evaluations : 674
best feasible solution : ( 1 1 1 ) h=0 f=1.073537728e-52

function_precision

- Keywords Area
- method
- mesh_adaptive_search
- function_precision

Specify the maximum precision of the analysis code responses

Specification

Alias: none
Argument(s): REAL
Default: 1.0e-10

Description

The function_precision control provides the algorithm with an estimate of the accuracy to which the problem functions can be computed. This is used to prevent the algorithm from trying to distinguish between function values that differ by less than the inherent error in the calculation.

seed

- Keywords Area
- method
- mesh_adaptive_search
- seed

Seed of the random number generator

Specification

Alias: none
Argument(s): INTEGER
Default: system-generated (non-repeatable)
Description

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

**Default Behavior**
If not specified, the seed is randomly generated.

**Expected Output**
If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

**Usage Tips**
If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

**Examples**

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

**history_file**

- **Keywords Area**
- **method**
- **mesh_adaptive_search**
- **history_file**

Name of file where mesh adaptive search records all evaluation points.

**Specification**

**Alias:** none

**Argument(s):** STRING

**Default:** mads_history

**Description**

The `history_file` is used to specify the name of a file to which mesh adaptive direct search will write its own list of evaluated points.

**Default Behavior**
By default, mesh adaptive direct search will write the list of evaluation points in a file named `mads_history.-xxxx`, where `xxxx` corresponds to a randomly generated number.
6.2. METHOD

Examples

The example below shows the syntax for specifying the name of the history file.

```python
method
  mesh_adaptive_search
  history_file = 'output.log'
  seed = 1234
```

display_format

- Keywords Area
- method
- mesh_adaptive_search
- display_format

Information to be reported from mesh adaptive search’s internal records.

Specification

Alias: none

Argument(s): STRING

Description

The display_format keyword is used to specify the set of information to be reported by the mesh adaptive direct search method. This is information mostly internal to the method and not reported via Dakota output.

Default Behavior

By default, only the number of function evaluations (bbe) and the objective function value (obj) are reported. The full list of options is as follows. Note that case does not matter.

- BBE: Blackbox evaluations.
- BBO: Blackbox outputs.
- EVAL: Evaluations (includes cache hits).
- MESH_INDEX: Mesh index.
- MESH_SIZE: Mesh size parameter.
- OBJ: Objective function value.
- POLL_SIZE: Poll size parameter.
- SOL: Solution, with format iSOLj where i and j are two (optional) strings: i will be displayed before each coordinate, and j after each coordinate (except the last).
- STAT_AVG: The AVG statistic.
- STAT_SUM: The SUM statistic defined by argument.
- TIME: Wall-clock time.
• \text{VAR}i: \text{Value of variable } i. \text{ The index 0 corresponds to the first variable.}

\textbf{Expected Outputs}

A list of the requested information will be printed to the screen.

\textbf{Usage Tips}

This will most likely only be useful for power users who want to understand and/or report more detailed information on method behavior.

\textbf{Examples}

The following example shows the syntax for specifying \texttt{display_format}. Note that all desired information options should be listed within a single string.

\begin{verbatim}
method
  mesh_adaptive_search
  display_format 'bbe obj poll_size'
  seed = 1234
\end{verbatim}

Below is the output reported for the above example.

\begin{verbatim}
MADS run {
BBE OBJ POLL_SIZE

Argument(s): REAL

Default: 0.0

Description

The variable_neighborhood_search keyword is used to set the percentage (in decimal form) of function evaluations used to escape local minima. The mesh adaptive direct search method will try to perform a maximum of that percentage of the function evaluations within this more extensive search.

Default Behavior
By default, `variable_neighborhood_search` is not used.

Usage Tips

Using `variable_neighborhood_search` results in an increased number of function evaluations. If the desired result is a local minimum, the added cost is of little or no value, so the recommendation is not to use it. If the desired result is the best local minimum possible within a computational budget, then there is value in setting this parameter. Note that the higher the value, the greater the computational cost.

Examples

The following example shows the syntax used to set `variable_neighborhood_search`.

```python
method
  mesh_adaptive_search
    seed = 1234
    variable_neighborhood_search = 0.1
```

`neighbor_order`

- **Keywords Area**
- **method**
- **mesh_adaptive_search**
- **neighbor_order**

Number of dimensions in which to perturb categorical variables.

Specification

Alias: none

Argument(s): INTEGER

Description

The `neighbor_order` keyword allows the user to specify the number of categorical dimensions to perturb when determining neighboring points that will be used by the mesh adaptive direct search method to augment its search. When greater than 1, the neighbors are defined from the tensor product of the admissible 1-dimensional perturbations.

Default Behavior

By default, the categorical neighbors will be defined by perturbing only one categorical variable at a time (according to the corresponding adjacency_matrix; see `adjacency_matrix`) while leaving the others fixed at their current values.

Usage Tips

The maximum meaningful value `neighbor_order` can take on is the number of categorical variables.

Examples

In this example, suppose we have the following categorical variables and associated adjacency matrices.
variables
discrete_design_set
  real = 2
categorical yes yes
num_set_values = 3 5
set_values = 1.2 2.3 3.4
  1.2 3.3 4.4 5.5 7.7
adjacency_matrix = 1 1 0
  1 1 1
  1 0 1 0 1
  0 1 0 1 0
  1 0 1 0 1
  0 1 0 1 0
  1 0 1 0 1

Also suppose that we have the following method specification.

method
  mesh_adaptive_search
  seed = 1234

If the mesh adaptive direct search is at the point (1.2, 1.2), then the neighbors will be defined by the default 1-dimensional perturbations and would be the following:

(2.3, 1.2)
(1.2, 4.4)
(1.2, 7.7)

If, instead, the method specification is the following:

method
  mesh_adaptive_search
  seed = 1234
  neighbor_order = 2

The neighbors will be defined by 2-dimensional perturbations defined from the tensor product of the 1-dimensional perturbation and would be the following:

(2.3, 1.2)
(2.3, 4.4)
(2.3, 7.7)
(1.2, 4.4)
(1.2, 7.7)

- adjacency_matrix

display_all_evaluations

- Keywords Area
- method
- mesh_adaptive_search
- display_all_evaluations

Shows mesh adaptive search’s internally held list of all evaluations
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none
  Argument(s): none
  Default: false

Description

If set, display_all_evaluations will instruct the mesh adaptive direct search method to print out its own record of all evaluations. The information reported may be controlled using display_format.

  Default Behavior
  By default, mesh adaptive direct search does not report information on all evaluations, only on those for which an improvement in the objective function is found.

  Expected Outputs
  The information specified by display_format will be reported to the screen for every function evaluation.

  Usage Tips
  This will most likely only be useful for power users who want to understand and/or report more detailed information on method behavior.

Examples

The following example shows the syntax for specifying display_all_evaluations.

```
method
  mesh_adaptive_search
  display_all_evaluations
  max_function_evaluations=20
  seed = 1234

  Note that the output below reports information (default for display_format) for all function evaluations.

MADS run {
  BBE OBJ
  1 17.0625000000
  2 1.0625000000
  3 1297.0625000000
  4 257.0625000000
  5 81.0625000000
  6 151.0625000000
  7 1051.0625000000
  8 40.0625000000
  9 17.0625000000
 10 40.0625000000
 11 1.0625000000
 12 102.0625000000
 13 0.0625000000
 14 231.0625000000
 15 16.0625000000
 16 5.0625000000
 17 16.0625000000
 18 71.0625000000
 19 0.0625000000
 20 1.0625000000
} end of run (max number of blackbox evaluations)
```
blackbox evaluations : 20
best feasible solution : ( 1 0.5 1 ) h=0 f=0.0625

That is in contrast with what would be reported by default.

MADS run {

BBE OBJ

1  17.0625000000
2  1.0625000000
13  0.0625000000
20  0.0625000000

} end of run (max number of blackbox evaluations)

blackbox evaluations : 20
best feasible solution : ( 1 0.5 1 ) h=0 f=0.0625

linear_inequality_constraint_matrix

- Keywords Area

- method

- mesh_adaptive_search

- linear_inequality_constraint_matrix

Define coefficients of the linear inequality constraints

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): REALLIST

Default: no linear inequality constraints
Description

In the inequality case, the constraint matrix $A$ provides coefficients for the variables in the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where the bounds are optionally specified by `linear.inequality.lower_bounds`, and `linear.inequality.upper_bounds`. The bounds, if not specified, will default to -infinity, and 0, respectively, resulting in one-sided inequalities of the form

$$Ax \leq 0.0$$

linear.inequality.lower_bounds

- Keywords Area
- method
- mesh_adaptive_search
- linear.inequality.lower_bounds

Define lower bounds for the linear inequality constraint

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = -infinity

Description

In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where $A$ is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see `objective.functions`), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$Ax \leq 0.0$$

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than +bigRealBoundSize (1.e+30, as defined in Minimizer) are treated as +infinity and any lower bound values less than -bigRealBoundSize are treated as -infinity.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since -DBL_MAX < -bigRealBoundSize).
6.2. METHOD

linear_inequality_upper_bounds

- Keywords Area
- method
- mesh_adaptive_search
- linear_inequality_upper_bounds

Define upper bounds for the linear inequality constraint

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = 0.

Description

In the inequality case, the lower \( a_l \) and upper \( a_u \) bounds provide constraint limits for the two-sided formulation:

\[
a_l \leq Ax \leq a_u
\]

Where \( A \) is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see objective functions), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

\[
Ax \leq 0.0
\]

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than \(+\text{bigRealBoundSize} (1.e+30, as defined in Minimizer)\) are treated as \(+\infty\) and any lower bound values less than \(-\text{bigRealBoundSize}\) are treated as \(-\infty\).

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since \(-\text{DBL\_MAX} < \text{-bigRealBoundSize}\)).

linear_inequality_scale_types

- Keywords Area
- method
- mesh_adaptive_search
- linear_inequality_scale_types

Specify how each linear inequality constraint is scaled
Topics
This keyword is related to the topics:

- linear_constraints

Specification
Alias: none
Argument(s): STRINGLIST
Default: vector values = 'none'

Description
linear_inequality_scale_types provide strings specifying the scaling type for each linear inequality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- 'none' - no scaling
- 'value' - characteristic value if this is chosen, then linear_inequality_scales must be specified
- 'auto' - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables x:

\[ \tilde{x}^j = \frac{x^j - x^j_O}{x^j_M} \]

we have the following system for linear inequality constraints

\[ a_L \leq A_i x \leq a_U \]
\[ a_L \leq A_i (\text{diag}(x_M) \tilde{x} + x_O) \leq a_U \]
\[ a_L - A_i x_O \leq A_i \text{diag}(x_M) \tilde{x} \leq a_U - A_i x_O \]
\[ \tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U \]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

linear_inequality_scales

- Keywords Area
- method
- mesh_adaptive_search
- linear_inequality_scales

Define the characteristic values to scale linear inequalities
6.2. METHOD

Topics
This keyword is related to the topics:

- linear_constraints

Specification
Alias: none
Argument(s): REALLIST
Default: vector values = 1. (no scaling)

Description
Each entry in `linear_inequality_scales` may be a user-specified, nonzero characteristic value to be used in scaling each constraint. Behavior depends on the choice of `linear_inequality_scale_type`:

- `scale_type` - behavior of `linear_inequality_scales`
  - 'none' - ignored
  - 'value' - required
  - 'auto' - optional

If a single real value is specified it will apply to all components of the constraint.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables \( x \):

\[
\tilde{x}^j = \frac{x^j - \bar{x}^j}{\bar{x}^j}
\]

we have the following system for linear inequality constraints

\[
a_L \leq A_i x \leq a_U \\
\bar{a}_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U \\
\bar{a}_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O \\
\bar{a}_L \leq \tilde{A}_i \tilde{x} \leq \bar{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to \([0,1]\).

`linear_equality_constraint_matrix`

- Keywords Area
- method
- mesh_adaptive_search
- `linear_equality_constraint_matrix`

Define coefficients of the linear equalities
Topics
This keyword is related to the topics:

- linear_constraints

Specification
Alias: none
Argument(s): REALLIST
Default: no linear equality constraints

Description
In the equality case, the constraint matrix $A$ provides coefficients for the variables on the left hand side of:

$$Ax = a_t$$

linear.equality.targets

- Keywords Area
- method
- mesh_adaptive_search
- linear.equality.targets

Define target values for the linear equality constraints

Topics
This keyword is related to the topics:

- linear_constraints

Specification
Alias: none
Argument(s): REALLIST
Default: vector values = 0 .

Description
In the equality case, the targets $a_t$ provide the equality constraint right hand sides:

$$Ax = a_t$$

If this is not specified, the defaults for the equality constraint targets enforce a value of 0. for each constraint:

$$Ax = 0.0$$
6.2. METHOD

linear_equality_scale_types

- Keywords Area
- method
- mesh_adaptive_search
- linear_equality_scale_types

Specify how each linear equality constraint is scaled

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): STRINGLIST

Default: vector values = 'none'

Description

`linear_equality_scale_types` provide strings specifying the scaling type for each linear equality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- ‘none’ - no scaling
- ‘value’ - characteristic value if this is chosen, then `linear.equality.scales` must be specified
- ‘auto’ - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables \( x \):

\[
\tilde{x}^j = \frac{x^j - x_O^j}{x_M^j}
\]

we have the following system for linear equality constraints

\[
a_L \leq A_i x \leq a_U
\]

\[
a_L \leq A_i (\text{diag}(x_M) \tilde{x} + x_M) \leq a_U
\]

\[
a_L - A_i x_O \leq A_i \text{diag}(x_M) \tilde{x} \leq a_U - A_i x_O
\]

\[
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to \([0,1]\).
linear\_equality\_scales

- Keywords Area
- method
- mesh\_adaptive\_search
- linear\_equality\_scales

Define the characteristic values to scale linear equalities

Topics

This keyword is related to the topics:

- linear\_constraints

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = 1 (no scaling)

Description

Each entry in linear\_equality\_scales may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

See the scaling page for details on how to use this keyword.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables $x$:

$$
\tilde{x}^j = \frac{x^j - x_O^j}{x_M^j}
$$

we have the following system for linear inequality constraints

$$
a_L \leq A_i x \leq a_U
$$

$$
a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U
$$

$$
a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O
$$

$$
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
$$

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].
6.2. METHOD

model_pointer

- Keywords Area
- method
- mesh_adaptive_search
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.

See block_pointer for details about pointers.

Examples

environment
  tabular_graphics_data
  method_pointer = 'UQ'

method

### Description

moga stands for Multi-objective Genetic Algorithm, which is a global optimization method that does Pareto optimization for multiple objectives. It supports general constraints and a mixture of real and discrete variables.

#### Constraints

moga can utilize linear constraints using the keywords:

- `linear_inequality_lower_bounds`
- `linear_inequality_upper_bounds`
- `linear_inequality_scale_types`
- `linear_inequality_scales`

- `linear_inequality_constraint_matrix`
- `linear_inequality_targets`
- `linear_inequality_scale_types`
- `linear_inequality_scales`

- `linear_equality_constraint_matrix`
- `linear_equality_targets`
- `linear_equality_scale_types`
- `linear_equality_scales`

#### Configuration

The genetic algorithm configurations are:

1. fitness
2. replacement
3. niching
4. convergence
5. postprocessor

6.2. METHOD

6. initialization

7. crossover

8. mutation

9. population size

The steps followed by the algorithm are listed below. The configurations will effect how the algorithm completes each step.

Stopping Criteria
The moga method respects the max.iterations and max.function_evaluations method independent controls to provide integer limits for the maximum number of generations and function evaluations, respectively.

The algorithm also stops when convergence is reached. This involves repeated assessment of the algorithm’s progress in solving the problem, until some criterion is met.

The specification for convergence in a moga can either be metric_tracker or can be omitted all together. If omitted, no convergence algorithm will be used and the algorithm will rely on stopping criteria only.

Outputs
The moga method respects the output method independent control to vary the amount of information presented to the user during execution.

The final results are written to the Dakota tabular output. Additional information is also available - see the log_file and print_each_pop keywords.

Note that moga and SOGA create additional output files during execution. "finaldata.dat" is a file that holds the final set of Pareto optimal solutions after any post-processing is complete. "discards.dat" holds solutions that were discarded from the population during the course of evolution.

It can often be useful to plot objective function values from these files to visually see the Pareto front and ensure that finaldata.dat solutions dominate discards.dat solutions. The solutions are written to these output files in the format "Input1...InputN..Output1...OutputM".

Important Notes
The pool of potential members is the current population and the current set of offspring.

Choice of fitness assessors is strongly related to the type of replacement algorithm being used and can have a profound effect on the solutions selected for the next generation.

If using the fitness types layer.rank or domination_count, it is strongly recommended that you use the replacement_type below.limit (although the roulette wheel selectors can also be used).

The functionality of the domination_count selector of JEGA v1.0 can now be achieved using the domination_count fitness type and below.limit replacement type.

Theory
The basic steps of the moga algorithm are as follows:

1. Initialize the population

2. Evaluate the population (calculate the values of the objective function and constraints for each population member)

3. Loop until converged, or stopping criteria reached
   (a) Perform crossover
   (b) Perform mutation
   (c) Evaluate the new population
(d) Assess the fitness of each member in the population
(e) Replace the population with members selected to continue in the next generation
(f) Apply niche pressure to the population
(g) Test for convergence

4. Perform post processing

If moga is used in a hybrid optimization method (which requires one optimal solution from each individual optimization method to be passed to the subsequent optimization method as its starting point), the solution in the Pareto set closest to the “utopia” point is given as the best solution. This solution is also reported in the Dakota output.

This “best” solution in the Pareto set has minimum distance from the utopia point. The utopia point is defined as the point of extreme (best) values for each objective function. For example, if the Pareto front is bounded by (1,100) and (90,2), then (1,2) is the utopia point. There will be a point in the Pareto set that has minimum L2-norm distance to this point, for example (10,10) may be such a point.

If moga is used in a method which may require passing multiple solutions to the next level (such as the surrogate_based_global method or hybrid methods), the orthogonal_distance postprocessor type may be used to specify the distances between each solution value to winnow down the solutions in the full Pareto front to a subset which will be passed to the next iteration.

Description

The two JEGA methods use different fitness types, which are described on their respective pages.

**layer_rank**

- **Keywords Area**
- **method**
- **moga**
- **fitness_type**
- **layer_rank**

Assign each member to a layer, based on domination the rank based on layers

**Specification**

Alias: none

Argument(s): none

Description

The fitness_type: layer_rank has been specifically designed to avoid problems with aggregating and scaling objective function values and transforming them into a single objective.

The layer_rank fitness assessor works by assigning all non-dominated designs a layer of 0, then from what remains, assigning all the non-dominated a layer of 1, and so on until all designs have been assigned a layer. The values are negated to follow the higher-is-better fitness convention.

Use of the below_limit selector with the layer_rank fitness assessor has the effect of keeping all those designs whose layer is below a certain threshold again subject to the shrinkage limit.

**domination_count**

- **Keywords Area**
- **method**
- **moga**
CHAPTER 6. KEYWORDS AREA

- fitness_type
- domination_count

Rank each member by the number of members that dominate it

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The `fitness_type: domination_count` has been specifically designed to avoid problems with aggregating and scaling objective function values and transforming them into a single objective.

Instead, the `domination_count` fitness assessor works by ordering population members by the negative of the number of designs that dominate them. The values are negated in keeping with the convention that higher fitness is better.

The `layer_rank` fitness assessor works by assigning all non-dominated designs a layer of 0, then from what remains, assigning all the non-dominated a layer of 1, and so on until all designs have been assigned a layer. Again, the values are negated for the higher-is-better fitness convention.

Use of the `below_limit` selector with the `domination_count` fitness assessor has the effect of keeping all designs that are dominated by fewer than a limiting number of other designs subject to the shrinkage limit.

Using it with the `layer_rank` fitness assessor has the effect of keeping all those designs whose layer is below a certain threshold again subject to the shrinkage limit.

</tr>
</tbody>
</table>

**Description**

Replace the population with members selected to continue in the next generation. The pool of potential members is the current population and the current set of offspring. The `replacement_type` of `roulette_wheel` or `unique_roulette_wheel` may be used either with MOGA or SOGA problems however they are not recommended for use with MOGA. Given that the only two fitness assessors for MOGA are the `layer_rank` and `domination_count`, the recommended selector is the `below_limit` selector. The `below_limit` replacement will only keep designs that are dominated by fewer than a limiting number of other designs.

In `roulette_wheel` replacement, each design is conceptually allotted a portion of a wheel proportional to its fitness relative to the fitnesses of the other Designs. Then, portions of the wheel are chosen at random and the design occupying those portions are duplicated into the next population. Those Designs allotted larger portions of the wheel are more likely to be selected (potentially many times). `unique_roulette_wheel` replacement is the same as `roulette_wheel` replacement, with the exception that a design may only be selected once. The `below_limit` selector attempts to keep all designs for which the negated fitness is below a certain limit. The values are negated to keep with the convention that higher fitness is better. The inputs to the `below_limit` selector are the limit as a real value, and a `shrinkage_percentage` as a real value. The `shrinkage_percentage` defines the minimum amount of selections that will take place if enough designs are available. It is interpreted as a percentage of the population size that must go on to the subsequent generation. To enforce this, `below_limit` makes all the selections it would make anyway and if that is not enough, it takes the remaining that it needs from the best of what is left (effectively raising its limit as far as it must to get the minimum number of selections). It continues until it has made enough selections. The `shrinkage_percentage` is designed to prevent extreme decreases in the population size at any given generation, and thus prevent a big loss of genetic diversity in a very short time. Without a shrinkage limit, a small group of "super" designs may appear and quickly cull the population down to a size on the order of the limiting value. In this case, all the diversity of the population is lost and it is expensive to re-diversify and spread the population. The `replacement_type` for a SOGA may be `roulette_wheel`, `unique_roulette_wheel`, `elitist`, or `favor_feasible`. The elitist selector simply chooses the required number of designs taking the most fit. For example, if 100 selections are requested, then the top 100 designs as ranked by fitness will be selected and the remaining will be discarded. The `favor_feasible` replacement type first considers feasibility as a selection criteria. If that does not produce a "winner" then it moves on to considering fitness value. Because of this, any fitness assessor used with the `favor_feasible` selector must only account objectives in the creation of fitness. Therefore, there is such a fitness assessor and it’s use is enforced when the `favor_feasible` selector is chosen. In that case, and if the output level is set high enough, a message will be presented indicating that the `weighted_sum_only` fitness assessor will be used.

**elitist**

- Keywords Area
- method
- moga
- replacement_type
• elitist

Use the best designs to form a new population

**Specification**

*Alias:* none

*Argument(s):* none

**Description**

The elitist (default) setting creates a new population using (a) the replacement_size best individuals from the current population, (b) and population_size - replacement_size individuals randomly selected from the newly generated individuals. It is possible in this case to lose a good solution from the newly generated individuals if it is not randomly selected for replacement; however, the default new_solutions-generated value is set such that the entire set of newly generated individuals will be selected for replacement.

Decrease the population size by a percentage

### Specification

- **Alias:** shrinkage_percentage

- **Argument(s):** REAL

- **Default:** 0.9

### Description

As of JEGA v2.0, all replacement types are common to both MOGA and SOGA. They include the `roulette_wheel`, `unique_roulette_wheel`, `elitist`, and `below_limit` selectors. In `roulette_wheel` replacement, each design is conceptually allotted a portion of a wheel proportional to its fitness relative to the fitnesses of the other Designs. Then, portions of the wheel are chosen at random and the design occupying those portions are duplicated into the next population. Those Designs allotted larger portions of the wheel are more likely to be selected (potentially many times). `unique_roulette_wheel` replacement is the same as `roulette_wheel` replacement, with the exception that a design may only be selected once. The `below_limit` selector attempts to keep all designs for which the negated fitness is below a certain limit. The values are negated to keep with the convention that higher fitness is better. The inputs to the `below_limit` selector are the limit as a real value, and a `shrinkage_percentage` as a real value. The `shrinkage_percentage` defines the minimum amount of selections that will take place if enough designs are available. It is interpreted as a percentage of the population size that must go on to the subsequent generation. To enforce this, `below_limit` makes all the selections it would make anyway and if that is not enough, it takes the remaining that it needs from the best of what is left (effectively raising its limit as far as it must to get the minimum number of selections). It continues until it has made enough selections. The `shrinkage_percentage` is designed to prevent extreme decreases in the population size at any given generation, and thus prevent a big loss of genetic diversity in a very short time. Without a shrinkage limit, a small group of “super” designs may appear and quickly cull the population down to...
6.2. METHOD

a size on the order of the limiting value. In this case, all the diversity of the population is lost and it is expensive to re-diversify and spread the population. The elitist selector simply chooses the required number of designs taking the most fit. For example, if 100 selections are requested, then the top 100 designs as ranked by fitness will be selected and the remaining will be discarded.

<tr>
<td>max_designs</td>
<td></td>
<td>max_designs</td>
<td>Limit number of solutions to remain in the population</td>
</tr>
</tbody>
</table>

**Description**

The purpose of niching is to encourage differentiation along the Pareto frontier and thus a more even and uniform sampling.

This is typically accomplished by discourage clustering of design points in the performance space. In JEGA, the application of niche pressure occurs as a secondary selection operation. The nicher is given a chance to perform a pre-selection operation prior to the operation of the selection (replacement) operator, and is then called to perform niching on the set of designs that were selected by the selection operator.

The radial nicher takes information input from the user to compute a minimum allowable distance between designs in the performance space and acts as a secondary selection operator whereby it enforces this minimum distance. The distance nicher requires that solutions must be separated from other solutions by a minimum distance in each dimension (vs. Euclidean distance for the radial niching). After niching is complete, all designs in the population will be at least the minimum distance from one another in all directions.

The radial niche pressure applicator works by enforcing a minimum Euclidean distance between designs in the performance space at each generation. The algorithm proceeds by starting at the (or one of the) extreme
designs along objective dimension 0 and marching through the population removing all designs that are too close
to the current design. One exception to the rule is that the algorithm will never remove an extreme design which
is defined as a design that is maximal or minimal in all but 1 objective dimension (for a classical 2 objective
problem, the extreme designs are those at the tips of the non-dominated frontier). The distance nicher enforces
a minimum distance in each dimension.

The designs that are removed by the nicher are not discarded. They are buffered and re-inserted into
the population during the next pre-selection operation. This way, the selector is still the only operator that discards
designs and the algorithm will not waste time "re-filling" gaps created by the nicher.

The radial nicher requires as input a vector of fractions with length equal to the number of objectives.
The elements of the vector are interpreted as percentages of the non-dominated range for each objective defining
a minimum distance to all other designs. All values should be in the range (0, 1). The minimum allowable
distance between any two designs in the performance space is the Euclidian (simple square-root-sum-of-squares
calculation) distance defined by these percentages. The distance nicher has a similar input vector requirement,
only the distance is the minimum distance in each dimension.

The max designs niche pressure applicator is designed to choose a limited number of solutions to remain
in the population. That number is specified by num_designs. It does so in order to balance the tendency for
populations to grow very large and thus consuming too many computer resources. It operates by ranking designs
according to their fitness standing and a computed count of how many other designs are too close to them. Too
close is a function of the supplied niche_vector, which specifies the minimum distance between any two points
in the performance space along each dimension individually. Once the designs are all ranked, the top c \cdot num_designs
designs are kept in the population and the remaining ones are buffered or discarded. Note that like other
niching operators, this one will not discard an extreme design.

radial

**metric_tracker**

- Keywords Area
- method
- moga
- convergence_type
- metric_tracker

Track changes in the non-dominated frontier
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none

Argument(s): none

Default: metric_tracker

Description

The moga converger (metric_tracker) operates by tracking various changes in the non-dominated frontier from generation to generation. When the changes occurring over a user specified number of generations fall below a user specified threshold, the algorithm stops.

If metric_tracker is specified, then a percent_change and num_generations must be supplied as well. These are listed as optional keywords in the input spec.

Theory

The metric_tracker converger tracks 3 metrics specific to the non-dominated frontier from generation to generation. All 3 of these metrics are computed as percent changes between the generations. In order to compute these metrics, the converger stores a duplicate of the non-dominated frontier at each generation for comparison to the non-dominated frontier of the next generation.

The first metric is one that indicates how the expanse of the frontier is changing. The expanse along a given objective is defined by the range of values existing within the non-dominated set. The expansion metric is computed by tracking the extremes of the non-dominated frontier from one generation to the next. Any movement of the extreme values is noticed and the maximum percentage movement is computed as:

\[ Em = \max_{j} \left\{ \frac{\text{abs}(\text{range}(j, i) - \text{range}(j, i-1))}{\text{range}(j, i-1)} \right\} \]

where \( Em \) is the max expansion metric, \( j \) is the objective function index, \( i \) is the current generation number, and \( \text{nof} \) is the total number of objectives. The range is the difference between the largest value along an objective and the smallest when considering only non-dominated designs.

The second metric monitors changes in the density of the non-dominated set. The density metric is computed as the number of non-dominated points divided by the hypervolume of the non-dominated region of space. Therefore, changes in the density can be caused by changes in the number of non-dominated points or by changes in size of the non-dominated space or both. The size of the non-dominated space is computed as:

\[ Vps(i) = \text{product over } j \{ \text{range}(j, i) \} \]

where \( Vps(i) \) is the hypervolume of the non-dominated space at generation \( i \) and all other terms have the same meanings as above.

The density of a given non-dominated space is then:

\[ Dps(i) = \frac{\text{Pct}(i)}{Vps(i)} \]

where \( \text{Pct}(i) \) is the number of points on the non-dominated frontier at generation \( i \).

The percentage increase in density of the frontier is then calculated as

\[ Cd = \frac{\text{abs}((Dps(i) - Dps(i-1)) / Dps(i-1))}{Dps(i-1)} \]

where \( Cd \) is the change in density metric.

The final metric is one that monitors the "goodness" of the non-dominated frontier. This metric is computed by considering each design in the previous population and determining if it is dominated by any designs in the current population. All that are determined to be dominated are counted. The metric is the ratio of the number that are dominated to the total number that exist in the previous population.

As mentioned above, each of these metrics is a percentage. The tracker records the largest of these three at each generation. Once the recorded percentage is below the supplied percent change for the supplied number of generations consecutively, the algorithm is converged.
6.2. METHOD

percent_change

- Keywords Area
- method
- moga
- convergence_type
- percent_change

Define the convergence criterion for JEGA methods

**Specification**

Alias: none

Argument(s): REAL

</table>

**Description**

The purpose of this operation is to perform any needed data manipulations on the final solution deemed necessary. Currently the orthogonal_distance is the only one. It reduces the final solution set size such that a minimum distance in each direction exists between any two designs.

orthogonal_distance

- Keywords Area
- method
- moga
- postprocessor_type
- orthogonal_distance

Get subset of Pareto front based on distance

**Specification**

Alias: none

Argument(s): REALLIST

Default: 0.01 for all objectives
6.2. METHOD

Description

Note that MOGA and SOGA create additional output files during execution. "finaldata.dat" is a file that holds the final set of Pareto optimal solutions after any post-processing is complete. "discards.dat" holds solutions that were discarded from the population during the course of evolution. The solutions are written to these output files in the format "Input1...InputN..Output1...OutputM". If MOGA is used in a hybrid optimization meta-iteration (which requires one optimal solution from each individual optimization method to be passed to the subsequent optimization method as its starting point), the solution in the Pareto set closest to the "utopia" point is given as the best solution. This solution is also reported in the Dakota output. This "best" solution in the Pareto set has minimum distance from the utopia point. The utopia point is defined as the point of extreme (best) values for each objective function. For example, if the Pareto front is bounded by (1,100) and (90,2), then (1,2) is the utopia point. There will be a point in the Pareto set that has minimum L2-norm distance to this point, for example (10,10) may be such a point. In SOGA, the solution that minimizes the single objective function is returned as the best solution. If moga is used in meta-iteration which may require passing multiple solutions to the next level (such as the surrogate_based_global or hybrid methods), the orthogonal_distance postprocessor type may be used to specify the distances between each solution value to winnow down the solutions in the full Pareto front to a subset which will be passed to the next iteration.

population_size

- Keywords Area
- method
- moga
- population_size

Set the initial population size in JEGA methods

Specification

Alias: none

Argument(s): INTEGER
Default: 50

Description

The number of designs in the initial population is specified by the population_size. Note that the population_size only sets the size of the initial population. The population size may vary in the JEGA methods according to the type of operators chosen for a particular optimization run.

log_file

- Keywords Area
- method
- moga
- log_file

Specify the name of a log file
Specification

Alias: none
  Argument(s): STRING
  Default: JEGAGlobal.log

Description

New as of JEGA v2.0 is the introduction of the log_file specification. JEGA now uses a logging library to output messages and status to the user. JEGA can be configured at build time to log to both the console window and a text file, one or the other, or neither. The log_file input is a string name of a file into which to log. If the build was configured without file logging in JEGA, this input is ignored. If file logging is enabled and no log_file is specified, the default file name of JEGAGlobal.log is used.

print_each_pop

- Keywords Area
- method
- moga
- print_each_pop

Print every population to a population file

Specification

Alias: none
  Argument(s): none
  Default: No printing

Description

New to JEGA v2.0 is the introduction of the print_each_pop specification. It serves as a flag and if supplied, the population at each generation will be printed to a file named "population<GEN#>.dat" where <GEN#> is the number of the current generation.

initialization_type

- Keywords Area
- method
- moga
- initialization_type

Specify how to initialize the population

Specification

Alias: none
  Argument(s): none
  Default: unique_random
## Description

The initialization_type defines how the initial population is created for the GA. There are three types:

1. **simple_random**
2. **unique_random** (default)
3. **flat_file**

**simple_random**

- **Keywords Area**
  - method
  - moga
  - initialization_type
  - simple_random

Create random initial solutions.

**Specification**

- **Alias:** none
- **Argument(s):** none

**Description**

**simple_random** creates initial solutions with random variable values according to a uniform random number distribution. It gives no consideration to any previously generated designs.
unique_random

- Keywords Area
- method
- moga
- initialization_type
- unique_random

Create random initial solutions, but enforce uniqueness (default)

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

unique_random is the same as simple_random, except that when a new solution is generated, it is checked against the rest of the solutions. If it duplicates any of them, it is rejected.

flat_file

- Keywords Area
- method
- moga
- initialization_type
- flat_file

Read initial solutions from file

**Specification**

**Alias:** none

**Argument(s):** STRING

**Description**

flat_file allows the initial population to be read from a flat file. If flat_file is specified, a file name must be given.

Variables can be delimited in the flat file in any way you see fit with a few exceptions. The delimiter must be the same on any given line of input with the exception of leading and trailing whitespace. So a line could look like: 1.1, 2.2, 3.3 for example but could not look like: 1.1, 2.2, 3.3. The delimiter can vary from line to line within the file which can be useful if data from multiple sources is pasted into the same input file. The delimiter can be any string that does not contain any of the characters .+-dDeE or any of the digits 0-9. The input will be read until the end of the file. The algorithm will discard any configurations for which it was unable to retrieve at least the
number of design variables. The objective and constraint entries are not required but if ALL are present, they will be recorded and the design will be tagged as evaluated so that evaluators may choose not to re-evaluate them.

Setting the size for this initializer has the effect of requiring a minimum number of designs to create. If this minimum number has not been created once the files are all read, the rest are created using the unique_random initializer and then the simple_random initializer if necessary.

crossover_type

- Keywords Area
- method
- moga
- crossover_type

Select a crossover type for JEGA methods

### Specification

**Alias:** none  
**Argument(s):** none  
**Default:** shuffle_random

<table>
<thead>
<tr>

</tr>
<tr>
<td></td>
<td></td>
<td>shuffle_random</td>
<td>Perform crossover by choosing design variable(s)</td>
</tr>
</tbody>
</table>

| Optional | crossover_rate | Specify the probability of a crossover event |

### Description

There are many crossover types available. `multi_point_binary` crossover requires an integer number, N, of crossover points. This crossover type performs a bit switching crossover at N crossover points in the binary encoded genome of two designs. Thus, crossover may occur at any point along a solution chromosome (in the middle of a gene representing a design variable, for example). `multi_point_parameterized_binary` crossover is similar in that it performs a bit switching crossover routine at N crossover points. However, this crossover type performs crossover on each design variable individually. So the individual chromosomes are crossed at N locations. `multi_point_real` crossover performs a variable switching crossover routing at N crossover points in the real real valued genome of two designs. In this scheme, crossover only occurs between design variables
(chromosomes). Note that the standard solution chromosome representation in the JEGA algorithm is real encoded and can handle integer or real design variables. For any crossover types that use a binary representation, real variables are converted to long integers by multiplying the real number by 10^6 and then truncating. Note that this assumes a precision of only six decimal places. Discrete variables are represented as integers (indices within a list of possible values) within the algorithm and thus require no special treatment by the binary operators.

The final crossover type is shuffle_random. This crossover type performs crossover by choosing design variables at random from a specified number of parents enough times that the requested number of children are produced. For example, consider the case of 3 parents producing 2 children. This operator would go through and for each design variable, select one of the parents as the donor for the child. So it creates a random shuffle of the parent design variable values. The relative numbers of children and parents are controllable to allow for as much mixing as desired. The more parents involved, the less likely that the children will wind up exact duplicates of the parents.

All crossover types take a crossover_rate. The crossover rate is used to calculate the number of crossover operations that take place. The number of crossovers is equal to the rate * population_size.

multi_point_binary

- Keywords Area
- method
- moga
- crossover_type
- crossover_rate

Specify the probability of a crossover event

**Specification**

Alias: none

Argument(s): REAL

Default: 0.8

**Description**

The `crossover_type` controls what approach is employed for combining parent genetic information to create offspring, and the `crossover_rate` specifies the probability of a crossover operation being performed to generate a new offspring. The SCOLIB EA method supports three forms of crossover, `two_point`, `blend`, and `uniform`, which generate a new individual through combinations of two parent individuals. Two-point crossover divides each parent into three regions, where offspring are created from the combination of the middle region from one parent and the end regions from the other parent. Since the SCOLIB EA does not utilize bit representations of variable values, the crossover points only occur on coordinate boundaries, never within the bits of a particular coordinate. Uniform crossover creates offspring through random combination of coordinates from the two parents. Blend crossover generates a new individual randomly along the multidimensional vector connecting the two parents.

**mutation_type**

- Keywords Area
- method
- moga
- mutation_type

Select a mutation type for JEGA methods

**Specification**

Alias: none

Argument(s): none

Default: replace_uniform
6.2. METHOD

- **replace_uniform**: Use uniformly distributed value over range of parameter
- **offset_normal**: Set mutation offset to use a normal distribution
- **offset_cauchy**: Use a Cauchy distribution for the mutation offset
- **offset_uniform**: Set mutation offset to use a uniform distribution

**Optional**

- **mutation_rate**: Set probability of a mutation

### Description

Five mutation types are available for selection by keyword: `replace_uniform`, `bit_random`, `offset_cauchy`, `offset_normal`, and `offset_uniform`. They are described in greater detail on their respective keyword pages.

The `offset_*` mutators all act by adding a random "offset" to a variable value. The random amount has a mean of zero in all cases. The size of the offset is controlled using the `mutation_scale` keyword, which is interpreted differently for each `offset_*` type.

The rate of mutations for all types is controlled using the `mutation_rate`. The rate is applied differently in each `mutation_type`.

**bit_random**

- Keywords Area
- method
- moga
- mutation_type
- bit_random

Mutate by flipping a random bit

### Specification

**Alias**: none

**Argument(s)**: none
Description

The bit_random mutator introduces random variation by first converting a randomly chosen variable of a randomly chosen design into a binary string. It then flips a randomly chosen bit in the string from a 1 to a 0 or visa versa. In this mutation scheme, the resulting value has more probability of being similar to the original value.

replace_uniform

- Keywords Area
- method
- moga
- mutation_type
- replace_uniform

Use uniformly distributed value over range of parameter

Specification

Alias: none
Argument(s): none

Description

replace_uniform introduces random variation by first randomly choosing a design variable of a randomly selected design and reassigning it to a random valid value for that variable. No consideration of the current value is given when determining the new value.

offset_normal

- Keywords Area
- method
- moga
- mutation_type
- offset_normal

Set mutation offset to use a normal distribution

Specification

<td>Scales mutation across range of parameter</td>
</tr>
</tbody>
</table>
6.2. METHOD

Description

The `offset_normal` mutator introduces random variation by adding a Gaussian random amount to a variable value. The random amount has a standard deviation dependent on the `mutation_scale`.

```
mutation_scale
```
- Keywords Area
- method
- moga
- mutation_type
- offset_normal
- mutation_scale

Scales mutation across range of parameter

Specification

Alias: none

| Argument(s): | REAL |
| Default:     | 0.15 |

Description

The `mutation_scale` is a fraction in the range [0, 1] and is meant to help control the amount of variation that takes place when a variable is mutated. Its behavior depends on the selected `mutation_type`. For `offset_normal` and `offset_cauchy`, `mutation_scale` is multiplied by the range of the variable being mutated to obtain the standard deviation of the offset. For `offset_uniform`, the range of possible deviation amounts is +/- 1/2 * (mutation_scale * variable range).

```
offset_cauchy
```
- Keywords Area
- method
- moga
- mutation_type
- offset_cauchy

Use a Cauchy distribution for the mutation offset

Specification

- `mutation_scale`
  - **Keywords Area**
  - `method`
  - `moga`
  - `mutation_type`
  - `offset_uniform`
  - `mutation_scale`

  Scales mutation across range of parameter

### Specification

**Alias:** none

**Argument(s):** REAL

**Default:** 0.15

#### Description

The `mutation_scale` is a fraction in the range [0, 1] and is meant to help control the amount of variation that takes place when a variable is mutated. Its behavior depends on the selected `mutation_type`. For `offset_normal` and `offset_cauchy`, `mutation_scale` is multiplied by the range of the variable being mutated to obtain the standard deviation of the offset. For `offset_uniform`, the range of possible deviation amounts is +/- 1/2 * (`mutation_scale` * variable range).

- `mutation_rate`
  - **Keywords Area**
  - `method`
  - `moga`
  - `mutation_type`
• **mutation rate**

Set probability of a mutation

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 0.08

**Description**

All mutation types have a `mutation_rate`, which controls the number of mutations performed. For `replace_uniform` and all the `offset_*` types, the number of mutations performed is the product of `mutation_rate` and `population_size`. For `bit_random`, it's the product of the `mutation_rate`, number of design variables, and population size.

**seed**

• **Keywords Area**

• method

• moga

• seed

Seed of the random number generator

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** system-generated (non-repeatable)

**Description**

The random **seed** control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

**Default Behavior**

If not specified, the seed is randomly generated.

**Expected Output**

If **seed** is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

**Usage Tips**

If a stochastic study was run without **seed** specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.
6.2. METHOD

Examples

```python
method
    sampling
        sample_type lhs
        samples = 10
        seed = 15347
```

**linear_inequality_constraint_matrix**

- **Keywords Area**
- **method**
- **moga**
- **linear_inequality_constraint_matrix**

Define coefficients of the linear inequality constraints

**Topics**

This keyword is related to the topics:

- **linear_constraints**

**Specification**

**Alias:** none

- **Argument(s):** REALLIST
- **Default:** no linear inequality constraints

**Description**

In the inequality case, the constraint matrix $A$ provides coefficients for the variables in the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where the bounds are optionally specified by `linear_inequality_lower_bounds`, and `linear_inequality_upper_bounds`. The bounds, if not specified, will default to -infinity, and 0, respectively, resulting in one-sided inequalities of the form

$$Ax \leq 0.0$$

**linear_inequality_lower_bounds**

- **Keywords Area**
- **method**
- **moga**
- **linear_inequality_lower_bounds**

Define lower bounds for the linear inequality constraint
Topics
This keyword is related to the topics:

- linear_constraints

Specification
Alias: none
Argument(s): REALLIST
Default: vector values = -infinity

Description
In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where $A$ is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see objective_functions), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$Ax \leq 0.0$$

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than $+\text{bigRealBoundSize}$ (1e+30, as defined in Minimizer) are treated as $+\infty$ and any lower bound values less than $-\text{bigRealBoundSize}$ are treated as $-\infty$.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since $-\text{DBL_MAX} < -\text{bigRealBoundSize}$).

linear_inequality_upper_bounds

- Keywords Area
- method
- moga
- linear_inequality_upper_bounds

Define upper bounds for the linear inequality constraint

Topics
This keyword is related to the topics:

- linear_constraints
6.2. **METHOD**

**Description**

In the inequality case, the lower \( a_l \) and upper \( a_u \) bounds provide constraint limits for the two-sided formulation:

\[
a_l \leq Ax \leq a_u
\]

Where \( A \) is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see **objective functions**), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

\[
Ax \leq 0.0
\]

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than \(+\text{bigRealBoundSize}\) (1.e+30, as defined in Minimizer) are treated as \(+\text{infinity}\) and any lower bound values less than \(-\text{bigRealBoundSize}\) are treated as \(-\text{infinity}\).

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since \(-\text{DBL_MAX} < -\text{bigRealBoundSize}\)).

**linear_inequality_scale_types**

- **Keywords Area**
- **method**
- **moga**
- **linear_inequality_scale_types**

Specify how each linear inequality constraint is scaled

**Topics**

This keyword is related to the topics:

- **linear_constraints**

**Specification**

**Alias:** none

**Argument(s):** STRINGLIST

**Default:** vector values = ’none’

**Description**

**linear_inequality_scale_types** provide strings specifying the scaling type for each linear inequality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- ’none’ - no scaling
- ’value’ - characteristic value if this is chosen, then **linear_inequality_scales** must be specified
• ‘auto’ - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables \( x \):

\[
\tilde{x}^j = \frac{x^j - x^j_O}{x^j_M}
\]

we have the following system for linear inequality constraints

\[
a_L \leq A_i x \leq a_U
\]

\[
a_L \leq A_i (\text{diag}(x_M) \tilde{x} + x_O) \leq a_U
\]

\[
a_L - A_i x_O \leq A_i \text{diag}(x_M) \tilde{x} \leq a_U - A_i x_O
\]

\[
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to \([0,1]\).

\textbf{linear_inequality_scales}

- Keywords Area
- method
- moga
- \textbf{linear_inequality_scales}

Define the characteristic values to scale linear inequalities

\textbf{Topics}

This keyword is related to the topics:

- \textbf{linear_constraints}

\textbf{Specification}

\textbf{Alias:} none

\textbf{Argument(s):} REALLIST

\textbf{Default:} vector values = 1 . (no scaling)

\textbf{Description}

Each entry in \textbf{linear_inequality_scales} may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

Behavior depends on the choice of \textbf{linear_inequality_scale_type}:

- \textbf{scale_type} - behavior of \textbf{linear_inequality_scales}
- ‘none’ - ignored
6.2. METHOD

• 'value' - required
• 'auto' - optional

If a single real value is specified it will apply to all components of the constraint.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables $x$:

$$\tilde{x}^j = \frac{x^j - x^j_O}{x^j_M}$$

we have the following system for linear inequality constraints

$$a_L \leq A_i x \leq a_U$$

$$a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U$$

$$a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O$$

$$\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U$$

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to $[0,1]$.

- linear_equalityEnginegmentS

Define target values for the linear equality constraints

**Topics**

This keyword is related to the topics:

- linear_constraintS

**Specification**

Alias: none

**Argument(s):** REALLIST

**Default:** vector values = 0.

**Description**

In the equality case, the targets \( a_t \) provide the equality constraint right hand sides:

\[
Ax = a_t
\]

If this is not specified, the defaults for the equality constraint targets enforce a value of 0. for each constraint:

\[
Ax = 0.0
\]

linear_equalityEngineement_scale_types

- Keywords Area
- method
- moga
- linear_equalityEngineement_scale_types

Specify how each linear equality constraint is scaled

**Topics**

This keyword is related to the topics:

- linear_constraintS
### 6.2. METHOD

**Specification**

**Alias:** none

**Argument(s):** STRINGLIST

**Default:** vector values = 'none'

**Description**

`linear.equality.scale_types` provide strings specifying the scaling type for each linear equality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- `'none'` - no scaling
- `'value'` - characteristic value if this is chosen, then `linear.equality.scales` must be specified
- `'auto'` - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables \( x \):

\[
\tilde{x}^j = \frac{x^j - x^j_O}{x^j_M - x^j_O}
\]

we have the following system for linear equality constraints

\[
a_L \leq A_i x \leq a_U
\]

\[
a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U
\]

\[
a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O
\]

\[
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to \([0,1]\).

**linear.equality.scales**

- **Keywords Area**
- **method**
- **moga**
- **linear.equality.scales**

Define the characteristic values to scale linear equalities

**Topics**

This keyword is related to the topics:

- **linear_constraints**
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none

Argument(s): REALIST

Default: vector values = 1 . (no scaling)

Description

Each entry in linear equality scales may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

See the scaling page for details on how to use this keyword.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables \( x \):

\[
\tilde{x}_j = \frac{x_j - x_O^j}{x_M^j}
\]

we have the following system for linear inequality constraints

\[
a_L \leq A_i x \leq a_U
\]

\[
a_L \leq A_i (\text{diag}(x_M^j) \tilde{x} + x_O) \leq a_U
\]

\[
a_L - A_i x_O \leq A_i \text{diag}(x_M^j) \tilde{x} \leq a_U - A_i x_O
\]

\[
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

model_pointer

- Keywords Area
- method
- moga
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)
6.2. METHOD

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

Examples

```plaintext
environment
tabular_graphics_data
method_pointer = 'UQ'

method
id_method = 'UQ'
model_pointer = 'SURRE
sampling,
samples = 10
seed = 98765 rng rnum2
response_levels = 0.1 0.2 0.6
0.1 0.2 0.6
0.1 0.2 0.6
sample_type lhs
distribution cumulative

model
id_model = 'SURRE
surrogate global,
dace_method_pointer = 'DACE'
polynomial quadratic

**CHAPTER 6. KEYWORDS AREA**

### Description

`soga` stands for Single-objective Genetic Algorithm, which is a global optimization method that supports general constraints and a mixture of real and discrete variables. `soga` is part of the JEGA library.

**Constraints** `soga` can utilize linear constraints.

**Configuration**

The genetic algorithm configurations are:

1. fitness
2. replacement
3. convergence
4. initialization
5. crossover
6. mutation
7. population size

The pool of potential members is the current population and the current set of offspring. Choice of fitness assessors is strongly related to the type of replacement algorithm being used and can have a profound effect on the solutions selected for the next generation.

**Stopping Criteria**

The `soga` method respects the `max_iterations` and `max_function_evaluations` method independent controls to provide integer limits for the maximum number of generations and function evaluations, respectively.

The algorithm also stops when convergence is reached. This involves repeated assessment of the algorithm’s progress in solving the problem, until some criterion is met.

**Outputs** The `soga` method respects the `output` method independent control to vary the amount of information presented to the user during execution.

The final results are written to the Dakota tabular output. Additional information is also available - see the `log_file` and `print_each_pop` keywords.

### Theory

The basic steps of the `soga` algorithm are as follows:

1. Initialize the population
2. Evaluate the population (calculate the values of the objective function and constraints for each population member)
3. Loop until converged, or stopping criteria reached
   
   (a) Perform crossover
   
   (b) Perform mutation
6.2. METHOD

(c) Evaluate the new population
(d) Assess the fitness of each member in the population
(e) Replace the population with members selected to continue in the next generation
(f) Test for convergence

Balance goals of reducing objective function and satisfying constraints
CHAPTER 6. KEYWORDS AREA

Specification
Alias: none
Argument(s): none

Description
A merit function is a function in constrained optimization that attempts to provide joint progress toward reducing the objective function and satisfying the constraints.

constraint_penalty
- Keywords Area
- method
- soga
- fitness_type
- constraint_penalty

Multiplier for the penalty function

Specification
Alias: none
Argument(s): REAL
Default: 1.0

Description
The merit function fitness assessor uses an exterior penalty function formulation to penalize infeasible designs. The specification allows the input of a constraint_penalty which is the multiplier to use on the constraint violations.

replacement_type
- Keywords Area
- method
- soga
- replacement_type

Select a replacement type for JEGA methods

Specification
Alias: none
Argument(s): none
Default: elitist
### Description

Replace the population with members selected to continue in the next generation. The pool of potential members is the current population and the current set of offspring. The replacement_type of roulette_wheel or unique_roulette_wheel may be used either with MOGA or SOGA problems however they are not recommended for use with MOGA. Given that the only two fitness assessors for MOGA are the layer_rank and domination_count, the recommended selector is the below_limit selector. The below_limit replacement will only keep designs that are dominated by fewer than a limiting number of other designs.

In roulette_wheel replacement, each design is conceptually allotted a portion of a wheel proportional to its fitness relative to the fitnesses of the other Designs. Then, portions of the wheel are chosen at random and the design occupying those portions are duplicated into the next population. Those Designs allotted larger portions of the wheel are more likely to be selected (potentially many times). unique_roulette_wheel replacement is the same as roulette_wheel replacement, with the exception that a design may only be selected once. The below_limit selector attempts to keep all designs for which the negated fitness is below a certain limit. The values are negated to keep with the convention that higher fitness is better. The inputs to the below_limit selector are the limit as a real value, and a shrinkage_percentage as a real value. The shrinkage_percentage defines the minimum amount of selections that will take place if enough designs are available. It is interpreted as a percentage of the population size that must go on to the subsequent generation. To enforce this, below_limit makes all the selections it would make anyway and if that is not enough, it takes the remaining that it needs from the best of what is left (effectively raising its limit as far as it must to get the minimum number of selections). It continues until it has made enough selections. The shrinkage_percentage is designed to prevent extreme decreases in the population size at any given generation, and thus prevent a big loss of genetic diversity in a very short time. Without a shrinkage limit, a small group of "super" designs may appear and quickly cull the population down to a size on the order of the limiting value. In this case, all the diversity of the population is lost and it is expensive to re-diversify and spread the population. The

The replacement_type for a SOGA may be roulette_wheel, unique_roulette_wheel, elitist, or favor_feasible. The elitist selector simply chooses the required number of designs taking the most fit. For example, if 100 selections are requested, then the top 100 designs as ranked by fitness will be selected and the remaining will be discarded. The favor_feasible replacement type first considers feasibility as a selection criteria. If that does not produce a "winner" then it moves on to considering fitness value. Because of this, any fitness assessor used with the favor_feasible selector must only account objectives in the creation of fitness. Therefore, there is such a fitness assessor and it’s use is enforced when the favor_feasible selector is chosen. In that case, and if the output level is set high enough, a message will be presented indicating that the weighted_sum_only fitness assessor will be used.

### Keywords

- **elitist**
  - **Keywords Area**
  - **method**
• soga
• replacement_type
• elitist

Use the best designs to form a new population

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The elitist (default) setting creates a new population using (a) the replacement_size best individuals from the current population, (b) and population_size-replacement_size individuals randomly selected from the newly generated individuals. It is possible in this case to lose a good solution from the newly generated individuals if it is not randomly selected for replacement; however, the default new_solutions_generated value is set such that the entire set of newly generated individuals will be selected for replacement.

**favor_feasible**

• Keywords Area
• method
• soga
• replacement_type
• favor_feasible

Prioritize feasible designs

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

This replacement operator will always prefer a more feasible design to a less feasible one. Beyond that, it favors solutions based on an assigned fitness value which must have been installed by the weighted sum only fitness assessor.

The favor_feasible replacement type first considers feasibility as a selection criteria. If that does not produce a "winner" then it moves on to considering fitness value. Because of this, any fitness assessor used with the favor_feasible selector must only account objectives in the creation of fitness. Therefore, there is such a fitness assessor and it's use is enforced when the favor_feasible selector is chosen. In that case, and if the output level is set high enough, a message will be presented indicating that the weighted_sum_only fitness assessor will be used.

- soga
- convergence_type
- average_fitness_tracker
- num_generations

Define the convergence criterion for JEGA methods

**Specification**

Alias: none
Argument(s): INTEGER
Default: 10

**Description**

The `num_generations` is the number of generations over which the metric value should be tracked. Convergence will be attained if the recorded metric is below `percent_change` for `num_generations` consecutive generations.

population_size

- Keywords Area
- method
- soga
- population_size

Set the initial population size in JEGA methods

**Specification**

Alias: none
Argument(s): INTEGER
Default: 50

**Description**

The number of designs in the initial population is specified by the `population_size`. Note that the `population_size` only sets the size of the initial population. The population size may vary in the JEGA methods according to the type of operators chosen for a particular optimization run.
6.2. **METHOD**

**log_file**

- **Keywords Area**
- **method**
- **soga**
- **log_file**

Specify the name of a log file

**Specification**

**Alias:** none  
**Argument(s):** STRING  
**Default:** JEGAGlobal.log

**Description**

New as of JEGA v2.0 is the introduction of the `log_file` specification. JEGA now uses a logging library to output messages and status to the user. JEGA can be configured at build time to log to both the console window and a text file, one or the other, or neither. The `log_file` input is a string name of a file into which to log. If the build was configured without file logging in JEGA, this input is ignored. If file logging is enabled and no `log_file` is specified, the default file name of JEGAGlobal.log is used.

**print_each_pop**

- **Keywords Area**
- **method**
- **soga**
- **print_each_pop**

Print every population to a population file

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** No printing

**Description**

New to JEGA v2.0 is the introduction of the `print_each_pop` specification. It serves as a flag and if supplied, the population at each generation will be printed to a file named "population<GEN#>.dat" where <GEN#> is the number of the current generation.
**CHAPTER 6. KEYWORDS AREA**

**initialization_type**
- **Keywords Area**
- **method**
- **soga**
- **initialization_type**

Specify how to initialize the population

### Specification

<th>Required/-Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Required (Choose One)</strong></td>
<td>Group 1</td>
<td>simple_random</td>
<td>Create random initial solutions</td>
</tr>
</tbody>
</table>

#### simple_random

- **Keywords Area**
- **method**
- **soga**
- **initialization_type**
- **simple_random**

Create random initial solutions

Setting the size for the flat_file initializer has the effect of requiring a minimum number of designs to create. If this minimum number has not been created once the files are all read, the rest are created using the unique_random initializer and then the simple_random initializer if necessary.
6.2. METHOD

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

`simple.random` creates initial solutions with random variable values according to a uniform random number distribution. It gives no consideration to any previously generated designs.

**unique_random**

- Keywords Area
- method
- soga
- initialization_type
- unique_random

Create random initial solutions, but enforce uniqueness (default)

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

`unique.random` is the same as `simple.random`, except that when a new solution is generated, it is checked against the rest of the solutions. If it duplicates any of them, it is rejected.

**flat_file**

- Keywords Area
- method
- soga
- initialization_type
- flat_file

Read initial solutions from file

**Specification**

**Alias:** none  
**Argument(s):** STRING
**Description**

`flat_file` allows the initial population to be read from a flat file. If `flat_file` is specified, a file name must be given.

Variables can be delimited in the flat file in any way you see fit with a few exceptions. The delimiter must be the same on any given line of input with the exception of leading and trailing whitespace. So a line could look like: 1.1, 2.2, 3.3 for example but could not look like: 1.1, 2.2 3.3. The delimiter can vary from line to line within the file which can be useful if data from multiple sources is pasted into the same input file. The delimiter can be any string that does not contain any of the characters .+-dDeE or any of the digits 0-9. The input will be read until the end of the file. The algorithm will discard any configurations for which it was unable to retrieve at least the number of design variables. The objective and constraint entries are not required but if ALL are present, they will be recorded and the design will be tagged as evaluated so that evaluators may choose not to re-evaluate them.

Setting the size for this initializer has the effect of requiring a minimum number of designs to create. If this minimum number has not been created once the files are all read, the rest are created using the `unique_random` initializer and then the `simple_random` initializer if necessary.

crossover_type

- **Keywords Area**
- **method**

</tr>
</tbody>
</table>

6.2. **METHOD**

**Description**

There are many crossover types available. `multi_point_binary` crossover requires an integer number, \( N \), of crossover points. This crossover type performs a bit switching crossover at \( N \) crossover points in the binary encoded genome of two designs. Thus, crossover may occur at any point along a solution chromosome (in the middle of a gene representing a design variable, for example). `multi_point_parameterized_binary` crossover is similar in that it performs a bit switching crossover routine at \( N \) crossover points. However, this crossover type performs crossover on each design variable individually. So the individual chromosomes are crossed at \( N \) locations. `multi_point_real` crossover performs a variable switching crossover routing at \( N \) crossover points in the real real valued genome of two designs. In this scheme, crossover only occurs between design variables (chromosomes). Note that the standard solution chromosome representation in the JEGA algorithm is real encoded and can handle integer or real design variables. For any crossover types that use a binary representation, real variables are converted to long integers by multiplying the real number by \( 10^6 \) and then truncating. Note that this assumes a precision of only six decimal places. Discrete variables are represented as integers (indices within a list of possible values) within the algorithm and thus require no special treatment by the binary operators.

The final crossover type is `shuffle_random`. This crossover type performs crossover by choosing design variables at random from a specified number of parents enough times that the requested number of children are produced. For example, consider the case of 3 parents producing 2 children. This operator would go through and for each design variable, select one of the parents as the donor for the child. So it creates a random shuffle of the parent design variable values. The relative numbers of children and parents are controllable to allow for as much mixing as desired. The more parents involved, the less likely that the children will wind up exact duplicates of the parents.

All crossover types take a `crossover_rate`. The crossover rate is used to calculate the number of crossover operations that take place. The number of crossovers is equal to the rate * population size.

<tr>
<td>Optional</td>
<td>num_offspring</td>
<td></td>
<td>Number of offspring in random shuffle crossover</td>
</tr>
</tbody>
</table>
Description

The final crossover type is `shuffle_random`. This crossover type performs crossover by choosing design variables at random from a specified number of parents enough times that the requested number of children are produced. For example, consider the case of 3 parents producing 2 children. This operator would go through and for each design variable, select one of the parents as the donor for the child. So it creates a random shuffle of the parent design variable values. The relative numbers of children and parents are controllable to allow for as much mixing as desired. The more parents involved, the less likely that the children will wind up exact duplicates of the parents.

```
num_parents
```

Description

Number of offspring in random shuffle crossover

crossover_rate

- Keywords Area
- method
- soga
- crossover_type
- crossover_rate

Specify the probability of a crossover event

Specification

Alias: none
Argument(s): REAL
Default: 0.8

Description

The crossover_type controls what approach is employed for combining parent genetic information to create offspring, and the crossover_rate specifies the probability of a crossover operation being performed to generate a new offspring. The SCOLIB EA method supports three forms of crossover, two_point, blend, and uniform, which generate a new individual through combinations of two parent individuals. Two-point crossover divides each parent into three regions, where offspring are created from the combination of the middle region from one parent and the end regions from the other parent. Since the SCOLIB EA does not utilize bit representations of variable values, the crossover points only occur on coordinate boundaries, never within the bits of a particular coordinate. Uniform crossover creates offspring through random combination of coordinates from the two parents. Blend crossover generates a new individual randomly along the multidimensional vector connecting the two parents.

mutation_type

</tbody>
</table>

Description

Five mutation types are available for selection by keyword: replace_uniform, bit_random, offset_-cauchy, offset_normal, and offset_uniform. They are described in greater detail on their respective keyword pages.

The offset_* mutators all act by adding a random "offset" to a variable value. The random amount has a mean of zero in all cases. The size of the offset is controlled using the mutation_scale keyword, which is interpreted differently for each offset_* type.

The rate of mutations for all types is controlled using the mutation_rate. The rate is applied differently in each mutation_type.

bit_random

- Keywords Area
- method
- soga
- mutation_type
- bit_random

Mutate by flipping a random bit
6.2. **METHOD**

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The `bit_random` mutator introduces random variation by first converting a randomly chosen variable of a randomly chosen design into a binary string. It then flips a randomly chosen bit in the string from a 1 to a 0 or visa versa. In this mutation scheme, the resulting value has more probability of being similar to the original value.

**replace_uniform**

- **Keywords Area**
- **method**
- **soga**
- **mutation_type**
- **replace_uniform**

Use uniformly distributed value over range of parameter

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

`replace_uniform` introduces random variation by first randomly choosing a design variable of a randomly selected design and reassigning it to a random valid value for that variable. No consideration of the current value is given when determining the new value.

**offset_normal**

- **Keywords Area**
- **method**
- **soga**
- **mutation_type**
- **offset_normal**

Set mutation offset to use a normal distribution

**Specification**

**Alias:** none

**Argument(s):** none
Description

The *offset_normal* mutator introduces random variation by adding a Gaussian random amount to a variable value. The random amount has a standard deviation dependent on the *mutation_scale*.

```markdown
**mutation_scale**
- Keywords Area
- method
- soga
- mutation_type
- offset_normal
- mutation_scale

Scales mutation across range of parameter
```

Specification

Alias: none
Argument(s): REAL
Default: 0.15

Description

The *mutation_scale* is a fraction in the range [0, 1] and is meant to help control the amount of variation that takes place when a variable is mutated. Its behavior depends on the selected *mutation_type*. For *offset_normal* and *offset_cauchy*, *mutation_scale* is multiplied by the range of the variable being mutated to obtain the standard deviation of the offset. For *offset_uniform*, the range of possible deviation amounts is +/- 1/2 * (mutation_scale * variable range).

```markdown
**offset_cauchy**
- Keywords Area
- method
- soga
- mutation_type
- offset_cauchy

Use a Cauchy distribution for the mutation offset
```

6.2. METHOD

**mutation_rate**

- Keywords Area
- method
- soga
- mutation_type
- mutation_rate

Set probability of a mutation

**Specification**

Alias: none  
Argument(s): REAL  
Default: 0.08

**Description**

All mutation types have a mutation_rate, which controls the number of mutations performed. For replace-uniform and all the offset-* types, the number of mutations performed is the product of mutation_rate and population_size. For bit_random, it’s the product of the mutation_rate, number of design variables, and population size.

**seed**

- Keywords Area
- method
- soga
- seed

Seed of the random number generator

**Specification**

Alias: none  
Argument(s): INTEGER  
Default: system-generated (non-repeatable)

**Description**

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

**Default Behavior**

- If not specified, the seed is randomly generated.

**Expected Output**

- If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.
Usage Tips
If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347

linear_inequality_constraint_matrix

- Keywords Area
- method
- soga
- linear_inequality_constraint_matrix

Define coefficients of the linear inequality constraints

Topics
This keyword is related to the topics:
- linear_constraints

Specification
Alias: none
Argument(s): REALLIST
Default: no linear inequality constraints

Description
In the inequality case, the constraint matrix $A$ provides coefficients for the variables in the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where the bounds are optionally specified by linear_inequality_lower_bounds, and linear_inequality_upper_bounds. The bounds, if not specified, will default to -infinity, and 0, respectively, resulting in one-sided inequalities of the form

$$Ax \leq 0.0$$
Define lower bounds for the linear inequality constraint

**Topics**

This keyword is related to the topics:

- `linear_constraints`

**Specification**

**Alias:** none  
**Argument(s):** `REALLIST`  
**Default:** vector values = -infinity

**Description**

In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where $A$ is the constrain matrix of variable coefficients. As with nonlinear inequality constraints (see `objective_functions`), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$Ax \leq 0.0$$

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than `+bigRealBoundSize` (i.e. 30, as defined in Minimizer) are treated as +infinity and any lower bound values less than `-bigRealBoundSize` are treated as -infinity.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since $-DBL_{MAX} < -bigRealBoundSize$).

Define upper bounds for the linear inequality constraint
Topics
This keyword is related to the topics:

- linear_constraints

Specification
Alias: none
Argument(s): REALLIST
Default: vector values = 0.

Description
In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where $A$ is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see objective functions), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$Ax \leq 0.0$$

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than $+\text{bigRealBoundSize}$ ($1.e+30$, as defined in Minimizer) are treated as $+\text{infinity}$ and any lower bound values less than $-\text{bigRealBoundSize}$ are treated as $-\text{infinity}$.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since $-\text{DBL_MAX} < -\text{bigRealBoundSize}$).

linear_inequality_scale_types

- Keywords Area
- method
- soga
- linear_inequality_scale_types

Specify how each linear inequality constraint is scaled

Topics
This keyword is related to the topics:

- linear_constraints

Specification
Alias: none
Argument(s): STRINGLIST
Default: vector values = 'none'
6.2. METHOD

Description

`linear_inequality_scale_types` provide strings specifying the scaling type for each linear inequality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:
- `'none'` - no scaling
- `'value'` - characteristic value if this is chosen, then `linear_inequality_scales` must be specified
- `'auto'` - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables \( x \):

\[
\tilde{x}^j = \frac{x^j - x^j_\Omega}{x^j_M}
\]

we have the following system for linear inequality constraints

\[
a_L \leq A_i x \leq a_U
\]

\[
a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U
\]

\[
a_L - A_i x_O \leq A_i(\text{diag}(x_M)\tilde{x}) \leq a_U - A_i x_O
\]

\[
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

`linear_inequality_scales`

- **Keywords Area**
- **method**
- **soga**
- **linear_inequality_scales**

Define the characteristic values to scale linear inequalities

**Topics**

This keyword is related to the topics:

- **linear_constraints**

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Default:** vector values = 1. (no scaling)
CHAPTER 6. KEYWORDS AREA

Description

Each entry in `linear_inequality_scales` may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

Behavior depends on the choice of `linear_inequality_scale_type`:

- `scale_type` - behavior of `linear_inequality_scales`
- `'none'` - ignored
- `'value'` - required
- `'auto'` - optional

If a single real value is specified it will apply to all components of the constraint.

Scaling for linear constraints is applied after any continuous variable scaling. For example, for variable scaling on continuous design variables $x$:

$$\tilde{x}^j \equiv \frac{x^j - x^j_O}{x^j_M}$$

we have the following system for linear inequality constraints

$$a_L \leq A_i \tilde{x} \leq a_U$$
$$a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U$$
$$a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O$$
$$\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U$$

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

**linear_equality_constraint_matrix**

- Keywords Area
- method
- soga
- `linear_equality_constraint_matrix`

Define coefficients of the linear equalities

Topics

This keyword is related to the topics:

- `linear_constraints`

Specification

Alias: none

- model_pointer

Identifier for model block to be used by a method

Topics
This keyword is related to the topics:

- block_pointer
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The \texttt{model_pointer} is used to specify which \texttt{model} block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a \texttt{model} block in the Dakota input file that has a corresponding \texttt{id_model} with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a \texttt{model-pointer} for each method is imperative.

See \texttt{block_pointer} for details about pointers.

Examples

\begin{verbatim}

|            |                      |                 | Set the factor by which a search pattern can be expanded |
### Description

Pattern search techniques are nongradient-based optimization methods which use a set of offsets from the current iterate to locate improved points in the design space.

See the page package_scolib for important information regarding all SCOLIB methods.
Traditional pattern search methods search with a fixed pattern of search directions to try to find improvements to the current iterate. The SCOLIB pattern search methods generalize this simple algorithmic strategy to enable control of how the search pattern is adapted, as well as how each search pattern is evaluated. The stochastic and synchronization specifications denote how the the trial points are evaluated. The stochastic specification indicates that the trial points are considered in a random order. For parallel pattern search, synchronization dictates whether the evaluations are scheduled using a blocking scheduler or a nonblocking scheduler. In the blocking case, all points in the pattern are evaluated (in parallel), and if the best of these trial points is an improving point, then it becomes the next iterate. These runs are reproducible, assuming use of the same seed in the stochastic case. In the nonblocking case, all points in the pattern may not be evaluated, since the first improving point found becomes the next iterate. Since the algorithm steps will be subject to parallel timing variabilities, these runs will not generally be repeatable. The synchronization specification has similar connotations for sequential pattern search. If blocking is specified, then each sequential iteration terminates after all trial points have been considered, and if nonblocking is specified, then each sequential iteration terminates after the first improving trial point is evaluated. In this release, both blocking and nonblocking specifications result in blocking behavior (except in the case where exploratory_moves below is set to adaptive_pattern). Nonblocking behavior will be re-enabled after some underlying technical issues have been resolved.

The particular form of the search pattern is controlled by the pattern_basis specification. If pattern_basis is coordinate basis, then the pattern search uses a plus and minus offset in each coordinate direction, for a total of $2n$ function evaluations in the pattern. This case is depicted in Figure 5.3 for three coordinate dimensions.
If `pattern_basis` is `simplex`, then pattern search uses a minimal positive basis simplex for the parameter space, for a total of $n+1$ function evaluations in the pattern. Note that the `simplex` pattern basis can be used for unbounded problems only. The `total_pattern_size` specification can be used to augment the basic coordinate and `simplex` patterns with additional function evaluations, and is particularly useful for parallel load balancing. For example, if some function evaluations in the pattern are dropped due to duplication or bound constraint interaction, then the `total_pattern_size` specification instructs the algorithm to generate new offsets to bring the total number of evaluations up to this consistent total.

The `exploratory_moves` specification controls how the search pattern is adapted. (The search pattern can be adapted after an improving trial point is found, or after all trial points in a search pattern have been found to be unimproving points.) The following exploratory moves selections are supported by SCOLIB:

- **The basic_pattern case** is the simple pattern search approach, which uses the same pattern in each iteration.

- **The multi_step case** examines each trial step in the pattern in turn. If a successful step is found, the pattern search continues examining trial steps about this new point. In this manner, the effects of multiple successful steps are cumulative within a single iteration. This option does not support any parallelism and will result in a serial pattern search.

- **The adaptive_pattern case** invokes a pattern search technique that adaptively rescales the different search directions to maximize the number of redundant function evaluations. See[45] for details of this
6.2. METHOD

In preliminary experiments, this method had more robust performance than the standard basic_pattern case in serial tests. This option supports a limited degree of parallelism. After successful iterations (where the step length is not contracted), a parallel search will be performed. After unsuccessful iterations (where the step length is contracted), only a single evaluation is performed.

The initial_delta and threshold_delta specifications provide the initial offset size and the threshold size at which to terminate the algorithm. For any dimension that has both upper and lower bounds, this step length will be internally rescaled to provide search steps of length initial_delta * range * 0.1. This rescaling does not occur for other dimensions, so search steps in those directions have length initial_delta. Note that the factor of 0.1 in the rescaling could result in an undesirably small initial step. This can be offset by providing a large initial_delta.

In general, pattern search methods can expand and contract their step lengths. SCOLIB pattern search methods contract the step length by the value contraction_factor, and they expand the step length by the value (1/contraction_factor). The expand_after_success control specifies how many successful objective function improvements must occur with a specific step length prior to expansion of the step length, whereas the no_expansion flag instructs the algorithm to forgo pattern expansion altogether.

Finally, constraint infeasibility can be managed in a somewhat more sophisticated manner than the simple weighted penalty function. If the constant_penalty specification is used, then the simple weighted penalty scheme described above is used. Otherwise, the constraint penalty is adapted to the value constraint_penalty/L, where L is the the smallest step length used so far.

CHAPTER 6. KEYWORDS AREA

Description

Finally, constraint infeasibility can be managed in a somewhat more sophisticated manner than the simple weighted penalty function. If the constant_penalty specification is used, then the simple weighted penalty scheme described above is used. Otherwise, the constraint penalty is adapted to the value constraint_penalty/L, where L is the smallest step length used so far.

no_expansion

- Keywords Area
- method
- coliny_pattern_search
- no_expansion

Don’t allow expansion of the search pattern

Specification

Alias: none
Argument(s): none
Default: algorithm may expand pattern size

Description

In general, pattern search methods can expand and contract their step lengths. SCOLIB pattern search methods contract the step length by the value contraction_factor, and they expand the step length by the value (1/contraction_factor). The expand_after_success control specifies how many successful objective function improvements must occur with a specific step length prior to expansion of the step length, whereas the no_-expansion flag instructs the algorithm to forgo pattern expansion altogether.

expand_after_success

- Keywords Area
- method
- coliny_pattern_search
- expand_after_success

Set the factor by which a search pattern can be expanded

Specification

Alias: none
Argument(s): INTEGER
Default: 5
6.2. **METHOD**

### Description

In general, pattern search methods can expand and contract their step lengths. SCOLIB pattern search methods contract the step length by the value \texttt{contraction\_factor}, and they expand the step length by the value \((1/\texttt{contraction\_factor})\). The \texttt{expand\_after\_success} control specifies how many successful objective function improvements must occur with a specific step length prior to expansion of the step length, whereas the \texttt{no\_expansion} flag instructs the algorithm to forgo pattern expansion altogether.

**pattern\_basis**

- **Keywords Area**
- **method**
- **coliny\_pattern\_search**
- **pattern\_basis**

Pattern basis selection

### Specification

**Alias:** none

**Argument(s):** none

**Default:** coordinate

<table>
<thead>

<td></td>
<td></td>
<td>Use coordinate directions as search pattern</td>
</tr>
<tr>
<td><strong>simplex</strong></td>
<td></td>
<td></td>
<td>Use a minimal simplex for the search pattern</td>
</tr>
</tbody>
</table>

**Description**

The particular form of the search pattern is controlled by the \texttt{pattern\_basis} specification. If \texttt{pattern\_basis} is \texttt{coordinate} basis, then the pattern search uses a plus and minus offset in each coordinate direction, for a total of \(2n\) function evaluations in the pattern. This case is depicted in Figure 5.3 for three coordinate dimensions.

**coordinate**

- **Keywords Area**
- **method**
- **coliny\_pattern\_search**
- **pattern\_basis**
- **coordinate**

Use coordinate directions as search pattern
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none

Argument(s): none

Description

The particular form of the search pattern is controlled by the pattern_basis specification. If pattern_basis is coordinate basis, then the pattern search uses a plus and minus offset in each coordinate direction, for a total of $2n$ function evaluations in the pattern. This case is depicted in Figure 5.3 for three coordinate dimensions.

simplex

- Keywords Area
- method
- coliny_pattern_search
- pattern_basis
- simplex

Use a minimal simplex for the search pattern

Specification

Alias: none

Argument(s): none

Description

If pattern_basis is simplex, then pattern search uses a minimal positive basis simplex for the parameter space, for a total of $n+1$ function evaluations in the pattern. Note that the simplex pattern basis can be used for unbounded problems only. The total_pattern_size specification can be used to augment the basic coordinate and simplex patterns with additional function evaluations, and is particularly useful for parallel load balancing. For example, if some function evaluations in the pattern are dropped due to duplication or bound constraint interaction, then the total_pattern_size specification instructs the algorithm to generate new offsets to bring the total number of evaluations up to this consistent total.

stochastic

- Keywords Area
- method
- coliny_pattern_search
- stochastic

Generate trial points in random order
6.2. METHOD

Specification

Alias: none
Argument(s): none

Description

Traditional pattern search methods search with a fixed pattern of search directions to try to find improvements to the current iterate. The SCOLIB pattern search methods generalize this simple algorithmic strategy to enable control of how the search pattern is adapted, as well as how each search pattern is evaluated. The stochastic and synchronization specifications denote how the trial points are evaluated. The stochastic specification indicates that the trial points are considered in a random order. For parallel pattern search, synchronization dictates whether the evaluations are scheduled using a blocking scheduler or a nonblocking scheduler (i.e.,

\textbf{total\_pattern\_size}

- Keywords Area
- \textbf{method}
- \textbf{coliny\_pattern\_search}
- \textbf{total\_pattern\_size}

Total number of points in search pattern

 Specification

Alias: none
Argument(s): INTEGER
Default: no augmentation of basic pattern

Description

If \textit{pattern\_basis} is simplex, then pattern search uses a minimal positive basis simplex for the parameter space, for a total of \(n+1\) function evaluations in the pattern. Note that the simplex pattern basis can be used for unbounded problems only. The total\_pattern\_size specification can be used to augment the basic coordinate and simplex patterns with additional function evaluations, and is particularly useful for parallel load balancing. For example, if some function evaluations in the pattern are dropped due to duplication or bound constraint interaction, then the total\_pattern\_size specification instructs the algorithm to generate new offsets to bring the total number of evaluations up to this consistent total.

exploratory\_moves

- Keywords Area
- \textbf{method}
- \textbf{coliny\_pattern\_search}
- \textbf{exploratory\_moves}

Exploratory moves selection
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none
Argument(s): none
Default: basic_pattern

<table>
<thead>
<tr>
<th>Required/-Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required(Choose One)</td>
<td></td>
<td>multi_step</td>
<td>Examine trial step around successful new point</td>
</tr>
<tr>
<td></td>
<td></td>
<td>adaptive_pattern</td>
<td>Adaptively rescale search directions</td>
</tr>
<tr>
<td></td>
<td></td>
<td>basic_pattern</td>
<td>Use the same search pattern every iteration</td>
</tr>
</tbody>
</table>

Description

The **exploratory_moves** specification controls how the search pattern is adapted. (The search pattern can be adapted after an improving trial point is found, or after all trial points in a search pattern have been found to be unimproving points.) The following exploratory moves selections are supported by SCOLIB:

**multi_step**

- **Keywords Area**
- **method**
- **coliny_pattern_search**
- **exploratory_moves**
- **multi_step**

Examine trial step around successful new point

Specification

Alias: none
Argument(s): none

Description

The **multi_step** case examines each trial step in the pattern in turn. If a successful step is found, the pattern search continues examining trial steps about this new point. In this manner, the effects of multiple successful steps are cumulative within a single iteration. This option does not support any parallelism and will result in a serial pattern.
6.2. METHOD

adaptive_pattern

- Keywords Area
- method
- coliny_pattern_search
- exploratory_moves
- adaptive_pattern

Adaptively rescale search directions

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The adaptive_pattern case invokes a pattern search technique that adaptively rescales the different search directions to maximize the number of redundant function evaluations. See [45] for details of this method. In preliminary experiments, this method had more robust performance than the standard basic_pattern case in serial tests. This option supports a limited degree of parallelism. After successful iterations (where the step length is not contracted), a parallel search will be performed. After unsuccessful iterations (where the step length is contracted), only a single evaluation is performed.

basic_pattern

- Keywords Area
- method
- coliny_pattern_search
- exploratory_moves
- basic_pattern

Use the same search pattern every iteration

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The basic_pattern case is the simple pattern search approach, which uses the same pattern in each iteration.
synchronization

- Keywords Area
- method
- coliny_pattern_search
- synchronization

Select how Dakota schedules function evaluations in a pattern search

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** nonblocking

<table>
<thead>
<tr>
<th>Required/Optional Required (Choose One)</th>
<th>Description of Group Group 1</th>
<th>Dakota Keyword blocking</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>nonblocking</td>
<td>Evaluate points in the pattern until an improving point is found</td>
</tr>
</tbody>
</table>

**Description**

The synchronization specification can be used to specify the use of either blocking or nonblocking schedulers.

**blocking**

- Keywords Area
- method
- coliny_pattern_search
- synchronization
- blocking

Evaluate all points in a pattern

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

In the blocking case, all points in the pattern are evaluated (in parallel), and if the best of these trial points is an improving point, then it becomes the next iterate. These runs are reproducible, assuming use of the same seed in the stochastic case.
6.2. **METHOD**

**nonblocking**

- Keywords Area
- method
- coliny_pattern_search
- synchronization
- nonblocking

Evaluate points in the pattern until an improving point is found

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

In the nonblocking case, all points in the pattern may not be evaluated. The first improving point found becomes the next iterate. Since the algorithm steps will be subject to parallel timing variabilities, these runs will not generally be repeatable.

**contraction_factor**

- Keywords Area
- method
- coliny_pattern_search
- contraction_factor

Amount by which step length is rescaled

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 0.5

**Description**

For pattern search methods, contraction_factor specifies the amount by which step length is rescaled after unsuccessful iterates, must be strictly between 0 and 1.

For methods that can expand the step length, the expansion is \(1/\text{contraction\_factor}\)
CHAPTER 6. KEYWORDS AREA

constraint_penalty

- Keywords Area
- method
- coliny_pattern_search
- constraint_penalty

Multiplier for the penalty function

**Specification**

Alias: none

Argument(s): REAL

Default: 1.0

**Description**

Most SCOLIB optimizers treat constraints with a simple penalty scheme that adds `constraint_penalty` times the sum of squares of the constraint violations to the objective function. The default value of `constraint_penalty` is 1000.0, except for methods that dynamically adapt their constraint penalty, for which the default value is 1.0.

initial_delta

- Keywords Area
- method
- coliny_pattern_search
- initial_delta

Initial step size for non-gradient based optimizers

**Specification**

Alias: none

Argument(s): REAL

Default: 1.0 (COBYLA), 0.1*range (PS, SW)

**Description**

If `initial_delta` is supplied by the user, it will be applied in an absolute sense in all coordinate directions. APPS documentation advocates choosing `initial_delta` to be the approximate distance from the initial point to the solution. If this is unknown, it is advisable to err on the side of choosing an `initial_delta` that is too large or to not specify it. In the latter case, APPS will take a full step to the boundary in each direction. Relative application of `initial_delta` is not available unless the user scales the problem accordingly.
6.2. METHOD

threshold_delta

- Keywords Area
- method
- coliny_pattern_search
- threshold_delta

Stopping criteria based on step length or pattern size

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 1.0e-4 (COBYLA), 1.0e-5 (PS), 1.0e-6 (SW)

**Description**

*threshold_delta* is the step length or pattern size used to determine convergence.

**solution_target**

- Keywords Area
- method
- coliny_pattern_search
- solution_target

Stopping criteria based on objective function value

**Specification**

**Alias:** solution_accuracy

**Argument(s):** REAL

**Default:** -DBL_MAX

**Description**

*solution_target* is a termination criterion. The algorithm will terminate when the function value falls below *solution_target*.

**seed**

- Keywords Area
- method
- coliny_pattern_search
- seed

Seed of the random number generator
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none
Argument(s): INTEGER
Default: system-generated (non-repeatable)

Description

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior
If not specified, the seed is randomly generated.

Expected Output
If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips
If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

```
show_m misc_options
```

• Keywords Area
• method
• coliny_pattern_search
• show_m misc_options

Show algorithm parameters not exposed in Dakota input

Specification

Alias: none
Argument(s): none
Default: no dump of specification options

Description

All SCOLIB methods support the show_m misc_options optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The misc_options optional specification provides a means for inputting additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using
this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

**misc_options**

- Keywords Area
- method
- coliny_pattern_search
- misc_options

Set method options not available through Dakota spec

**Specification**

**Alias:** none

**Argument(s):** STRINGLIST

**Default:** no misc options

**Description**

All SCOLIB methods support the `show_misc_options` optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The `misc_options` optional specification provides a means for inputing additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

**model_pointer**

- Keywords Area
- method
- coliny_pattern_search
- model_pointer

Identifier for model block to be used by a method

**Topics**

This keyword is related to the topics:

- block_pointer
CHAPTER 6. KEYWORDS AREA

Specification

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)

Description

The *model_pointer* is used to specify which *model* block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a *model* block in the Dakota input file that has a corresponding *id_model* with the same name.

**Usage Tips**

When doing advanced analyses that involve using multiple methods and multiple models, defining a *model-pointer* for each method is imperative.

See *block_pointer* for details about pointers.

Examples

```
environment
  tabular_graphics_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10

## Description

The Solis-Wets method is a simple greedy local search heuristic for continuous parameter spaces. Solis-Wets generates trial points using a multivariate normal distribution, and unsuccessful trial points are reflected about the current point to find a descent direction.

See the page package\_scolib for important information regarding all SCOLIB methods

Coliny\_solis\_wets is inherently serial, no concurrency is used.

These specifications have the same meaning as corresponding specifications for Coliny\_pattern\_search. Please see that page for specification details.

In particular, coliny\_solis\_wets supports dynamic rescaling of the step length, and dynamic rescaling of the constraint penalty. The only new specification is contract\_after\_failure, which specifies the number of unsuccessful cycles which must occur with a specific delta prior to contraction of the delta.

contract_after_failure

- Keywords Area
- method
- coliny_solis_wets
- contract_after_failure

The number of unsuccessful cycles prior to contraction.

Specification

Alias: none
  Argument(s): INTEGER
  Default: 4*number of variables

Description

In particular, coliny_solis_wets supports dynamic rescaling of the step length, and dynamic rescaling of the constraint penalty. The only new specification is contract_after_failure, which specifies the number of unsuccessful cycles which must occur with a specific delta prior to contraction of the delta.

no_expansion

- Keywords Area
- method
- coliny_solis_wets
- no_expansion

Don’t allow expansion of the search pattern

Specification

Alias: none
  Argument(s): none
  Default: algorithm may expand pattern size
Description

In general, pattern search methods can expand and contract their step lengths. SCOLIB pattern search methods contract the step length by the value $\text{contraction\_factor}$, and they expand the step length by the value $(1/\text{contraction\_factor})$. The $\text{expand\_after\_success}$ control specifies how many successful objective function improvements must occur with a specific step length prior to expansion of the step length, whereas the $\text{no\_expansion}$ flag instructs the algorithm to forgo pattern expansion altogether.

$\text{expand\_after\_success}$

- Keywords Area
- method

Description
The Constrained Optimization BY Linear Approximations (COBYLA) algorithm is an extension to the Nelder-Mead simplex algorithm for handling general linear/nonlinear constraints and is invoked using the coliny_cobyla group specification. The COBYLA algorithm employs linear approximations to the objective and constraint functions, the approximations being formed by linear interpolation at N+1 points in the space of the variables. We regard these interpolation points as vertices of a simplex. The step length parameter controls the size of the simplex and it is reduced automatically from initial_delta to threshold_delta. One advantage
that COBYLA has over many of its competitors is that it treats each constraint individually when calculating a
change to the variables, instead of lumping the constraints together into a single penalty function.

See the page `package_scilab` for important information regarding all SCOLIB methods

`coliny_cobyla` is inherently serial.

Stopping Criteria

DIRECT can be terminated with:

- `max_function_evaluations`
- `solution_target`

COBYLA currently only supports termination based on the `max_function_evaluations` and `solution_target` specifications.

See Also

These keywords may also be of interest:

- `coliny_beta`
- `coliny_direct`
- `coliny_pattern_search`
- `coliny_ea`
- `coliny_solis_wets`

**initial_delta**

- Keywords Area
- `method`
- `coliny_cobyla`
- `initial_delta`

Initial step size for non-gradient based optimizers

**Specification**

Alias: none

**Argument(s):** REAL

**Default:** 1.0 (COBYLA), 0.1 *range (PS, SW)*

**Description**

If `initial_delta` is supplied by the user, it will be applied in an absolute sense in all coordinate directions. APPS documentation advocates choosing `initial_delta` to be the approximate distance from the initial point to the solution. If this is unknown, it is advisable to err on the side of choosing an `initial_delta` that is too large or to not specify it. In the latter case, APPS will take a full step to the boundary in each direction. Relative application of `initial_delta` is not available unless the user scales the problem accordingly.
threshold_delta

- Keywords Area
- method
- coliny_cobyla
- threshold_delta

Stopping criteria based on step length or pattern size

**Specification**

**Alias:** none  
**Argument(s):** REAL  
**Default:** 1.0e-4 (COBYLA), 1.0e-5 (PS), 1.0e-6 (SW)

**Description**

threshold_delta is the step length or pattern size used to determine convergence.

solution_target

- Keywords Area
- method
- coliny_cobyla
- solution_target

Stopping criteria based on objective function value

**Specification**

**Alias:** solution_accuracy  
**Argument(s):** REAL  
**Default:** -DBL_MAX

**Description**

solution_target is a termination criterion. The algorithm will terminate when the function value falls below solution_target.

seed

- Keywords Area
- method
- coliny_cobyla
- seed

Seed of the random number generator
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)

Description

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior
If not specified, the seed is randomly generated.

Expected Output
If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips
If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method sampling
  sample_type lhs
  samples = 10
  seed = 15347

show_misc_options
```

- Keywords Area
- method
- coliny_cobyla
- show_misc_options

Show algorithm parameters not exposed in Dakota input

Specification

Alias: none

Argument(s): none

Default: no dump of specification options

Description

All SCOLIB methods support the show_misc_options optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The misc_options optional specification provides a means for inputing additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using
this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

**misc_options**

This keyword is related to the topics:

- **block_pointer**
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model-pointer for each method is imperative.

See block_pointer for details about pointers.

</tbody>
</table>
## Description

The DIviding RECTangles (DIRECT) optimization algorithm is a derivative free global optimization method that balances local search in promising regions of the design space with global search in unexplored regions. As shown in Figure 5.1, DIRECT adaptively subdivides the space of feasible design points so as to guarantee that iterates are generated in the neighborhood of a global minimum in finitely many iterations.

![Design space partitioning with DIRECT](latexit direct1.eps)

In practice, DIRECT has proven an effective heuristic for engineering design applications, for which it is able to quickly identify candidate solutions that can be further refined with fast local optimizers.

See the page package_scolib for important information regarding all SCOLIB methods.

The DIRECT algorithm supports concurrency up to twice the number of variables being optimized.

DIRECT uses the `solution_target`, `constraint_penalty` and `show_misc_options` specifications that are described in package_scolib. Note, however, that DIRECT uses a fixed penalty value for constraint violations (i.e. it is not dynamically adapted as is done in coliny_pattern_search).

### Search Parameters

The `global_balance` parameter controls how much global search is performed by only allowing a subregion to be subdivided if the size of the subregion divided by the size of the largest subregion is at least `global_balance`. Intuitively, this forces large subregions to be subdivided before the smallest subregions are refined. The `local_balance` provides a tolerance for estimating whether the smallest subregion can provide a sufficient decrease to be worth subdividing; the default value is a small value that is suitable for most applications.

Tolerance for whether a subregion is worth dividing

**Specification**

Alias: none

Argument(s): REAL
Default: 0.0

**Description**

The `global_balance_parameter` controls how much global search is performed by only allowing a subregion to be subdivided if the size of the subregion divided by the size of the largest subregion is at least `global_balance_parameter`. Intuitively, this forces large subregions to be subdivided before the smallest subregions are refined.

**local_balance_parameter**

- **Keywords Area**
- **Method**
- **coliny_direct**
- **local_balance_parameter**

Tolerance for whether a subregion is worth dividing

**Specification**

Alias: none

Argument(s): REAL
Default: 1.e-8

**Description**

See parent page. The `local_balance_parameter` provides a tolerance for estimating whether the smallest subregion can provide a sufficient decrease to be worth subdividing; the default value is a small value that is suitable for most applications.
max_boxsize_limit

- Keywords Area
- method
- coliny_direct
- max_boxsize_limit

Stopping Criterion based on longest edge of hyperrectangle

**Specification**

**Alias:** none

**Argument(s):** REAL  
**Default:** 0.0

**Description**

Each subregion considered by DIRECT has a size, which corresponds to the longest diagonal of the subregion. 

The `max_boxsize_limit` specification terminates DIRECT if the size of the largest subregion falls below this threshold.

min_boxsize_limit

- Keywords Area
- method
- coliny_direct
- min_boxsize_limit

Stopping Criterion based on shortest edge of hyperrectangle

**Specification**

**Alias:** none

**Argument(s):** REAL  
**Default:** 1.0e-4

**Description**

`min_boxsize_limit` is a setting that terminates the optimization when the measure of a hyperrectangle S with f(c(S)) = fmin is less than min_boxsize_limit. 

Each subregion considered by DIRECT has a size, which corresponds to the longest diagonal of the subregion. 

The `min_boxsize_limit` specification terminates DIRECT if the size of the smallest subregion falls below this threshold. 

In practice, this specification is likely to be more effective at limiting DIRECT’s search.
6.2. METHOD

constraint_penalty

- Keywords Area
- method
- coliny_direct
- constraint_penalty

Multiplier for the penalty function

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 1000.0

**Description**

Most SCOLIB optimizers treat constraints with a simple penalty scheme that adds `constraint_penalty` times the sum of squares of the constraint violations to the objective function. The default value of `constraint_penalty` is 1000.0, except for methods that dynamically adapt their constraint penalty, for which the default value is 1.0.

solution_target

- Keywords Area
- method
- coliny_direct
- solution_target

Stopping criteria based on objective function value

**Specification**

**Alias:** solution_accuracy

**Argument(s):** REAL

**Default:** -DBL_MAX

**Description**

`solution_target` is a termination criterion. The algorithm will terminate when the function value falls below `solution_target`. 
seed

### Description

Evolutionary Algorithm

*See the page `package_scolib` for important information regarding all SCOLIB methods*

*coliny_pattern_search* supports concurrency up to the size of the population

The random seed control provides a mechanism for making a stochastic optimization repeatable. That is, the use of the same random seed in identical studies will generate identical results. The population size control specifies how many individuals will comprise the EA's population.

The initialization type defines the type of initialization for the population of the EA. There are three types: *simple_random*, *unique_random*, and *flat_file*. *simple_random* creates initial solutions with

random variable values according to a uniform random number distribution. It gives no consideration to any previously generated designs. The number of designs is specified by the population_size. unique_random is the same as simple_random, except that when a new solution is generated, it is checked against the rest of the solutions. If it duplicates any of them, it is rejected. flat_file allows the initial population to be read from a flat file. If flat_file is specified, a file name must be given.

The fitness_type controls how strongly differences in "fitness" (i.e., the objective function) are weighted in the process of selecting "parents" for crossover:

- the linear_rank setting uses a linear scaling of probability of selection based on the rank order of each individual’s objective function within the population
- the merit_function setting uses a proportional scaling of probability of selection based on the relative value of each individual’s objective function within the population

The replacement_type controls how current populations and newly generated individuals are combined to create a new population. Each of the replacement_type selections accepts an integer value, which is referred to below as the replacement_size.

- The random setting creates a new population using (a) replacement_size randomly selected individuals from the current population, and (b) population_size - replacement_size individuals randomly selected from among the newly generated individuals (the number of which is optionally specified using new_solutions_generated) that are created for each generation (using the selection, crossover, and mutation procedures).

- The chc setting creates a new population using (a) the replacement_size best individuals from the combination of the current population and the newly generated individuals, and (b) population_size - replacement_size individuals randomly selected from among the remaining individuals in this combined pool. The chc setting is the preferred selection for many engineering problems.

- The elitist (default) setting creates a new population using (a) the replacement_size best individuals from the current population, (b) and population_size - replacement_size individuals randomly selected from the newly generated individuals. It is possible in this case to lose a good solution from the newly generated individuals if it is not randomly selected for replacement; however, the default new_solutions_generated value is set such that the entire set of newly generated individuals will be selected for replacement.

Note that new_solutions_generated is not recognized by Dakota as a valid keyword unless replacement_type has been specified.

Theory

The basic steps of an evolutionary algorithm are depicted in Figure 5.2.
They can be enumerated as follows:

1. Select an initial population randomly and perform function evaluations on these individuals
2. Perform selection for parents based on relative fitness
3. Apply crossover and mutation to generate new solutions generated new individuals from the selected parents
   - Apply crossover with a fixed probability from two selected parents
   - If crossover is applied, apply mutation to the newly generated individual with a fixed probability
   - If crossover is not applied, apply mutation with a fixed probability to a single selected parent
4. Perform function evaluations on the new individuals
5. Perform replacement to determine the new population
6. Return to step 2 and continue the algorithm until convergence criteria are satisfied or iteration limits are exceeded

<td>simple_random</td>
<td>Create random initial solutions</td>
</tr>
<tr>
<td></td>
<td></td>
<td>unique_random</td>
<td>Create random initial solutions, but enforce uniqueness (default)</td>
</tr>
</tbody>
</table>
Description

The initialization_type defines how the initial population is created for the GA. There are three types:

1. simple_random
2. unique_random (default)
3. flat_file

Setting the size for the flat_file initializer has the effect of requiring a minimum number of designs to create. If this minimum number has not been created once the files are all read, the rest are created using the unique_random initializer and then the simple_random initializer if necessary.

simple_random

- method
- coliny_ea
- initialization_type
- unique_random

Create random initial solutions, but enforce uniqueness (default)
6.2. **METHOD**

**Specification**

*Alias:* none
  *Argument(s):* none

**Description**

*unique_random* is the same as *simple_random*, except that when a new solution is generated, it is checked against the rest of the solutions. If it duplicates any of them, it is rejected.

**flat_file**

*Keywords Area*
  *method*
  *coliny_ea*
  *initialization_type*
  *flat_file*

Read initial solutions from file

**Specification**

*Alias:* none
  *Argument(s):* STRING

**Description**

*flat_file* allows the initial population to be read from a flat file. If *flat_file* is specified, a file name must be given.

**fitness_type**

*Keywords Area*
  *method*
  *coliny_ea*
  *fitness_type*

Select fitness type

**Specification**

*Alias:* none
  *Argument(s):* none
  *Default:* linear_rank

</tr>
</tbody>
</table>

Description

The **fitness_type** controls how strongly differences in “fitness” (i.e., the objective function) are weighted in the process of selecting "parents" for crossover. It has two options, `linear_rank` and `merit_function`.

**linear_rank**

- **Keywords Area**
- **method**
- **coliny_ea**
- **fitness_type**
- **linear_rank**

Set selection scaling

**Specification**

**Alias**: none

**Argument(s)**: none

**Description**

The **linear_rank** setting uses a linear scaling of probability of selection based on the rank order of each individual’s objective function within the population.

**merit_function**

- **Keywords Area**
- **method**
- **coliny_ea**
- **fitness_type**
- **merit_function**

Balance goals of reducing objective function and satisfying constraints
6.2. METHOD

Specification

Alias: none
Argument(s): none

Description

A merit function is a function in constrained optimization that attempts to provide joint progress toward reducing the objective function and satisfying the constraints.

replacement_type

- Keywords Area
- method
- coliny_ea
- replacement_type

Select a replacement type for SCOLIB evolutionary algorithm (coliny_ea)

Specification

Alias: none
Argument(s): none
Default: elitist=1

<table>
<thead>

<td>Use the best designs to form a new population</td>
<td></td>
</tr>
<tr>
<td>Optional</td>
<td>new_solutions_generated</td>
<td>Replace population with individuals chosen from population</td>
<td></td>
</tr>
</tbody>
</table>

Description

The replacement_type controls how current populations and newly generated individuals are combined to create a new population. Each of the replacement_type selections accepts an associated integer value, which is specified by the replacement_size:

The random setting creates a new population using (a) replacement_size randomly selected individuals from the current population, and (b) population_size - replacement_size individuals randomly
selected from among the newly generated individuals (the number of which is optionally specified using `new_solutions_generated`) that are created for each generation (using the selection, crossover, and mutation procedures).

The chc setting creates a new population using (a) the `replacement_size` best individuals from the combination of the current population and the newly generated individuals, and (b) `population_size` - `replacement_size` individuals randomly selected from among the remaining individuals in this combined pool. The chc setting is the preferred selection for many engineering problems.

The elitist (default) setting creates a new population using (a) the `replacement_size` best individuals from the current population, (b) and `population_size` - `replacement_size` individuals randomly selected from the newly generated individuals. It is possible in this case to lose a good solution from the newly generated individuals if it is not randomly selected for replacement; however, the default `new_solutions_generated` value is set such that the entire set of newly generated individuals will be selected for replacement.

Note that `new_solutions_generated` is not recognized by Dakota as a valid keyword unless `replacement_type` has been specified.

random

- Keywords Area
- method
- coliny_ea
- replacement_type
- random

Create new population randomly

Specification

Alias: none

Argument(s): INTEGER

Description

The `replacement_type` controls how current populations and newly generated individuals are combined to create a new population. Each of the `replacement_type` selections accepts an integer value, which is referred as the `replacement_size`:

The random setting creates a new population using:

- `replacement_size` randomly selected individuals from the current population, and
- `population_size` - `replacement_size` individuals randomly selected from among the newly generated individuals (the number of which is optionally specified using `new_solutions_generated`) that are created for each generation (using the selection, crossover, and mutation procedures).
6.2. METHOD

- coliny_ea
- replacement_type
- chc

Create new population using replacement

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Description**

The `replacement_type` controls how current populations and newly generated individuals are combined to create a new population. Each of the `replacement_type` selections accepts an integer value, which is referred to as the `replacement_size`:

The `chc` setting creates a new population using (a) the `replacement_size` best individuals from the combination of the current population and the newly generated individuals, and (b) `population_size - replacement_size` individuals randomly selected from among the remaining individuals in this combined pool. The `chc` setting is the preferred selection for many engineering problems.

**elitist**

- **Keywords Area**

- **coliny_ea**
- **replacement_type**
- **elitist**

Use the best designs to form a new population

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Description**

The `elitist` (default) setting creates a new population using (a) the `replacement_size` best individuals from the current population, (b) and `population_size - replacement_size` individuals randomly selected from the newly generated individuals. It is possible in this case to lose a good solution from the newly generated individuals if it is not randomly selected for replacement; however, the default `new_solutions_generated` value is set such that the entire set of newly generated individuals will be selected for replacement.
new\_solutions\_generated

- Keywords Area
- method
- coliny\_ea
- replacement\_type
- new\_solutions\_generated

Replace population with individuals chosen from population

**Specification**

Alias: none

**Argument(s):** INTEGER

**Default:** population\_size - replacement\_size

**Description**

- The random setting creates a new population using (a) replacement\_size randomly selected individuals from the current population, and (b) population\_size - replacement\_size individuals randomly selected from among the newly generated individuals (the number of which is optionally specified using new\_solutions\_generated) that are created for each generation (using the selection, crossover, and mutation procedures).

crossover\_rate

- Keywords Area
- method
- coliny\_ea
- crossover\_rate

Specify the probability of a crossover event

**Specification**

Alias: none

**Argument(s):** REAL

**Default:** 0.8
6.2. METHOD

Description

The \texttt{crossover\_type} controls what approach is employed for combining parent genetic information to create offspring, and the \texttt{crossover\_rate} specifies the probability of a crossover operation being performed to generate a new offspring. The SCOLIB EA method supports three forms of crossover, \texttt{two\_point}, \texttt{blend}, and \texttt{uniform}, which generate a new individual through combinations of two parent individuals. Two-point crossover divides each parent into three regions, where offspring are created from the combination of the middle region from one parent and the end regions from the other parent. Since the SCOLIB EA does not utilize bit representations of variable values, the crossover points only occur on coordinate boundaries, never within the bits of a particular coordinate. Uniform crossover creates offspring through random combination of coordinates from the two parents. Blend crossover generates a new individual randomly along the multidimensional vector connecting the two parents.

\textbf{crossover\_type}

- Keywords Area
- method
- coliny\_ea
- crossover\_type

Select a crossover type

\textbf{Specification}

\textbf{Alias:} none
\textbf{Argument(s):} none

\textbf{Description}

The \texttt{crossover\_type} controls what approach is employed for combining parent genetic information to create offspring. The SCOLIB EA method supports three forms of crossover, \texttt{two\_point}, \texttt{blend}, and \texttt{uniform}, which generate a new individual through combinations of two parent individuals.

\textbf{two\_point}

- Keywords Area
CHAPTER 6. KEYWORDS AREA

- method
- coliny_ea
- crossover_type
- two_point

Combine middle of one parent with end of another

**Specification**

*Alias*: none

**Argument(s)**: none

**Description**

Two-point crossover divides each parent into three regions, where offspring are created from the combination of the middle region from one parent and the end regions from the other parent. Since the SCOLIB EA does not utilize bit representations of variable values, the crossover points only occur on coordinate boundaries, never within the bits of a particular coordinate.

**blend**

- Keywords Area
- method
- coliny_ea
- crossover_type
- blend

Random blend of parents

**Specification**

*Alias*: none

**Argument(s)**: none

**Description**

blend crossover generates a new individual randomly along the multidimensional vector connecting the two parents.
6.2. METHOD

uniform
- Keywords Area
- method
- coliny_ea
- crossover_type
- uniform

Randomly combine coordinates from parents

Specification

Alias: none
Argument(s): none

Description
Uniform crossover creates offspring through random combination of coordinates from the two parents.

mutation_rate
- Keywords Area
- method
- coliny_ea
- mutation_rate

Set probability of a mutation

Specification

Alias: none
Argument(s): REAL
Default: 1.0

Description
The mutation_rate controls the probability of mutation being performed on an individual, both for new individuals generated by crossover (if crossover occurs) and for individuals from the existing population. It is the fraction of trial points that are mutated in a given iteration and therefore must be specified to be between 0 and 1.

mutation_type
- Keywords Area
- method
- coliny_ea
- mutation_type

Select a mutation type
CHAPTER 6. KEYWORDS AREA

Specification

**Alias:** none  
**Argument(s):** none  
**Default:** offset_normal

<table>
<thead>

<td></td>
<td>offset_uniform</td>
<td>Set mutation offset to use a uniform distribution</td>
</tr>
<tr>
<td><strong>Optional</strong></td>
<td></td>
<td>non_adaptive</td>
<td>Disable self-adaptive mutation</td>
</tr>
</tbody>
</table>

Description

The *mutation_type* controls what approach is employed in randomly modifying continuous design variables within the EA population. Each of the mutation methods generates coordinate-wise changes to individuals, usually by adding a random variable to a given coordinate value (an *offset_* mutation), but also by replacing a given coordinate value with a random variable (a *replace_* mutation).

Discrete design variables are always mutated using the *offset_uniform* method.

**replace_uniform**

- Keywords Area
- method
- coliny_ea
- mutation_type
- replace_uniform

Replace coordinate with randomly generated value

Specification

**Alias:** none  
**Argument(s):** none
Description

The replace_uniform mutation type generates a replacement value for a coordinate using a uniformly distributed value over the total range for that coordinate.

offset_normal

- Keywords Area
- method
- coliny_ea
- mutation_type
- offset_normal

Set mutation offset to use a normal distribution

Specification

Alias: none
Argument(s): none

<table>
<thead>
<tr>

<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>mutation_scale</td>
<td>Scales mutation across range of parameter</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>mutation_range</td>
<td>Set uniform offset control for discrete parameters</td>
</tr>
</tbody>
</table>

Description

The offset_normal type is an "offset" mutation that adds a 0-mean random variable with a normal uniform distribution to the existing coordinate value. The offset is limited in magnitude by mutation_scale.

mutation_scale

- Keywords Area
- method
- coliny_ea
- mutation_type
- offset_normal
- mutation_scale

Scales mutation across range of parameter
CHAPTER 6. KEYWORDS AREA

**Specification**

**Alias:** none  
**Argument(s):** REAL  
**Default:** 0.1

**Description**

The `mutation_scale` specifies a scale factor which scales continuous mutation offsets; this is a fraction of the total range of each dimension, so `mutation_scale` is a relative value between 0 and 1.

**mutation_range**

- Keywords Area
- method
- coliny_ea
- mutation_type
- offset_normal
- mutation_range

Set uniform offset control for discrete parameters

**Specification**

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** 1

**Description**

The `mutation_range` is used to control `offset_uniform` mutation used for discrete parameters. The replacement discrete value is the original value plus or minus an integer value up to `mutation_range`.

**offset_cauchy**

- Keywords Area
- method
- coliny_ea
- mutation_type
- offset_cauchy

Use a Cauchy distribution for the mutation offset

**Specification**

**Alias:** none  
**Argument(s):** none

</tbody>
</table>

Description
The offset_uniform type is an "offset” mutation that adds a 0-mean random variable with a uniform distribution to the existing coordinate value. The offset is limited in magnitude by mutation_scale.

For discrete design variables, offset_uniform is always used, and mutation_range controls the magnitude of the mutation.

mutation_scale
- Keywords Area
- method
- coliny_ea
- mutation_type
6.2. METHOD

- offset_uniform
- mutation_scale

Scales mutation across range of parameter

Specification

Alias: none
Argument(s): REAL
Default: 0.1

Description

The mutation_scale specifies a scale factor which scales continuous mutation offsets; this is a fraction of the total range of each dimension, so mutation_scale is a relative value between 0 and 1.

- mutation_range
- Keywords Area
- method
- coliny_ea
- mutation_type
- offset_uniform
- mutation_range

Set uniform offset control for discrete parameters

Specification

Alias: none
Argument(s): INTEGER
Default: 1

Description

The mutation_range is used to control offset_uniform mutation used for discrete parameters. The replacement discrete value is the original value plus or minus an integer value up to mutation_range.

non_adaptive

- Keywords Area
- method
- coliny_ea
- mutation_type
- non_adaptive

Disable self-adaptive mutation
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none

Argument(s): none

Default: Adaptive mutation

Description

The SCOLIB EA method uses self-adaptive mutation, which modifies the mutation scale dynamically. This mechanism is borrowed from EAs like evolution strategies. The non_adaptive flag can be used to deactivate the self-adaptation, which may facilitate a more global search.

Note that non_adaptive is not recognized by Dakota as a valid keyword unless mutation_type has been specified.

corstraint_penalty

- Keywords Area
- method
- coliny_ea
- constraint_penalty

Multiplier for the penalty function

Specification

Alias: none

Argument(s): REAL

Description

Most SCOLIB optimizers treat constraints with a simple penalty scheme that adds constraint_penalty times the sum of squares of the constraint violations to the objective function. The default value of constraint_penalty is 1000.0, except for methods that dynamically adapt their constraint penalty, for which the default value is 1.0.

solution_target

- Keywords Area
- method
- coliny_ea
- solution_target

Stopping criteria based on objective function value
6.2. METHOD

Specification

Alias: solution_accuracy

Argument(s): REAL

Default: -DBL_MAX

Description

solution_target is a termination criterion. The algorithm will terminate when the function value falls below solution_target.

seed

- Keywords Area

- method

- coliny_ea

- seed

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-replicable)

Description

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

method sampling
  sample_type lhs
  samples = 10
  seed = 15347
show_misc_options

- Keywords Area
- method
- coliny_ea
- show_misc_options

Show algorithm parameters not exposed in Dakota input

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** no dump of specification options

**Description**

All SCOLIB methods support the `show_misc_options` optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The `misc_options` optional specification provides a means for inputing additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

misc_options

- Keywords Area
- method
- coliny_ea
- misc_options

Set method options not available through Dakota spec

**Specification**

**Alias:** none

**Argument(s):** STRINGLIST

**Default:** no misc options
6.2. METHOD

Description

All SCOLIB methods support the show_misc_options optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The misc_options optional specification provides a means for inputting additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

model_pointer

- Keywords Area
- method
- coliny_ea
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model-pointer for each method is imperative.

See block_pointer for details about pointers.

- **block_pointer**

**Specification**

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)

**Description**

The `model_pointer` is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

**Usage Tips**

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

**Examples**

```plaintext
environment
tabular_graphics_data
method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SRR'
  sampling,
  samples = 10
  seed = 98765 rng rnum2

**Description**

NL2SOL is available as *nl2sol* and addresses unconstrained and bound-constrained least squares problems. It uses a trust-region method (and thus can be viewed as a generalization of the Levenberg-Marquardt algorithm) and adaptively chooses between two Hessian approximations, the Gauss-Newton approximation alone and the Gauss-Newton approximation plus a quasi-Newton approximation to the rest of the Hessian. Even on small-residual problems, the latter Hessian approximation can be useful when the starting guess is far from the solution. On problems that are not over-parameterized (i.e., that do not involve more optimization variables than the data support), NL2SOL usually exhibits fast convergence.

Several internal NL2SOL convergence tolerances are adjusted in response to `function_precision`, which gives the relative precision to which responses are computed.

These tolerances may also be specified explicitly using:

- `convergence_tolerance (NL2SOL's rfctol)`
- `x_conv.tol (NL2SOL's xctol)`
- `absolute_conv_tol (NL2SOL's afctol)`
- `singular_conv_tol (NL2SOL's sctol)`
- `false_conv_tol (NL2SOL's xftol)`
- `initial_trust_radius (NL2SOL's lmax0)`

The internal NL2SOL defaults can be obtained for many of these controls by specifying the value -1. The internal defaults are often functions of machine epsilon (as limited by `function_precision`).
Examples

An example of \texttt{nl2sol} is given below, and is discussed in the User’s Manual.

Note that in this usage of \texttt{calibration_terms}, the driver script \texttt{rosenbrock}, is returning “residuals”, which the \texttt{nl2sol} method is attempting to minimize. Another use case is to provide a data file, which Dakota will attempt to match the model responses to. See \texttt{calibration_data_file}. Finally, as of Dakota 6.2, the field data capability may be used with \texttt{nl2sol}. That is, the user can specify field simulation data and field experiment data, and Dakota will interpolate and provide the proper residuals for the calibration.

```plaintext
# Dakota Input File: rosen_opt_nls.in
environment
    tabular_data
        tabular_data_file = ‘rosen_opt_nls.dat’
method
    max_iterations = 100
    convergence_tolerance = 1e-4
    nl2sol
model
    single

interface
    analysis_driver = ‘rosenbrock’
    direct
responses
    calibration_terms = 2
    analytic_gradients
    no_hessians
```

Theory

\texttt{NL2SOL} has a variety of internal controls as described in AT&T Bell Labs CS TR 153 (\texttt{http://cm.bell-labs.com/cm/cs/cstr/153.ps.gz}). A number of existing Dakota controls (method independent controls and responses controls) are mapped into these \texttt{NL2SOL} internal controls. In particular, Dakota’s \texttt{convergence_tolerance}, \texttt{max_iterations}, \texttt{max_function_evaluations}, and \texttt{fd_gradient_step_size} are mapped directly into \texttt{NL2SOL}’s \texttt{rfctol}, \texttt{mxiter}, \texttt{mxfcal}, and \texttt{dltfdj} controls, respectively. In addition, Dakota’s \texttt{fd_hessian_step_size} is mapped into both \texttt{delta0} and \texttt{dltfdc}, and Dakota’s output verbosity is mapped into \texttt{NL2SOL}’s \texttt{auxprt} and \texttt{outlev} (for normal/verbose/debug output, \texttt{NL2SOL} prints initial guess, final solution, solution statistics, nondefault values, and changes to the active bound constraint set on every iteration; for quiet output, \texttt{NL2SOL} prints only the initial guess and final solution; and for silent output, \texttt{NL2SOL} output is suppressed).

6.2. METHOD

- `optpp_x_newton`
- `field_calibration_terms`

`function_precision`

- **Keywords Area**
- **method**
- **nl2sol**
- **function_precision**

Specify the maximum precision of the analysis code responses

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 1.0e-10

**Description**

The `function_precision` control provides the algorithm with an estimate of the accuracy to which the problem functions can be computed. This is used to prevent the algorithm from trying to distinguish between function values that differ by less than the inherent error in the calculation.

`absolute_conv_tol`

- **Keywords Area**
- **method**
- **nl2sol**
- **absolute_conv_tol**

Absolute convergence tolerance

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** -1. (use NL2SOL internal default)

**Description**

`absolute_conv_tol` (NL2SOL's `afctol`) is the absolute function convergence tolerance (stop when half the sum of squares is less than `absolute_conv_tol`, which is mainly of interest on zero-residual test problems).

The internal default is a function of machine epsilon (as limited by `function_precision`). The default is selected with a value of -1.
x_conv_tol

- Keywords Area
- method
- nl2sol
- x_conv_tol

X-convergence tolerance

**Specification**

Alias: none

**Argument(s):** REAL

**Default:** -1. (use NL2SOL internal default)

**Description**

*x_conv_tol* maps to the internal NL2SOL control *xctol*. It is the X-convergence tolerance (scaled relative accuracy of the solution variables).

The internal default is a function of machine epsilon (as limited by *function_precision*). The default is selected with a value of -1.

singular_conv_tol

- Keywords Area
- method
- nl2sol
- singular_conv_tol

Singular convergence tolerance

**Specification**

Alias: none

**Argument(s):** REAL

**Default:** -1. (use NL2SOL internal default)

**Description**

*singular_conv_tol* (NL2SOL’s *sctol*) is the singular convergence tolerance, which works in conjunction with *singular_radius* to test for underdetermined least-squares problems (stop when the relative reduction yet possible in the sum of squares appears less than *singular_conv_tol* for steps of scaled length at most *singular_radius*).

The internal default is a function of machine epsilon (as limited by *function_precision*). The default is selected with a value of -1.
6.2. METHOD

singular_radius

- Keywords Area
- method
- nl2sol
- singular_radius

Singular radius

Specification

Alias: none

Argument(s): REAL
Default: -1. (use NL2SOL internal default of 1)

Description

singular_radius works in conjunction with singular_conv_tol to test for underdetermined least-squares problems (stop when the relative reduction yet possible in the sum of squares appears less than singular_conv_tol for steps of scaled length at most singular_radius).

The internal default results in the internal use of steps of length 1. The default is selected with a value of -1.

false_conv_tol

- Keywords Area
- method
- nl2sol
- false_conv_tol

False convergence tolerance

Specification

Alias: none

Argument(s): REAL
Default: -1. (use NL2SOL internal default)

Description

false_conv_tol (NL2SOL's xftol) is the false-convergence tolerance (stop with a suspicion of discontinuity when a more favorable stopping test is not satisfied and a step of scaled length at most false_conv_tol is not accepted)

The internal default is a function of machine epsilon (as limited by function_precision). The default is selected with a value of -1.
initial\_trust\_radius

- Keywords Area
- method
- nl2sol
- initial\_trust\_radius

Initial trust region radius

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** -1. (use NL2SOL internal default of 1)

**Description**

initial\_trust\_radius specification (NL2SOL’s lmax0) specifies the initial trust region radius for the algorithm.

The internal default results in the internal use of steps of length 1. The default is selected with a value of -1.

covariance

- Keywords Area
- method
- nl2sol
- covariance

Determine how the final covariance matrix is computed

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 0 (no covariance)

**Description**

covariance (NL2SOL’s covreq) specifies whether and how NL2SOL computes a final covariance matrix.

The desired covariance approximation:

- 0 = default = none
- 1 or -1 == $\sigma^2 H^{-1} J^T J H^{-1}$
- 2 or -2 == $\sigma^2 H^{-1}$
- 3 or -3 == $\sigma^2 (J^T J)^{-1}$
6.2. METHOD

- Negative values ==> estimate the final Hessian H by finite differences of function values only (using \texttt{fd.hessian_step_size})
- Positive values ==> differences of gradients (using \texttt{fd.hessian_step_size})

\textbf{regression_diagnostics}

- Keywords Area
- method
- \texttt{nl2sol}
- \texttt{regression_diagnostics}

Turn on regression diagnostics

\textbf{Specification}

\textbf{Alias}: none
\textbf{Argument(s)}: none
\textbf{Default}: no regression diagnostics

\textbf{Description}

When \texttt{regression_diagnostics} (\texttt{NL2SOL}'s \texttt{rdreq}) is specified and a positive-definite final Hessian approximation H is computed, \texttt{NL2SOL} computes and prints a regression diagnostic vector RD such that if omitting the i-th observation would cause alpha times the change in the solution that omitting the j-th observation would cause, then \( RD[i] = |alpha| RD[j] \). The finite-difference step-size tolerance affecting H is \texttt{fd_step_size} (\texttt{NL2SOL}'s \texttt{delta0} and \texttt{dltfdc}).

\textbf{model_pointer}

Description

North Carolina State University (NCSU) has an implementation of the DIRECT algorithm (DIviding RECTangles algorithm that is outlined in the SCOLIB method section above). This version is documented in [28] We have found that the NCSU DIRECT implementation works better and is more robust for some problems than coliny-direct. Currently, we maintain both versions of DIRECT in Dakota; in the future, we may deprecate one.

The NCSU DIRECT method is selected with ncsu_direct. We have tried to maintain consistency between the keywords in SCOLIB and NCSU implementation of DIRECT, but the algorithms have different parameters, so the keywords sometimes have slightly different meaning.

Stopping Criteria

The algorithm stops based on:

1. max_iterations - number of iterations
2. max_function_evaluations - number of function evaluations
3. solution_target and convergence_tolerance
4. min_boxsize_limit
5. volume_boxsize_limit

This method will always strictly respect the number of iterations, but may slightly exceed the number of function evaluations, as it will always explore all sub-rectangles at the current level.

- solution_target

Specifies a globally optimal value toward which the optimizer should track

Specification

Alias: solution_accuracy

Argument(s): REAL
Default: 0

Description

The solution target specifies a goal toward which the optimizer should track.

This is used for test problems, when the true global minimum is known (call it solution_target \(= f_{\text{global}}\)). Then, the optimization terminates when \(100(f_{\text{min}} - f_{\text{global}}) / \max(1, \abs{f_{\text{global}}}) < \text{convergence}\_\text{tolerance}\). The default for fglobal is \(-1.0e100\) and the default for convergence tolerance is described at convergence\_tolerance.

min_boxsize_limit

- Keywords Area
- method
- ncsu_direct
- min_boxsize_limit

Stopping Criterion based on shortest edge of hyperrectangle

Specification

Alias: none

Argument(s): REAL
Default: 1.0e-4
Description

\( \text{min\_boxsize\_limit} \) is a setting that terminates the optimization when the measure of a hyperrectangle \( S \) with \( f(c(S)) = f_{\text{min}} \) is less than \( \text{min\_boxsize\_limit} \).

Each subregion considered by DIRECT has a size, which corresponds to the longest diagonal of the subregion. \( \text{min\_boxsize\_limit} \) specification terminates DIRECT if the size of the smallest subregion falls below this threshold.

In practice, this specification is likely to be more effective at limiting DIRECT’s search.

\[ \text{volume\_boxsize\_limit} \]

- **Description**

  \( \text{volume\_boxsize\_limit} \) is a setting that terminates the optimization when the volume of a hyperrectangle \( S \) with \( f(c(S)) = f_{\text{min}} \) is less than \( \text{volume\_boxsize\_limit} \) percent of the original hyperrectangle. Basically, \( \text{volume\_boxsize\_limit} \) stops the optimization when the volume of the particular rectangle which has \( f_{\text{min}} \) is less than a certain percentage of the whole volume.

**Specification**

Alias: none

Argument(s): REAL

Default: 1.0e-6

**Description**

\( \text{volume\_boxsize\_limit} \) is a setting that terminates the optimization when the volume of a hyperrectangle \( S \) with \( f(c(S)) = f_{\text{min}} \) is less than \( \text{volume\_boxsize\_limit} \) percent of the original hyperrectangle. Basically, \( \text{volume\_boxsize\_limit} \) stops the optimization when the volume of the particular rectangle which has \( f_{\text{min}} \) is less than a certain percentage of the whole volume.

- method
- genie_opt_darts

Voronoi-based high-dimensional global Lipschitzian optimization

Specification

Alias: none
Argument(s): none

<table>
<thead>
<tr>
<th>Required/-Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>seed</td>
<td>Seed of the random number generator</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>model_pointer</td>
<td>Identifier for model block to be used by a method</td>
</tr>
</tbody>
</table>

Description

OPT-Darts method is a fast alternative to DIRECT for global Lipschitzian optimization purposes. Instead of hyperrectangular, OPT-Darts decomposes a high-dimensional domain into Voronoi cells, and places samples via stochastic blue noise instead of deterministic cell division.

To refine a cell, OPT-Darts first adds a new sample within it via spoke-dart sampling, then set the conflict radius to the cells inscribed hypersphere radius, to avoid adding a sample point that is too close to a prior sample, then divide that cell (and update its neighboring cells) via the approximate Delaunay graph, and use the computed witnesses to decide the next refinement candidate. These two steps replace the corresponding deterministic center-sample and rectangular cell division in DIRECT, respectively.

OPT-Darts is the first exact stochastic Lipschitzian optimization technique that combines the benefits of guaranteed convergence in [Jones et al. 1993] and high dimensional efficiency in [Spall 2005]. Computing blue noise and Voronoi regions has been intractable in high dimensions, and are being done within OPT-Darts using Spoke-Darts.
6.2. METHOD

seed

- Keywords Area
- method
- genie_opt_darts
- seed

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER
Default: system-generated (non-repeatable)

Description

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior
If not specified, the seed is randomly generated.

Expected Output
If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips
If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

Description

DIRECT (DIviding RECTangles) partitions the domain into hyperrectangles and uses an iterative Lipschitzian optimization approach to search for a global optimal point.

DIRECT begins by scaling the domain into the unit hypercube by adopting a center-sampling strategy. The objective function is evaluated at the midpoint of the domain, where a lower bound is constructed. In one-dimension, the domain is tri-sected and two new center points are sampled. At each iteration (dividing and sampling), DIRECT identifies intervals that contain the best minimal value of the objective function found up to that point. This strategy of selecting and dividing gives DIRECT its performance and convergence properties compared to other deterministic methods.
CHAPTER 6. KEYWORDS AREA

The classical DIRECT method [Shubert 1972] has two limitations: poor scaling to high dimensions; and relying on a global K; whose exact value is often unknown. The enhanced DIRECT algorithm [Jones et al. 1993] generalizes [Shubert 1972] to higher dimensions and does not require knowledge of the Lipschitz constant.

**seed**

- **Keywords Area**
- **method**
- **genie_direct**
- **seed**

Seed of the random number generator

---

**Specification**

**Alias:** none

**Argument(s):** INTEGER  
**Default:** system-generated (non-repeatable)

---

**Description**

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

**Default Behavior**

If not specified, the seed is randomly generated.

**Expected Output**

If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

**Usage Tips**

If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

---

**Examples**

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

---

**model_pointer**

- **method**
- **genie_direct**
- **model_pointer**

Identifier for model block to be used by a method
6.2. METHOD

Topics
This keyword is related to the topics:

- block_pointer

Specification

Alias: none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

**Usage Tips**

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

Examples

```plaintext
environment
  tabular_graphics_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'

### Description

The Efficient Global Optimization (EGO) method was first developed by Jones, Schonlau, and Welch\[54\]. In EGO, a stochastic response surface approximation for the objective function is developed based on some sample points from the "true" simulation.

Note that several major differences exist between our implementation and that of\[54\]. First, rather than using a branch and bound method to find the point which maximizes the EIF, we use the DIRECT global optimization method.

Second, we support both global optimization and global nonlinear least squares as well as general nonlinear constraints through abstraction and subproblem recasting.

The efficient global method is in prototype form. Currently, we do not expose any specification controls for the underlying Gaussian process model used or for the optimization of the expected improvement function (which is currently performed by the NCSU DIRECT algorithm using its internal defaults).

By default, EGO uses the Surfpack GP (Kriging) model, but the Dakota implementation may be selected instead. If `use_derivatives` is specified the GP model will be built using available derivative data (Surfpack GP only).

### Theory

The particular response surface used is a Gaussian process (GP). The GP allows one to calculate the prediction at a new input location as well as the uncertainty associated with that prediction. The key idea in EGO is to maximize the Expected Improvement Function (EIF). The EIF is used to select the location at which a new training point should be added to the Gaussian process model by maximizing the amount of improvement in the objective function that can be expected by adding that point. A point could be expected to produce an improvement in the objective function if its predicted value is better than the current best solution, or if the uncertainty in its prediction is such that the probability of it producing a better solution is high. Because the uncertainty is higher in regions of the design space with few observations, this provides a balance between exploiting areas of the design space that predict good solutions, and exploring areas where more information is needed. EGO trades off this "exploitation vs. exploration." The general procedure for these EGO-type methods is:

- Build an initial Gaussian process model of the objective function
- Find the point that maximizes the EIF. If the EIF value at this point is sufficiently small, stop.

### Parameters

Select the built in Gaussian Process surrogate

dakota

Description

Use the Gaussian process (GP) surrogate from Surfpack, which is specified using the surfpack keyword. An alternate version of GP surrogates was available in prior versions of Dakota. For now, both versions are supported but the dakota version is deprecated and intended to be removed in a future release.

surfpack

• Keywords Area

• method

• efficient_global
Use the Surfpack version of Gaussian Process surrogates

**Specification**

Alias: none

**Argument(s):** none

**Description**

This keyword specifies the use of the Gaussian process that is incorporated in our surface fitting library called Surfpack.

Several user options are available:

1. **Optimization methods:**

   Maximum Likelihood Estimation (MLE) is used to find the optimal values of the hyper-parameters governing the trend and correlation functions. By default the global optimization method DIRECT is used for MLE, but other options for the optimization method are available. See `optimization_method`.

   The total number of evaluations of the likelihood function can be controlled using the `max_trials` keyword followed by a positive integer. Note that the likelihood function does not require running the "truth" model, and is relatively inexpensive to compute.

2. **Trend Function:**

   The GP models incorporate a parametric trend function whose purpose is to capture large-scale variations. See `trend`.

3. **Correlation Lengths:**

   Correlation lengths are usually optimized by Surfpack, however, the user can specify the lengths manually. See `correlation_lengths`.

4. **Ill-conditioning**

   One of the major problems in determining the governing values for a Gaussian process or Kriging model is the fact that the correlation matrix can easily become ill-conditioned when there are too many input points close together. Since the predictions from the Gaussian process model involve inverting the correlation matrix, ill-conditioning can lead to poor predictive capability and should be avoided.

   Note that a sufficiently bad sample design could require correlation lengths to be so short that any interpolatory GP model would become inept at extrapolation and interpolation.

   The `surfpack` model handles ill-conditioning internally by default, but behavior can be modified using `gradient`.

5. **Gradient Enhanced Kriging (GEK).**

   The `use_derivatives` keyword will cause the Surfpack GP to be constructed from a combination of function value and gradient information (if available).

   See notes in the Theory section.
Theory

Gradient Enhanced Kriging

Incorporating gradient information will only be beneficial if accurate and inexpensive derivative information is available, and the derivatives are not infinite or nearly so. Here "inexpensive" means that the cost of evaluating a function value plus gradient is comparable to the cost of evaluating only the function value, for example gradients computed by analytical, automatic differentiation, or continuous adjoint techniques. It is not cost effective to use derivatives computed by finite differences. In tests, GEK models built from finite difference derivatives were also significantly less accurate than those built from analytical derivatives. Note that GEK’s correlation matrix tends to have a significantly worse condition number than Kriging for the same sample design.

This issue was addressed by using a pivoted Cholesky factorization of Kriging’s correlation matrix (which is a small sub-matrix within GEK’s correlation matrix) to rank points by how much unique information they contain. This reordering is then applied to whole points (the function value at a point immediately followed by gradient information at the same point) in GEK’s correlation matrix. A standard non-pivoted Cholesky is then applied to the reordered GEK correlation matrix and a bisection search is used to find the last equation that meets the constraint on the (estimate of) condition number. The cost of performing pivoted Cholesky on Kriging’s correlation matrix is usually negligible compared to the cost of the non-pivoted Cholesky factorization of GEK’s correlation matrix. In tests, it also resulted in more accurate GEK models than when pivoted Cholesky or whole-point-block pivoted Cholesky was performed on GEK’s correlation matrix.

- dakota

Select the built in Gaussian Process surrogate

Specification

Alias: none

Argument(s): none

Description

A second version of GP surrogates was available in prior versions of Dakota. For now, both versions are supported but the dakota version is deprecated and intended to be removed in a future release.

Historically these models were drastically different, but in Dakota 5.1, they became quite similar. They now differ in that the Surfpack GP has a richer set of features/options and tends to be more accurate than the Dakota version. Due to how the Surfpack GP handles ill-conditioned correlation matrices (which significantly contributes to its greater accuracy), the Surfpack GP can be a factor of two or three slower than Dakota’s. As of Dakota 5.2, the Surfpack implementation is the default in all contexts except Bayesian calibration.

More details on the gaussian_process dakota model can be found in [58].

Dakota’s GP deals with ill-conditioning in two ways. First, when it encounters a non-invertible correlation matrix it iteratively increases the size of a "nugget," but in such cases the resulting approximation smooths rather than interpolates the data. Second, it has a point_selection option (default off) that uses a greedy algorithm
to select a well-spaced subset of points prior to the construction of the GP. In this case, the GP will only interpo-
late the selected subset. Typically, one should not need point selection in trust-region methods because a small
number of points are used to develop a surrogate within each trust region. Point selection is most beneficial when
constructing with a large number of points, typically more than order one hundred, though this depends on the
number of variables and spacing of the sample points.

This differs from the point_selection option of the Dakota GP which initially chooses a well-spaced
subset of points and finds the correlation parameters that are most likely for that one subset.

use_derivatives

• Keywords Area
• method
• efficient_global
• use_derivatives

Use derivative data to construct surrogate models

Specification

Alias: none
Argument(s): none
Default: use function values only

Description

The use_derivatives flag specifies that any available derivative information should be used in global approx-
imation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack
Gaussian process).

However, it’s use with Surfpack Gaussian process is not recommended.

import_points_file

• Keywords Area
• method
• efficient_global
• import_points_file

File containing variable values and corresponding responses

Specification

Alias: none
Argument(s): STRING
Default: no point import from a file
### Description

The `import_points_file` allows the user to specify a file that contains a list of variable values and the model responses computed at those values. These can be used by a number of methods in place of model evaluations. When used to construct surrogate models or emulators these are often called build points or training data.

**Default Behavior**

By default, methods do not import points from a file.

**Usage Tips**

Dakota parses input files without regard to whitespace, but the `import_points_file` must be in one of three formats:

- `annotated` (default)
- `custom.annotated`
- `freeform`

**Examples**

```plaintext
method
  list_parameter_study
  import_points_file = 'dakota_pstudy.3.dat'
```

### Examples

- **efficient_global**
- **import_points_file**
- **annotated**

Selects annotated tabular file format
6.2. METHOD

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom.annotated header eval_id

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```environment
tabular_data
  tabular_data_file = 'dakota_summary.dat'
annotated
```

Resulting tabular file:

```
%eval_id interface  x1  x2  obj_fn  nln_ineq_con_1  nln_ineq_con_2
1  NO_ID  0.9  1.1  0.0002  0.26  0.76
2  NO_ID  0.90009  1.1  0.0001996404857  0.2601620081  0.759955
3  NO_ID  0.89991  1.1  0.0002003604863  0.2598380081  0.760045
...```
custom.annotated

- Keywords Area
- method
- efficient_global
- import_points_file
- custom.annotated

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none
Default: annotated format

| Required/- | Description of | Dakota Keyword | Dakota Keyword Description |
| Optional   | Group          | header         | Enable header row in custom-annotated tabular file |
| Optional   |                | eval_id        | Enable evaluation ID column in custom-annotated tabular file |
| Optional   |                | interface_id   | Enable interface ID column in custom-annotated tabular file |

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior
The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom.annotated, followed by options, in the relevant export/import context.

Usage Tips
6.2. METHOD

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```dakota
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
custom_annotated header eval_id
```

Resulting tabular file:

```
 %eval_id  x1   x2  obj_fn  nln_ineq_con_1  nln_ineq_con_2
 1  0.9   1.1  0.0002  0.26          0.76
 2  0.90009 1.1 0.0001996404857 0.2601620081 0.759955

6.2. METHOD

freeform

- Keywords Area
- method
- efficient_global
- import_points_file
- freeform

Selects freeform file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.
Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```python
environment
    tabular_data
        tabular_data_file = 'dakota_summary.dat'
    freeform

Resulting tabular file:

```

0.9 1.1 0.0002 0.26 0.76
0.90009 1.1 0.0001996404857 0.2601620081 0.759955

- **method**
- **efficient_global**
- **import_points_file**
- **active_only**

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- **file_formats**

Specification

**Alias:** none

**Argument(s):** none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.
export_points_file

**Description**

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval\_id column, and interface\_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

**Default Behavior**

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom\_annotated, followed by options, in the relevant export/import context.

**Usage Tips**
• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples
Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id  x1    x2    obj_fn nln_ineq_con_1 nln_ineq_con_2
1  0.9    1.1   0.0002  0.26      0.76
2  0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3  0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...
```

freeform

- Keywords Area
- method
- efficient_global
- export_points_file
- freeform

Selects freeform file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.
Examples
Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```plaintext
evironment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

<table>
<thead>
<tr>

seed
- Keywords Area
- method
- efficient_global
- seed

Seed of the random number generator

Specification
Alias: none
- Argument(s): INTEGER
- Default: system-generated (non-repeatable)

Description
The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

- Default Behavior
  - If not specified, the seed is randomly generated.
- Expected Output
  - If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.
- Usage Tips
  - If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples
```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```
model_pointer

- Keywords Area
- method
- efficient_global
- model_pointer

Identifier for model block to be used by a method

**Topics**

This keyword is related to the topics:

- block_pointer

**Specification**

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)

**Description**

The `model_pointer` is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding `id_model` with the same name.

**Usage Tips**

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

**Examples**

```plaintext
environment
  tabular_graphics_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
      0.1 0.2 0.6
      0.1 0.2 0.6
  sample_type lhs

## Description

The polynomial chaos expansion (PCE) is a general framework for the approximate representation of random response functions in terms of finite-dimensional series expansions in standardized random variables

\[ R = \sum_{i=0}^{P} \alpha_i \Psi_i(\xi) \]

where \( \alpha_i \) is a deterministic coefficient, \( \Psi_i \) is a multidimensional orthogonal polynomial, and \( \xi \) is a vector of standardized random variables. An important distinguishing feature of the methodology is that the functional relationship between random inputs and outputs is captured, not merely the output statistics as in the case of many nondeterministic methodologies.

### Basis polynomial family (Group 1)

Group 1 keywords are used to select the type of basis, \( \Psi_i \), of the expansion. Three approaches may be employed:

- **Wiener**: employs standard normal random variables in a transformed probability space, corresponding to Hermite orthogonal basis polynomials (see \texttt{wiener}).

- **Askey**: employs standard normal, standard uniform, standard exponential, standard beta, and standard gamma random variables in a transformed probability space, corresponding to Hermite, Legendre, Laguerre, Jacobi, and generalized Laguerre orthogonal basis polynomials, respectively (see \texttt{askey}).

| Optional | probability_levels | Specify probability levels at which to estimate the corresponding response value |
| Optional | gen_reliability_levels | Specify generalized reliability levels at which to estimate the corresponding response value |
| Optional | rng | Selection of a random number generator |
| Optional | samples | Number of samples for sampling-based methods |
| Optional | seed | Seed of the random number generator |
| Optional | model_pointer | Identifier for model block to be used by a method |
• Extended (default if no option is selected): The Extended option avoids the use of any nonlinear variable transformations by augmenting the Askey approach with numerically-generated orthogonal polynomials for non-Askey probability density functions. Extended polynomial selections replace each of the sub-optimal Askey basis selections for bounded normal, lognormal, bounded lognormal, loguniform, triangular, gumbel, frechet, weibull, and bin-based histogram.

For supporting correlated random variables, certain fallbacks must be implemented.

• The Extended option is the default and supports only Gaussian correlations.

• If needed to support prescribed correlations (not under user control), the Extended and Askey options will fall back to the Wiener option on a per variable basis. If the prescribed correlations are also unsupported by Wiener expansions, then Dakota will exit with an error.

Refer to variable support for additional information on supported variable types, with and without correlation.

Coefficient estimation approach (Group 2)
To obtain the coefficients $\alpha_i$ of the expansion, seven options are provided:

1. multidimensional integration by a tensor-product of Gaussian quadrature rules (specified with quadrature-order, and, optionally, dimension preference).

2. multidimensional integration by the Smolyak sparse grid method (specified with sparse_grid_level and, optionally, dimension preference)

3. multidimensional integration by Stroud cubature rules and extensions as specified with cubature-integrand.

4. multidimensional integration by Latin hypercube sampling (specified with expansion_order and expansion-samples).

5. linear regression (specified with expansion_order and either collocation_points or collocation_ratio), using either over-determined (least squares) or under-determined (compressed sensing) approaches.

6. orthogonal least interpolation (specified with orthogonal_least_interpolation and collocation_points)

7. coefficient import from a file (specified with import_expansion_file). The expansion can be comprised of a general set of expansion terms, as indicated by the multi-index annotation within the file.

It is important to note that, while quadrature_order, sparse_grid_level, and expansion_order are array inputs, only one scalar from these arrays is active at a time for a particular expansion estimation. These scalars can be augmented with dimension_preference to support anisotropy across the random dimension set. The array inputs are present to support advanced use cases such as multifidelity UQ, where multiple grid resolutions can be employed.

Active Variables
The default behavior is to form expansions over aleatory uncertain continuous variables. To form expansions over a broader set of variables, one needs to specify active followed by state, epistemic, design, or all in the variables specification block.

For continuous design, continuous state, and continuous epistemic uncertain variables included in the expansion, Legendre chaos bases are used to model the bounded intervals for these variables. However, these variables are not assumed to have any particular probability distribution, only that they are independent variables. Moreover, when probability integrals are evaluated, only the aleatory random variable domain is integrated, leaving behind a polynomial relationship between the statistics and the remaining design/state/epistemic variables.
6.2. METHOD

Covariance type (Group 3)
These two keywords are used to specify how this method computes, stores, and outputs the covariance of the responses. In particular, the diagonal covariance option is provided for reducing post-processing overhead and output volume in high dimensional applications.

Optional Keywords regarding method outputs
Each of these sampling specifications refer to sampling on the PCE approximation for the purposes of generating approximate statistics.

- sample_type
- samples
- seed
- fixed_seed
- rng
- probability_refinement
- distribution
- reliability_levels
- response_levels
- probability_levels
- gen_reliability_levels

which should be distinguished from simulation sampling for generating the PCE coefficients as described in options 4, 5, and 6 above (although these options will share the sample_type, seed, and rng settings, if provided).

When using the probability_refinement control, the number of refinement samples is not under the user’s control (these evaluations are approximation-based, so management of this expense is less critical). This option allows for refinement of probability and generalized reliability results using importance sampling.

Multi-fidelity UQ
The advanced use case of multifidelity UQ automatically becomes active if the model selected for iteration by the method specification is a multifidelity surrogate model (see hierarchical). In this case, an expansion will first be formed for the model discrepancy (the difference between response results if additive correction or the ratio of results if multiplicative correction), using the first quadrature_order, sparse_grid_level, or expansion_order value along with any specified refinement strategy. Second, an expansion will be formed for the low fidelity surrogate model, using the second quadrature_order, sparse_grid_level, or expansion_order value (if present; the first is reused if not present) along with any specified refinement strategy. Then the two expansions are combined (added or multiplied) into an expansion that approximates the high fidelity model, from which the final set of statistics are generated. For polynomial chaos expansions, this high fidelity expansion can differ significantly in form from the low fidelity and discrepancy expansions, particularly in the multiplicative case where it is expanded to include all of the basis products.

Usage Tips
If \( n \) is small (e.g., two or three), then tensor-product Gaussian quadrature is quite effective and can be the preferred choice. For moderate to large \( n \) (e.g., five or more), tensor-product quadrature quickly becomes too expensive and the sparse grid and regression approaches are preferred. Random sampling for coefficient estimation is generally not recommended due to its slow convergence rate. For incremental studies, approaches 4 and 5 support reuse of previous samples through the incremental_lhs and reuse_points specifications, respectively.
In the quadrature and sparse grid cases, growth rates for nested and non-nested rules can be synchronized for consistency. For a non-nested Gauss rule used within a sparse grid, linear one-dimensional growth rules of $m = 2l + 1$ are used to enforce odd quadrature orders, where $l$ is the grid level and $m$ is the number of points in the rule. The precision of this Gauss rule is then $i = 2m - 1 = 4l + 1$. For nested rules, order growth with level is typically exponential; however, the default behavior is to restrict the number of points to be the lowest order rule that is available that meets the one-dimensional precision requirement implied by either a level $l$ for a sparse grid ($i = 4l + 1$) or an order $m$ for a tensor grid ($i = 2m - 1$). This behavior is known as ”restricted growth” or ”delayed sequences.” To override this default behavior in the case of sparse grids, the unrestricted keyword can be used; it cannot be overridden for tensor grids using nested rules since it also provides a mapping to the available nested rule quadrature orders. An exception to the default usage of restricted growth is the dimension_adaptive_p_refinement generalized sparse grid case described previously, since the ability to evolve the index sets of a sparse grid in an unstructured manner eliminates the motivation for restricting the exponential growth of nested rules.

Description

The **p-refinement** keyword specifies the usage of automated polynomial order refinement, which can be either **uniform** or **dimension_adaptive**.

The **dimension_adaptive** option is supported for the tensor-product quadrature and Smolyak sparse grid options and **uniform** is supported for tensor and sparse grids as well as regression approaches (**collocation_points** or **collocation_ratio**).

Each of these refinement cases makes use of the **max_iterations** and **convergence_tolerance** method independent controls. The former control limits the number of refinement iterations, and the latter control terminates refinement when the two-norm of the change in the response covariance matrix (or, in goal-oriented approaches, the two-norm of change in the statistical quantities of interest (QOI)) falls below the tolerance.

The **dimension_adaptive** case can be further specified to utilize **sobol**, **decay**, or **generalized** refinement controls. The former two cases employ anisotropic tensor/sparse grids in which the anisotropic dimension preference (leading to anisotropic integrations/expansions with differing refinement levels for different random dimensions) is determined using either total Sobol’ indices from variance-based decomposition (**sobol** case: high indices result in high dimension preference) or using spectral coefficient decay rates from a rate estimation technique similar to Richardson extrapolation (**decay** case: low decay rates result in high dimension preference). In these two cases as well as the **uniform** refinement case, the **quadrature_order** or **sparse_grid_level** are ramped by one on each refinement iteration until either of the two convergence controls is satisfied. For the **uniform** refinement case with regression approaches, the **expansion_order** is ramped by one on each iteration while the oversampling ratio (either defined by **collocation_ratio** or inferred from **collocation_points** based on the initial expansion) is held fixed. Finally, the generalized **dimension_adaptive** case is the default adaptive approach; it refers to the generalized sparse grid algorithm, a greedy approach in which candidate index sets are evaluated for their impact on the statistical QOI, the most influential sets are selected and used to generate additional candidates, and the index set frontier of a sparse grid is evolved in an unstructured and goal-oriented manner (refer to User’s Manual PCE descriptions for additional specifics).
For the case of \texttt{p\_refinement} or the case of an explicit nested override, Gauss-Hermite rules are replaced with Genz-Keister nested rules and Gauss-Legendre rules are replaced with Gauss-Patterson nested rules, both of which exchange lower integrand precision for greater point reuse.

\textbf{uniform}

- Keywords Area
- method

\end{tabular}
## Description

Perform anisotropic expansion refinement by preferentially adapting in dimensions that are detected to hold higher ‘importance’ in resolving statistical quantities of interest.

Dimension importance must be estimated as part of the refinement process. Techniques include either sobol or generalized for stochastic collocation and either sobol, decay, or generalized for polynomial chaos. Each of these automated refinement approaches makes use of the max_iterations and convergence_tolerance iteration controls.

### sobol

- **Keywords Area**
- **method**
- **polynomial_chaos**
- **p_refinement**
- **dimension_adaptive**
- **sobol**

Estimate dimension preference for automated refinement of stochastic expansion using total Sobol’ sensitivity indices.
CHAPTER 6. KEYWORDS AREA

Specification
Alias: none
  Argument(s): none
  Default: generalized

Description
Determine dimension preference for refinement of a stochastic expansion from the total Sobol’ sensitivity indices obtained from global sensitivity analysis. High indices indicate high importance for resolving statistical quantities of interest and therefore result in high dimension preference.

Examples
method, polynomial_chaos
  sparse_grid_level = 3
  dimension_adaptive p_refinement sobol
  max_iterations = 20
  convergence_tol = 1.e-4

decay

- Keywords Area
- method
- polynomial_chaos
- p_refinement
- dimension_adaptive
- decay

Estimate spectral coefficient decay rates to guide dimension-adaptive refinement.

Specification
Alias: none
  Argument(s): none

Description
Estimate spectral coefficient decay rates from a rate estimation technique similar to Richardson extrapolation. These decay rates are used to guide dimension-adaptive refinement, where slower decay rates result in higher dimension preference.

Examples
method, polynomial_chaos
  sparse_grid_level = 3
  dimension_adaptive p_refinement decay
  max_iterations = 20
  convergence_tol = 1.e-4
6.2. METHOD

**generalized**
- **Keywords Area**
- method
- polynomial_chaos
- p_refinement
- dimension_adaptive
- generalized

Use the generalized sparse grid dimension adaptive algorithm to refine a sparse grid approximation of stochastic expansion.

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

The generalized sparse grid algorithm is a greedy approach in which candidate index sets are evaluated for their impact on the statistical QOI, the most influential sets are selected and used to generate additional candidates, and the index set frontier of a sparse grid is evolved in an unstructured and goal-oriented manner (refer to User’s Manual PCE descriptions for additional specifics).

**Examples**

```plaintext
method,  
  polynomial_chaos  
  sparse_grid_level = 3  
  dimension_adaptive p_refinement generalized  
  max_iterations = 20  
  convergence_tol = 1.e-4
```

**askey**
- **Keywords Area**

Default: extended (Askey + numerically-generated)

Description

The Wiener option employs standard normal random variables in a transformed probability space, corresponding to a Hermite orthogonal polynomial basis. This is the same nonlinear variable transformation used by local and global reliability methods (and therefore has the same variable support).

Description

Multidimensional integration by a tensor-product of Gaussian quadrature rules (specified with quadrature_order, and, optionally, dimension_preference). The default rule selection is to employ non_nested Gauss rules including Gauss-Hermite (for normals or transformed normals), Gauss-Legendre (for uniforms or transformed uniforms), Gauss-Jacobi (for betas), Gauss-Laguerre (for exponentials), generalized Gauss-Laguerre (for gammas), and numerically-generated Gauss rules (for other distributions when using an Extended basis). For the case of \( p_{\text{refinement}} \) or the case of an explicit nested override, Gauss-Hermite rules are replaced with Genz-Keister nested rules and Gauss-Legendre rules are replaced with Gauss-Patterson nested rules, both of which exchange lower integrand precision for greater point reuse. By specifying a dimension_preference, where higher preference leads to higher order polynomial resolution, the tensor grid may be rendered anisotropic. The dimension specified to have highest preference will be set to the specified quadrature_order and all other dimensions will be reduced in proportion to their reduced preference; any non-integral portion is truncated. To synchronize with tensor-product integration, a tensor-product expansion is used, where the order \( p_i \) of the expansion in each dimension is selected to be half of the integrand precision available from the rule in use, rounded down. In the case of non-nested Gauss rules with integrand precision \( 2m_i - 1 \), \( p_i \) is one less than the quadrature order \( m_i \) in each dimension (a one-dimensional expansion contains the same number of terms, \( p + 1 \), as the number of Gauss points). The total number of terms, \( N \), in a tensor-product expansion involving \( n \) uncertain input variables is

\[
N = 1 + P = \prod_{i=1}^{n} (p_i + 1)
\]
In some advanced use cases (e.g., multifidelity UQ), multiple grid resolutions can be employed; for this reason, the `quadrature_order` specification supports an array input.

### Description

Multi-dimensional integration by the Smolyak sparse grid method (specified with sparse_grid_level and, optionally, dimension_preference). The underlying one-dimensional integration rules are the same as for the tensor-product quadrature case; however, the default rule selection is nested for sparse grids (Genz-Keister for normals/transformed normals and Gauss-Patterson for uniforms/transformed uniforms). This default can be overridden with an explicit non_nested specification (resulting in Gauss-Hermite for normals/transformed normals and Gauss-Legendre for uniforms/transformed uniforms). As for tensor quadrature, the dimension_preference specification enables the use of anisotropic sparse grids (refer to the PCE description in the User’s Manual for the anisotropic index set constraint definition). Similar to anisotropic tensor grids, the dimension with greatest preference will have resolution at the full sparse_grid_level and all other dimension resolutions will be reduced in proportion to their reduced preference. For PCE with either isotropic or anisotropic sparse grids, a summation of tensor-product expansions is used, where each anisotropic tensor-product quadrature rule underlying the sparse grid construction results in its own anisotropic tensor-product expansion as described in case 1. These anisotropic tensor-product expansions are summed into a sparse PCE using the standard Smolyak summation (again, refer to the User’s Manual for additional details). As for quadrature_order, the sparse_grid_level specification admits an array input for enabling specification of multiple grid resolutions used by certain advanced solution methodologies.

This keyword can be used when using sparse grid integration to calculate PCE coefficients or when generating samples for sparse grid collocation.
6.2. METHOD

restricted

- Keywords Area
- method
- polynomial_chaos
- sparse_grid_level
- restricted

Restrict the growth rates for nested and non-nested rules can be synchronized for consistency.

Specification

Alias: none
Argument(s): none
Default: restricted (except for generalized sparse grids)

Description

In the quadrature and sparse grid cases, growth rates for nested and non-nested rules can be synchronized for consistency. For a non-nested Gauss rule used within a sparse grid, linear one-dimensional growth rules of \( m = 2l + 1 \) are used to enforce odd quadrature orders, where \( l \) is the grid level and \( m \) is the number of points in the rule. The precision of this Gauss rule is then \( i = 2m - 1 = 4l + 1 \). For nested rules, order growth with level is typically exponential; however, the default behavior is to restrict the number of points to be the lowest order rule that is available that meets the one-dimensional precision requirement implied by either a level \( l \) for a sparse grid (\( i = 4l + 1 \)) or an order \( m \) for a tensor grid (\( i = 2m - 1 \)). This behavior is known as "restricted growth" or "delayed sequences." To override this default behavior in the case of sparse grids, the unrestricted keyword can be used; it cannot be overridden for tensor grids using nested rules since it also provides a mapping to the available nested rule quadrature orders. An exception to the default usage of restricted growth is the dimension_adaptive_p_refinement generalized sparse grid case described previously, since the ability to evolve the index sets of a sparse grid in an unstructured manner eliminates the motivation for restricting the exponential growth of nested rules.

unrestricted

- Keywords Area

- cubature_integrand

Cubature using Stroud rules and their extensions

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Description**

Multi-dimensional integration by Stroud cubature rules [77] and extensions [90], as specified with `cubature_integrand`. A total-order expansion is used, where the isotropic order $p$ of the expansion is half of the integrand order, rounded down. The total number of terms $N$ for an isotropic total-order expansion of order $p$ over $n$ variables is given by

$$N = 1 + P = 1 + \sum_{s=1}^{p} \frac{1}{s!} \prod_{r=0}^{s-1} (n + r) = \frac{(n + p)!}{n!p!}$$

Since the maximum integrand order is currently five for normal and uniform and two for all other types, at most second- and first-order expansions, respectively, will be used. As a result, cubature is primarily useful for global sensitivity analysis, where the Sobol' indices will provide main effects and, at most, two-way interactions. In addition, the random variable set must be independent and identically distributed (\textit{iid}), so the use of \texttt{askey} or \texttt{wiener} transformations may be required to create \textit{iid} variable sets in the transformed space (as well as to allow usage of the higher order cubature rules for normal and uniform). Note that global sensitivity analysis often assumes uniform bounded regions, rather than precise probability distributions, so the \textit{iid} restriction would not be problematic in that case.

expansion_order

- expansion_order

The (initial) order of a polynomial expansion

**Specification**

**Alias:** none

**Argument(s):** INTEGERLIST
### Description

When the `expansion_order` for a polynomial chaos expansion is specified, the coefficients may be computed by integration based on random samples or by regression using either random or sub-sampled tensor product quadrature points.

Multidimensional integration by Latin hypercube sampling (specified with `expansion_samples`). In this case, the expansion order \( p \) cannot be inferred from the numerical integration specification and it is necessary to provide an `expansion_order` to specify \( p \) for a total-order expansion.

Linear regression (specified with either `collocation_points` or `collocation_ratio`). A total-order expansion is used and must be specified using `expansion_order` as described in the previous option. To avoid requiring the user to calculate \( N \) from \( n \) and \( p \), the `collocation_ratio` allows for specification of a

</table>
constant factor applied to \( N \) (e.g., \( \text{collocation\_ratio} = 2 \) produces samples \( = 2N \)). In addition, the default linear relationship with \( N \) can be overridden using a real-valued exponent specified using \( \text{ratio\_order} \). In this case, the number of samples becomes \( cN^o \) where \( c \) is the \text{collocation\_ratio} and \( o \) is the \text{ratio\_order}. The \text{use\_derivatives} flag informs the regression approach to include derivative matching equations (limited to gradients at present) in the least squares solutions, enabling the use of fewer collocation points for a given expansion order and dimension (number of points required becomes \( \frac{cN^o}{n+1} \)). When admissible, a constrained least squares approach is employed in which response values are first reproduced exactly and error in reproducing response derivatives is minimized. Two collocation grid options are supported: the default is Latin hypercube sampling (“point collocation”), and an alternate approach of “probabilistic collocation” is also available through inclusion of the \text{tensor\_grid} keyword. In this alternate case, the collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

If \text{collocation\_points} or \text{collocation\_ratio} is specified, the PCE coefficients will be determined by regression. If no regression specification is provided, appropriate defaults are defined. Specifically SVD-based least-squares will be used for solving over-determined systems and under-determined systems will be solved using LASSO. For the situation when the number of function values is smaller than the number of terms in a PCE, but the total number of samples including gradient values is greater than the number of terms, the resulting over-determined system will be solved using equality constrained least squares. Technical information on the various methods listed below can be found in the Linear regression section of the Theory Manual. Some of the regression methods (OMP, LASSO, and LARS) are able to produce a set of possible PCE coefficient vectors (see the Linear regression section in the Theory Manual). If cross validation is inactive, then only one solution, consistent with the \text{noise\_tolerance}, will be returned. If cross validation is active, Dakota will choose between possible coefficient vectors found internally by the regression method across the set of expansion orders (1,...,\text{expansion\_order}) and the set of specified noise tolerances and return the one with the lowest cross validation error indicator.

**Argument(s):** REALLIST

**Default:** 1e-3 for BPDN, 0. otherwise (algorithms run until termination)

**Description**

The noise tolerance used when performing cross validation in the presence of noise or truncation errors.
12_penalty

- Keywords Area
- method
- polynomial_chaos
- expansion_order
- collocation_points
- least_absolute_shrinkage
- l2_penalty

The $l_2$ penalty used when performing compressed sensing with elastic net.

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 0. (reverts to standard LASSO formulation)

**Description**

The $l_2$ penalty used when performing compressed sensing with elastic net.

**cross_validation**

- Keywords Area
- method
- polynomial_chaos
- expansion_order
- collocation_points
- cross_validation

Use cross validation to choose the 'best' polynomial order of a polynomial chaos expansion.

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

Use cross validation to choose the 'best' polynomial degree of a polynomial chaos expansion. 10 fold cross validation is used to estimate the cross validation error of a total-order polynomial expansion for orders 1 through to order. The order chosen is the one that produces the lowest cross validation error. If there are not enough points to perform 10 fold cross validation then one-at-a-time cross validation will be performed.
6.2. METHOD

**use_derivatives**

- **Keywords Area**
- **method**
- **polynomial_chaos**
- **expansion_order**
- **collocation_points**
- **use_derivatives**

Use derivative data to construct surrogate models

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** use function values only

**Description**

The `use_derivatives` flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, its use with Surfpack Gaussian process is not recommended.

**tensor_grid**

- **Keywords Area**
- **method**
- **polynomial_chaos**
- **expansion_order**
- **collocation_points**
- **tensor_grid**

Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** regression with LHS sample set (point collocation)
CHAPTER 6. KEYWORDS AREA

Description

The collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

reuse_points

• Keywords Area
• method
• polynomial_chaos
• expansion_order
• collocation_points
• reuse_points

This describes the behavior of reuse of points in constructing polynomial chaos expansion models.

Specification

Alias: reuse_samples
Argument(s): none
Default: no sample reuse in coefficient estimation

Description

The reuse_points option controls the reuse behavior of points for various types of polynomial chaos expansions, including: collocation_points, collocation_ratio, expansion_samples, or orthogonal_least_interpolation. If any of these approaches are specified to create a set of points for the polynomial chaos expansion, one can specify reuse_points so that any points that have been previously generated (for example, from the import_points file) can be reused.

colocation_ratio

• Keywords Area
• method
• polynomial_chaos
• expansion_order
• collocation_ratio

Set the number of points used to build a PCE via regression to be proportional to the number of terms in the expansion.

Specification

Alias: none
Argument(s): REAL

**Description**

Set the number of points used to build a PCE via regression to be proportional to the number of terms in the expansion. To avoid requiring the user to calculate $N$ from $n$ and $p$, the collocation_ratio allows for specification of a constant factor applied to $N$ (e.g., collocation_ratio = 2. produces samples = 2N). In addition, the default linear relationship with $N$ can be overridden using a real-valued exponent specified using ratio_order. In this case, the number of samples becomes $cN^o$ where $c$ is the collocation_ratio and $o$ is the ratio_order. The use_derivatives flag informs the regression approach to include derivative matching equations (limited to gradients at present) in the least squares solutions, enabling the use of fewer collocation points for a given expansion order and dimension (number of points required becomes $\frac{cN^o}{n+1}$).

**ratio_order**

- **Keywords** Area
- method
- polynomial_chaos
- expansion_order
- collocation_ratio
- ratio_order

Specify a non-linear the relationship between the expansion order of a polynomial chaos expansion and the number of samples that will be used to compute the PCE coefficients.

**Specification**

**Alias:** none  
**Argument(s):** REAL  
**Default:** 1.

**Description**

When using regression type methods (specified with either collocation_points or collocation_ratio), a total-order expansion can be specified using expansion_order. To avoid requiring the user to calculate $N$ from $n$ and $p$), the collocation_ratio allows for specification of a constant factor applied to $N$ (e.g., collocation_ratio = 2. produces samples = 2N). In addition, the default linear relationship with $N$ can be overridden using a real-valued exponent specified using ratio_order. In this case, the number of samples becomes $cN^o$ where $c$ is the collocation_ratio and $o$ is the ratio_order.
least_squares

<td></td>
<td>Calculate the coefficients of a polynomial chaos expansion using equality constrained least squares.</td>
</tr>
</tbody>
</table>

**Description**

Compute the coefficients of a polynomial expansion using least squares. Specifically SVD-based least-squares will be used for solving over-determined systems. For the situation when the number of function values is smaller than the number of terms in a PCE, but the total number of samples including gradient values is greater than the number of terms, the resulting over-determined system will be solved using equality constrained least squares

svd

</tr>
</tbody>
</table>

Description

The Number simulation samples to estimate the PCE coefficients. In this case, the expansion order $p$ cannot be inferred from the numerical integration specification and it is necessary to provide an expansion order to specify $p$ for a total-order expansion.

**reuse_points**

- Keywords Area
- method
- polynomial_chaos
- expansion_order
- expansion_samples
- reuse_points

This describes the behavior of reuse of points in constructing polynomial chaos expansion models.

Specification

Alias: reuse_samples

Argument(s): none

Default: no sample reuse in coefficient estimation

Description

The `reuse_points` option controls the reuse behavior of points for various types of polynomial chaos expansions, including: collocation_points, collocation_ratio, expansion_samples, or orthogonal_least_interpolation. If any of these approaches are specified to create a set of points for the polynomial chaos expansion, one can specify `reuse_points` so that any points that have been previously generated (for example, from the import_points file) can be reused.
6.2. METHOD

incremental_lhs

- Keywords Area
- method
- polynomial_chaos
- expansion_order
- expansion_samples
- incremental_lhs

Augments an existing Latin Hypercube Sampling (LHS) study

Specification

Alias: none
- Argument(s): none
- Default: no sample reuse in coefficient estimation

Description

incremental_lhs will augment an existing LHS sampling study with more samples to get better estimates of mean, variance, and percentiles. The number of samples in the second set MUST currently be 2 times the number of previous samples, although incremental sampling based on any power of two may be supported in future releases.

Default Behavior

Incremental Latin Hypercube Sampling is not used by default. To change this behavior, the `incremental_lhs` keyword must be specified in conjunction with the `sample_type` keyword. Additionally, a previous LHS (or incremental LHS) sampling study with sample size \( N \) must have already been performed, and the dakota restart file must be available from this previous study. The variables and responses specifications must be the same in both studies.

Usage Tips

The incremental approach is useful if it is uncertain how many simulations can be completed within available time.

See the examples below and the Usage and Restarting Dakota Studies pages.

Examples

For example, say a user performs an initial study using `lhs` as the `sample_type`, and generates 10 samples.

One way to ensure the restart file is saved is to specify a non-default name, via a command line option:

```
dakota -i LHS_10.in -w LHS_10.rst
```

which uses the input file:

```
# LHS_10.in
environment
  tabular_data
    tabular_data_file = 'lhs10.dat'

method
```
CHAPTER 6. KEYWORDS AREA

sampling
  sample_type lhs
  samples = 10

model
  single

variables
  uniform_uncertain = 2
  descriptors = 'input1' 'input2'
  lower_bounds = -2.0 -2.0
  upper_bounds = 2.0 2.0

interface
  analysis_drivers 'text_book'
  fork

responses
  response_functions = 1
  no_gradients
  no_hessians

and the restart file is written to LHS_10.rst.

Then an incremental LHS study can be run with:

dakota -i LHS_20.in -r LHS_10.rst -w LHS_20.rst

where LHS_20.in is shown below, and LHS_10.rst is the restart file containing the results of the previous LHS study.

# LHS_20.in

environment
  tabular_data
    tabular_data_file = 'lhs_incremental_20.dat'

method
  sampling
    sample_type incremental_lhs
    samples = 20
    previous_samples = 10

model
  single

variables
  uniform_uncertain = 2
  descriptors = 'input1' 'input2'
  lower_bounds = -2.0 -2.0
  upper_bounds = 2.0 2.0

interface
  analysis_drivers 'text_book'
  fork

responses
  response_functions = 1
  no_gradients
  no_hessians

The user will get 10 new LHS samples which maintain both the correlation and stratification of the original LHS sample. The new samples will be combined with the original samples to generate a combined sample of size 20.

This is clearly seen by comparing the two tabular data files.
6.2. METHOD

import_points_file
- Keywords Area
- method
- polynomial_chaos
- expansion_order
- import_points_file

File containing variable values and corresponding responses

Specification

Alias: none
Argument(s): STRING
Default: no point import from a file

<table>
<thead>
<tr>
<th>Required/-Optional</th>
<th>Description of Group tabular format (Group 1)</th>
<th>Dakota Keyword annotated</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional/Choose One</td>
<td></td>
<td>custom_annotated</td>
<td>Selects annotated tabular file format</td>
</tr>
<tr>
<td></td>
<td></td>
<td>freeform</td>
<td>Selects freeform file format</td>
</tr>
</tbody>
</table>

| Optional           | active_only                                   | Import only active variables from tabular data file |

Description

The **import_points_file** allows the user to specify a file that contains a list of variable values and the model responses computed at those values. These can be used by a number of methods in place of model evaluations. When used to construct surrogate models or emulators these are often called build points or training data.

Default Behavior
Be default, methods do not import points from a file.

Usage Tips
Dakota parses input files without regard to whitespace, but the **import_points_file** must be in one of three formats:
- annotated (default)
- custom_annotated
- freeform
CHAPTER 6. KEYWORDS AREA

Examples

```python
method
  list_parameter_study
  import_points_file = 'dakota_pstudy.3.dat'

annotated

- Keywords Area
- method
- polynomial_chaos
- expansion_order
- import_points_file
- annotated

Selects annotated tabular file format
```

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The `annotated` keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify `custom.annotated header eval_id`

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.
6.2. METHOD

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```python
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated

Resulting tabular file:

<table>
<thead>
<tr>
<th>eval_id</th>
<th>interface</th>
<th>x1</th>
<th>x2</th>
<th>obj_fn</th>

CHAPTER 6. KEYWORDS AREA

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```plaintext
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id  x1  x2  obj_fn  nln_ineq_con_1  nln_ineq_con_2
1  0.9  1.1  0.0002  0.26  0.76
2  0.90009  1.1  0.0001996404857  0.2601620081  0.759955
3  0.89991  1.1  0.0002003604863  0.2598380081  0.760045
...
```

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** annotated format
6.2. METHOD

Description
A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior
The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips
- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples
Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
freeform
```

Resulting tabular file:
```
0.9 1.1 0.0002 0.26 0.76
0.90009 1.1 0.0001996404857 0.2601620081 0.759955
0.89991 1.1 0.0002003604863 0.2598380081 0.760045

- method
- polynomial_chaos
- expansion_order
- import_points_file
- active_only

Import only active variables from tabular data file

Topics
This keyword is related to the topics:
- file_formats
CHAPTER 6. KEYWORDS AREA

**Specification**

Alias: none

Argument(s): none

**Description**

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

**orthogonal_least_interpolation**

- **Keywords Area**
- method
- polynomial_chaos
- orthogonal_least_interpolation

Build a polynomial chaos expansion from simulation samples using orthogonal least interpolation.

**Specification**

Alias: least_interpolation_oli

Argument(s): none

**Argument(s):** INTEGERLIST

**Description**

Specify the number of collocation points used to estimate PCE coefficients using orthogonal least interpolation.

**cross_validation**
- **Keywords Area**
- **method**
• polynomial_choas

• orthogonal_least_interpolation

• cross_validation

Use cross validation to choose the ‘best’ polynomial order of a polynomial chaos expansion.

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

Use cross validation to choose the ‘best’ polynomial degree of a polynomial chaos expansion. 10 fold cross validation is used to estimate the cross validation error of a total-order polynomial expansion for orders 1 through to order. The order chosen is the one that produces the lowest cross validation error. If there are not enough points to perform 10 fold cross validation then one-at-a-time cross validation will be performed.

tensor_grid

• Keywords Area

• method

• polynomial_choas

• orthogonal_least_interpolation

• tensor_grid

Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.

**Specification**

**Alias:** none

**Argument(s):** INTEGERLIST

**Default:** regression with LHS sample set (point collocation)

**Description**

The collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.
6.2. METHOD

reuse_points

- Keywords Area
- method
- polynomial_chaos
- orthogonal_least_interpolation
- reuse_points

This describes the behavior of reuse of points in constructing polynomial chaos expansion models.

Specification

Alias: reuse_samples

Argument(s): none

Default: no sample reuse in coefficient estimation

Description

The reuse_points option controls the reuse behavior of points for various types of polynomial chaos expansions, including: collocation_points, collocation_ratio, expansion_samples, or orthogonal_least_interpolation. If any of these approaches are specified to create a set of points for the polynomial chaos expansion, one can specify reuse_points so that any points that have been previously generated (for example, from the import_points file) can be reused.

import_points_file

- Keywords Area
- method
- polynomial_chaos
- orthogonal_least_interpolation
- import_points_file

File containing variable values and corresponding responses

Specification

Alias: none

Argument(s): STRING

Default: no point import from a file

<table>

<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
CHAPTER 6. KEYWORDS AREA

### Description

The `import_points_file` allows the user to specify a file that contains a list of variable values and the model responses computed at those values. These can be used by a number of methods in place of model evaluations. When used to construct surrogate models or emulators these are often called build points or training data.

**Default Behavior**

Be default, methods do not import points from a file.

**Usage Tips**

Dakota parses input files without regard to whitespace, but the `import_points_file` must be in one of three formats:

- annotated (default)
- custom_annotated
- freeform

**Examples**

```plaintext
method
  list_parameter_study
  import_points_file = 'dakota_pstudy.3.dat'
```

- annotated
  - Keywords Area
  - method
  - polynomial_chaos

  - import_points_file
  - annotated

Selects annotated tabular file format
6.2. Method

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
annotated
```

Resulting tabular file:

```
%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 NO_ID 0.9 1.1 0.0002 0.26 0.76
2 NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955

<td>Optional</td>
<td>interaction_order</td>
<td></td>
<td>Specify the maximum number of variables allowed in an interaction when reporting interaction metrics.</td>
</tr>
</tbody>
</table>
CHAPTER 6. KEYWORDS AREA

Optional | drop_tolerance | Suppresses output of sensitivity indices with values lower than this tolerance

### Description
Dakota can calculate sensitivity indices through variance-based decomposition using the keyword `variance_based_decomp`. This approach decomposes main, interaction, and total effects in order to identify the most important variables and combinations of variables in contributing to the variance of output quantities of interest.

### Default Behavior
Because of processing overhead and output volume, `variance_based_decomp` is inactive by default, unless required for dimension-adaptive refinement using Sobol’ indices.

### Expected Outputs
When `variance_based_decomp` is specified, sensitivity indices for main effects, total effects, and any interaction effects will be reported. Each of these effects represents the percent contribution to the variance in the model response, where main effects include the aggregated set of *univariate* terms for each individual variable, interaction effects represent the set of *mixed* terms (the complement of the univariate set), and total effects represent the *complete* set of terms (univariate and mixed) that contain each individual variable. The aggregated set of main and interaction sensitivity indices will sum to one, whereas the sum of total effects sensitivity indices will be greater than one due to redundant counting of mixed terms.

### Usage Tips
An important consideration is that the number of possible interaction terms grows exponentially with dimension and expansion order. To mitigate this, both in terms of compute time and output volume, possible interaction effects are suppressed whenever no contributions are present due to the particular form of an expansion. In addition, the `interaction_order` and `drop_tolerance` controls can further limit the computational and output requirements.

### Examples
```
method,
polynomial_chaos # or stoch_collocation
sparse_grid_level = 3
variance_based_decomp interaction_order = 2
```

### Theory
In this context, we take sensitivity analysis to be global, not local as when calculating derivatives of output variables with respect to input variables. Our definition is similar to that of[73]: “The study of how uncertainty in the output of a model can be apportioned to different sources of uncertainty in the model input.”

Variance based decomposition is a way of using sets of samples to understand how the variance of the output behaves, with respect to each input variable. A larger value of the sensitivity index, $S_i$, means that the uncertainty in the input variable $i$ has a larger effect on the variance of the output. More details on the calculations and interpretation of the sensitivity indices can be found in[87].

### interaction_order
- Keywords Area
6.2. METHOD

- method
- polynomial_chaos
- variance_based_decomp
- interaction_order

Specify the maximum number of variables allowed in an interaction when reporting interaction metrics.

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** Unrestricted (VBD includes all interaction orders present in the expansion)

**Description**

The interaction_order option has been added to allow suppression of higher-order interactions, since the output volume (and memory and compute consumption) of these results could be extensive for high dimensional problems (note: the previous univariate_effects specification is equivalent to interaction_order = 1 in the current specification). Similar to suppression of interactions is the covariance control, which can be selected to be diagonal_covariance or full_covariance, with the former supporting suppression of the off-diagonal covariance terms (to again save compute and memory resources and reduce output volume)

**drop_tolerance**

- Keywords Area
- method
- polynomial_chaos
- variance_based_decomp
- drop_tolerance

Suppresses output of sensitivity indices with values lower than this tolerance

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** All VBD indices displayed

**Description**

The drop_tolerance keyword allows the user to specify a value below which sensitivity indices generated by variance_based_decomp are not displayed.

**Default Behavior**

By default, all sensitivity indices generated by variance_based_decomp are displayed.

**Usage Tips**
For polynomial_chaos, which outputs main, interaction, and total effects by default, the univariate_effects may be a more appropriate option. It allows suppression of the interaction effects since the output volume of these results can be prohibitive for high dimensional problems. Similar to suppression of these interactions is the covariance control, which can be selected to be diagonal_covariance or full_covariance, with the former supporting suppression of the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

Examples

```
method,
  sampling
    sample_type lhs
    samples = 100
    variance_based_decomp
    drop_tolerance = 0.001
```

diagonal_covariance

- Keywords Area
- method
- polynomial_chaos
- diagonal_covariance

Display only the diagonal terms of the covariance matrix

Specification

Alias: none
Argument(s): none
Default: diagonal_covariance for response vector > 10; else full_covariance

Description

With a large number of responses, the covariance matrix can be very large. diagonal_covariance is used to suppress the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

full_covariance

- Keywords Area
- method
- polynomial_chaos
- full_covariance

Display the full covariance matrix

Specification

Alias: none
Argument(s): none
6.2. METHOD

Description
With a large number of responses, the covariance matrix can be very large. `full_covariance` is used to force Dakota to output the full covariance matrix.

normalized
- **Keywords Area**
- **method**
- **polynomial_chaos**
- **normalized**

The normalized specification requests output of PCE coefficients that correspond to normalized orthogonal basis polynomials.

Specification
**Alias:** none
**Argument(s):** none
**Default:** PCE coefficients correspond to unnormalized basis polynomials

Description
The normalized specification requests output of PCE coefficients that correspond to normalized orthogonal basis polynomials.

sample_type
- **Keywords Area**
- **method**
- **polynomial_chaos**
- **sample_type**

Selection of sampling strategy.

Specification
**Alias:** none
**Argument(s):** none
**Default:** lhs

<table>

<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
CHAPTER 6. KEYWORDS AREA

### Description

The `sample_type` keyword allows the user to select between multiple random sampling approaches. There are two primary types of sampling: Monte Carlo (pure random) and Latin Hypercube Sampling. Additionally, these methods have incremental variants that allow an existing study to be augmented with additional samples to get better estimates of mean, variance, and percentiles.

**Default Behavior**

If the `sample_type` keyword is present, it must be accompanied by `lhs`, `random`, `incremental_lhs`, or `incremental_random`. Otherwise, `lhs` will be used by default.

### Examples

```plaintext
method
  sampling
    sample_type lhs
    samples = 20
```

### `lhs`

- **Keywords Area**
- **method**
- **polynomial_chaos**
- **sample_type**
- **lhs**

Uses Latin Hypercube Sampling (LHS) to sample variables

### Specification

**Alias:** none

**Argument(s):** none

### Description

The `lhs` keyword invokes Latin Hypercube Sampling as the means of drawing samples of uncertain variables according to their probability distributions. This is a stratified, space-filling approach that selects variable values from a set of equi-probable bins.

**Default Behavior**
By default, Latin Hypercube Sampling is used. To explicitly specify this in the Dakota input file, however, the \texttt{lhs} keyword must appear in conjunction with the \texttt{sample_type} keyword.

**Usage Tips**

Latin Hypercube Sampling is very robust and can be applied to any problem. It is fairly effective at estimating the mean of model responses and linear correlations with a reasonably small number of samples relative to the number of variables.

**Examples**

```dakota
method
  sampling
  sample_type lhs
  samples = 20
```

**random**

- **Keywords Area**
- **method**
- **polynomial_chaos**
- **sample_type**
- **random**

Uses purely random Monte Carlo sampling to sample variables

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The \texttt{random} keyword invokes Monte Carlo sampling as the means of drawing samples of uncertain variables according to their probability distributions.

**Default Behavior**

Monte Carlo sampling is not used by default. To change this behavior, the \texttt{random} keyword must be specified in conjunction with the \texttt{sample_type} keyword.

**Usage Tips**

Monte Carlo sampling is more computationally expensive than Latin Hypercube Sampling as it requires a larger number of samples to accurately estimate statistics.

**Examples**

```dakota
method
  sampling
  sample_type random
  samples = 200
```
probability_refinement

- Keywords Area
- method
- polynomial_chaos
- probability_refinement

Allow refinement of probability and generalized reliability results using importance sampling.

Topics

This keyword is related to the topics:

- reliability_methods

Specification

Alias: sample_refinement
Argument(s): none
Default: no refinement

<table>
<thead>
<tr>
<th>Required/-Optional</th>

<td>Optional</td>
<td>refinement_samples</td>
<td>adapt_import</td>
<td>Importance sampling option</td>
</tr>
<tr>
<td></td>
<td></td>
<td>mm_adapt_import</td>
<td>Sampling option</td>
</tr>
</tbody>
</table>

Description

The probability_refinement allows refinement of probability and generalized reliability results using importance sampling. If one specifies probability_refinement, there are some additional options. One can specify which type of importance sampling to use (import, adapt_import, or mm_adapt_import). Additionally, one can specify the number of refinement samples to use with refinement_samples and the seed to use with seed.

The probability_refinement density reweighting accounts originally was developed based on Gaussian distributions. It now accounts for additional non-Gaussian cases.

import

- Keywords Area
- method
- polynomial_chaos
6.2. **METHOD**

- **probability_refinement**
- **import**

**Sampling option**

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

**import** centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level).

**adapt_import**

- **Keywords Area**
- **method**
- **polynomial_chaos**
- **probability_refinement**
- **adapt_import**

**Importance sampling option**

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

**adapt_import** centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level). This continues iteratively until the failure probability estimate converges.

**mm_adapt_import**

- **Keywords Area**
- **method**
- **polynomial_chaos**
- **probability_refinement**
- **mm_adapt_import**

**Sampling option**
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none
Argument(s): none

Description

`mm_adapt_import` starts with all of the samples located in the failure region to build a multimodal sampling density. First, it uses a small number of samples around each of the initial samples in the failure region. Note that these samples are allocated to the different points based on their relative probabilities of occurrence: more probable points get more samples. This early part of the approach is done to search for "representative" points. Once these are located, the multimodal sampling density is set and then `mm_adapt_import` proceeds similarly to `adapt_import` (sample until convergence).

refinement_samples

- Keywords Area
- method
- polynomial_chaos
- probability_refinement
- refinement_samples

Specify the number of samples used to improve a probability estimate.

Specification

Alias: none
Argument(s): INTEGER

Description

Specify the number of samples used to improve a probability estimate. If using uni-modal sampling all samples are assigned to the sampling center. If using multi-modal sampling the samples are split between multiple samples according to some internally computed weights.

export_points_file

- Keywords Area
- method
- polynomial_chaos
- export_points_file

Output file for evaluations of a surrogate model

Specification

Alias: none
Argument(s): STRING
Default: no point export to a file
### Description

File of points (input variable values and predicted approximate outputs from the surrogate) evaluated on the surrogate model. The export points contain test point values and the emulator predictions at these points.

#### Usage Tips

Dakota exports tabular data in one of three formats:

- annotated (default)
- custom_annotated
- freeform

#### annotated

- **Keywords Area**
- method
- polynomial_​chaos
- export_​points_​file
- annotated

Selects annotated tabular file format

### Topics

This keyword is related to the topics:

- file_​formats

### Specification

**Alias:** none  
**Argument(s):** none  
**Default:** annotated format
Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The `annotated` keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify `custom_annotated` header eval_id
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```environment
  tabular_data
  tabular_data_file = 'dakota_summary.dat'
  annotated
```

Resulting tabular file:

<table>
<thead>
<tr>
<th>eval_id</th>
<th>interface</th>
<th>x1</th>
<th>x2</th>
<th>obj_fn</th>
<th>nln_ineq_con_1</th>
<th>nln_ineq_con_2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>NO_ID</td>
<td>0.9</td>

</tbody>
</table>

**custom_annotated**

- Keywords Area
- method
- polynomial_chaos
- export_points_file
- custom_annotated

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- file_formats
6.2. METHOD

Specification

Alias: none
Argument(s): none
Default: annotated format

<table>
<thead>
<tr>
<th>Required/-Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>header</td>
<td>Enable header row in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>eval_id</td>
<td>Enable evaluation ID column in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>interface_id</td>
<td>Enable interface ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```dakota
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
custom_annotated header eval_id
```

Resulting tabular file:
### eval_id

- file_formats

**Specification**

**Alias:** none
**Argument(s):** none
**Default:** annotated format
CHAPTER 6. KEYWORDS AREA

Description
A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior
The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips
- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples
Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
  tabular_data
  tabular_data_file = 'dakota_summary.dat'
  freeform
Resulting tabular file:

<table>
<thead>
<tr>
<th>0.9</th>
<th>1.1</th>
<th>0.0002</th>
<th>0.26</th>
<th>0.76</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

export_expansion_file
- Keywords Area
- method
- polynomial_chaos
- export_expansion_file

Export the coefficients and multi-index of a Polynomial Chaos Expansion (PCE) to a file

Specification
Alias: none
Argument(s): STRING
6.2. **METHOD**

**Description**

Export the coefficients and multi-index of a Polynomial Chaos Expansion (PCE) to a file. The multi-index written will be sparse. Specifically the expansion will consist only of the indices corresponding to the non-zero coefficients of the PCE.

**fixed_seed**

- **Keywords Area**
- **method**
- **polynomial_chaos**
- **fixed_seed**

Reuses the same seed value for multiple random sampling sets

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** not fixed; pattern varies run-to-run

**Description**

The **fixed_seed** flag is relevant if multiple sampling sets will be generated over the course of a Dakota analysis. This occurs when using advance methods (e.g., surrogate-based optimization, optimization under uncertainty). The same seed value is reused for each of these multiple sampling sets, which can be important for reducing variability in the sampling results.

**Default Behavior**

The default behavior is to not use a fixed seed, as the repetition of the same sampling pattern can result in a modeling weakness that an optimizer could potentially exploit (resulting in actual reliabilities that are lower than the estimated reliabilities). For repeatable studies, the **seed** must also be specified.

**Examples**

```
method
  sampling
    sample_type lhs
    samples = 10
    fixed_seed
```

**reliability_levels**

- **Keywords Area**
- **method**
- **polynomial_chaos**
- **reliability_levels**

Specify reliability levels at which the response values will be estimated
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none

Argument(s): REALLIST

Default: No CDF/CCDF response levels to compute

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>num_reliability_levels</td>
<td></td>
<td>Specify which reliability_levels correspond to which response</td>
</tr>
</tbody>
</table>

Description

Response levels are calculated for specified CDF/CCDF reliabilities by projecting out the prescribed number of sample standard deviations from the sample mean.

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).

num_reliability_levels

- Keywords Area
- method
- polynomial_chaos
- reliability_levels
- num_reliability_levels

Specify which reliability_levels correspond to which response

Specification

Alias: none

Argument(s): INTEGERLIST

Default: reliability_levels evenly distributed among response functions

Description

See parent page
6.2. METHOD

response_levels

- Keywords Area
- method
- polynomial_chaos
- response_levels

Values at which to estimate desired statistics for each response

**Specification**

*Alias:* none

*Argument(s):* REALLIST

*Default:* No CDF/CCDF probabilities/reliabilities to compute

<table>
<thead>
<tr>
<th>Required/-</th>
<th>Description of</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>Group</td>
<td>num_response_levels</td>
<td>num_response_levels</td>
</tr>
</tbody>
</table>

**Description**

The `response_levels` specification provides the target response values for which to compute probabilities, reliabilities, or generalized reliabilities (forward mapping).

**Default Behavior**

If `response_levels` are not specified, no statistics will be computed. If they are, probabilities will be computed by default.

**Expected Outputs**

The particular statistics reported for each response level depend on the method, and they include:

1. Reliabilities
2. CDF probabilities
3. CCDF probabilities

**Usage Tips**

The `num_response_levels` is used to specify which arguments of the `response_level` correspond to which response.
CHAPTER 6. KEYWORDS AREA

Examples

For example, specifying a response level of 52.3 followed with compute probabilities will result in the calculation of the probability that the response value is less than or equal to 52.3, given the uncertain distributions on the inputs.

For an example with multiple responses, the following specification

```plaintext
response_levels = 1. 2. .1 .2 .3 .4 10. 20. 30.
num_response_levels = 2 4 3
```

would assign the first two response levels (1., 2.) to response function 1, the next four response levels (.1, .2, .3, .4) to response function 2, and the final three response levels (10., 20., 30.) to response function 3. If the num_response_levels key were omitted from this example, then the response levels would be evenly distributed among the response functions (three levels each in this case).

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

A forward mapping involves computing the belief and plausibility probability level for a specified response level.

num_response_levels

- Keywords Area
- method
- polynomial_chaos
- response_levels
- num_response_levels

Number of values at which to estimate desired statistics for each response

Specification

Alias: none

Argument(s): INTEGERLIST

Default: response_levels evenly distributed among response functions

Description

The num_response_levels keyword allows the user to specify the number of response values, for each response, at which estimated statistics are of interest. Statistics that can be computed are probabilities and reliabilities, both according to either a cumulative distribution function or a complementary cumulative distribution function.

Default Behavior

If num_response_levels is not specified, the response_levels will be evenly distributed among the responses.
Expected Outputs
The specific output will be determined by the type of statistics that are specified. In a general sense, the output will be a list of response level-statistic pairs that show the estimated value of the desired statistic for each response level specified.

Examples
method
  sampling
    samples = 100
    seed = 34785
    num_response_levels = 1 1 1
    response_levels = 0.5 0.5 0.5

compute
  • Keywords Area
  • method
  • polynomial_choas

</tbody>
</table>
CHAPTER 6. KEYWORDS AREA

<table>
<thead>
<tr>
<th>Optional</th>
<th>system</th>
<th>gen_reliabilities</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Computes generalized reliabilities associated with response levels</td>
</tr>
</tbody>
</table>

### Description

The `compute` keyword is used to select which forward statistical mapping is calculated at each response level.

#### Default Behavior

If `response_levels` is not specified, no statistics are computed. If `response_levels` is specified but `compute` is not, probabilities will be computed by default. If both `response_levels` and `compute` are specified, then one of the following must be specified: `probabilities`, `reliabilities`, or `gen_reliabilities`.

#### Expected Output

The type of statistics specified by `compute` will be reported for each response level.

#### Usage Tips

CDF/CCDF probabilities are calculated for specified response levels using a simple binning approach. CDF/CCDF reliabilities are calculated for specified response levels by computing the number of sample standard deviations separating the sample mean from the response level.

### Examples

```plaintext
method
sampling
  sample_type random
  samples = 100 seed = 1
  complementary distribution
  response_levels = 3.6e+11 4.0e+11 4.4e+11
  6.0e+04 6.5e+04 7.0e+04
  3.5e+05 4.0e+05 4.5e+05
compute reliabilities
```

### probabilities

- **Keywords Area**
- **method**
- **polynomial_chaos**
- **response_levels**
- **compute**
- **probabilities**

Computes probabilities associated with response levels
6.2. METHOD

Specification

Alias: none

Argument(s): none

Description

The probabilities keyword directs Dakota to compute the probability that the model response will be below (cumulative) or above (complementary cumulative) a specified response value. This is done for every response level designated for each response.

Default Behavior

If response_levels is specified, the probabilities are computed by default. To explicitly specify it in the Dakota input file, though, the probabilities keyword should be specified in conjunction with the compute keyword.

Expected Outputs

The Dakota output is a set of response level-probability pairs that give the probability that the model response will be below or above the corresponding response level, depending on the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
  complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
       6.0e+04 6.5e+04 7.0e+04
       3.5e+05 4.0e+05 4.5e+05
    compute probabilities
```

reliabilities

- reliabilities

Computes reliabilities associated with response levels

Specification

Alias: none

Argument(s): none
CHAPTER 6. KEYWORDS AREA

Description

The `reliabilities` keyword directs Dakota to compute reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

**Default Behavior**

If `response_levels` is specified, the reliabilities are not computed by default. To change this behavior, the `reliabilities` keyword should be specified in conjunction with the `compute` keyword.

**Expected Outputs**

The Dakota output is a set of response level-reliability pairs according to the distribution defined.

Examples

```plaintext
method
    sampling
        sample_type random
        samples = 100 seed = 1
        complementary distribution
        response_levels = 3.6e+11 4.0e+11 4.4e+11
                          6.0e+04 6.5e+04 7.0e+04
                          3.5e+05 4.0e+05 4.5e+05
        compute reliabilities

        gen_reliabilities
```

- **Keywords Area**
- **method**
- **polynomial_chaos**
- **response_levels**
- **compute**
- **gen_reliabilities**

Computes generalized reliabilities associated with response levels

Specification

**Alias:** none

**Argument(s):** none

Description

The `gen_reliabilities` keyword directs Dakota to compute generalized reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

**Default Behavior**

If `response_levels` is specified, the generalized reliabilities are not computed by default. To change this behavior, the `gen_reliabilities` keyword should be specified in conjunction with the `compute` keyword.

**Expected Outputs**

The Dakota output is a set of response level-generalized reliability pairs according to the distribution defined.
6.2. METHOD

Examples

```plaintext
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                      6.0e+04 6.5e+04 7.0e+04
                      3.5e+05 4.0e+05 4.5e+05
    compute gen_reliabilities

system

• polynomial_choas
• response_levels
• compute
• system

Compute system reliability (series or parallel)

Specification

Alias: none
Argument(s): none

| Required/-  | Description of          | Dakota Keyword  | Dakota Keyword |
| Optional     | Group                      |                 | Description    |
| Required(Choose One) | Group 1                      |                 | Description     |
| series       | Aggregate response statistics assuming a series system |
| parallel     | Aggregate response statistics assuming a parallel system |

Description

With the system probability/reliability option, statistics for specified response_levels are calculated and reported assuming the response functions combine either in series or parallel to produce a total system response.

For a series system, the system fails when any one component (response) fails. The probability of failure is the complement of the product of the individual response success probabilities.

For a parallel system, the system fails only when all components (responses) fail. The probability of failure is the product of the individual response failure probabilities.

**Description**

The `distribution` keyword allows the user to select between a cumulative distribution/belief/plausibility function and a complementary cumulative distribution/belief/plausibility function. This choice affects how probabilities and reliability indices are reported.

**Default Behavior**

If the `distribution` keyword is present, it must be accompanied by either `cumulative` or `complementary`. Otherwise, a cumulative distribution will be used by default.

**Expected Outputs**

Output will be a set of model response-probability pairs determined according to the choice of distribution. The choice of distribution also defines the sign of the reliability or generalized reliability indices.

**Examples**

```
method sampling
  sample_type lhs
  samples = 10
  distribution cumulative
```
cumulative

- **Keywords Area**
- **method**
- **polynomial_choas**
- **distribution**
- **cumulative**

Computes statistics according to cumulative functions

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

Statistics on model responses will be computed according to a cumulative distribution/belief/plausibility function.

**Default Behavior**

By default, a cumulative distribution/belief/plausibility function will be used. To explicitly specify it in the Dakota input file, however, the `cumulative` keyword must be appear in conjunction with the `distribution` keyword.

**Expected Outputs**

Output will be a set of model response-probability pairs determined according to a cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls below given response thresholds.

**Examples**

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

complementary

</table>

**Description**

Response levels are calculated for specified CDF/CCDF probabilities by indexing into a sorted samples array (the response levels computed are not interpolated and will correspond to one of the sampled values).
Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).

CHAPTER 6. KEYWORDS AREA

Description
The \texttt{rnum2} keyword directs Dakota to use pseudo-random numbers generated by the Pecos package.

\textbf{Default Behavior}
\texttt{rnum2} is not used by default. To change this behavior, it must be specified in conjunction with the \texttt{rng} keyword.

\textbf{Usage Tips}
Use of the Mersenne twister random number generator (\texttt{mt19937}) is recommended over \texttt{rnum2}.

Examples

\begin{verbatim}
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2
\end{verbatim}

\textbf{samples}

- \texttt{Keywords Area}
- \texttt{method}
- \texttt{polynomial\_chaos}
- \texttt{samples}

Number of samples for sampling-based methods

Specification

\texttt{Alias: none}

\texttt{Argument(s): INTEGER}

\texttt{Default: method-dependent}

Description
The \texttt{samples} keyword is used to define the number of samples (i.e., randomly chosen sets of variable values) at which to execute a model.

\textbf{Default Behavior}
By default, Dakota will use the minimum number of samples required by the chosen method.

\textbf{Usage Tips}
To obtain linear sensitivities or to construct a linear response surface, at least \texttt{dim+1} samples should be used, where "\texttt{dim}" is the number of variables. For sensitivities to quadratic terms or quadratic response surfaces, at least \texttt{(dim+1)(dim+2)/2} samples are needed. For uncertainty quantification, we recommend at least 10+\texttt{dim} samples. For \texttt{variance\_based\_decomp}, we recommend hundreds to thousands of samples. Note that for \texttt{variance\_based\_decomp}, the number of simulations performed will be \texttt{N*(dim+2)}.

Examples

\begin{verbatim}
method
  sampling
    sample_type lhs
    samples = 20
\end{verbatim}
6.2. *METHOD*

**seed**

- **Keywords Area**
- **method**
- **polynomial_chaos**
- **seed**

Seed of the random number generator

**Specification**

**Alias:** none
- **Argument(s):** INTEGER
- **Default:** system-generated (non-repeatable)

**Description**

The random *seed* control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

**Default Behavior**
- If not specified, the seed is randomly generated.

**Expected Output**
- If *seed* is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

**Usage Tips**
- If a stochastic study was run without *seed* specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

**Examples**

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

CHAPTER 6. KEYWORDS AREA

Topics
This keyword is related to the topics:

- block_pointer

Specification
Alias: none
Argument(s): STRING
Default: method use of last model parsed (or use of default model if none parsed)

Description
The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior
If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips
When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.

See block_pointer for details about pointers.

Examples

```plaintext
environment
tabular_graphics_data
method_pointer = 'UQ'

method
id_method = 'UQ'
model_pointer = 'SURRE'

6.2. METHOD

Description

Stochastic collocation is a general framework for approximate representation of random response functions in terms of finite-dimensional interpolation bases.

The stochastic collocation (SC) method is very similar to polynomial chaos, with the key difference that the orthogonal polynomial basis functions are replaced with interpolation polynomial bases. The interpolation polynomials may be either local or global and either value-based or gradient-enhanced. In the local case, value-based are piecewise linear splines and gradient-enhanced are piecewise cubic splines, and in the global case, value-based are Lagrange interpolants and gradient-enhanced are Hermite interpolants. A value-based expansion takes the form

\[ R = \sum_{i=1}^{N_p} r_i L_i(\xi) \]

where \( N_p \) is the total number of collocation points, \( r_i \) is a response value at the \( i^{th} \) collocation point, \( L_i \) is the \( i^{th} \) multidimensional interpolation polynomial, and \( \xi \) is a vector of standardized random variables.

Thus, in PCE, one forms coefficients for known orthogonal polynomial basis functions, whereas SC forms multidimensional interpolation functions for known coefficients.

Basis polynomial family (Group 2)

In addition to the askey and wiener basis types also supported by polynomial chaos, SC supports the option of piecewise local basis functions. These are piecewise linear splines, or in the case of gradient-enhanced interpolation via the use_derivatives specification, piecewise cubic Hermite splines. Both of these basis options provide local support only over the range from the interpolated point to its nearest 1D neighbors (within a tensor grid or within each of the tensor grids underlying a sparse grid), which exchanges the fast convergence of global bases for smooth functions for robustness in the representation of nonsmooth response functions (that can induce Gibbs oscillations when using high-order global basis functions). When local basis functions are used, the usage of nonequidistant collocation points (e.g., the Gauss point selections described above) is not well motivated, so equidistant Newton-Cotes points are employed in this case, and all random variable types are transformed to standard uniform probability space. The global gradient-enhanced interpolants (Hermite interpolation polynomials) are also restricted to uniform or transformed uniform random variables (due to the need to compute collocation weights by integration of the basis polynomials) and share the variable support shown in variable support for Piecewise SE. Due to numerical instability in these high-order basis polynomials, they are deactivated by default but can be activated by developers using a compile-time switch.

Interpolation grid type (Group 3)

To form the multidimensional interpolants \( L_i \) of the expansion, two options are provided.

1. interpolation on a tensor-product of Gaussian quadrature points (specified with quadrature_order and, optionally, dimension_preference for anisotropic tensor grids). As for PCE, non-nested Gauss rules are employed by default, although the presence of p_refinement or h_refinement will result in default usage of nested rules for normal or uniform variables after any variable transformations have been applied (both defaults can be overridden using explicit nested or non_nested specifications).
CHAPTER 6. KEYWORDS AREA

2. interpolation on a Smolyak sparse grid (specified with sparse_grid_level and, optionally, dimension_preference for anisotropic sparse grids) defined from Gaussian rules. As for sparse PCE, nested rules are employed unless overridden with the non_nested option, and the growth rules are restricted unless overridden by the unrestricted keyword.

Another distinguishing characteristic of stochastic collocation relative to polynomial chaos is the ability to reformulate the interpolation problem from a nodal interpolation approach into a hierarchical formulation in which each new level of interpolation defines a set of incremental refinements (known as hierarchical surpluses) layered on top of the interpolants from previous levels. This formulation lends itself naturally to uniform or adaptive refinement strategies, since the hierarchical surpluses can be interpreted as error estimates for the interpolant. Either global or local/piecewise interpolants in either value-based or gradient-enhanced approaches can be formulated using hierarchical interpolation. The primary restriction for the hierarchical case is that it currently requires a sparse grid approach using nested quadrature rules (Genz-Keister, Gauss-Patterson, or Newton-Cotes for standard normals and standard uniforms in a transformed space: Askey, Wiener, or Piecewise settings may be required), although this restriction can be relaxed in the future. A selection of hierarchical interpolation will provide greater precision in the increments to mean, standard deviation, covariance, and reliability-based level mappings induced by a grid change within uniform or goal-oriented adaptive refinement approaches (see following section).

It is important to note that, while quadrature_order and sparse_grid_level are array inputs, only one scalar from these arrays is active at a time for a particular expansion estimation. These scalars can be augmented with a dimension_preference to support anisotropy across the random dimension set. The array inputs are present to support advanced use cases such as multifidelity UQ, where multiple grid resolutions can be employed.

Automated refinement type (Group 1)
Automated expansion refinement can be selected as either p_refinement or h_refinement, and either refinement specification can be either uniform or dimension_adaptive. The dimension_adaptive case can be further specified as either sobol or generalized (decay not supported). Each of these automated refinement approaches makes use of the max_iterations and convergence_tolerance iteration controls. The h_refinement specification involves use of the same piecewise interpolants (linear or cubic Hermite splines) described above for the piecewise specification option (it is not necessary to redundantly specify piecewise in the case of h_refinement). In future releases, the hierarchical interpolation approach will enable local refinement in addition to the current uniform and dimension_adaptive options.

Covariance type (Group 5)
These two keywords are used to specify how this method computes, stores, and outputs the covariance of the responses. In particular, the diagonal covariance option is provided for reducing post-processing overhead and output volume in high dimensional applications.

Active Variables
The default behavior is to form expansions over aleatory uncertain continuous variables. To form expansions over a broader set of variables, one needs to specify active followed by state, epistemic, design, or all in the variables specification block.

For continuous design, continuous state, and continuous epistemic uncertain variables included in the expansion, interpolation points for these dimensions are based on Gauss-Legendre rules if non-nested, Gauss-Patterson rules if nested, and Newton-Cotes points in the case of piecewise bases. Again, when probability integrals are evaluated, only the aleatory random variable domain is integrated, leaving behind a polynomial relationship between the statistics and the remaining design/state/epistemic variables.

Optional Keywords regarding method outputs
Each of these sampling specifications refer to sampling on the SC approximation for the purposes of generating approximate statistics.

• sample_type
6.2. METHOD

- samples
- seed
- fixed_seed
- rng
- probability_refinement
- distribution
- reliability_levels
- response_levels
- probability_levels
- gen.reliability_levels

Since SC approximations are formed on structured grids, there should be no ambiguity with simulation sampling for generating the SC expansion.

When using the probability_refinement control, the number of refinement samples is not under the user’s control (these evaluations are approximation-based, so management of this expense is less critical). This option allows for refinement of probability and generalized reliability results using importance sampling.

**Multi-fidelity UQ**

When using multifidelity UQ, the high fidelity expansion generated from combining the low fidelity and discrepancy expansions retains the polynomial form of the low fidelity expansion (only the coefficients are updated). Refer to polynomial_chaos for information on the multifidelity interpretation of array inputs for quadrature_order and sparse_grid_level.

**Usage Tips**

If \( n \) is small, then tensor-product Gaussian quadrature is again the preferred choice. For larger \( n \), tensor-product quadrature quickly becomes too expensive and the sparse grid approach is preferred. For self-consistency in growth rates, nested rules employ restricted exponential growth (with the exception of the dimension_adaptive_p_refinement generalized case) for consistency with the linear growth used for non-nested Gauss rules (integrand precision \( i = 4l + 1 \) for sparse grid level \( l \) and \( i = 2m - 1 \) for tensor grid order \( m \)).

**Additional Resources**

**Examples**

```plaintext
method,
    stoch_collocation
    sparse_grid_level = 2

    variance_based_decomp
```
CHAPTER 6. KEYWORDS AREA

Theory

As mentioned above, a value-based expansion takes the form

\[ R = \sum_{i=1}^{N_p} r_i L_i(\xi) \]

The \( i^{th} \) interpolation polynomial assumes the value of 1 at the \( i^{th} \) collocation point and 0 at all other collocation points, involving either a global Lagrange polynomial basis or local piecewise splines. It is easy to see that the approximation reproduces the response values at the collocation points and interpolates between these values at other points. A gradient-enhanced expansion (selected via the \texttt{use derivatives} keyword) involves both type 1 and type 2 basis functions as follows:

\[ R = \sum_{i=1}^{N_p} [r_i H_i^{(1)}(\xi) + \sum_{j=1}^{n} \frac{dr_i}{d\xi_j} H_i^{(2)}(\xi)] \]

where the \( i^{th} \) type 1 interpolant produces 1 for the value at the \( i^{th} \) collocation point, 0 for values at all other collocation points, and 0 for derivatives (when differentiated) at all collocation points, and the \( ij^{th} \) type 2 interpolant produces 0 for values at all collocation points, 1 for the \( j^{th} \) derivative component at the \( i^{th} \) collocation point, and 0 for the \( j^{th} \) derivative component at all other collocation points. Again, this expansion reproduces the response values at each of the collocation points, and when differentiated, also reproduces each component of the gradient at each of the collocation points. Since this technique includes the derivative interpolation explicitly, it eliminates issues with matrix ill-conditioning that can occur in the gradient-enhanced PCE approach based on regression. However, the calculation of high-order global polynomials with the desired interpolation properties can be similarly numerically challenging such that the use of local cubic splines is recommended due to numerical stability.

</tr>
</tbody>
</table>

Description

The p-refinement keyword specifies the usage of automated polynomial order refinement, which can be either uniform or dimension_adaptive.

The dimension_adaptive option is supported for the tensor-product quadrature and Smolyak sparse grid options and uniform is supported for tensor and sparse grids as well as regression approaches (collocation_points or collocation_ratio).

Each of these refinement cases makes use of the max_iterations and convergence_tolerance method independent controls. The former control limits the number of refinement iterations, and the latter control terminates refinement when the two-norm of the change in the response covariance matrix (or, in goal-oriented approaches, the two-norm of change in the statistical quantities of interest (QOI)) falls below the tolerance.

The dimension_adaptive case can be further specified to utilize sobol, decay, or generalized refinement controls. The former two cases employ anisotropic tensor/sparse grids in which the anisotropic dimension preference (leading to anisotropic integrations/expansions with differing refinement levels for different random dimensions) is determined using either total Sobol’ indices from variance-based decomposition (sobol case: high indices result in high dimension preference) or using spectral coefficient decay rates from a rate estimation technique similar to Richardson extrapolation (decay case: low decay rates result in high dimension preference). In these two cases as well as the uniform refinement case, the quadrature_order or sparse_grid_level are ramped by one on each refinement iteration until either of the two convergence controls is satisfied. For the uniform refinement case with regression approaches, the expansion_order is ramped by one on each iteration while the oversampling ratio (either defined by collocation_ratio or inferred from collocation_points based on the initial expansion) is held fixed. Finally, the generalized dimension_adaptive case is the default adaptive approach; it refers to the generalized sparse grid algorithm, a greedy approach in which candidate index sets are evaluated for their impact on the statistical QOI, the most influential sets are selected and used to generate additional candidates, and the index set frontier of a sparse grid is evolved in an unstructured and goal-oriented manner (refer to User’s Manual PCE descriptions for additional specifics).
For the case of p_refinement or the case of an explicit nested override, Gauss-Hermite rules are replaced with Genz-Keister nested rules and Gauss-Legendre rules are replaced with Gauss-Patterson nested rules, both of which exchange lower integrand precision for greater point reuse.

**uniform**

**Description**
The quadrature_order or sparse_grid_level are ramped by one on each refinement iteration until either of the two convergence controls is satisfied. For the uniform refinement case with regression approaches, the expansion_order is ramped by one on each iteration while the oversampling ratio (either defined by collocation_ratio or inferred from collocation_points based on the initial expansion) is held fixed.

**dimension_adaptive**
- Keywords Area
- method
- stoch_collocation
- p_refinement

**Description**

Perform anisotropic expansion refinement by preferentially adapting in dimensions that are detected to hold higher ‘importance’ in resolving statistical quantities of interest.

Dimension importance must be estimated as part of the refinement process. Techniques include either sobol or generalized for stochastic collocation and either sobol, decay, or generalized for polynomial chaos. Each of these automated refinement approaches makes use of the max_iterations and convergence_tolerance iteration controls.

sobol

- Keywords Area
- method
- stoch_collocation
- p_refinement
- dimension_adaptive
- sobol

Estimate dimension preference for automated refinement of stochastic expansion using total Sobol’ sensitivity indices.

**Specification**

Alias: none

Argument(s): none

Default: generalized
CHAPTER 6. KEYWORDS AREA

Description
Determine dimension preference for refinement of a stochastic expansion from the total Sobol’ sensitivity indices obtained from global sensitivity analysis. High indices indicate high importance for resolving statistical quantities of interest and therefore result in high dimension preference.

Examples

```plaintext
method,
    polynomial_chaos
    sparse_grid_level = 3
    dimension_adaptive p_refinement sobol
    max_iterations = 20
    convergence_tol = 1.e-4

    generalized
    • Keywords Area
    • method
    • stoch_collocation
    • p_refinement
    • dimension_adaptive
    • generalized

Use the generalized sparse grid dimension adaptive algorithm to refine a sparse grid approximation of stochastic expansion.

Specification
Alias: none
Argument(s): none

Description
The generalized sparse grid algorithm is a greedy approach in which candidate index sets are evaluated for their impact on the statistical QOI, the most influential sets are selected and used to generate additional candidates, and the index set frontier of a sparse grid is evolved in an unstructured and goal-oriented manner (refer to User’s Manual PCE descriptions for additional specifics).

Examples

```plaintext
method,
    polynomial_chaos
    sparse_grid_level = 3
    dimension_adaptive p_refinement generalized
    max_iterations = 20
    convergence_tol = 1.e-4
```
6.2. METHOD

h_refinement

• Keywords Area
• method
• stoch_collocation
• h_refinement

Employ h-refinement to refine the grid

Specification

Alias: none
Argument(s): none
Default: no refinement

Description

Automated expansion refinement can be selected as either p_refinement or h_refinement, and either refinement specification can be either uniform or dimension_adaptive. The dimension_adaptive case can be further specified as either sobol or generalized (decay not supported). Each of these automated refinement approaches makes use of the max_iterations and convergence_tolerance iteration controls. The h_refinement specification involves use of the same piecewise interpolants (linear or cubic Hermite splines) described above for the piecewise specification option (it is not necessary to redundantly specify piecewise in the case of h_refinement). In future releases, the hierarchical interpolation approach will enable local refinement in addition to the current uniform and dimension_adaptive options.
uniform

- Keywords Area
- method
- stoch_collocation
- h_refinement
- uniform

Refine an expansion uniformly in all dimensions.

**Specification**

6.2. METHOD

local_adaptive

• Keywords Area
• method
• stoch_collocation
• h_refinement
• local_adaptive

Planned future capability for local pointwise refinement within a generalized sparse grid.

Specification

Alias: none
Argument(s): none

Description

Sparse grid interpolation admits approaches for pointwise local refinement within the general framework of generalized sparse grids. This algorithmic capability is currently in a partial prototype stage.

piecewise

• Keywords Area
• method
• stoch_collocation
• piecewise

Use piecewise local basis functions

Specification

Alias: none
Argument(s): none
Default: extended (Askey + numerically-generated)

Description

SC also supports the option of piecewise local basis functions. These are piecewise linear splines, or in the case of gradient-enhanced interpolation via the use_derivatives specification, piecewise cubic Hermite splines. Both of these basis selections provide local support only over the range from the interpolated point to its nearest 1D neighbors (within a tensor grid or within each of the tensor grids underlying a sparse grid), which exchanges the fast convergence of global bases for smooth functions for robustness in the representation of nonsmooth response functions (that can induce Gibbs oscillations when using high-order global basis functions). When local basis functions are used, the usage of nonequidistant collocation points (e.g., the Gauss point selections described above) is not well motivated, so equidistant Newton-Cotes points are employed in this case, and all random variable types are transformed to standard uniform probability space.
askey

- Keywords Area
- method
- stoch_collocation
- askey

Select the standardized random variables (and associated basis polynomials) from the Askey family that best match the user-specified random variables.

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** extended (Askey + numerically-generated)

**Description**

The Askey option employs standard normal, standard uniform, standard exponential, standard beta, and standard gamma random variables in a transformed probability space. These selections correspond to Hermite, Legendre, Laguerre, Jacobi, and generalized Laguerre orthogonal polynomials, respectively.

Specific mappings for the basis polynomials are based on a closest match criterion, and include Hermite for normal (optimal) as well as bounded normal, lognormal, bounded lognormal, gumbel, frechet, and weibull (sub-optimal); Legendre for uniform (optimal) as well as loguniform, triangular, and bin-based histogram (sub-optimal); Laguerre for exponential (optimal); Jacobi for beta (optimal); and generalized Laguerre for gamma (optimal).

**See Also**

**quadrature_order**

- Keywords Area
- method
- stoch_collocation
- quadrature_order

Cubature using tensor-products of Gaussian quadrature rules

**Specification**

Alias: none

Argument(s): INTEGERLIST

**Description**

Multidimensional integration by a tensor-product of Gaussian quadrature rules (specified with quadrature_order, and, optionally, dimension_preference). The default rule selection is to employ non_nested Gauss rules including Gauss-Hermite (for normals or transformed normals), Gauss-Legendre (for uniforms or transformed uniforms), Gauss-Jacobi (for betas), Gauss-Laguerre (for exponentials), generalized Gauss-Laguerre (for gammas), and numerically-generated Gauss rules (for other distributions when using an Extended basis). For the case of p_refinement or the case of an explicit nested override, Gauss-Hermite rules are replaced with Genz-Keister nested rules and Gauss-Legendre rules are replaced with Gauss-Patterson nested rules, both of which exchange lower integrand precision for greater point reuse. By specifying a dimension_preference, where higher preference leads to higher order polynomial resolution, the tensor grid may be rendered anisotropic. The dimension specified to have highest preference will be set to the specified quadrature_order and all other dimensions will be reduced in proportion to their reduced preference; any non-integral portion is truncated. To synchronize with tensor-product integration, a tensor-product expansion is used, where the order \( p_i \) of the expansion in each dimension is selected to be half of the integrand precision available from the rule in use,
rounded down. In the case of non-nested Gauss rules with integrand precision \(2m_i - 1\), \(p_i\) is one less than the quadrature order \(m_i\) in each dimension (a one-dimensional expansion contains the same number of terms, \(p + 1\), as the number of Gauss points). The total number of terms, \(N\), in a tensor-product expansion involving \(n\) uncertain input variables is

\[
N = 1 + P = \prod_{i=1}^{n}(p_i + 1)
\]

In some advanced use cases (e.g., multifidelity UQ), multiple grid resolutions can be employed; for this reason, the quadrature_order specification supports an array input.

**sparse_grid_level**

## Description

Multi-dimensional integration by the Smolyak sparse grid method (specified with `sparse_grid_level` and, optionally, `dimension_preference`). The underlying one-dimensional integration rules are the same as for the tensor-product quadrature case; however, the default rule selection is nested for sparse grids (Genz-Keister for normals/transformed normals and Gauss-Patterson for uniforms/transformed uniforms). This default can be overridden with an explicit non_nested specification (resulting in Gauss-Hermite for normals/transformed normals and Gauss-Legendre for uniforms/transformed uniforms). As for tensor quadrature, the `dimension_preference` specification enables the use of anisotropic sparse grids (refer to the PCE description in the User’s Manual for the anisotropic index set constraint definition). Similar to anisotropic tensor grids, the dimension with greatest preference will have resolution at the full `sparse_grid_level` and all other dimension resolutions will be reduced in proportion to their reduced preference. For PCE with either isotropic or anisotropic sparse grids, a summation of tensor-product expansions is used, where each anisotropic tensor-product quadrature rule underlying the sparse grid construction results in its own anisotropic tensor-product expansion as described in case 1. These anisotropic tensor-product expansions are summed into a sparse PCE using the standard Smolyak summation (again, refer to the User’s Manual for additional details). As for quadrature order, the `sparse_grid_level` specification admits an array input for enabling specification of multiple grid resolutions used by certain advanced solution methodologies.

This keyword can be used when using sparse grid integration to calculate PCE coefficients or when generating samples for sparse grid collocation.

- *method*
- *stoch_collocation*
- *sparse_grid_level*
- *unrestricted*

  Override the default restriction of growth rates for nested and non-nested rules that are by default synchronized for consistency.

**Specification**

*Alias:* none
- *Argument(s):* none

**Description**

In the quadrature and sparse grid cases, growth rates for nested and non-nested rules can be synchronized for consistency. For a non-nested Gauss rule used within a sparse grid, linear one-dimensional growth rules of \( m = 2l + 1 \) are used to enforce odd quadrature orders, where \( l \) is the grid level and \( m \) is the number of points in the
6.2. METHOD

The precision of this Gauss rule is then \( i = 2m - 1 = 4l + 1 \). For nested rules, order growth with level is typically exponential; however, the default behavior is to restrict the number of points to be the lowest order rule that is available that meets the one-dimensional precision requirement implied by either a level \( l \) for a sparse grid \( (i = 4l + 1) \) or an order \( m \) for a tensor grid \( (i = 2m - 1) \). This behavior is known as "restricted growth" or "delayed sequences." To override this default behavior in the case of sparse grids, the unrestricted keyword can be used; it cannot be overridden for tensor grids using nested rules since it also provides a mapping to the available nested rule quadrature orders. An exception to the default usage of restricted growth is the dimensionadaptive p-refinement generalized sparse grid case described previously, since the ability to evolve the index sets of a sparse grid in an unstructured manner eliminates the motivation for restricting the exponential growth of nested rules.

</tr>
<tr>
<td>Optional</td>
<td>drop_tolerance</td>
<td></td>
<td>Suppresses output of sensitivity indices with values lower than this tolerance</td>
</tr>
</tbody>
</table>

Description

Dakota can calculate sensitivity indices through variance-based decomposition using the keyword `variance_based_decomp`. This approach decomposes main, interaction, and total effects in order to identify the most important variables and combinations of variables in contributing to the variance of output quantities of interest.

Default Behavior

Because of processing overhead and output volume, `variance_based_decomp` is inactive by default, unless required for dimension-adaptive refinement using Sobol’ indices.

Expected Outputs

When `variance_based_decomp` is specified, sensitivity indices for main effects, total effects, and any interaction effects will be reported. Each of these effects represents the percent contribution to the variance in the model response, where main effects include the aggregated set of univariate terms for each individual variable, interaction effects represent the set of mixed terms (the complement of the univariate set), and total effects represent the complete set of terms (univariate and mixed) that contain each individual variable. The aggregated set of main and interaction sensitivity indices will sum to one, whereas the sum of total effects sensitivity indices will be greater than one due to redundant counting of mixed terms.

Usage Tips

An important consideration is that the number of possible interaction terms grows exponentially with dimension and expansion order. To mitigate this, both in terms of compute time and output volume, possible interaction effects are suppressed whenever no contributions are present due to the particular form of an expansion. In addition, the `interaction_order` and `drop_tolerance` controls can further limit the computational and output requirements.

Examples

```bash
method,
polynomial_chaos # or stoch_collocation
sparse_grid_level = 3
variance_based_decomp interaction_order = 2
```

Theory

In this context, we take sensitivity analysis to be global, not local as when calculating derivatives of output variables with respect to input variables. Our definition is similar to that of [73]: “The study of how uncertainty in the output of a model can be apportioned to different sources of uncertainty in the model input.”
Variance based decomposition is a way of using sets of samples to understand how the variance of the output behaves, with respect to each input variable. A larger value of the sensitivity index, \( S_i \), means that the uncertainty in the input variable \( i \) has a larger effect on the variance of the output. More details on the calculations and interpretation of the sensitivity indices can be found in[87].

**interaction_order**

- Keywords Area
- method
- stoch_collocation
- variance_based_decomp
- interaction_order

Specify the maximum number of variables allowed in an interaction when reporting interaction metrics.

**Specification**

Alias: none

Argument(s): INTEGER

Default: Unrestricted (VBD includes all interaction orders present in the expansion)

**Description**

The interaction_order option has been added to allow suppression of higher-order interactions, since the output volume (and memory and compute consumption) of these results could be extensive for high dimensional problems (note: the previous univariate_effects specification is equivalent to interaction_order = 1 in the current specification). Similar to suppression of interactions is the covariance control, which can be selected to be diagonal_covariance or full_covariance, with the former supporting suppression of the off-diagonal covariance terms (to again save compute and memory resources and reduce output volume)

**drop_tolerance**

- Keywords Area
- method
- stoch_collocation
- variance_based_decomp
- drop_tolerance

Suppresses output of sensitivity indices with values lower than this tolerance

**Specification**

Alias: none

Argument(s): REAL

Default: All VBD indices displayed
6.2. METHOD

Description

The `drop_tolerance` keyword allows the user to specify a value below which sensitivity indices generated by `variance_based_decomp` are not displayed.

**Default Behavior**

By default, all sensitivity indices generated by `variance_based_decomp` are displayed.

**Usage Tips**

For polynomial chaos, which outputs main, interaction, and total effects by default, the `univariate_effects` may be a more appropriate option. It allows suppression of the interaction effects since the output volume of these results can be prohibitive for high dimensional problems. Similar to suppression of these interactions is the covariance control, which can be selected to be `diagonal_c Covariance` or `full_c Covariance`, with the former supporting suppression of the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

**Examples**

```
method,
  sampling
    sample_type lhs
    samples = 100
    variance_based_decomp
drop_tolerance = 0.001
diagonal_c Covariance
```

**diagonal_c Covariance**

- **Keywords Area**
- **method**
- **stoch_collocation**
- **diagonal_c Covariance**

Display only the diagonal terms of the covariance matrix

**Specification**

Alias: none

**Argument(s):** none

**Default:** diagonal_c Covariance for response vector > 10; else full_c Covariance

**Description**

With a large number of responses, the covariance matrix can be very large. `diagonal_c Covariance` is used to suppress the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

**full_c Covariance**

- **Keywords Area**
- **method**
- **stoch_collocation**
• **full_covariance**

Display the full covariance matrix

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

With a large number of responses, the covariance matrix can be very large. `full_covariance` is used to force Dakota to output the full covariance matrix.

**sample_type**

- **Keywords Area**
- **method**
- **stoch_collocation**
- **sample_type**

Selection of sampling strategy

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** lhs

<table>

<td><strong>Uses Latin Hypercube Sampling (LHS) to sample variables</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>random</strong></td>
<td><strong>Uses purely random Monte Carlo sampling to sample variables</strong></td>
</tr>
</tbody>
</table>

**Description**

The `sample_type` keyword allows the user to select between multiple random sampling approaches. There are two primary types of sampling: Monte Carlo (pure random) and Latin Hypercube Sampling. Additionally, these methods have incremental variants that allow an existing study to be augmented with additional samples to get better estimates of mean, variance, and percentiles.

**Default Behavior**

If the `sample_type` keyword is present, it must be accompanied by `lhs`, `random`, `incremental_lhs`, or `incremental_random`. Otherwise, `lhs` will be used by default.
6.2. METHOD

Examples

```
method sampling
  sample_type lhs
  samples = 20
```

**lhs**

- **Keywords Area**
- **method**
- **stoch_collocation**
- **sample_type**
- **lhs**

Uses Latin Hypercube Sampling (LHS) to sample variables

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

The `lhs` keyword invokes Latin Hypercube Sampling as the means of drawing samples of uncertain variables according to their probability distributions. This is a stratified, space-filling approach that selects variable values from a set of equi-probable bins.

**Default Behavior**

By default, Latin Hypercube Sampling is used. To explicitly specify this in the Dakota input file, however, the `lhs` keyword must appear in conjunction with the `sample_type` keyword.

**Usage Tips**

Latin Hypercube Sampling is very robust and can be applied to any problem. It is fairly effective at estimating the mean of model responses and linear correlations with a reasonably small number of samples relative to the number of variables.

Examples

```
method sampling
  sample_type lhs
  samples = 20
```

**random**

- **Keywords Area**
- **method**
- **stoch_collocation**
- **sample_type**
• random

Uses purely random Monte Carlo sampling to sample variables

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The `random` keyword invokes Monte Carlo sampling as the means of drawing samples of uncertain variables according to their probability distributions.

**Default Behavior**

Monte Carlo sampling is not used by default. To change this behavior, the `random` keyword must be specified in conjunction with the `sample_type` keyword.

**Usage Tips**

Monte Carlo sampling is more computationally expensive than Latin Hypercube Sampling as it requires a larger number of samples to accurately estimate statistics.

**Examples**

```plaintext
method
  sampling
    sample_type random
    samples = 200

probability_refinement

  • Keywords Area
  • method
  • stoch_collocation
  • probability_refinement

  Allow refinement of probability and generalized reliability results using importance sampling

**Topics**

This keyword is related to the topics:

• reliability_methods

**Specification**

<tr>
<td></td>
<td></td>
<td>refinement_samples</td>
<td>Specify the number of samples used to improve a probability estimate.</td>
</tr>
</tbody>
</table>

## Description

The `probability_refinement` allows refinement of probability and generalized reliability results using importance sampling. If one specifies `probability_refinement`, there are some additional options. One can specify which type of importance sampling to use (`import`, `adapt`, or `mm`). Additionally, one can specify the number of refinement samples to use with `refinement_samples` and the seed to use with `seed`. The `probability_refinement` density reweighting accounts originally was developed based on Gaussian distributions. It now accounts for additional non-Gaussian cases.

### import

- **Keywords Area**
- **method**
- **stoch_collocation**
- **probability_refinement**
- **import**
- Sampling option

### Specification

**Alias:** none  
**Argument(s):** none

### Description

`import` centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level).

### adapt import

- **Keywords Area**
- **method**
• stoch_collocation

• probability_refinement

• adapt_import

Importance sampling option

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

**adapt_import** centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level). This continues iteratively until the failure probability estimate converges.

**mm_adapt_import**

- **Keywords Area**
- **method**
- **stoch_collocation**
- **probability_refinement**
- **mm_adapt_import**

Sampling option

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

**mm_adapt_import** starts with all of the samples located in the failure region to build a multimodal sampling density. First, it uses a small number of samples around each of the initial samples in the failure region. Note that these samples are allocated to the different points based on their relative probabilities of occurrence: more probable points get more samples. This early part of the approach is done to search for "representative" points. Once these are located, the multimodal sampling density is set and then **mm_adapt_import** proceeds similarly to **adapt_import** (sample until convergence).
6.2. METHOD

refinement_samples

- Keywords Area
- method
- stoch_collocation
- probability_refinement
- refinement_samples

Specify the number of samples used to improve a probability estimate.

Specification

Alias: none
Argument(s): INTEGER

Description

Specify the number of samples used to improve a probability estimate. If using uni-modal sampling all samples are assigned to the sampling center. If using multi-modal sampling the samples are split between multiple samples according to some internally computed weights.

export_points_file

- Keywords Area
- method
- stoch_collocation
- export_points_file

Output file for evaluations of a surrogate model

Specification

Alias: none
Argument(s): STRING
Default: no point export to a file

CHAPTER 6. KEYWORDS AREA

| custom_annotated | Selects custom-annotated tabular file format |
| freeform        | Selects freeform file format                |

**Description**

File of points (input variable values and predicted approximate outputs from the surrogate) evaluated on the surrogate model. The export points contain test point values and the emulator predictions at these points.

**Usage Tips**

Dakota exports tabular data in one of three formats:

- annotated (default)
- custom_annotated
- freeform

**annotated**

- **Keywords Area**
- **method**
- **stoch_collocation**
- **export_points_file**
- **annotated**

Selects annotated tabular file format

**Topics**

This keyword is related to the topics:

- **file_formats**

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** annotated format
6.2. METHOD

Description
An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior
By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips
• To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom.annotated header eval_id
• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples
Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated
```

Resulting tabular file:

```
%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 NO_ID 0.9 1.1 0.0002 0.26 0.76
2 NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 NO_ID 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...
```

custom.annotated

<td>eval_id</td>
<td>eval_id</td>
<td>Enable evaluation ID column in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td>interface_id</td>
<td>interface_id</td>
<td>Enable interface ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
  tabular_data_file = 'dakota_summary.dat'
  custom_annotated header eval_id
```

Resulting tabular file:

```

**Topics**

This keyword is related to the topics:

- file_formats

**Specification**

Alias: none

Argument(s): none

Default: annotated format
6.2. **METHOD**

**Description**

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

**Default Behavior**

The annotated format is the default for tabular export/import. To change this behavior, specify `freeform` in the relevant export/import context.

**Usage Tips**

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though `freeform` remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In `freeform`, the `num_rows x num_cols` total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

**Examples**

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```plaintext
evironment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    freeform
```

Resulting tabular file:

```
0.9 1.1 0.0002 0.26 0.76
0.90009 1.1 0.0001996404857 0.2601620081 0.759955
0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...
```

**fixed_seed**

- **Keywords Area**
  - method
  - stoch_collocation
  - fixed_seed

Reuses the same seed value for multiple random sampling sets

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** not fixed; pattern varies run-to-run
CHAPTER 6. KEYWORDS AREA

Description

The fixed_seed flag is relevant if multiple sampling sets will be generated over the coarse of a Dakota analysis. This occurs when using advance methods (e.g., surrogate-based optimization, optimization under uncertainty). The same seed value is reused for each of these multiple sampling sets, which can be important for reducing variability in the sampling results.

Default Behavior

The default behavior is to not use a fixed seed, as the repetition of the same sampling pattern can result in a modeling weakness that an optimizer could potentially exploit (resulting in actual reliabilities that are lower than the estimated reliabilities). For repeatable studies, the seed must also be specified.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    fixed_seed
```

reliability_levels

- Keywords Area
- method
- stoch_collocation
- reliability_levels

Specify reliability levels at which the response values will be estimated.

Specification

Alias: none

Argument(s): REALLIST

Default: No CDF/CCDF response levels to compute

<table>
<thead>
<tr>
<th>Required/-Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_reliability_levels</td>
<td></td>
<td></td>
<td>Specify which reliability_levels correspond to which response</td>
</tr>
</tbody>
</table>

Description

Response levels are calculated for specified CDF/CCDF reliabilities by projecting out the prescribed number of sample standard deviations from the sample mean.
Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function. In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).

num_reliability_levels

- Keywords Area
- method
- stoch_collocation
- reliability_levels
- num_reliability_levels

Specify which reliability_levels correspond to which response

Specification

Alias: none

Argument(s): INTEGERLIST
Default: reliability_levels evenly distributed among response functions

Description

See parent page

response_levels

- Keywords Area
- method
- stoch_collocation
- response_levels

Values at which to estimate desired statistics for each response

Specification

Alias: none

Argument(s): REALLIST
Default: No CDF/CCDF probabilities/reliabilities to compute
### Description

The `response_levels` specification provides the target response values for which to compute probabilities, reliabilities, or generalized reliabilities (forward mapping).

**Default Behavior**

If `response_levels` are not specified, no statistics will be computed. If they are, probabilities will be computed by default.

**Expected Outputs**

The particular statistics reported for each response level depend on the method, and they include:

1. Reliabilities
2. CDF probabilities
3. CCDF probabilities

**Usage Tips**

The `num_response_levels` is used to specify which arguments of the `response_level` correspond to which response.

### Examples

For example, specifying a `response_level` of 52.3 followed with `compute probabilities` will result in the calculation of the probability that the response value is less than or equal to 52.3, given the uncertain distributions on the inputs.

For an example with multiple responses, the following specification

```plaintext
response_levels = 1. 2. .1 .2 .3 .4 10. 20. 30.
num_response_levels = 2 4 3
```

would assign the first two response levels (1., 2.) to response function 1, the next four response levels (.1, .2, .3, .4) to response function 2, and the final three response levels (10., 20., 30.) to response function 3. If the `num_response_levels` key were omitted from this example, then the response levels would be evenly distributed among the response functions (three levels each in this case).
6.2. METHOD

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function. In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

A forward mapping involves computing the belief and plausibility probability level for a specified response level.

num_response_levels

- Keywords Area
- method
- stoch_collocation
- response_levels
- num_response_levels

Number of values at which to estimate desired statistics for each response

Specification

Alias: none

Argument(s): INTEGERLIST

Default: response_levels evenly distributed among response functions

Description

The num_response_levels keyword allows the user to specify the number of response values, for each response, at which estimated statistics are of interest. Statistics that can be computed are probabilities and reliabilities, both according to either a cumulative distribution function or a complementary cumulative distribution function.

Default Behavior

If num_response_levels is not specified, the response_levels will be evenly distributed among the responses.

Expected Outputs

The specific output will be determined by the type of statistics that are specified. In a general sense, the output will be a list of response level-statistic pairs that show the estimated value of the desired statistic for each response level specified.

Examples

method
  sampling
    samples = 100
    seed = 34785
    num_response_levels = 1 1 1
    response_levels = 0.5 0.5 0.5
compute
  • Keywords Area
  • method
  • stoch_collocation
  • response_levels
  • compute

Selection of statistics to compute at each response level

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** probabilities

<table>
<thead>
<tr>
<th>Required/-Optional</th>
<th>Description of Group</th>

<td>gen_reliabilities</td>
<td><strong>gen_reliabilities</strong></td>
<td>Computes generalized reliabilities associated with response levels</td>
</tr>
<tr>
<td><strong>Optional</strong></td>
<td>system</td>
<td><strong>system</strong></td>
<td>Compute system reliability (series or parallel)</td>
</tr>
</tbody>
</table>

**Description**

The `compute` keyword is used to select which forward statistical mapping is calculated at each response level.

**Default Behavior**

If `response_levels` is not specified, no statistics are computed. If `response_levels` is specified but `compute` is not, probabilities will be computed by default. If both `response_levels` and `compute` are specified, then one of the following must be specified: `probabilities`, `reliabilities`, or `gen_reliabilities`.

**Expected Output**

The type of statistics specified by `compute` will be reported for each response level.
6.2. METHOD

Usage Tips
CDF/CCDF probabilities are calculated for specified response levels using a simple binning approach.
CDF/CCDF reliabilities are calculated for specified response levels by computing the number of sample standard deviations separating the sample mean from the response level.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
  complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
    6.0e+04 6.5e+04 7.0e+04
    3.5e+05 4.0e+05 4.5e+05

probabilities
```

- **Keywords Area**
- method
- stoch_collocation
- response_levels
- compute
- probabilities

Computes probabilities associated with response levels

Specification

**Alias:** none

**Argument(s):** none

Description

The `probabilities` keyword directs Dakota to compute the probability that the model response will be below (cumulative) or above (complementary cumulative) a specified response value. This is done for every response level designated for each response.

**Default Behavior**
If `response_levels` is specified, the probabilities are computed by default. To explicitly specify it in the Dakota input file, though, the `probabilities` keyword should be specified in conjunction with the `compute` keyword.

**Expected Outputs**
The Dakota output is a set of response level-probability pairs that give the probability that the model response will be below or above the corresponding response level, depending on the distribution defined.
Examples

method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                      6.0e+04 6.5e+04 7.0e+04
                      3.5e+05 4.0e+05 4.5e+05
  compute probabilities

reliabilities
  
  Keywords Area
  method
  stoch_collocation
  response_levels
  compute
  reliabilities

Computes reliabilities associated with response levels

Specification

Alias: none
  Argument(s): none

Description

The reliabilities keyword directs Dakota to compute reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

Default Behavior

If response_levels is specified, the reliabilities are not computed by default. To change this behavior, the reliabilities keyword should be specified in conjunction with the compute keyword.

Expected Outputs

The Dakota output is a set of response level-reliability pairs according to the distribution defined.

Examples

method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                      6.0e+04 6.5e+04 7.0e+04
                      3.5e+05 4.0e+05 4.5e+05

<td>parallel</td>
<td>Aggregate response statistics assuming a parallel system</td>
</tr>
</tbody>
</table>

Description

With the system probability/reliability option, statistics for specified response levels are calculated and reported assuming the response functions combine either in series or parallel to produce a total system response.

For a series system, the system fails when any one component (response) fails. The probability of failure is the complement of the product of the individual response success probabilities.

For a parallel system, the system fails only when all components (responses) fail. The probability of failure is the product of the individual response failure probabilities.

| complementary | Computes statistics according to complementary cumulative functions |

Description

The `distribution` keyword allows the user to select between a cumulative distribution/belief/plausibility function and a complementary cumulative distribution/belief/plausibility function. This choice affects how probabilities and reliability indices are reported.

**Default Behavior**

- If the `distribution` keyword is present, it must be accompanied by either `cumulative` or `complementary`. Otherwise, a cumulative distribution will be used by default.

**Expected Outputs**

Output will be a set of model response-probability pairs determined according to the choice of distribution. The choice of distribution also defines the sign of the reliability or generalized reliability indices.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

**cumulative**

- `Keywords Area`
- `method`
- `stoch_collocation`
- `distribution`
- `cumulative`

Computes statistics according to cumulative functions

Specification

Alias: none

Argument(s): none

Description

Statistics on model responses will be computed according to a cumulative distribution/belief/plausibility function.

**Default Behavior**

By default, a cumulative distribution/belief/plausibility function will be used. To explicitly specify it in the Dakota input file, however, the `cumulative` keyword must be appear in conjunction with the `distribution` keyword.
6.2. METHOD

Expected Outputs
Output will be a set of model response-probability pairs determined according to a cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls below given response thresholds.

Examples
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative

complementary

- Keywords Area
- method
- stoch_collocation
- distribution
- complementary

Computes statistics according to complementary cumulative functions

Specification
Alias: none
  Argument(s): none

Description
Statistics on model responses will be computed according to a complementary cumulative distribution/belief/plausibility function.

Default Behavior
By default, a complementary cumulative distribution/belief/plausibility function will not be used. To change that behavior, the complementary keyword must be appear in conjunction with the distribution keyword.

Expected Outputs
Output will be a set of model response-probability pairs determined according to a complementary cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls above given response thresholds.

Examples
method
  sampling
    sample_type lhs
    samples = 10
    distribution complementary
probability_levels
- Keywords Area
- method
- stoch_collocation
- probability_levels

Specify probability levels at which to estimate the corresponding response value

**Specification**

Alias: none

**Argument(s):** REALLIST

**Default:** No CDF/CCDF response levels to compute

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>num_probability_levels</td>
<td></td>
<td>Specify which probability_levels correspond to which response</td>
</tr>
</tbody>
</table>

**Description**

Response levels are calculated for specified CDF/CCDF probabilities by indexing into a sorted samples array (the response levels computed are not interpolated and will correspond to one of the sampled values).

**Theory**

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).
6.2. METHOD

Specification

Alias: none

Argument(s): INTEGERLIST

Default: probability_levels evenly distributed among response functions

Description

See parent page

gen_reliability_levels

- Keywords Area
- method
- stoch_collocation
- gen_reliability_levels

Specify generalized reliability levels at which to estimate the corresponding response value

Specification

Alias: none

Argument(s): REALLIST

<td>Generates random numbers using the Mersenne twister</td>
</tr>
<tr>
<td></td>
<td></td>
<td>rnum2</td>
<td>Generates pseudo-random numbers using the Pecos package</td>
</tr>
</tbody>
</table>
6.2. METHOD

Description

The *rng* keyword is used to indicate a choice of random number generator.

**Default Behavior**

If specified, the *rng* keyword must be accompanied by either *rnum2* (pseudo-random numbers) or *mt19937* (random numbers generated by the Mersenne twister). Otherwise, *mt19937*, the Mersenne twister is used by default.

**Usage Tips**

The default is recommended, as the Mersenne twister is a higher quality random number generator.

**Examples**

```
method sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2
```

```
mt19937
```

- **Keywords Area**
- **method**
- **stoch_collocation**
- **rng**
- **mt19937**

Generates random numbers using the Mersenne twister

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The *mt19937* keyword directs Dakota to use the Mersenne twister to generate random numbers. Additional information can be found on wikipedia: [http://en.wikipedia.org/wiki/Mersenne_twister](http://en.wikipedia.org/wiki/Mersenne_twister).

**Default Behavior**

*mt19937* is the default random number generator. To specify it explicitly in the Dakota input file, however, it must be specified in conjuction with the *rng* keyword.

**Usage Tips**

Use of the Mersenne twister random number generator (*mt19937*) is recommended.

**Examples**

```
method sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng mt19937
```
**rnum2**

- Keywords Area
- method
- stoch_collocation
- rng
- rnum2

Generates pseudo-random numbers using the Pecos package

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The `rnum2` keyword directs Dakota to use pseudo-random numbers generated by the Pecos package.

**Default Behavior**

`rnum2` is not used by default. To change this behavior, it must be specified in conjunction with the `rng` keyword.

**Usage Tips**

Use of the Mersenne twister random number generator (`mt19937`) is recommended over `rnum2`.

**Examples**

```dakota
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2
```
6.2. METHOD

Description
The `samples` keyword is used to define the number of samples (i.e., randomly chosen sets of variable values) at which to execute a model.

Default Behavior
By default, Dakota will use the minimum number of samples required by the chosen method.

Usage Tips
To obtain linear sensitivities or to construct a linear response surface, at least `dim+1` samples should be used, where "dim" is the number of variables. For sensitivities to quadratic terms or quadratic response surfaces, at least `(dim+1)(dim+2)/2` samples are needed. For uncertainty quantification, we recommend at least `10*dim` samples. For `variance_based_decomp`, we recommend hundreds to thousands of samples. Note that for `variance_based_decomp`, the number of simulations performed will be `N*(dim+2)`.

Examples
```plaintext
method
  sampling
    sample_type lhs
    samples = 20

seed
  Keywords Area
  method
  stoch_collocation
  seed

  Seed of the random number generator
```

Specification

Alias: none
Argument(s): INTEGER
Default: system-generated (non-repeatable)

Description
The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior
If not specified, the seed is randomly generated.

Expected Output
If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips
If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.
Examples

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

**model_pointer**

- **Keywords Area**
- **method**
- **stoch_collocation**
- **model_pointer**

Identifier for model block to be used by a method

**Topics**

This keyword is related to the topics:

- **block_pointer**

**Specification**

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)

**Description**

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

**Usage Tips**

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

**Examples**

```plaintext
environment
  tabular_graphics_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
```
6.2. METHOD

```
seed = 98765 rng rnum2
response_levels = 0.1 0.2 0.6
sample_type lhs
distribution cumulative

model
  id_model = 'SURR'
surrogate global,
dace_method_pointer = 'DACE'
polynomial quadratic

method
  id_method = 'DACE'
  model_pointer = 'DACE_M'
sampling sample_type lhs
  samples = 121 seed = 5034 rng rnum2

model
  id_model = 'DACE_M'
single
  interface_pointer = 'I1'

variables
  uniform_uncertain = 2
    lower_bounds = 0. 0.
    upper_bounds = 1. 1.
    descriptors = 'x1' 'x2'

interface
  id_interface = 'I1'
system asynch evaluation_concurrency = 5
  analysis_driver = 'text_book'

responses
  response_functions = 3
  no_gradients
  no_hessians
```

6.2.53 sampling

</tbody>
</table>

**Description**

This method generates parameter values by drawing samples from the specified uncertain variable probability distributions. The computational model is executed over all generated parameter values to compute the responses for which statistics are computed. The statistics support sensitivity analysis and uncertainty quantification.

**Default Behavior**

By default, sampling methods operate on aleatory and epistemic uncertain variables. The types of variables can be restricted or expanded (to include design or state variables) through use of the active keyword in the variables block in the Dakota input file. If continuous design and/or state variables are designated as active, the sampling algorithm will treat them as parameters with uniform probability distributions between their upper and lower bounds. Refer to variable_support for additional information on supported variable types, with and without correlation.

The following keywords change how the samples are selected:

- sample_type
- fixed_seed
- rng
- samples
- seed
• variance_based_decomp

Expected Outputs

As a default, Dakota provides correlation analyses when running LHS. Correlation tables are printed with the simple, partial, and rank correlations between inputs and outputs. These can be useful to get a quick sense of how correlated the inputs are to each other, and how correlated various outputs are to inputs. variance_based_decomp is used to request more sensitivity information, with additional cost.

Additional statistics can be computed from the samples using the following keywords:

• response_levels
• reliability_levels
• probability_levels
• gen_reliability_levels

response_levels computes statistics at the specified response value. The other three allow the specification of the statistic value, and will estimate the corresponding response value.

distribution is used to specify whether the statistic values are from cumulative or complementary cumulative functions.

Usage Tips

sampling is a robust approach to doing sensitivity analysis and uncertainty quantification that can be applied to any problem. It requires more simulations than newer, advanced methods. Thus, an alternative may be preferable if the simulation is computationally expensive.

Examples

# tested on Dakota 6.0 on 140501

environment

responses
response_functions = 1
This example illustrates a basic sampling Dakota input file.

- LHS is used instead of purely random sampling.
- The default random number generator is used.
- Without a *seed* specified, this will not be reproducible.
- In the *variables* block, two types of variables are used.
- Only the uncertain variables are varied, this is the default behavior, and is also specified by the *active* keyword, w/ the *uncertain* option.

**See Also**

These keywords may also be of interest:

- *active*
- *incremental_lhs*

**FAQ**

Q: Do I need to keep the LHS* and S4 files? A: No.

**sample_type**

- *Keywords Area*
- *method*
- *sampling*
- *sample_type*

Selection of sampling strategy

**Specification**

Alias: none

Argument(s): none

Default: lhs
<table>
<thead>
<tr>
<th>Required/-Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required <em>(Choose One)</em></td>
<td>Dakota Keyword random</td>
<td>lhs</td>
<td>Uses purely random Monte Carlo sampling to sample variables</td>

<td></td>
<td></td>
<td>incremental_lhs</td>
<td>Augments an existing Latin Hypercube Sampling (LHS) study</td>
</tr>
<tr>
<td></td>
<td></td>
<td>incremental_random</td>
<td>Augments an existing random sampling study</td>
</tr>
</tbody>
</table>

**Description**

The `sample_type` keyword allows the user to select between multiple random sampling approaches. There are two primary types of sampling: Monte Carlo (pure random) and Latin Hypercube Sampling. Additionally, these methods have incremental variants that allow an existing study to be augmented with additional samples to get better estimates of mean, variance, and percentiles.

**Default Behavior**

If the `sample_type` keyword is present, it must be accompanied by `lhs`, `random`, `incremental_lhs`, or `incremental_random`. Otherwise, `lhs` will be used by default.

**Examples**

```plaintext
method sampling
  sample_type lhs
  samples = 20
```

**random**

- Keywords Area
- method
- sampling
- sample_type
- random

Uses purely random Monte Carlo sampling to sample variables
6.2. METHOD

Specification

Alias: none
Argument(s): none

Description

The random keyword invokes Monte Carlo sampling as the means of drawing samples of uncertain variables according to their probability distributions.

Default Behavior

Monte Carlo sampling is not used by default. To change this behavior, the random keyword must be specified in conjunction with the sample_type keyword.

Usage Tips

Monte Carlo sampling is more computationally expensive than Latin Hypercube Sampling as it requires a larger number of samples to accurately estimate statistics.

Examples

```dakota
method
sampling
    sample_type random
    samples = 200
```

lhs

- Keywords Area
- method
- sampling
- sample_type
- lhs

Uses Latin Hypercube Sampling (LHS) to sample variables

Specification

Alias: none
Argument(s): none

Description

The lhs keyword invokes Latin Hypercube Sampling as the means of drawing samples of uncertain variables according to their probability distributions. This is a stratified, space-filling approach that selects variable values from a set of equi-probable bins.

Default Behavior

By default, Latin Hypercube Sampling is used. To explicitly specify this in the Dakota input file, however, the lhs keyword must appear in conjunction with the sample_type keyword.

Usage Tips

Latin Hypercube Sampling is very robust and can be applied to any problem. It is fairly effective at estimating the mean of model responses and linear correlations with a reasonably small number of samples relative to the number of variables.
Examples

```
method
  sampling
    sample_type lhs
    samples = 20
```

```
incremental_lhs

- Keywords Area
- method
- sampling
- sample_type
- incremental_lhs
```

Augments an existing Latin Hypercube Sampling (LHS) study

Specification

Alias: none

Argument(s): none

Default: no sample reuse in coefficient estimation

<table>
<thead>
<tr>
<th>Required/-Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required</td>
<td></td>
<td>previous_samples</td>
<td>Number of samples from an already-completed sampling study</td>
</tr>
</tbody>
</table>

Description

incremental_lhs will augment an existing LHS sampling study with more samples to get better estimates of mean, variance, and percentiles. The number of samples in the second set MUST currently be 2 times the number of previous samples, although incremental sampling based on any power of two may be supported in future releases.

**Default Behavior**

Incremental Latin Hypercube Sampling is not used by default. To change this behavior, the `incremental_lhs` keyword must be specified in conjunction with the `sample_type` keyword. Additionally, a previous LHS (or incremental LHS) sampling study with sample size \( N \) must have already been performed, and the `dakota restart file` must be available from this previous study. The variables and responses specifications must be the same in both studies.

**Usage Tips**

The incremental approach is useful if it is uncertain how many simulations can be completed within available time.

See the examples below and the `Usage` and `Restarting Dakota Studies` pages.
6.2. METHOD

Examples

For example, say a user performs an initial study using \texttt{lhs} as the \texttt{sample_type}, and generates 10 samples. One way to ensure the restart file is saved is to specify a non-default name, via a command line option:

\begin{verbatim}
dakota -i LHS_10.in -w LHS_10.rst
which uses the input file:
\end{verbatim}

\begin{verbatim}
# LHS_10.in

environment
  tabular_data
    tabular_data_file = ‘lhs10.dat’

method
  sampling
    sample_type lhs
    samples = 10

model
  single

variables
  uniform_uncertain = 2
  descriptors = ‘input1’ ‘input2’
  lower_bounds = -2.0 -2.0
  upper_bounds = 2.0 2.0

interface
  analysis_drivers ‘text_book’
  fork

responses
  response_functions = 1
  no_gradients
  no_hessians

and the restart file is written to LHS_10.rst.

Then an incremental LHS study can be run with:

\begin{verbatim}
dakota -i LHS_20.in -r LHS_10.rst -w LHS_20.rst
\end{verbatim}

where \texttt{LHS_20.in} is shown below, and \texttt{LHS_10.rst} is the restart file containing the results of the previous LHS study.

\begin{verbatim}
# LHS_20.in

environment
  tabular_data
    tabular_data_file = ‘lhs_incremental_20.dat’

method
  sampling
    sample_type incremental_lhs
    samples = 20
    previous_samples = 10

model
  single

variables
  uniform_uncertain = 2
\end{verbatim}
The user will get 10 new LHS samples which maintain both the correlation and stratification of the original LHS sample. The new samples will be combined with the original samples to generate a combined sample of size 20.

This is clearly seen by comparing the two tabular data files.

**Previous Samples**

- **Keywords Area**
- **Method**
- **Sampling**
- **Sample Type**
- **Incremental LHS**
- **Previous Samples**

Number of samples from an already-completed sampling study

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 0 (no previous_samples)

**Description**

The `previous_samples` keyword allows the user to specify the number of samples in an existing sample set that is to be augmented using the `incremental_lhs` or `incremental_random` approach.

**Default Behavior**

If not specified, Dakota will assume that there are no existing samples. If specified, there must be a Dakota restart file available that contains the samples.

**Examples**

```
method
sampling
  sample_type incremental_lhs
  samples = 20
  previous_samples = 10
```
incremental_random

- Keywords Area
- method
- sampling
- sample_type
- incremental_random

Augments an existing random sampling study

**Specification**

**Alias:** none

**Argument(s):** none

<table>
<thead>
<tr>
<th>Required/-</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>previous_samples</td>
<td>Number of samples from an already-completed sampling study</td>
</tr>
<tr>
<td>Required</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Description**

incremental_random will augment an existing random sampling study with more samples to get better estimates of mean, variance, and percentiles. The number of samples in the second set MUST currently be 2 times the number of previous samples, although incremental sampling based on any power of two may be supported in future releases.

**Default Behavior**

Incremental random sampling is not used by default. To change this behavior, the incremental_random keyword must be specified in conjunction with the sample_type keyword. Additionally, a previous random sampling study with sample size N must have already been performed, and the dakota restart file must be available from this previous study. The variables and responses specifications must be the same in both studies.

**Usage Tips**

The incremental approach is useful if it is uncertain how many simulations can be completed within available time.

**Examples**

For example, say a user performs an initial study using random as the sample_type, and generates 50 samples. If the user creates a new input file where samples is now specified to be 100, the sample_type is defined to be incremental_random, and previous_samples is specified to be 50, the user will get 50 new random samples. The N new samples will be combined with the N previous samples to generate a combined sample of size 2N.

The method block would be the following:

```
method
  sampling
    sample_type incremental_random
    samples = 100
    previous_samples = 50
```
The syntax for running the second sample set is:

dakota -i input2.in -r dakota.rst

where input2.in is the file which specifies incremental sampling and dakota.rst is the restart file containing the results of the previous study.

previous_samples

- Keywords Area
- method
- sampling
- sample_type
- incremental_random
- previous_samples

Number of samples from an already-completed sampling study

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 0 (no previous_samples)

**Description**

The previous_samples keyword allows the user to specify the number of samples in an existing sample set that is to be augmented using the incremental_lhs or incremental_random approach.

**Default Behavior**

If not specified, Dakota will assume that there are no existing samples. If specified, there must be a Dakota restart file available that contains the samples.

**Examples**

```
method
  sampling
    sample_type incremental_lhs
    samples = 20
    previous_samples = 10
```

**variance_based_decomp**

- Keywords Area
- method
- sampling
- variance_based_decomp

Activates global sensitivity analysis based on decomposition of response variance into contributions from variables
6.2. METHOD

Specification

Alias: none

Argument(s): none

Default: no variance-based decomposition

<table>
<thead>
<tr>
<th>Required/-Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>drop_tolerance</td>
<td>Suppresses output of sensitivity indices with values lower than this tolerance</td>
</tr>
</tbody>
</table>

Description

Dakota can calculate sensitivity indices through variance based decomposition using the keyword `variance-based_decomp`. These indicate how important the uncertainty in each input variable is in contributing to the output variance.

Default Behavior

Because of the computational cost, `variance_based_decomp` is turned off as a default.

If the user specified a number of samples, \( N \), and a number of nondeterministic variables, \( M \), variance-based decomposition requires the evaluation of \( N \times (M+2) \) samples. **Note that specifying this keyword will increase the number of function evaluations above the number requested with the `samples` keyword since replicated sets of sample values are evaluated.**

Expected Outputs

When `variance_based_decomp` is specified, sensitivity indices for main effects and total effects will be reported. Main effects (roughly) represent the percent contribution of each individual variable to the variance in the model response. Total effects represent the percent contribution of each individual variable in combination with all other variables to the variance in the model response.

Usage Tips

To obtain sensitivity indices that are reasonably accurate, we recommend that \( N \), the number of samples, be at least one hundred and preferably several hundred or thousands.

Examples

```text
method,
sampling
    sample_type lhs
    samples = 100
    variance_based_decomp
```

Theory

In this context, we take sensitivity analysis to be global, not local as when calculating derivatives of output variables with respect to input variables. Our definition is similar to that of[73]: “The study of how uncertainty in the output of a model can be apportioned to different sources of uncertainty in the model input.”

Variance based decomposition is a way of using sets of samples to understand how the variance of the output behaves, with respect to each input variable. A larger value of the sensitivity index, \( S_i \), means that the uncertainty in the input variable \( i \) has a larger effect on the variance of the output. More details on the calculations and interpretation of the sensitivity indices can be found in[73] and[87].
drop_tolerance

- Keywords Area
- method
- sampling
- variance_based_decomp
- drop_tolerance

Suppresses output of sensitivity indices with values lower than this tolerance

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** All VBD indices displayed

**Description**

The `drop_tolerance` keyword allows the user to specify a value below which sensitivity indices generated by `variance_based_decomp` are not displayed.

**Default Behavior**

By default, all sensitivity indices generated by `variance_based_decomp` are displayed.

**Usage Tips**

For polynomial chaos, which outputs main, interaction, and total effects by default, the `univariate_effects` may be a more appropriate option. It allows suppression of the interaction effects since the output volume of these results can be prohibitive for high dimensional problems. Similar to suppression of these interactions is the covariance control, which can be selected to be diagonal_covariance or full_covariance, with the former supporting suppression of the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

**Examples**

```plaintext
method,
sampling
  sample_type lhs
  samples = 100
  variance_based_decomp
drop_tolerance = 0.001
```

**backfill**

- Keywords Area
- method
- sampling
- backfill

Ensures that the samples of discrete variables with finite support are unique
6.2. METHOD

Specification

Alias: none

Argument(s): none

Description

Traditional LHS can generate replicate samples when applied to discrete variables. This keyword enforces uniqueness, which is determined only over the set of discrete variables with finite support. This allows one to generate LHS for a mixed set of continuous and discrete variables whilst still enforcing that the set of discrete LHS components of all the samples are unique.

Default Behavior

Uniqueness of samples over discrete variables is not enforced.

Usage Tips

Uniqueness can be useful when applying discrete LHS to simulations without noise.

Examples

```plaintext
method,
  sampling
    samples = 12
    seed = 123456
    sample_type lhs backfill

variables,
  active all
  uniform_uncertain = 1
  lower_bounds = 0.
  upper_bounds = 1.
  descriptors = ‘continuous-uniform’

  discrete_uncertain_set
    integer = 1
    elements_per_variable = 4
    elements 1 3 5 7
    descriptors = ‘design-set-int’
    real = 1
    initial_point = 0.50
    set_values = 0.25 0.50 0.75 1.00
    descriptors = ‘design-set-real’

interface,
  direct analysis_driver = ‘text_book’

responses,
  response_functions = 3
  no_gradients
  no_hessians
```

See Also

These keywords may also be of interest:

- lhs
fixed_seed

- Keywords Area
- method
- sampling
- fixed_seed

Reuses the same seed value for multiple random sampling sets

**Specification**

*Alias*: none

*Argument(s)*: none

*Default*: not fixed; pattern varies run-to-run

**Description**

The `fixed_seed` flag is relevant if multiple sampling sets will be generated over the coarse of a Dakota analysis. This occurs when using advance methods (e.g., surrogate-based optimization, optimization under uncertainty). The same seed value is reused for each of these multiple sampling sets, which can be important for reducing variability in the sampling results.

**Default Behavior**

The default behavior is to not use a fixed seed, as the repetition of the same sampling pattern can result in a modeling weakness that an optimizer could potentially exploit (resulting in actual reliabilities that are lower than the estimated reliabilities). For repeatable studies, the `seed` must also be specified.

**Examples**

```dakota
method
sampling
  sample_type lhs
  samples = 10
  fixed_seed

reliability_levels

- Keywords Area
- method
- sampling
- reliability_levels

Specify reliability levels at which the response values will be estimated

**Specification**

*Alias*: none

*Argument(s)*: REALLIST

*Default*: No CDF/CCDF response levels to compute
### Description

Response levels are calculated for specified CDF/CCDF reliabilities by projecting out the prescribed number of sample standard deviations from the sample mean.

### Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).

**num_reliability_levels**

- **Keywords Area**

- **reliability_levels**
- **num_reliability_levels**

Specify which `reliability_levels` correspond to which response

### Specification

**Alias:** none

**Argument(s):** INTEGERLIST

**Default:** reliability_levels evenly distributed among response functions

### Description

See parent page
response_levels

- Keywords Area
- method
- sampling
- response_levels

Values at which to estimate desired statistics for each response

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Default:** No CDF/CCDF probabilities/reliabilities to compute

<table>
<thead>
<tr>
<th>Required/-Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>num_response_levels</td>
<td>num_response_levels</td>
<td>Number of values at which to estimate desired statistics for each response</td>
</tr>
<tr>
<td>Optional</td>
<td>compute</td>
<td>compute</td>
<td>Selection of statistics to compute at each response level</td>
</tr>
</tbody>
</table>

**Description**

The `response_levels` specification provides the target response values for which to compute probabilities, reliabilities, or generalized reliabilities (forward mapping).

**Default Behavior**

If `response_levels` are not specified, no statistics will be computed. If they are, probabilities will be computed by default.

**Expected Outputs**

The particular statistics reported for each response level depend on the method, and they include:

1. Reliabilities
2. CDF probabilities
3. CCDF probabilities

**Usage Tips**

The `num_response_levels` is used to specify which arguments of the `response_level` correspond to which response.
6.2. METHOD

Examples

For example, specifying a response_level of 52.3 followed with compute probabilities will result in the calculation of the probability that the response value is less than or equal to 52.3, given the uncertain distributions on the inputs.

For an example with multiple responses, the following specification

```plaintext
response_levels = 1. 2. .1 .2 .3 .4 10. 20. 30.
num_response_levels = 2 4 3
```

would assign the first two response levels (1., 2.) to response function 1, the next four response levels (.1, .2, .3, .4) to response function 2, and the final three response levels (10., 20., 30.) to response function 3. If the num_response_levels key were omitted from this example, then the response levels would be evenly distributed among the response functions (three levels each in this case).

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

A forward mapping involves computing the belief and plausibility probability level for a specified response level.

```plaintext
num_response_levels
```

- Keywords Area
- method
- sampling
- response_levels
- num_response_levels

Number of values at which to estimate desired statistics for each response

Specification

Alias: none

Argument(s): INTEGERLIST

Default: response_levels evenly distributed among response functions

Description

The num_response_levels keyword allows the user to specify the number of response values, for each response, at which estimated statistics are of interest. Statistics that can be computed are probabilities and reliabilities, both according to either a cumulative distribution function or a complementary cumulative distribution function.

Default Behavior

If num_response_levels is not specified, the response_levels will be evenly distributed among the responses.
Expected Outputs
The specific output will be determined by the type of statistics that are specified. In a general sense, the output will be a list of response level-statistic pairs that show the estimated value of the desired statistic for each response level specified.

Examples
method
sampling
  samples = 100
  seed = 34785
  num_response_levels = 1 1 1
  response_levels = 0.5 0.5 0.5
compute
  • Keywords Area
  • method
  • sampling
  • response_levels
  • compute
Selection of statistics to compute at each response level

Specification
Alias: none

</tr>
</tbody>
</table>

Computes probabilities associated with response levels
Computes reliabilities associated with response levels

### 6.2. METHOD

<table>
<thead>
<tr>
<th></th>
<th>gen_reliabilities</th>
<th>system</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>Compute system reliability (series or parallel)</td>
</tr>
</tbody>
</table>

**Description**

The `compute` keyword is used to select which forward statistical mapping is calculated at each response level.

**Default Behavior**

If `response_levels` is not specified, no statistics are computed. If `response_levels` is specified but `compute` is not, probabilities will be computed by default. If both `response_levels` and `compute` are specified, then one of the following must be specified: `probabilities`, `reliabilities`, or `gen_reliabilities`.

**Expected Output**

The type of statistics specified by `compute` will be reported for each response level.

**Usage Tips**

CDF/CCDF probabilities are calculated for specified response levels using a simple binning approach. CDF/CCDF reliabilities are calculated for specified response levels by computing the number of sample standard deviations separating the sample mean from the response level.

**Examples**

```plaintext
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
    6.0e+04 6.5e+04 7.0e+04
    3.5e+05 4.0e+05 4.5e+05
  compute reliabilities
```

  - method
  - sampling
  - response_levels
  - compute
  - probabilities

Computes probabilities associated with response levels
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none

Argument(s): none

Description

The probabilities keyword directs Dakota to compute the probability that the model response will be below (cumulative) or above (complementary cumulative) a specified response value. This is done for every response level designated for each response.

Default Behavior

If response_levels is specified, the probabilities are computed by default. To explicitly specify it in the Dakota input file, though, the probabilities keyword should be specified in conjunction with the compute keyword.

Expected Outputs

The Dakota output is a set of response level-probability pairs that give the probability that the model response will be below or above the corresponding response level, depending on the distribution defined.

Examples

method
  sampling
    sample_type random
    samples = 100 seed = 1
  complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
    6.0e+04 6.5e+04 7.0e+04

• reliabilities

Computes reliabilities associated with response levels

Specification

Alias: none

Argument(s): none
6.2. METHOD

Description

The `reliabilities` keyword directs Dakota to compute reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the reliabilities are not computed by default. To change this behavior, the `reliabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-reliability pairs according to the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
    6.0e+04 6.5e+04 7.0e+04

• response_levels

• compute

• gen_reliabilities

Computes generalized reliabilities associated with response levels

Specification

Alias: none

Argument(s): none

Description

The `gen_reliabilities` keyword directs Dakota to compute generalized reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the generalized reliabilities are not computed by default. To change this behavior, the `gen_reliabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-generalized reliability pairs according to the distribution defined.
Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                    6.0e+04 6.5e+04 7.0e+04

</tr>
<tr>
<td></td>
<td></td>
<td><strong>parallel</strong></td>
<td>Aggregate response statistics assuming a parallel system</td>
</tr>
</tbody>
</table>

Description

With the system probability/reliability option, statistics for specified `response_levels` are calculated and reported assuming the response functions combine either in series or parallel to produce a total system response.

For a series system, the system fails when any one component (response) fails. The probability of failure is the complement of the product of the individual response success probabilities.

For a parallel system, the system fails only when all components (responses) fail. The probability of failure is the product of the individual response failure probabilities.
6.2. METHOD

<th>Dakota Keyword cumulative</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>complementary</td>
<td>Computes statistics according to complementary cumulative functions</td>
</tr>
</tbody>
</table>

### Description

The `distribution` keyword allows the user to select between a cumulative distribution/belief/plausibility function and a complementary cumulative distribution/belief/plausibility function. This choice affects how probabilities and reliability indices are reported.

#### Default Behavior

If the `distribution` keyword is present, it must be accompanied by either `cumulative` or `complementary`. Otherwise, a cumulative distribution will be used by default.

#### Expected Outputs

Output will be a set of model response-probability pairs determined according to the choice of distribution. The choice of distribution also defines the sign of the reliability or generalized reliability indices.

### Examples

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
  distribution cumulative
```
cumulative

<td>Generates pseudo-random numbers using the Pecos package</td>
</tr>
</tbody>
</table>

**Description**

The rng keyword is used to indicate a choice of random number generator.

**Default Behavior**

If specified, the rng keyword must be accompanied by either rnum2 (pseudo-random numbers) or mt19937 (random numbers generated by the Mersenne twister). Otherwise, mt19937, the Mersenne twister is used by default.

**Usage Tips**

The default is recommended, as the Mersenne twister is a higher quality random number generator.

**Examples**

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2

mt19937
```

- Keywords Area
- method
• sampling
• rng
• mt19937

Generates random numbers using the Mersenne twister

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The `mt19937` keyword directs Dakota to use the Mersenne twister to generate random numbers. Additional information can be found on wikipedia: [http://en.wikipedia.org/wiki/Mersenne_twister](http://en.wikipedia.org/wiki/Mersenne_twister).

**Default Behavior**

`mt19937` is the default random number generator. To specify it explicitly in the Dakota input file, however, it must be specified in conjunction with the `rng` keyword.

**Usage Tips**

Use of the Mersenne twister random number generator (`mt19937`) is recommended.

**Examples**

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng mt19937

**Argument(s):** none
6.2. METHOD

Description
The `rnum2` keyword directs Dakota to use pseudo-random numbers generated by the Pecos package.

**Default Behavior**
`rnum2` is not used by default. To change this behavior, it must be specified in conjunction with the `rng` keyword.

**Usage Tips**
Use of the Mersenne twister random number generator (`mt19937`) is recommended over `rnum2`.

Examples
```
method sampling
  sample_type lhs
  samples = 10
  seed = 98765
  rng rnum2
```

**samples**
- **Keywords Area**
- **method**
- **sampling**
- **samples**

Number of samples for sampling-based methods

Specification
**Alias:** none
**Argument(s):** INTEGER
**Default:** method-dependent

Description
The `samples` keyword is used to define the number of samples (i.e., randomly chosen sets of variable values) at which to execute a model.

**Default Behavior**
By default, Dakota will use the minimum number of samples required by the chosen method.

**Usage Tips**
To obtain linear sensitivities or to construct a linear response surface, at least dim+1 samples should be used, where "dim" is the number of variables. For sensitivities to quadratic terms or quadratic response surfaces, at least (dim+1)(dim+2)/2 samples are needed. For uncertainty quantification, we recommend at least 10*dim samples. For variance-based decomposition, we recommend hundreds to thousands of samples. Note that for variance-based decomposition, the number of simulations performed will be N*(dim+2).

Examples
```
method sampling
  sample_type lhs
  samples = 20
```
Chapter 6. Keywords Area

Seed

• Keywords Area

• method

• sampling

• seed

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)

Description

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method
    sampling
        sample_type lhs
        samples = 10
        seed = 15347
```

model_pointer

• Keywords Area

• method

• sampling

• model_pointer

Identifier for model block to be used by a method
6.2. METHOD

Topics
This keyword is related to the topics:

- block_pointer

Specification
Alias: none
Argument(s): STRING
Default: method use of last model parsed (or use of default model if none parsed)

Description
The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior
If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips
When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.

See block_pointer for details about pointers.

Examples

```
environment
  tabular_graphics_data
  method_pointer = 'UQ'

</table>
The importance_sampling method is based on ideas in reliability modeling. An initial Latin Hypercube sampling is performed to generate an initial set of samples. These initial samples are augmented with samples from an importance density as follows:

- The variables are transformed to standard normal space.
- In the transformed space, the importance density is a set of normal densities centered around points which are in the failure region.
- Note that this is similar in spirit to the reliability methods, in which importance sampling is centered around a Most Probable Point (MPP).
- In the case of the LHS samples, the importance sampling density will simply be a mixture of normal distributions centered around points in the failure region.

Options

Choose one of the importance sampling options:
- import
- adapt_import
- mm_adapt_import

The options for importance sampling are as follows: import centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level). adapt_import is the same as import but is performed iteratively until the failure probability estimate converges. mm_adapt_import starts with all of the samples located in the failure region to build a multimodal sampling density. First, it uses a small number of samples around each of the initial samples in the failure region. Note that these samples are allocated to the different points based on their relative probabilities of occurrence: more probable points get more samples. This early part of the approach is done to search for "representative" points. Once these are located, the multimodal sampling density is set and then mm_adapt_import proceeds similarly to adapt_import (sample until convergence).

Theory

Importance sampling is a method that allows one to estimate statistical quantities such as failure probabilities (e.g. the probability that a response quantity will exceed a threshold or fall below a threshold value) in a way that is more efficient than Monte Carlo sampling. The core idea in importance sampling is that one generates samples that preferentially samples important regions in the space (e.g. in or near the failure region or user-defined region of interest), and then appropriately weights the samples to obtain an unbiased estimate of the failure probability [76]. In importance sampling, the samples are generated from a density which is called the importance density:
it is not the original probability density of the input distributions. The importance density should be centered near the failure region of interest. For black-box simulations such as those commonly interfaced with Dakota, it is difficult to specify the importance density a priori: the user often does not know where the failure region lies, especially in a high-dimensional space.[78]. We have developed two importance sampling approaches which do not rely on the user explicitly specifying an importance density.

- import

Sampling option

Specification
Alias: none

Argument(s): none

Description
import centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level).

adapt_import

- Keywords Area
- method
- importance_sampling
- adapt_import

Importance sampling option
CHAPTER 6. KEYWORDS AREA

Specification
Alias: none
  Argument(s): none

Description
adapt import centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level). This continues iteratively until the failure probability estimate converges.

mm adapt import
  • Keywords Area
  • method
  • importance_sampling
  • mm adapt import

Sampling option

Specification
Alias: none
  Argument(s): none

Description
mm adapt import starts with all of the samples located in the failure region to build a multimodal sampling density. First, it uses a small number of samples around each of the initial samples in the failure region. Note that these samples are allocated to the different points based on their relative probabilities of occurrence: more probable points get more samples. This early part of the approach is done to search for "representative" points. Once these are located, the multimodal sampling density is set and then mm adapt import proceeds similarly to adapt import (sample until convergence).

refinement samples
  • Keywords Area
  • method
  • importance_sampling
  • refinement samples

Specify the number of samples used to improve a probability estimate.

Specification
Alias: none
  Argument(s): INTEGER
6.2. METHOD

Description

Specify the number of samples used to improve a probability estimate. If using uni-modal sampling all samples are assigned to the sampling center. If using multi-modal sampling the samples are split between multiple samples according to some internally computed weights.

response_levels

- Keywords Area
- method
- importance_sampling
- response_levels

Values at which to estimate desired statistics for each response

Specification

Alias: none

Argument(s): REALLIST

Default: No CDF/CCDF probabilities/reliabilities to compute

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>num_response_levels</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>compute</td>
</tr>
</tbody>
</table>

Description

The response_levels specification provides the target response values for which to compute probabilities, reliabilities, or generalized reliabilities (forward mapping).

Default Behavior

If response_levels are not specified, no statistics will be computed. If they are, probabilities will be computed by default.

Expected Outputs

The particular statistics reported for each response level depend on the method, and they include:

1. Reliabilities
2. CDF probabilities
3. CCDF probabilities
Usage Tips

The `num_response_levels` is used to specify which arguments of the `response_level` correspond to which response.

Examples

For example, specifying a `response_level` of 52.3 followed with `compute probabilities` will result in the calculation of the probability that the response value is less than or equal to 52.3, given the uncertain distributions on the inputs.

For an example with multiple responses, the following specification

```plaintext
response_levels = 1. 2. .1 .2 .3 .4 10. 20. 30.
num_response_levels = 2 4 3
```

would assign the first two response levels (1., 2.) to response function 1, the next four response levels (.1, .2, .3, .4) to response function 2, and the final three response levels (10., 20., 30.) to response function 3. If the `num_response_levels` key were omitted from this example, then the response levels would be evenly distributed among the response functions (three levels each in this case).

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

A forward mapping involves computing the belief and plausibility probability level for a specified response level.

`num_response_levels`

- Keywords Area
- method
- importance_sampling
- response_levels
- `num_response_levels`

Number of values at which to estimate desired statistics for each response

Specification

Alias: none

Argument(s): INTEGERLIST

Default: response_levels evenly distributed among response functions
6.2. METHOD

Description

The `num_response_levels` keyword allows the user to specify the number of response values, for each response, at which estimated statistics are of interest. Statistics that can be computed are probabilities and reliabilities, both according to either a cumulative distribution function or a complementary cumulative distribution function.

Default Behavior

If `num_response_levels` is not specified, the response levels will be evenly distributed among the responses.

Expected Outputs

The specific output will be determined by the type of statistics that are specified. In a general sense, the output will be a list of response level-statistic pairs that show the estimated value of the desired statistic for each response level specified.

Examples

```plaintext
method sampling
  samples = 100
  seed = 34785
  num_response_levels = 1 1 1
  response_levels = 0.5 0.5 0.5
compute
```

Selection of statistics to compute at each response level

Specification

Alias: none

Argument(s): none

Default: probabilities

<table>
<thead>
<tr>

<th>Description of Group Group 1</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>probabilities</td>
<td>Computes probabilities associated with response levels</td>
</tr>
</tbody>
</table>
**CHAPTER 6. KEYWORDS AREA**

<table>
<thead>
<tr>
<th>gen_reliabilities</th>
<th>Computes generalized reliabilities associated with response levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>system</td>
</tr>
<tr>
<td></td>
<td>Compute system reliability (series or parallel)</td>
</tr>
</tbody>
</table>

**Description**

The `compute` keyword is used to select which forward statistical mapping is calculated at each response level.

**Default Behavior**

If `response_levels` is not specified, no statistics are computed. If `response_levels` is specified but `compute` is not, probabilities will be computed by default. If both `response_levels` and `compute` are specified, then one of the following must be specified: `probabilities`, `reliabilities`, or `gen_reliabilities`.

**Expected Output**

The type of statistics specified by `compute` will be reported for each response level.

**Usage Tips**

CDF/CCDF probabilities are calculated for specified response levels using a simple binning approach. CDF/CCDF reliabilities are calculated for specified response levels by computing the number of sample standard deviations separating the sample mean from the response level.

**Examples**

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                       6.0e+04 6.5e+04 7.0e+04
                       3.5e+05 4.0e+05 4.5e+05
  compute reliabilities
```

**probabilities**

- Keywords Area
- method
- importance_sampling
- response_levels
- compute
- probabilities

Computes probabilities associated with response levels
6.2. METHOD

Specification

Alias: none

Argument(s): none

Description

The `probabilities` keyword directs Dakota to compute the probability that the model response will be below (cumulative) or above (complementary cumulative) a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the probabilities are computed by default. To explicitly specify it in the Dakota input file, though, the `probabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-probability pairs that give the probability that the model response will be below or above the corresponding response level, depending on the distribution defined.

Examples

```plaintext
method sampling
    sample_type random
    samples = 100 seed = 1
complementary distribution
response_levels = 3.6e+11 4.0e+11 4.4e+11
                  6.0e+04 6.5e+04 7.0e+04
                  3.5e+05 4.0e+05 4.5e+05
compute probabilities

gen_reliabilities
```

• Keywords Area

• method

• importance_sampling

• response_levels

• compute

• gen_reliabilities

Computes generalized reliabilities associated with response levels

Specification

Alias: none

Argument(s): none
Description

The `gen_reliabilities` keyword directs Dakota to compute generalized reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the generalized reliabilities are not computed by default. To change this behavior, the `gen_reliabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-generalized reliability pairs according to the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                     6.0e+04 6.5e+04 7.0e+04
                     3.5e+05 4.0e+05 4.5e+05
    compute gen_reliabilities

system

<td>series</td>
<td>Aggregate response statistics assuming a series system</td>
</tr>
</tbody>
</table>
6.2. METHOD

| parallel | Aggregate response statistics assuming a parallel system |

**Description**

With the system probability/reliability option, statistics for specified `response_levels` are calculated and reported assuming the response functions combine either in series or parallel to produce a total system response.

For a series system, the system fails when any one component (response) fails. The probability of failure is the complement of the product of the individual response success probabilities.

For a parallel system, the system fails only when all components (responses) fail. The probability of failure is the product of the individual response failure probabilities.

<td></td>
<td></td>
<td>cumulative</td>
<td>Computes statistics according to cumulative functions</td>
</tr>
<tr>
<td></td>
<td></td>
<td>complementary</td>
<td>Computes statistics according to complementary cumulative functions</td>
</tr>
</tbody>
</table>

**Description**

The `distribution` keyword allows the user to select between a cumulative distribution/belief/plausibility function and a complementary cumulative distribution/belief/plausibility function. This choice affects how probabilities and reliability indices are reported.

**Default Behavior**

If the `distribution` keyword is present, it must be accompanied by either `cumulative` or `complementary`. Otherwise, a cumulative distribution will be used by default.
6.2. **METHOD**

**Expected Outputs**
Output will be a set of model response-probability pairs determined according to the choice of distribution. The choice of distribution also defines the sign of the reliability or generalized reliability indices.

**Examples**

```plaintext
method sampling
  sample_type lhs
  samples = 10
  distribution cumulative
```

**cumulative**
- **Keywords** Area
- **method**
- **importance_sampling**
- **distribution**

- importance_sampling
- probability_levels

Specify probability levels at which to estimate the corresponding response value.

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Default:** No CDF/CCDF response levels to compute
Description

Response levels are calculated for specified CDF/CCDF probabilities by indexing into a sorted samples array (the response levels computed are not interpolated and will correspond to one of the sampled values).

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).

Selection of a random number generator

Specification

Alias: none

Argument(s): none

Default: Mersenne twister ( mt19937 )

<p>| Required/- | Description of Group | Dakota Keyword | Dakota Keyword Description |</p>
<table>
<thead>
<tr>
<th>Optional Required (Choose One)</th>
<th>Group 1</th>
<th>mt19937</th>
<th>Generates random numbers using the Mersenne twister</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>rnum2</td>
<td>Generates pseudo-random numbers using the Pecos package</td>
</tr>
</tbody>
</table>

Description

The rng keyword is used to indicate a choice of random number generator.

Default Behavior

If specified, the rng keyword must be accompanied by either rnum2 (pseudo-random numbers) or mt19937 (random numbers generated by the Mersenne twister). Otherwise, mt19937, the Mersenne twister is used by default.

Usage Tips

The default is recommended, as the Mersenne twister is a higher quality random number generator.
Examples

method
    sampling
        sample_type lhs
        samples = 10
        seed = 98765
        rng rnum2

mt19937

- Keywords Area
- method
- importance_sampling
- rng
- mt19937

Generates random numbers using the Mersenne twister

Specification

Alias: none
Argument(s): none

Description

The mt19937 keyword directs Dakota to use the Mersenne twister to generate random numbers. Additional information can be found on wikipedia: http://en.wikipedia.org/wiki/Mersenne_twister.

Default Behavior
mt19937 is the default random number generator. To specify it explicitly in the Dakota input file, however, it must be specified in conjunction with the rng keyword.

Usage Tips
Use of the Mersenne twister random number generator (mt19937) is recommended.

Examples

method
    sampling
        sample_type lhs
        samples = 10
        seed = 98765
        rng mt19937

rnum2

- Keywords Area
- method
- importance_sampling
- rng
6.2. METHOD

- **rnum2**
  Generates pseudo-random numbers using the Pecos package

**Specification**

**Alias:** none
**Argument(s):** none

**Description**

The `rnum2` keyword directs Dakota to use pseudo-random numbers generated by the Pecos package.

**Default Behavior**

`rnum2` is not used by default. To change this behavior, it must be specified in conjunction with the `rng` keyword.

**Usage Tips**

Use of the Mersenne twister random number generator (`mt19937`) is recommended over `rnum2`.

**Examples**

```dakota
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2

samples

- **Keywords Area**
- **method**
- **importance_sampling**
- **samples**

Number of samples for sampling-based methods

**Specification**

**Alias:** none
**Argument(s):** INTEGER
**Default:** method-dependent

**Description**

The `samples` keyword is used to define the number of samples (i.e., randomly chosen sets of variable values) at which to execute a model.

**Default Behavior**

By default, Dakota will use the minimum number of samples required by the chosen method.

**Usage Tips**
To obtain linear sensitivities or to construct a linear response surface, at least $\text{dim}+1$ samples should be used, where "dim" is the number of variables. For sensitivities to quadratic terms or quadratic response surfaces, at least $(\text{dim}+1)(\text{dim}+2)/2$ samples are needed. For uncertainty quantification, we recommend at least $10+\text{dim}$ samples. For \texttt{variance\_based\_decomp}, we recommend hundreds to thousands of samples. Note that for \texttt{variance\_based\_decomp}, the number of simulations performed will be $N(\text{dim}+2)$.

**Examples**

```plaintext
method
  sampling
    sample_type lhs
    samples = 20

seed
  
  - Keywords Area
  - method
  - importance\_sampling
  - seed

  Seed of the random number generator
```

**Specification**

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)

**Description**

The random \texttt{seed} control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior
If not specified, the seed is randomly generated.

Expected Output
If \texttt{seed} is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips
If a stochastic study was run without \texttt{seed} specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

**Examples**

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```
6.2. METHOD

model_pointer

- Keywords Area
- method
- importance_sampling
- model_pointer

Identifier for model block to be used by a method

Topics
This keyword is related to the topics:
- block_pointer

Specification

Alias: none
- Argument(s): STRING
- Default: method use of last model parsed (or use of default model if none parsed)

Description
The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior
If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips
When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.
See block_pointer for details about pointers.

**Description**

gpais is recommended for problems that have a relatively small number of input variables (e.g. less than 10-20). This method, Gaussian Process Adaptive Importance Sampling, is outlined in the paper[?].

This method starts with an initial set of LHS samples and adds samples one at a time, with the goal of adaptively improving the estimate of the ideal importance density during the process. The approach uses a mixture of component densities. An iterative process is used to construct the sequence of improving component densities. At each iteration, a Gaussian process (GP) surrogate is used to help identify areas in the space where failure is likely to occur. The GPs are not used to directly calculate the failure probability; they are only used to approximate the importance density. Thus, the Gaussian process adaptive importance sampling algorithm overcomes limitations involving using a potentially inaccurate surrogate model directly in importance sampling calculations.

- emulator_samples

Number of data points used to train the surrogate model or emulator

**Specification**

Alias: none

Argument(s): INTEGER

Default: 10000
6.2. METHOD

Description

This keyword refers to the number of build points or training points used to construct a Gaussian process emulator. If the user specifies a number of emulator_samples that is less than the minimum number of points required to build the GP surrogate, Dakota will augment the samples to obtain the minimum required.

import_points_file

- Keywords Area
- method
- gpais
- import_points_file

File containing variable values and corresponding responses

Specification

Alias: none

Argument(s): STRING

Default: no point import from a file

<td>freeform</td>
<td>Selects freeform file format</td>
</tr>
<tr>
<td>Optional</td>
<td>active_only</td>
<td></td>
<td>Import only active variables from tabular data file</td>
</tr>
</tbody>
</table>

Description

The import_points_file allows the user to specify a file that contains a list of variable values and the model responses computed at those values. These can be used by a number of methods in place of model evaluations. When used to construct surrogate models or emulators these are often called build points or training data.

Default Behavior

Be default, methods do not import points from a file.

Usage Tips

Dakota parses input files without regard to whitespace, but the import_points_file must be in one of three formats:

- annotated (default)
• custom.annotated
• freeform

Examples

method
  list_parameter_study
  import_points_file = ‘dakota_pstudy.3.dat’

annotated

• import_points_file
• annotated
  Selects annotated tabular file format

Topics

This keyword is related to the topics:
• file.formats

Specification

Alias: none
  Argument(s): none
  Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

  Default Behavior
  By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

  Usage Tips
  • To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom.annotated header eval.id
  • Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
  • When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
  • Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.
6.2. METHOD

Examples
Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```python
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
annotated

Resulting tabular file:
```%

<table>

| Optional | Optional              | header         | Enable header row in custom-annotated tabular file |
CHAPTER 6. KEYWORDS AREA

### Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

#### Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

#### Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

#### Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id  x1   x2  obj_fn  nln_ineq_con_1  nln_ineq_con_2
1  0.9  1.1  0.0002  0.26  0.76

Selects freeform file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none
Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
6.2. METHOD

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```python
environment
tabular_data
    tabular_data_file = 'dakota_summary.dat'
    freeform
```

Resulting tabular file:

```
  0.9  1.1  0.0002  0.26  0.76
  0.90009  1.1  0.0001996404857  0.2601620081  0.759955

...```

active_only

- Keywords Area
  - method
  - gpais
  - import_points_file
  - active_only

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.
export_points_file

<td></td>
<td>Number of values at which to estimate desired statistics for each response</td>
</tr>
<tr>
<td>Optional</td>
<td>compute</td>
<td></td>
<td>Selection of statistics to compute at each response level</td>
</tr>
</tbody>
</table>

Description

The response_levels specification provides the target response values for which to compute probabilities, reliabilities, or generalized reliabilities (forward mapping).

**Default Behavior**

If response_levels are not specified, no statistics will be computed. If they are, probabilities will be computed by default.

**Expected Outputs**

The particular statistics reported for each response level depend on the method, and they include:
6.2. METHOD

1. Reliabilities
2. CDF probabilities
3. CCDF probabilities

Usage Tips
The `num_response_levels` is used to specify which arguments of the `response_level` correspond to which response.

Examples
For example, specifying a `response_level` of 52.3 followed with `compute probabilities` will result in the calculation of the probability that the response value is less than or equal to 52.3, given the uncertain distributions on the inputs.

For an example with multiple responses, the following specification

```plaintext
response_levels = 1. 2. 1.2 3.4 10. 20. 30.
num_response_levels = 2 4 3
```

would assign the first two response levels (1., 2.) to response function 1, the next four response levels (.1, .2, .3, .4) to response function 2, and the final three response levels (10., 20., 30.) to response function 3. If the `num_response_levels` key were omitted from this example, then the response levels would be evenly distributed among the response functions (three levels each in this case).

Theory
Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

A forward mapping involves computing the belief and plausibility probability level for a specified response level.

**num_response_levels**
- **Keywords Area**
- **method**
- **gpais**
- **response_levels**
- **num_response_levels**

Number of values at which to estimate desired statistics for each response

Specification
**Alias:** none
**Argument(s):** INTEGERLIST
**Default:** response_levels evenly distributed among response functions
**Description**

The `num_response_levels` keyword allows the user to specify the number of response values, for each response, at which estimated statistics are of interest. Statistics that can be computed are probabilities and reliabilities, both according to either a cumulative distribution function or a complementary cumulative distribution function.

**Default Behavior**

If `num_response_levels` is not specified, the response levels will be evenly distributed among the responses.

**Expected Outputs**

The specific output will be determined by the type of statistics that are specified. In a general sense, the output will be a list of response level-statistic pairs that show the estimated value of the desired statistic for each response level specified.

**Examples**

```plaintext
method
sampling
  samples = 100
  seed = 34785
  num_response_levels = 1 1 1
  response_levels = 0.5 0.5 0.5

compute
  • Keywords Area
  • method
  • gpais
  • response_levels
  • compute
```

Selection of statistics to compute at each response level

**Specification**

Alias: none  
Argument(s): none  
Default: probabilities

<table>
<thead>
<tr>
<th>Required/-</th>
<th>Description of Group 1</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional Required (Choose One)</td>
<td>probabilities</td>
<td>Computes probabilities associated with response levels</td>
</tr>
</tbody>
</table>
6.2. METHOD

<table>
<thead>
<tr>
<th>gen_reliabilities</th>
<th>Computes generalized reliabilities associated with response levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>system</td>
<td>Compute system reliability (series or parallel)</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
</tr>
</tbody>
</table>

**Description**

The `compute` keyword is used to select which forward statistical mapping is calculated at each response level.

**Default Behavior**

If `response_levels` is not specified, no statistics are computed. If `response_levels` is specified but `compute` is not, probabilities will be computed by default. If both `response_levels` and `compute` are specified, then one of the following must be specified: `probabilities`, `reliabilities`, or `gen_reliabilities`.

**Expected Output**

The type of statistics specified by `compute` will be reported for each response level.

**Usage Tips**

CDF/CCDF probabilities are calculated for specified response levels using a simple binning approach.

CDF/CCDF reliabilities are calculated for specified response levels by computing the number of sample standard deviations separating the sample mean from the response level.

**Examples**

```plaintext
method
sampling
  sample_type random
  samples = 100 seed = 1
  complementary_distribution
  response_levels = 3.6e+11 4.0e+11 4.4e+11
  6.0e+04 6.5e+04 7.0e+04
  3.5e+05 4.0e+05 4.5e+05
  compute reliabilities

probabilities
```

Argument(s): none

Description

The `probabilities` keyword directs Dakota to compute the probability that the model response will be below (cumulative) or above (complementary cumulative) a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the probabilities are computed by default. To explicitly specify it in the Dakota input file, though, the `probabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-probability pairs that give the probability that the model response will be below or above the corresponding response level, depending on the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
  complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                 6.0e+04 6.5e+04 7.0e+04
                 3.5e+05 4.0e+05 4.5e+05
    compute probabilities

gen_reliabilities
```

**Keywords Area**

- method
- `gpais`
- `response_levels`
- `compute`
- `gen_reliabilities`

Computes generalized reliabilities associated with response levels

Specification

Alias: none

Argument(s): none
6.2. METHOD

Description

The `gen_reliabilities` keyword directs Dakota to compute generalized reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

**Default Behavior**

If `response_levels` is specified, the generalized reliabilities are not computed by default. To change this behavior, the `gen_reliabilities` keyword should be specified in conjunction with the `compute` keyword.

**Expected Outputs**

The Dakota output is a set of response level-generalized reliability pairs according to the distribution defined.

**Examples**

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
  complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
    6.0e+04 6.5e+04 7.0e+04
    3.5e+05 4.0e+05 4.5e+05
  compute gen_reliabilities
```

CHAPTER 6. KEYWORDS AREA

### Description

With the system probability/reliability option, statistics for specified `response_levels` are calculated and reported assuming the response functions combine either in series or parallel to produce a total system response.

For a series system, the system fails when any one component (response) fails. The probability of failure is the complement of the product of the individual response success probabilities.

For a parallel system, the system fails only when all components (responses) fail. The probability of failure is the product of the individual response failure probabilities.

#### series

<th>Dakota Keyword cumulative</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td><code>complementary</code></td>
<td>Computes statistics according to complementary cumulative functions</td>
</tr>
</tbody>
</table>

**Description**

The `distribution` keyword allows the user to select between a cumulative distribution/belief/plausibility function and a complementary cumulative distribution/belief/plausibility function. This choice affects how probabilities and reliability indices are reported.

**Default Behavior**

If the `distribution` keyword is present, it must be accompanied by either `cumulative` or `complementary`. Otherwise, a cumulative distribution will be used by default.
Expected Outputs
Output will be a set of model response-probability pairs determined according to the choice of distribution. The choice of distribution also defines the sign of the reliability or generalized reliability indices.

Examples

method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative

cumulative
  • Keywords Area
  • method
gpais
distribution
cumulative

Computes statistics according to cumulative functions

Specification
Alias: none
  Argument(s): none

Description
Statistics on model responses will be computed according to a cumulative distribution/belief/plausibility function.

Default Behavior
By default, a cumulative distribution/belief/plausibility function will be used. To explicitly specify it in the Dakota input file, however, the cumulative keyword must be appear in conjunction with the distribution keyword.

Expected Outputs
Output will be a set of model response-probability pairs determined according to a cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls below given response threshholds.

Argument(s): none

Description

Statistics on model responses will be computed according to a complementary cumulative distribution/belief/plausibility function.

**Default Behavior**

By default, a complementary cumulative distribution/belief/plausibility function will not be used. To change that behavior, the complementary keyword must appear in conjunction with the distribution keyword.

**Expected Outputs**

Output will be a set of model response-probability pairs determined according to a complementary cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls above given response thresholds.

Examples

```plaintext
method sampling
   sample_type lhs
   samples = 10
   distribution complementary
```

**probability_levels**

- Keywords Area
- method
- gpais
- probability_levels

Specify probability levels at which to estimate the corresponding response value

Specification

Alias: none

Argument(s): REALLIST

Default: No CDF/CCDF response levels to compute
### Description
Response levels are calculated for specified CDF/CCDF probabilities by indexing into a sorted samples array (the response levels computed are not interpolated and will correspond to one of the sampled values).

### Theory
Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).

</tr>
<tr>
<td>mt19937</td>
<td>Group 1</td>
<td>rnum2</td>
<td>mt19937</td>
<td>Generates pseudo-random numbers using the Pecos package</td>
</tr>
</tbody>
</table>

Description

The rng keyword is used to indicate a choice of random number generator.

Default Behavior
If specified, the rng keyword must be accompanied by either rnum2 (pseudo-random numbers) or mt19937 (random numbers generated by the Mersenne twister). Otherwise, mt19937, the Mersenne twister is used by default.

Usage Tips
The default is recommended, as the Mersenne twister is a higher quality random number generator.
Examples

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2
```

**mt19937**

- **Keywords Area**
- **method**
- **gpais**
- **rng**
- **mt19937**

Generates random numbers using the Mersenne twister

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The `mt19937` keyword directs Dakota to use the Mersenne twister to generate random numbers. Additional information can be found on wikipedia: [http://en.wikipedia.org/wiki/Mersenne_twister](http://en.wikipedia.org/wiki/Mersenne_twister).

**Default Behavior**

`mt19937` is the default random number generator. To specify it explicitly in the Dakota input file, however, it must be specified in conjunction with the `rng` keyword.

**Usage Tips**

Use of the Mersenne twister random number generator (mt19937) is recommended.

Examples

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng mt19937
```

**rnum2**

- **Keywords Area**
- **method**
- **gpais**
- **rng**
• **rnum2**

Generates pseudo-random numbers using the Pecos package

**Specification**

Alias: none
Argument(s): none

**Description**

The `rnum2` keyword directs Dakota to use pseudo-random numbers generated by the Pecos package.

**Default Behavior**

`rnum2` is not used by default. To change this behavior, it must be specified in conjunction with the `rng` keyword.

**Usage Tips**

Use of the Mersenne twister random number generator (`mt19937`) is recommended over `rnum2`.

**Examples**

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2

samples
  - Keywords Area
  - method
  - gpais
  - samples

Number of samples for sampling-based methods
```

**Specification**

Alias: none
Argument(s): INTEGER
Default: method-dependent

**Description**

The `samples` keyword is used to define the number of samples (i.e., randomly chosen sets of variable values) at which to execute a model.

**Default Behavior**

By default, Dakota will use the minimum number of samples required by the chosen method.

**Usage Tips**
To obtain linear sensitivities or to construct a linear response surface, at least \( \dim+1 \) samples should be used, where \( \dim \) is the number of variables. For sensitivities to quadratic terms or quadratic response surfaces, at least \( (\dim+1)(\dim+2)/2 \) samples are needed. For uncertainty quantification, we recommend at least \( 10^*\dim \) samples. For \texttt{variance-based\_decomp}, we recommend hundreds to thousands of samples. Note that for \texttt{variance-based\_decomp}, the number of simulations performed will be \( N*(\dim+2) \).

\section*{Examples}

```
method
  sampling
    sample_type lhs
    samples = 20

seed
  Keywords Area
  method
  gpais
  seed

Seed of the random number generator
```

\section*{Specification}

\textbf{Alias:} none

\textbf{Argument(s):} INTEGER

\textbf{Default:} system-generated (non-repeatable)

\section*{Description}

The random \texttt{seed} control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

\textbf{Default Behavior}

If not specified, the seed is randomly generated.

\textbf{Expected Output}

If \texttt{seed} is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

\textbf{Usage Tips}

If a stochastic study was run without \texttt{seed} specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

\section*{Examples}

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```
model_pointer

- Keywords Area
- method
- gpais
- model_pointer

Identifier for model block to be used by a method

**Topics**

This keyword is related to the topics:

- block_pointer

**Specification**

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)

**Description**

The `model_pointer` is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding `id_model` with the same name.

**Usage Tips**

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

**Examples**

```plaintext
evironment
   tabular_graphics_data
   method_pointer = 'UQ'

method
   id_method = 'UQ'
   model_pointer = 'SURR'

</tbody>
</table>

Description

This is an experimental capability that is not ready for production use at this point.

The goal in performing adaptive sampling is to construct a surrogate model that can be used as an accurate predictor to some expensive simulation, thus it is to one’s advantage to build a surrogate that minimizes the error over the entire domain of interest using as little data as possible from the expensive simulation. The adaptive part alludes to the fact that the surrogate will be refined by focusing samples of the expensive simulation on particular areas of interest rather than rely on random selection or standard space-filling techniques.

At a high-level, the adaptive sampling pipeline is a four-step process:

- Evaluate the expensive simulation (referred to as the true model) at initial sample point
  1. Fit a surrogate model
  2. Create a candidate set and score based on information from surrogate
  3. Select a candidate point to evaluate the true model
  4. Loop until done

In terms of the Dakota implementation, the adaptive sampling method currently uses Latin Hypercube sampling (LHS) to generate the initial points in Step 1 above. For Step 2, we use a Gaussian process model.

The default behavior is to add one point at a time. At each iteration (e.g. each loop of Steps 2-4 above), a Latin Hypercube sample is generated (a new one, different from the initial sample) and the surrogate model is evaluated at this points. These are the candidate points that are then evaluated according to the fitness metric. The
number of candidates used in practice should be high enough to fill most of the input domain: we recommend at least hundreds of points for a low-dimensional problem. All of the candidates (samples on the emulator) are given a score and then the highest-scoring candidate is selected to be evaluated on the true model.

The adaptive sampling method also can generate batches of points to add at a time using the `batch_selection` and `batch_size` keywords.

**See Also**

These keywords may also be of interest:

- `gpais`
- `local_reliability`
- `global_reliability`
- `sampling`
- `importance_sampling`
- `polynomial_chaos`
- `stoch_collocation`

**emulator_samples**

- Keywords Area
- method
- `adaptive_sampling`
- `emulator_samples`

Number of data points used to train the surrogate model or emulator

**Specification**

Alias: none

Argument(s): INTEGER

Default: 400

**Description**

This keyword refers to the number of build points or training points used to construct a Gaussian process emulator. If the user specifies a number of `emulator_samples` that is less than the minimum number of points required to build the GP surrogate, Dakota will augment the samples to obtain the minimum required.
6.2. METHOD

**fitness_metric**

- Keywords Area
- method
- adaptive_sampling
- fitness_metric

(Experimental) Specify the `fitness_metric` used to select the next point

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** predicted_variance

<table>
<thead>
<tr>

</tr>
<tr>
<td></td>
<td></td>
<td>gradient</td>
<td>Fill the range space of the surrogate</td>
</tr>
</tbody>
</table>

**Description**

The adaptive sampling is an experimental capability that is not ready for production use at this time. The user can specify the `fitness_metric` used to select the next point (or points) to evaluate and add to the set. The fitness metrics used for scoring candidate points include:

- `predicted_variance`
- `distance`
- `gradient`

**predicted_variance**

- Keywords Area
- method
- adaptive_sampling
- fitness_metric
- predicted_variance

Pick points with highest variance

**Specification**

**Alias:** none  
**Argument(s):** none
CHAPTER 6. KEYWORDS AREA

Description
The predicted variance metric uses the predicted variance of the Gaussian process surrogate as the score of a candidate point. Thus, the adaptively chosen points will be in areas of highest uncertainty according to the Gaussian process model.

distance
- Keywords Area
- method
- adaptive_sampling
- fitness_metric
- distance

Space filling metric

Specification
Alias: none
Argument(s): none

Description
The distance metric calculates the Euclidean distance in domain space between the candidate and its nearest neighbor in the set of points already evaluated on the true model. Therefore, the most undersampled area of the domain will always be selected. Note that this is a space-filling metric.

gradient
- Keywords Area
- method
- adaptive_sampling
- fitness_metric
- gradient

Fill the range space of the surrogate

Specification
Alias: none
Argument(s): none

Description
The gradient metric calculates the score as the absolute value of the difference in range space (the outputs) of the two points. The output values used are predicted from the surrogate model. This method attempts to evenly fill the range space of the surrogate.
6.2. METHOD

batch_selection

<td>Use information from the existing surrogate model to predict what the surrogate upgrade will be with new points.</td>
</tr>
</tbody>
</table>
CHAPTER 6. KEYWORDS AREA

Description

The adaptive_sampling is an experimental capability that is not ready for production use at this time.

With batch or multi-point selection, the true model can be evaluated in parallel and thus increase throughput before refitting our surrogate model. This proposes a new challenge as the problem of choosing a single point and choosing multiple points off a surrogate are fundamentally different. Selecting the $n$ best scoring candidates is more than likely to generate a set of points clustered in one area which will not be conducive to adapting the surrogate.

We have implemented several strategies for batch selection of points. These are described in the User’s manual and are the subject of active research.

The batch_selection strategies include:

1. naive:
2. distance_penalty
3. constant_liar
4. topology

naive

- Keywords Area
- method
- adaptive_sampling
- batch_selection
- naive

Take the highest scoring candidates

Specification

Alias: none
Argument(s): none

Description

This strategy will select the $n$ highest scoring candidates regardless of their position. This tends to group an entire round of points in the same area.

distance_penalty

- Keywords Area
- method
- adaptive_sampling
6.2. METHOD

- batch_selection
- distance_penalty

Add a penalty to spread out the points in the batch

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

In this strategy, the highest scoring candidate is selected and then all remaining candidates are re-scored with a distance penalization factor added in to the score.

**topology**

- Keywords Area
- method
- adaptive_sampling
- batch_selection
- topology

In this selection strategy, we use information about the topology of the space from the Morse-Smale complex to identify next points to select.

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

In this strategy we look at the topology of the scoring function and select the \( n \) highest maxima in the topology. To determine local maxima, we construct the approximate Morse-Smale complex. This strategy does require the user to have the Morse-Smale package.

**constant liar**

- Keywords Area
- method
- adaptive_sampling
- batch_selection
- constant liar

Use information from the existing surrogate model to predict what the surrogate upgrade will be with new points.
CHAPTER 6. KEYWORDS AREA

**Specification**

Alias: none

**Argument(s):** none

**Description**

The strategy first selects the highest scoring candidate, and then refits the surrogate using a "lie" value at the point selected. The 'lie' value is based on the surrogate predictions and not the simulation. This process repeats until \( n \) points have been selected whereupon the lie values are removed from the surrogate and the selected points are evaluated on the true model and the surrogate is refit with these values.

**batch_size**

- Keywords Area
- method
- adaptive_sampling
- batch_size

The number of points to add in each batch.

**Specification**

Alias: none

**Argument(s):** INTEGER

**Default:** 1

**Description**

The number of points to add in each batch.

**import_points_file**

- Keywords Area
- method
- adaptive_sampling
- import_points_file

File containing variable values and corresponding responses

**Specification**

Alias: none

**Argument(s):** STRING

**Default:** no point import from a file
### 6.2. METHOD

<table>
<thead>
<tr>

<tr>
<td></td>
<td></td>
<td>freeform</td>
<td>Selects freeform file format</td>
</tr>
<tr>
<td>Optional</td>
<td>active_only</td>
<td></td>
<td>Import only active variables from tabular data file</td>
</tr>
</tbody>
</table>

### Description

The `import_points_file` allows the user to specify a file that contains a list of variable values and the model responses computed at those values. These can be used by a number of methods in place of model evaluations. When used to construct surrogate models or emulators these are often called build points or training data.

**Default Behavior**

By default, methods do not import points from a file.

**Usage Tips**

Dakota parses input files without regard to whitespace, but the `import_points_file` must be in one of three formats:

- annotated (default)
- custom_annotated
- freeform

### Examples

```plaintext
method
list_parameter_study

Selects annotated tabular file format
Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The `annotated` keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify `custom_annotated header eval Id`

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to `annotated` format, though `freeform` remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
  annotated
```

Resulting tabular file:

```
%eval_id interface   x1   x2   obj_fn nln_ineq_con_1 nln_ineq_con_2
1   NO_ID   0.9   1.1   0.0002   0.26   0.76
2   NO_ID   0.90009   1.1   0.0001996404857   0.2601620081   0.759955
3   NO_ID   0.89991   1.1   0.0002003604863   0.2598380081   0.760045

<tr>
<td>Optional</td>
<td>interface_id</td>
<td></td>
<td>Enable interface ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

**Description**

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

**Default Behavior**

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

**Usage Tips**
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

**Examples**

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface-id), and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id  x1  x2  obj_fn  nln_ineq_con_1  nln_ineq_con_2
1  0.9  1.1  0.0002  0.26  0.76

- method
- adaptive_sampling
- import_points_file
- freeform

Selects freeform file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.
6.2. METHOD

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```python
environment
tabular_data
    tabular_data_file = 'dakota_summary.dat'
    freeform

**active_only**

- Keywords Area
- method
- adaptive_sampling
- import_points_file
- active_only

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- file_formats

Specification

**Alias:** none

**Argument(s):** none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.
export_points_file

- Keywords Area
- method
- adaptive_sampling
- export_points_file

Output file for evaluations of a surrogate model

**Specification**

Alias: none

**Argument(s):** STRING

**Default:** no point export to a file

- adaptive_sampling
- response_levels

Values at which to estimate desired statistics for each response

Specification

**Alias:** none  
**Argument(s):** REALLIST  
**Default:** No CDF/CCDF probabilities/reliabilities to compute

<table>
<thead>
<tr>
<th>Required/-</th>
<th>Description of</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>Group</td>
<td>num_response_-</td>
<td>levels</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>compute</td>
<td></td>
</tr>
</tbody>
</table>

**Description**
The `response_levels` specification provides the target response values for which to compute probabilities, reliabilities, or generalized reliabilities (forward mapping).

**Default Behavior**
If `response_levels` are not specified, no statistics will be computed. If they are, probabilities will be computed by default.

**Expected Outputs**
The particular statistics reported for each response level depend on the method, and they include:
6.2. METHOD

1. Reliabilities
2. CDF probabilities
3. CCDF probabilities

Usage Tips
The `num_response_levels` is used to specify which arguments of the `response_level` correspond to which response.

Examples
For example, specifying a `response_level` of 52.3 followed with `compute probabilities` will result in the calculation of the probability that the response value is less than or equal to 52.3, given the uncertain distributions on the inputs.

For an example with multiple responses, the following specification

```plaintext
response_levels = 1. 2. 1.2 .3 .4 10. 20. 30.
num_response_levels = 2 4 3
```

would assign the first two response levels (1., 2.) to response function 1, the next four response levels (.1, .2, .3, .4) to response function 2, and the final three response levels (10., 20., 30.) to response function 3. If the `num_response_levels` key were omitted from this example, then the response levels would be evenly distributed among the response functions (three levels each in this case).

Theory
Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

A forward mapping involves computing the belief and plausibility probability level for a specified response level.

**num_response_levels**

- Keywords Area
- method
- adaptive_sampling
- response_levels
- num_response_levels

Number of values at which to estimate desired statistics for each response

Specification
Alias: none
Argument(s): INTEGERLIST
Default: response_levels evenly distributed among response functions
Description

The `num_response_levels` keyword allows the user to specify the number of response values, for each response, at which estimated statistics are of interest. Statistics that can be computed are probabilities and reliabilities, both according to either a cumulative distribution function or a complementary cumulative distribution function.

Default Behavior

If `num_response_levels` is not specified, the response levels will be evenly distributed among the responses.

Expected Outputs

The specific output will be determined by the type of statistics that are specified. In a general sense, the output will be a list of response level-statistic pairs that show the estimated value of the desired statistic for each response level specified.

Examples

```
method
  sampling
    samples = 100
    seed = 34785
    num_response_levels = 1 1 1
    response_levels = 0.5 0.5 0.5
```

compute

- Keywords Area
- method
- adaptive_sampling
- response_levels
- compute

Selection of statistics to compute at each response level

Specification

Alias: none

Argument(s): none

Default: probabilities

<table>
<thead>
<tr>
<th>Required/-Optional Required (Choose One)</th>
<th>Description of Group 1</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>probabilities</td>
<td></td>
<td>Computes probabilities associated with response levels</td>
</tr>
</tbody>
</table>
6.2. METHOD

<table>
<thead>
<tr>
<th>compute keyword</th>
<th>response levels</th>
<th>compute probabilities</th>
<th>gen_reliabilities</th>
<th>Compute system reliability (series or parallel)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>system</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Description**

The `compute` keyword is used to select which forward statistical mapping is calculated at each response level.

**Default Behavior**

If `response_levels` is not specified, no statistics are computed. If `response_levels` is specified but `compute` is not, probabilities will be computed by default. If both `response_levels` and `compute` are specified, then one of the following must be specified: `probabilities`, `reliabilities`, or `gen_reliabilities`.

**Expected Output**

The type of statistics specified by `compute` will be reported for each response level.

**Usage Tips**

CDF/CCDF probabilities are calculated for specified response levels using a simple binning approach. CDF/CCDF reliabilities are calculated for specified response levels by computing the number of sample standard deviations separating the sample mean from the response level.

**Examples**

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary_distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                        6.0e+04 6.5e+04 7.0e+04

    compute reliabilities

probabilities
```

**Keywords Area**

- method
- adaptive_sampling
- response_levels
- compute
- probabilities

Computes probabilities associated with response levels.
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none
  Argument(s): none

Description

The *probabilities* keyword directs Dakota to compute the probability that the model response will be below (cumulative) or above (complementary cumulative) a specified response value. This is done for every response level designated for each response.

Default Behavior

If *response_levels* is specified, the probabilities are computed by default. To explicitly specify it in the Dakota input file, though, the *probabilities* keyword should be specified in conjunction with the *compute* keyword.

Expected Outputs

The Dakota output is a set of response level-probability pairs that give the probability that the model response will be below or above the corresponding response level, depending on the distribution defined.

Examples

```
method sampling
  sample_type random
  samples = 100 seed = 1
  complementary distribution
  response_levels = 3.6e+11 4.0e+11 4.4e+11
                     6.0e+04 6.5e+04 7.0e+04
                     3.5e+05 4.0e+05 4.5e+05
  compute probabilities
```

- **method**

- **adaptive_sampling**

- **response_levels**

- **compute**

- **gen_reliabilities**

Computes generalized reliabilities associated with response levels

Specification

Alias: none
  Argument(s): none
6.2. METHOD

Description

The `gen_reliabilities` keyword directs Dakota to compute generalized reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the generalized reliabilities are not computed by default. To change this behavior, the `gen_reliabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-generalized reliability pairs according to the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
  complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                    6.0e+04 6.5e+04 7.0e+04

</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>cumulative</td>
<td>Computes statistics according to cumulative functions</td>
</tr>
<tr>
<td></td>
<td></td>
<td>complementary</td>
<td>Computes statistics according to complementary cumulative functions</td>
</tr>
</tbody>
</table>

**Description**

The `distribution` keyword allows the user to select between a cumulative distribution/belief/plausibility function and a complementary cumulative distribution/belief/plausibility function. This choice affects how probabilities and reliability indices are reported.

**Default Behavior**

If the `distribution` keyword is present, it must be accompanied by either `cumulative` or `complementary`. Otherwise, a cumulative distribution will be used by default.

**Expected Outputs**

Output will be a set of model response-probability pairs determined according to the choice of distribution. The choice of distribution also defines the sign of the reliability or generalized reliability indices.

**Examples**

```latex
method sampling
  sample_type lhs
  samples = 10
  distribution cumulative
```

cumulative

- Keywords Area
- method
- adaptive_sampling
- distribution
- cumulative

Computes statistics according to cumulative functions

**Specification**

Alias: none

Argument(s): none
6.2. **METHOD**

**Description**

Statistics on model responses will be computed according to a cumulative distribution/belief/plausibility function.

**Default Behavior**

By default, a cumulative distribution/belief/plausibility function will be used. To explicitly specify it in the Dakota input file, however, the `cumulative` keyword must appear in conjunction with the `distribution` keyword.

**Expected Outputs**

Output will be a set of model response-probability pairs determined according to a cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls below given response thresholds.

**Examples**

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

**complementary**

- **Keywords Area**
- **method**
- **adaptive_sampling**
- **distribution**
- **complementary**

Computes statistics according to complementary cumulative functions

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

Statistics on model responses will be computed according to a complementary cumulative distribution/belief/plausibility function.

**Default Behavior**

By default, a complementary cumulative distribution/belief/plausibility function will not be used. To change that behavior, the `complementary` keyword must appear in conjunction with the `distribution` keyword.

**Expected Outputs**

Output will be a set of model response-probability pairs determined according to a complementary cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls above given response thresholds.
Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    distribution complementary
```

```
probability_levels

  - Keywords Area
  - method
  - adaptive_sampling
  - probability_levels

  Specify probability levels at which to estimate the corresponding response value
```

Specification

Alias: none

Argument(s): REALLIST

Default: No CDF/CCDF response levels to compute

<table>
<thead>

<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>num_probability_-levels</td>
<td></td>
<td>Specify which probability_-levels correspond to which response</td>
</tr>
</tbody>
</table>

Description

Response levels are calculated for specified CDF/CCDF probabilities by indexing into a sorted samples array (the response levels computed are not interpolated and will correspond to one of the sampled values).

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).
6.2. METHOD

</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>mt19937</td>
<td>Generates random numbers using the Mersenne twister</td>
</tr>
<tr>
<td></td>
<td></td>
<td>rnum2</td>
<td>Generates pseudo-random numbers using the Pecos package</td>
</tr>
</tbody>
</table>

#### Description

The `rng` keyword is used to indicate a choice of random number generator.

**Default Behavior**

If specified, the `rng` keyword must be accompanied by either `rnum2` (pseudo-random numbers) or `mt19937` (random numbers generated by the Mersenne twister). Otherwise, `mt19937`, the Mersenne twister is used by default.

**Usage Tips**

The default is recommended, as the Mersenne twister is a higher quality random number generator.

#### Examples

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
  rng rnum2
```

**mt19937**

- Keywords Area
- method
- adaptive_sampling
- rng
- mt19937

Generates random numbers using the Mersenne twister

#### Specification

**Alias:** none

**Argument(s):** none
Description

The mt19937 keyword directs Dakota to use the Mersenne twister to generate random numbers. Additional information can be found on wikipedia: [http://en.wikipedia.org/wiki/Mersenne_twister](http://en.wikipedia.org/wiki/Mersenne_twister).

**Default Behavior**

mt19937 is the default random number generator. To specify it explicitly in the Dakota input file, however, it must be specified in conjunction with the rng keyword.

**Usage Tips**

Use of the Mersenne twister random number generator (mt19937) is recommended.

**Examples**

```plaintext
method	sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng mt19937
```

**rnum2**

- **Keywords Area**
- **method**
- **adaptive_sampling**
- **rng**
- **rnum2**

Generates pseudo-random numbers using the Pecos package

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The rnum2 keyword directs Dakota to use pseudo-random numbers generated by the Pecos package.

**Default Behavior**

rnum2 is not used by default. To change this behavior, it must be specified in conjunction with the rng keyword.

**Usage Tips**

Use of the Mersenne twister random number generator (mt19937) is recommended over rnum2.

**Examples**

```plaintext
method	sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2
```
6.2. METHOD

samples

- Keywords Area
- method
- adaptive_sampling
- samples

Number of samples for sampling-based methods

**Specification**

**Alias:** none

- **Argument(s):** INTEGER
- **Default:** method-dependent

**Description**

The `samples` keyword is used to define the number of samples (i.e., randomly chosen sets of variable values) at which to execute a model.

**Default Behavior**

By default, Dakota will use the minimum number of samples required by the chosen method.

**Usage Tips**

To obtain linear sensitivities or to construct a linear response surface, at least $\text{dim}+1$ samples should be used, where "$\text{dim}"$ is the number of variables. For sensitivities to quadratic terms or quadratic response surfaces, at least $(\text{dim}+1)(\text{dim}+2)/2$ samples are needed. For uncertainty quantification, we recommend at least $10\times\text{dim}$ samples. For `variance_based_decomp`, we recommend hundreds to thousands of samples. Note that for `variance_based_decomp`, the number of simulations performed will be $N\times(\text{dim}+2)$.

**Examples**

```dakota
method
  sampling
    sample_type lhs
    samples = 20

seed

- Keywords Area
- method
- adaptive_sampling
- seed

Seed of the random number generator

**Specification**

**Alias:** none

- **Argument(s):** INTEGER
- **Default:** system-generated (non-repeatable)
CHAPTER 6. KEYWORDS AREA

Description

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```plaintext
method sampling
  sample_type lhs
  samples = 10
  seed = 15347
```

model_pointer

- Keywords Area
- method
- adaptive_sampling
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.
6.2. METHOD

Usage Tips
When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.
See `block_pointer` for details about pointers.

Examples

```plaintext
environment
tabular_graphics_data
method_pointer = 'UQ'

method
id_method = 'UQ'
model_pointer = 'SURR'
sampling,
samples = 10
seed = 98765 rng rnum2

### Description

*pof_darts* is a novel method for estimating the probability of failure based on random sphere-packing. Random spheres are sampled from the domain with the constraint that each new sphere center has to be outside prior disks. The radius of each sphere is chosen such that the entire sphere lie either in the failure or the non-failure region. This radius depends of the function evaluation at the disk center, the failure threshold and an estimate of the function gradient at the disk center.

We utilize a global surrogate for evaluating the gradient and hence only one function evaluation is required for each sphere.

After exhausting the sampling budget specified by *samples*, which is the number of spheres per failure threshold, the domain is decomposed into two regions. These regions correspond to failure and non-failure, each represented by the union of the spheres of each type. The volume of the union of failure spheres gives a lower bound on the required estimate of the probability of failure, while the volume of the union of the non-failure spheres subtracted from the volume of the domain gives an upper estimate. We currently report the average of both estimates.

*pof_darts* handles multiple response functions and allows each to have multiple failure thresholds. For each failure threshold, *pof_darts* will insert a number of spheres specified by the user-input parameter *samples*.

However, estimating the probability of failure for each failure threshold would utilize the total number of disks sampled for all failure thresholds. For each failure threshold, the sphere radii changes to generate the right spatial decomposition.

</tbody>
</table>

**Description**

There are two types of Lipschitz estimation used in sizing the disks used in POF Darts: *global* and *local*. The global approach uses one Lipschitz estimate for the entire domain. The local approach calculates the Lipschitz estimate separately for each Voronoi region based on nearby points. The local method is more expensive but more accurate.

**local**

- **Keywords Area**
- **method**
- **pof_darts**
- **lipschitz**
- **local**

Specify local estimation of the Lipschitz constant

**Specification**

**Alias:** none

**Argument(s):** none
6.2. METHOD

Description

The local approach to estimating the Lipschitz constant calculates the Lipschitz estimate separately for each Voronoi region based on nearby points. The local method is more expensive but more accurate than the global method.

global

- Keywords Area
- method
- pof_darts
- lipschitz
- global

Specify global estimation of the Lipschitz estimate

Specification

Alias: none
Argument(s): none

Description

The global approach uses one Lipschitz estimate for the entire domain.

evaluator_samples

- Keywords Area
- method
- pof_darts
- emulator_samples

Specify the number of samples taken on the emulator to estimate the Probability of Failure in POF Darts

Specification

Alias: none
Argument(s): INTEGER

Description

The last step of the POF Darts method involves constructing an emulator over the points identified thus far, and sampling that emulator extensively to estimate the probability of failure. emulator_samples allows one to specify the number of samples taken on the emulator. The default is 1E+6. If the probability of failure estimate is zero, the user may want to increase the number of emulator samples.
response_levels

- Keywords Area
- method
- pof_darts
- response_levels

Values at which to estimate desired statistics for each response

**Specification**

**Alias:** none

**Argument(s):** REALIST

**Default:** No CDF/CCDF probabilities/reliabilities to compute

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>num_response_levels</td>
<td>Number of values at which to estimate desired statistics for each response</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>compute</td>
<td>Selection of statistics to compute at each response level</td>
</tr>
</tbody>
</table>

**Description**

The `response_levels` specification provides the target response values for which to compute probabilities, reliabilities, or generalized reliabilities (forward mapping).

**Default Behavior**

If `response_levels` are not specified, no statistics will be computed. If they are, probabilities will be computed by default.

**Expected Outputs**

The particular statistics reported for each response level depend on the method, and they include:

1. Reliabilities
2. CDF probabilities
3. CCDF probabilities

**Usage Tips**

The `num_response_levels` is used to specify which arguments of the `response_level` correspond to which response.
6.2. METHOD

Examples

For example, specifying a response level of 52.3 followed with compute probabilities will result in the calculation of the probability that the response value is less than or equal to 52.3, given the uncertain distributions on the inputs.

For an example with multiple responses, the following specification

```
response_levels = 1. 2. .1 .2 .3 .4 10. 20. 30.
num_response_levels = 2 4 3
```

would assign the first two response levels (1., 2.) to response function 1, the next four response levels (.1, .2, .3, .4) to response function 2, and the final three response levels (10., 20., 30.) to response function 3. If the num_response_levels key were omitted from this example, then the response levels would be evenly distributed among the response functions (three levels each in this case).

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

A forward mapping involves computing the belief and plausibility probability level for a specified response level.

```
num_response_levels
```

- Keywords Area
- method
- pof_darts
- response_levels
- num_response_levels

Number of values at which to estimate desired statistics for each response

Specification

Alias: none

Argument(s): INTEGERLIST

Default: response_levels evenly distributed among response functions

Description

The num_response_levels keyword allows the user to specify the number of response values, for each response, at which estimated statistics are of interest. Statistics that can be computed are probabilities and reliabilities, both according to either a cumulative distribution function or a complementary cumulative distribution function.

Default Behavior

If num_response_levels is not specified, the response_levels will be evenly distributed among the responses.
**Expected Outputs**

The specific output will be determined by the type of statistics that are specified. In a general sense, the output will be a list of response level-statistic pairs that show the estimated value of the desired statistic for each response level specified.

**Examples**

```plaintext
method
  sampling
    samples = 100
    seed = 34785
  num_response_levels = 1 1 1
  response_levels = 0.5 0.5 0.5

compute
  • Keywords Area
  • method
  • pof_darts
  • response_levels
  • compute

Selection of statistics to compute at each response level
```

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** probabilities

<p>| Required/- | Description of | Dakota Keyword | Dakota Keyword |</p>

<tbody>
<tr>
<td>Required (Choose One)</td>
<td></td>
<td>probabilities</td>
<td>computes probabilities associated with response levels</td>
</tr>
</tbody>
</table>

- **probabilities**: Computes probabilities associated with response levels.
- **gen_reliabilities**: Computes generalized reliabilities associated with response levels.
6.2. METHOD

<table>
<thead>
<tr>
<th>Optional</th>
<th>system</th>
<th>Compute system reliability (series or parallel)</th>
</tr>
</thead>
</table>

**Description**

The `compute` keyword is used to select which forward statistical mapping is calculated at each response level.

**Default Behavior**

If `response_levels` is not specified, no statistics are computed. If `response_levels` is specified but `compute` is not, probabilities will be computed by default. If both `response_levels` and `compute` are specified, then one of the following must be specified: `probabilities`, `reliabilities`, or `gen_reliabilities`.

**Expected Output**

The type of statistics specified by `compute` will be reported for each response level.

**Usage Tips**

CDF/CCDF probabilities are calculated for specified response levels using a simple binning approach.

CDF/CCDF reliabilities are calculated for specified response levels by computing the number of sample standard deviations separating the sample mean from the response level.

**Examples**

```plaintext
method sampling
sample_type random
samples = 100 seed = 1
complementary distribution
response_levels = 3.6e+11 4.0e+11 4.4e+11
                  6.0e+04 6.5e+04 7.0e+04
                  3.5e+05 4.0e+05 4.5e+05
compute reliabilities

- **pof_darts**
- **response_levels**
- **compute**
- **probabilities**

Computes probabilities associated with response levels

**Specification**

**Alias:** none

**Argument(s):** none
CHAPTER 6. KEYWORDS AREA

Description

The `probabilities` keyword directs Dakota to compute the probability that the model response will be below (cumulative) or above (complementary cumulative) a specified response value. This is done for every response level designated for each response.

**Default Behavior**

If `response_levels` is specified, the probabilities are computed by default. To explicitly specify it in the Dakota input file, though, the `probabilities` keyword should be specified in conjunction with the `compute` keyword.

**Expected Outputs**

The Dakota output is a set of response level-probability pairs that give the probability that the model response will be below or above the corresponding response level, depending on the distribution defined.

Examples

```plaintext
method sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                     6.0e+04 6.5e+04 7.0e+04
                     3.5e+05 4.0e+05 4.5e+05
    compute probabilities
```

`gen_reliabilities`

- **Keywords Area**
- **method**
- **pof_darts**
- **response_levels**
- **compute**
- **gen_reliabilities**

Computes generalized reliabilities associated with response levels

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The `gen_reliabilities` keyword directs Dakota to compute generalized reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

**Default Behavior**

If `response_levels` is specified, the generalized reliabilities are not computed by default. To change this behavior, the `gen_reliabilities` keyword should be specified in conjunction with the `compute` keyword.

**Expected Outputs**

The Dakota output is a set of response level-generalized reliability pairs according to the distribution defined.
6.2. METHOD

Examples

```dakota
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                     6.0e+04 6.5e+04 7.0e+04
                     3.5e+05 4.0e+05 4.5e+05

<td></td>
<td></td>
<td>series</td>
<td>Aggregate response statistics assuming a series system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>parallel</td>
<td>Aggregate response statistics assuming a parallel system</td>
</tr>
</tbody>
</table>

Description

With the system probability/reliability option, statistics for specified `response_levels` are calculated and reported assuming the response functions combine either in series or parallel to produce a total system response.

For a series system, the system fails when any one component (response) fails. The probability of failure is the complement of the product of the individual response success probabilities.

For a parallel system, the system fails only when all components (responses) fail. The probability of failure is the product of the individual response failure probabilities.

</tbody>
</table>

**Description**

The `distribution` keyword allows the user to select between a cumulative distribution/belief/plausibility function and a complementary cumulative distribution/belief/plausibility function. This choice affects how probabilities and reliability indices are reported.

**Default Behavior**

If the `distribution` keyword is present, it must be accompanied by either `cumulative` or `complementary`. Otherwise, a cumulative distribution will be used by default.

**Expected Outputs**

Output will be a set of model response-probability pairs determined according to the choice of distribution. The choice of distribution also defines the sign of the reliability or generalized reliability indices.

**Examples**

```
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```
cumulative

- Keywords Area
- method
- pof_darts
- distribution
- cumulative

Computes statistics according to cumulative functions

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

Statistics on model responses will be computed according to a cumulative distribution/belief/plausibility function.

**Default Behavior**

By default, a cumulative distribution/belief/plausibility function will be used. To explicitly specify it in the Dakota input file, however, the cumulative keyword must be appear in conjunction with the distribution keyword.

**Expected Outputs**

Output will be a set of model response-probability pairs determined according to a cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls below given response thresholds.

**Examples**

```dm
method
  sampling
    sample_type lhs
    samples = 10
  distribution cumulative
```

complementary

- Keywords Area
- method
- pof_darts
- distribution
- complementary

Computes statistics according to complementary cumulative functions
6.2. METHOD

Specification

Alias: none
Argument(s): none

Description

Statistics on model responses will be computed according to a complementary cumulative distribution/belief/plausibility function.

Default Behavior
By default, a complementary cumulative distribution/belief/plausibility function will not be used. To change that behavior, the `complementary` keyword must be appear in conjunction with the `distribution` keyword.

Expected Outputs
Output will be a set of model response-probability pairs determined according to a complementary cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls above given response thresholds.

Examples

```
method sampling
  sample_type lhs
  samples = 10
  distribution complementary
```

```probability_levels```

Keywords Area
- method
- pof_darts
- probability_levels

Specify probability levels at which to estimate the corresponding response value

Specification

Alias: none
Argument(s): REALLIST
Default: No CDF/CCDF response levels to compute

<p>| Required/- | Description of | Dakota Keyword | Dakota Keyword |</p>
<table>
<thead>
<tr>
<th>Optional</th>
<th>Group</th>
<th>num_probability_-levels</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td></td>
<td>Specify which probability_-levels correspond to which response</td>
</tr>
</tbody>
</table>

Description

Response levels are calculated for specified CDF/CCDF probabilities by indexing into a sorted samples array (the response levels computed are not interpolated and will correspond to one of the sampled values).
Theory
Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).

num_probability_levels
- Keywords Area
- method
- pof_darts
- probability_levels
- num_probability_levels

Specify which probability_levels correspond to which response

Specification
Alias: none
Argument(s): INTEGERLIST
Default: probability_levels evenly distributed among response functions

Description
See parent page

gen_reliability_levels
- Keywords Area
- method
- pof_darts
- gen_reliability_levels

Specify generalized reliability levels at which to estimate the corresponding response value

Specification
Alias: none
Argument(s): REALLIST
Default: No CDF/CCDF response levels to compute
### Description

Response levels are calculated for specified generalized reliabilities by indexing into a sorted samples array (the response levels computed are not interpolated and will correspond to one of the sampled values).

### Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).

<td></td>
<td>Generates random numbers using the Mersenne twister</td>
</tr>
<tr>
<td>rnum2</td>
<td></td>
<td></td>
<td></td>
<td>Generates pseudo-random numbers using the Pecos package</td>
</tr>
</tbody>
</table>

Description

The rng keyword is used to indicate a choice of random number generator.

Default Behavior

If specified, the rng keyword must be accompanied by either rnum2 (pseudo-random numbers) or mt19937 (random numbers generated by the Mersenne twister). Otherwise, mt19937, the Mersenne twister is used by default.

Usage Tips

The default is recommended, as the Mersenne twister is a higher quality random number generator.

Examples

```
method
    sampling
        sample_type lhs
        samples = 10
        seed = 98765
        rng rnum2
```

mt19937

- Keywords Area
- method
6.2. METHOD

- pof_darts
- rng
- mt19937

Generates random numbers using the Mersenne twister

Specification

Alias: none
Argument(s): none

Description

The mt19937 keyword directs Dakota to use the Mersenne twister to generate random numbers. Additional information can be found on wikipedia: http://en.wikipedia.org/wiki/Mersenne_twister.

Default Behavior

mt19937 is the default random number generator. To specify it explicitly in the Dakota input file, however, it must be specified in conjunction with the rng keyword.

Usage Tips

Use of the Mersenne twister random number generator (mt19937) is recommended.

Examples

```
method sampling
  sample_type lhs
  samples = 10
  seed = 98765
  rng mt19937
```

rnum2

- Keywords Area
- method
- pof_darts
- rng
- rnum2

Generates pseudo-random numbers using the Pecos package

Specification

Alias: none
Argument(s): none
CHAPTER 6. KEYWORDS AREA

Description

The \texttt{rnum2} keyword directs Dakota to use pseudo-random numbers generated by the Pecos package.

**Default Behavior**

\texttt{rnum2} is not used by default. To change this behavior, it must be specified in conjunction with the \texttt{rng} keyword.

**Usage Tips**

Use of the Mersenne twister random number generator (\texttt{mt19937}) is recommended over \texttt{rnum2}.

Examples

```dakota
method
   sampling
      sample_type lhs
      samples = 10
      seed = 98765
      rng rnum2
```

**samples**

- **Keywords Area**
- **method**
- **pof_darts**
- **samples**

Number of samples for sampling-based methods

Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** method-dependent

Description

The \texttt{samples} keyword is used to define the number of samples (i.e., randomly chosen sets of variable values) at which to execute a model.

**Default Behavior**

By default, Dakota will use the minimum number of samples required by the chosen method.

**Usage Tips**

To obtain linear sensitivities or to construct a linear response surface, at least \texttt{dim+1} samples should be used, where "\texttt{dim}" is the number of variables. For sensitivities to quadratic terms or quadratic response surfaces, at least \texttt{(dim+1)(dim+2)/2} samples are needed. For uncertainty quantification, we recommend at least \texttt{10*dim} samples. For \texttt{variance_based_decomp}, we recommend hundreds to thousands of samples. Note that for \texttt{variance_based_decomp}, the number of simulations performed will be \texttt{N*(dim+2)}.

Examples

```dakota
method
   sampling
      sample_type lhs
      samples = 20
```
6.2. METHOD

seed

- **Keywords Area**
- method
- pof_darts
- seed

Seed of the random number generator

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** system-generated (non-repeatable)

**Description**

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

**Default Behavior**

If not specified, the seed is randomly generated.

**Expected Output**

If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

**Usage Tips**

If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

**Examples**

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

**model_pointer**

- **Keywords Area**
- method
- pof_darts
- model_pointer

Identifier for model block to be used by a method
CHAPTER 6. KEYWORDS AREA

Topics
This keyword is related to the topics:

- block_pointer

Specification
Alias: none

Argument(s): STRING
Default: method use of last model parsed (or use of default model if none parsed)

Description
The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior
If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips
When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.

See block_pointer for details about pointers.

Examples

```
environment
tabular_graphics_data
method_pointer = 'UQ'

method
id_method = 'UQ'
model_pointer = 'SRR'
sampling,
samples = 10
seed = 98765 rng rnum2
response_levels = 0.1 0.2 0.6
0.1 0.2 0.6
0.1 0.2 0.6

6.2.58 efficient_subspace

• Keywords Area

• method

• efficient_subspace

(Experimental) efficient subspace method (ESM)

Topics

This keyword is related to the topics:

• uncertainty_quantification

Specification

Alias: nond_efficient_subspace

Argument(s): none
### Description

ESM is experimental and its implementation is incomplete. It is an active subspace method, intended for use with models with high dimensional input parameter spaces and analytic gradients. The method works by evaluating the response gradient at a number of points in the input parameter space and using a singular value decomposition to identify key linear combinations of input directions along which the response varies. Then UQ is performed in the reduced input parameter space.
6.2. METHOD

emulator_samples

- Keywords Area
- method
- efficient_subspace
- emulator_samples

Number of data points used to train the surrogate model or emulator

**Specification**

Alias: none

Argument(s): INTEGER

**Description**

This keyword refers to the number of build points or training points used to construct a Gaussian process emulator. If the user specifies a number of emulator_samples that is less than the minimum number of points required to build the GP surrogate, Dakota will augment the samples to obtain the minimum required.

batch_size

- Keywords Area
- method
- efficient_subspace
- batch_size

The number of points to add in each batch.

**Specification**

Alias: none

Argument(s): INTEGER

Default: 1

**Description**

The number of points to add in each batch.

distribution

- Keywords Area
- method
- efficient_subspace
- distribution

Selection of cumulative or complementary cumulative functions
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none

Argument(s): none

Default: cumulative (CDF)

6.2. METHOD

**Optional**

| probability_levels | Specify probability levels at which to estimate the corresponding response value.
| gen_reliability_levels | Specify generalized reliability levels at which to estimate the corresponding response value.
| rng | Selection of a random number generator.
| samples | Number of samples for sampling-based methods.
| seed | Seed of the random number generator.
| model_pointer | Identifier for model block to be used by a method.

### Description

global_evidence allows the user to specify several global approaches for calculating the belief and plausibility functions:

- **lhs** - note: this takes the minimum and maximum of the samples as the bounds per "interval cell combination."

- **ego** - uses Efficient Global Optimization which is based on an adaptive Gaussian process surrogate.

- **sbo** - uses a Gaussian process surrogate (non-adaptive) within an optimization process.

- **ea** - uses an evolutionary algorithm. This can be expensive as the ea will be run for each interval cell combination.

Note that to calculate the plausibility and belief cumulative distribution functions, one has to look at all combinations of intervals for the uncertain variables. In terms of implementation, if one is using LHS sampling as outlined above, this method creates a large sample over the response surface, then examines each cell to determine the minimum and maximum sample values within each cell. To do this, one needs to set the number of samples relatively high: the default is 10,000 and we recommend at least that number. If the model you are running is a simulation that is computationally quite expensive, we recommend that you set up a surrogate model within the Dakota input file so that global_evidence performs its sampling and calculations on the surrogate and not on the original model. If one uses optimization methods instead to find the minimum and maximum sample values within each cell, this can also be computationally expensive.
CHAPTER 6. KEYWORDS AREA

Additional Resources
See the topic page evidence_theory for important background information and usage notes.
Refer to variable_support for information on supported variable types.

Theory
The basic idea is that one specifies an "evidence structure” on uncertain inputs and propagates that to obtain belief and plausibility functions on the response functions. The inputs are defined by sets of intervals and Basic Probability Assignments (BPAs). Evidence propagation is computationally expensive, since the minimum and maximum function value must be calculated for each ”interval cell combination.” These bounds are aggregated into belief and plausibility.

Description

A surrogate-based optimization method will be used. The surrogate employed in sbo is a Gaussian process surrogate.

The main difference between ego and the sbo approach is the objective function being optimized. ego relies on an expected improvement function, while in sbo, the optimization proceeds using an evolutionary algorithm (coliny_ea) on the Gaussian process surrogate: it is a standard surrogate-based optimization. Also note that the sbo option can support optimization over discrete variables (the discrete variables are relaxed) while ego cannot. This is not the same as surrogate_based_global.

gaussian_process

- sbo
- gaussian_process

Gaussian Process surrogate model

Specification

Alias: kriging

Argument(s): none

Default: Surfpack Gaussian process
Description
Use the Gaussian process (GP) surrogate from Surfpack, which is specified using the `surfpack` keyword.

An alternate version of GP surrogates was available in prior versions of Dakota. For now, both versions are supported but the `dakota` version is deprecated and intended to be removed in a future release.

  * method
  * global_evidence
  * sbo
  * gaussian_process
  * surfpack
```

Use the Surfpack version of Gaussian Process surrogates

Specification
Alias: none
Argument(s): none

Description
This keyword specifies the use of the Gaussian process that is incorporated in our surface fitting library called Surfpack.

Several user options are available:

1. Optimization methods:

   Maximum Likelihood Estimation (MLE) is used to find the optimal values of the hyper-parameters governing the trend and correlation functions. By default the global optimization method DIRECT is used for MLE, but other options for the optimization method are available. See `optimization_method`.

   The total number of evaluations of the likelihood function can be controlled using the `max_trials` keyword followed by a positive integer. Note that the likelihood function does not require running the "truth" model, and is relatively inexpensive to compute.
2. Trend Function:
   The GP models incorporate a parametric trend function whose purpose is to capture large-scale variations. See `trend`.

3. Correlation Lengths:
   Correlation lengths are usually optimized by Surfpack, however, the user can specify the lengths manually. See `correlation_lengths`.

4. Ill-conditioning
   One of the major problems in determining the governing values for a Gaussian process or Kriging model is the fact that the correlation matrix can easily become ill-conditioned when there are too many input points close together. Since the predictions from the Gaussian process model involve inverting the correlation matrix, ill-conditioning can lead to poor predictive capability and should be avoided.

   Note that a sufficiently bad sample design could require correlation lengths to be so short that any interpolatory GP model would become inept at extrapolation and interpolation.

   The `surfpack` model handles ill-conditioning internally by default, but behavior can be modified using `5. Gradient Enhanced Kriging (GEK).` The `use_derivatives` keyword will cause the Surfpack GP to be constructed from a combination of function value and gradient information (if available).

   See notes in the Theory section.

**Theory**

**Gradient Enhanced Kriging**

Incorporating gradient information will only be beneficial if accurate and inexpensive derivative information is available, and the derivatives are not infinite or nearly so. Here “inexpensive” means that the cost of evaluating a function value plus gradient is comparable to the cost of evaluating only the function value, for example gradients computed by analytical, automatic differentiation, or continuous adjoint techniques. It is not cost effective to use derivatives computed by finite differences. In tests, GEK models built from finite difference derivatives were also significantly less accurate than those built from analytical derivatives. Note that GEK’s correlation matrix tends to have a significantly worse condition number than Kriging for the same sample design.

This issue was addressed by using a pivoted Cholesky factorization of Kriging’s correlation matrix (which is a small sub-matrix within GEK’s correlation matrix) to rank points by how much unique information they contain. This reordering is then applied to whole points (the function value at a point immediately followed by gradient information at the same point) in GEK’s correlation matrix. A standard non-pivoted Cholesky is then applied to the reordered GEK correlation matrix and a bisection search is used to find the last equation that meets the constraint on the (estimate of) condition number. The cost of performing pivoted Cholesky on Kriging’s correlation matrix is usually negligible compared to the cost of the non-pivoted Cholesky factorization of GEK’s correlation matrix. In tests, it also resulted in more accurate GEK models than when pivoted Cholesky or whole-point-block pivoted Cholesky was performed on GEK’s correlation matrix.

- dakota

Select the built in Gaussian Process surrogate

Specification

Alias: none
Argument(s): none

Description

A second version of GP surrogates was available in prior versions of Dakota. For now, both versions are supported but the dakota version is deprecated and intended to be removed in a future release.

Historically these models were drastically different, but in Dakota 5.1, they became quite similar. They now differ in that the Surfpack GP has a richer set of features/options and tends to be more accurate than the Dakota version. Due to how the Surfpack GP handles ill-conditioned correlation matrices (which significantly contributes to its greater accuracy), the Surfpack GP can be a factor of two or three slower than Dakota’s. As of Dakota 5.2, the Surfpack implementation is the default in all contexts except Bayesian calibration.

More details on the gaussian_process dakota model can be found in[58].

Dakota’s GP deals with ill-conditioning in two ways. First, when it encounters a non-invertible correlation matrix it iteratively increases the size of a “nugget,” but in such cases the resulting approximation smooths rather than interpolates the data. Second, it has a point_selection option (default off) that uses a greedy algorithm to select a well-spaced subset of points prior to the construction of the GP. In this case, the GP will only interpolate the selected subset. Typically, one should not need point selection in trust-region methods because a small number of points are used to develop a surrogate within each trust region. Point selection is most beneficial when constructing with a large number of points, typically more than order one hundred, though this depends on the number of variables and spacing of the sample points.

This differs from the point_selection option of the Dakota GP which initially chooses a well-spaced subset of points and finds the correlation parameters that are most likely for that one subset.

use_derivatives

- Keywords Area
- method
- global_evidence
- sbo
- use_derivatives

Use derivative data to construct surrogate models

Specification

Alias: none
Argument(s): none
Default: use function values only
6.2. METHOD

Description

The use_derivatives flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, its use with Surfpack Gaussian process is not recommended.

import_points_file

- Keywords Area
- method
- global_evidence
- sbo
- import_points_file

File containing variable values and corresponding responses

Specification

Alias: none

Argument(s): STRING

Default: no point import from a file

| Required/- | Description of Group | Dakota Keyword | Dakota Keyword |
| Optional | tabular format | annotated | Description |
| (Choose One) | (Group 1) | | Selects annotated tabular file format |
| | | custom_annotated | Selects custom-annotated tabular file format |
| | | freeform | Selects freeform file format |
| Optional | active_only | Import only active variables from tabular data file |

Description

The import_points_file allows the user to specify a file that contains a list of variable values and the model responses computed at those values. These can be used by a number of methods in place of model evaluations. When used to construct surrogate models or emulators these are often called build points or training data.

Default Behavior

- Default, methods do not import points from a file.

Usage Tips

- Dakota parses input files without regard to whitespace, but the import_points_file must be in one of three formats:
• annotated (default)
• custom_annotated
• freeform

Examples

method
  list_parameter_study
    import_points_file = 'dakota_pstudy.3.dat'

annotated

• method
• global_evidence
• sbo
• import_points_file
• annotated

Selects annotated tabular file format

Topics

This keyword is related to the topics:

• file_formats

Specification

Alias: none
  Argument(s): none
  Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

• To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id

• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples
Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```python
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
annotated
```

Resulting tabular file:

```
%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 NO_ID 0.9 1.1 0.0002 0.26 0.76
2 NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 NO_ID 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...```

</tr>
<tr>
<td>Optional</td>
<td></td>
<td>interface_id</td>
<td>Enable interface ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
custom_annotated header eval_id
```

Resulting tabular file:

```%eval_id   x1   x2   obj_fn   nln_ineq_con_1   nln_ineq_con_2
1         0.9   1.1   0.0002   0.26         0.76

Selects freeform file format

**Topics**

This keyword is related to the topics:

- file_formats

**Specification**

Alias: none

Argument(s): none

Default: annotated format
Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
freeform
```

Resulting tabular file:

```
   0.9    1.1    0.0002    0.26    0.76

**Default:** Surfpack Gaussian process
**Description**

Use the Gaussian process (GP) surrogate from Surfpack, which is specified using the `surfpack` keyword. An alternate version of GP surrogates was available in prior versions of Dakota. **For now, both versions are supported but the dakota version is deprecated and intended to be removed in a future release.**

```markdown
surfpack

- Keywords Area
- method
- global_evidence
- ego
- gaussian_process
- surfpack

Use the Surfpack version of Gaussian Process surrogates
```

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

This keyword specifies the use of the Gaussian process that is incorporated in our surface fitting library called Surfpack.

Several user options are available:

1. **Optimization methods:**

   Maximum Likelihood Estimation (MLE) is used to find the optimal values of the hyper-parameters governing the trend and correlation functions. By default the global optimization method DIRECT is used for MLE, but other options for the optimization method are available. See `optimization_method`.

   The total number of evaluations of the likelihood function can be controlled using the `max_trials` keyword followed by a positive integer. Note that the likelihood function does not require running the "truth" model, and is relatively inexpensive to compute.
6.2. METHOD

2. Trend Function:
   The GP models incorporate a parametric trend function whose purpose is to capture large-scale variations. See trend.

3. Correlation Lengths:
   Correlation lengths are usually optimized by Surfpack, however, the user can specify the lengths manually. See correlation lengths.

4. Ill-conditioning
   One of the major problems in determining the governing values for a Gaussian process or Kriging model is the fact that the correlation matrix can easily become ill-conditioned when there are too many input points close together. Since the predictions from the Gaussian process model involve inverting the correlation matrix, ill-conditioning can lead to poor predictive capability and should be avoided.
   Note that a sufficiently bad sample design could require correlation lengths to be so short that any interpolatory GP model would become inept at extrapolation and interpolation.
   The surfpack model handles ill-conditioning internally by default, but behavior can be modified using Gradient Enhanced Kriging (GEK).

5. Gradient Enhanced Kriging (GEK).
   The use_derivatives keyword will cause the Surfpack GP to be constructed from a combination of function value and gradient information (if available).
   See notes in the Theory section.

Theory

Gradient Enhanced Kriging
   Incorporating gradient information will only be beneficial if accurate and inexpensive derivative information is available, and the derivatives are not infinite or nearly so. Here “inexpensive” means that the cost of evaluating a function value plus gradient is comparable to the cost of evaluating only the function value, for example gradients computed by analytical, automatic differentiation, or continuous adjoint techniques. It is not cost effective to use derivatives computed by finite differences. In tests, GEK models built from finite difference derivatives were also significantly less accurate than those built from analytical derivatives. Note that GEK’s correlation matrix tends to have a significantly worse condition number than Kriging for the same sample design.
   This issue was addressed by using a pivoted Cholesky factorization of Kriging’s correlation matrix (which is a small sub-matrix within GEK’s correlation matrix) to rank points by how much unique information they contain. This reordering is then applied to whole points (the function value at a point immediately followed by gradient information at the same point) in GEK’s correlation matrix. A standard non-pivoted Cholesky is then applied to the reordered GEK correlation matrix and a bisection search is used to find the last equation that meets the constraint on the (estimate of) condition number. The cost of performing pivoted Cholesky on Kriging’s correlation matrix is usually negligible compared to the cost of the non-pivoted Cholesky factorization of GEK’s correlation matrix. In tests, it also resulted in more accurate GEK models than when pivoted Cholesky or whole-point-block pivoted Cholesky was performed on GEK’s correlation matrix.

   • method
   • global_evidence
Select the built in Gaussian Process surrogate

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

A second version of GP surrogates was available in prior versions of Dakota. **For now, both versions are supported but the **dakota** version is deprecated and intended to be removed in a future release.**

Historically these models were drastically different, but in Dakota 5.1, they became quite similar. They now differ in that the Surfpack GP has a richer set of features/options and tends to be more accurate than the Dakota version. Due to how the Surfpack GP handles ill-conditioned correlation matrices (which significantly contributes to its greater accuracy), the Surfpack GP can be a factor of two or three slower than Dakota’s. As of Dakota 5.2, the Surfpack implementation is the default in all contexts except Bayesian calibration.

More details on the **gaussian_process** dakota model can be found in[58].

Dakota’s GP deals with ill-conditioning in two ways. First, when it encounters a non-invertible correlation matrix it iteratively increases the size of a “nugget,” but in such cases the resulting approximation smooths rather than interpolates the data. Second, it has a **point_selection** option (default off) that uses a greedy algorithm to select a well-spaced subset of points prior to the construction of the GP. In this case, the GP will only interpolate the selected subset. Typically, one should not need point selection in trust-region methods because a small number of points are used to develop a surrogate within each trust region. Point selection is most beneficial when constructing with a large number of points, typically more than order one hundred, though this depends on the number of variables and spacing of the sample points.

This differs from the **point_selection** option of the Dakota GP which initially chooses a well-spaced subset of points and finds the correlation parameters that are most likely for that one subset.

**use_derivatives**

- **Keywords Area**
- **method**
- **global_evidence**
- **ego**
- **use_derivatives**

Use derivative data to construct surrogate models

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** use function values only
6.2. METHOD

Description

The use_derivatives flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, its use with Surfpack Gaussian process is not recommended.

import_points_file

<td>freeform</td>
<td>Selects freeform file format</td>
</tr>
</tbody>
</table>

**Optional**

| | active_only | Import only active variables from tabular data file |

Description

The import_points_file allows the user to specify a file that contains a list of variable values and the model responses computed at those values. These can be used by a number of methods in place of model evaluations. When used to construct surrogate models or emulators these are often called build points or training data.

**Default Behavior**

Be default, methods do not import points from a file.

**Usage Tips**

Dakota parses input files without regard to whitespace, but the import_points_file must be in one of three formats:
• annotated (default)
• custom_annotated
• freeform

Examples

```python
method
list_parameter_study
  import_points_file = 'dakota_pstudy.3.dat'

annotated

• Keywords Area
• method
• global_evidence
• ego
• import_points_file
• annotated

Selects annotated tabular file format

Topics

This keyword is related to the topics:

• file Formats

Specification

Alias: none
  Argument(s): none
  Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

• To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id

• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
6.2. METHOD

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```python
environment
tabular_data
    tabular_data_file = 'dakota_summary.dat'
annotated

Resulting tabular file:

%eval_id interface x1 x2 obj_fn nl_nln_ineq_con_1 nl_nln_ineq_con_2
1 NO_ID 0.9 1.1 0.0002 0.26 0.76
2 NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955

- import_points_file

- custom_annotated

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format
Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

**Default Behavior**

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

**Usage Tips**

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

**Examples**

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id

Resulting tabular file:

%eval_id  x1   x2  obj_fn  nln_ineq_con_1  nln_ineq_con_2
1  0.9   1.1  0.0002  0.26   0.76
2  0.90009  1.1  0.00001996404857  0.2601620081  0.759955
3  0.89991  1.1  0.00002003604863  0.2598380081  0.760045

**Specification**

*Alias:* none

*Argument(s):* none

*Default:* annotated format
6.2. METHOD

Description
A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior
The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips
• Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples
Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```environment
tabular_data
    tabular_data_file = 'dakota_summary.dat'
    freeform
```

Resulting tabular file:

```
0.9 1.1 0.0002 0.26 0.76

• import_points_file
• active_only

Import only active variables from tabular data file

Topics
This keyword is related to the topics:

• file_formats
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none

Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

**export_points_file**

- Keywords Area
- method

Use an evolutionary algorithm

Specification

Alias: none

Argument(s): none
6.2. METHOD

Description
In this approach, the evolutionary algorithm from Coliny, coliny_ea, is used to perform the interval optimization with no surrogate model involved. Again, this option of ea can support interval optimization over discrete variables.

lhs

- Keywords Area
- method
- global_evidence
- lhs

Uses Latin Hypercube Sampling (LHS) to sample variables

Specification

Alias: none
Argument(s): none

Description
The lhs keyword invokes Latin Hypercube Sampling as the means of drawing samples of uncertain variables according to their probability distributions. This is a stratified, space-filling approach that selects variable values from a set of equi-probable bins.

Default Behavior
By default, Latin Hypercube Sampling is used. To explicitly specify this in the Dakota input file, however, the lhs keyword must appear in conjunction with the sample_type keyword.

Usage Tips
Latin Hypercube Sampling is very robust and can be applied to any problem. It is fairly effective at estimating the mean of model responses and linear correlations with a reasonably small number of samples relative to the number of variables.

Examples

method
  sampling
    sample_type lhs
    samples = 20

response_levels

- Keywords Area
- method
- global_evidence
- response_levels

Values at which to estimate desired statistics for each response
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none

Argument(s): REALLIST

Default: No CDF/CCDF probabilities/reliabilities to compute

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>num_response_levels</td>
<td></td>
<td>Number of values at which to estimate desired statistics for each response</td>
</tr>
<tr>
<td>Optional</td>
<td>compute</td>
<td></td>
<td>Selection of statistics to compute at each response level</td>
</tr>
</tbody>
</table>

Description

The `response_levels` specification provides the target response values for which to compute probabilities, reliabilities, or generalized reliabilities (forward mapping).

Default Behavior

If `response_levels` are not specified, no statistics will be computed. If they are, probabilities will be computed by default.

Expected Outputs

The particular statistics reported for each response level depend on the method, and they include:

1. Reliabilities
2. CDF probabilities
3. CCDF probabilities

Usage Tips

The `num_response_levels` is used to specify which arguments of the `response_level` correspond to which response.

Examples

For example, specifying a `response_level` of 52.3 followed with `compute probabilities` will result in the calculation of the probability that the response value is less than or equal to 52.3, given the uncertain distributions on the inputs.

For an example with multiple responses, the following specification

```plaintext
response_levels = 1. 2. .1 .2 .3 .4 10. 20. 30.  
num_response_levels = 2 4 3
```

would assign the first two response levels (1., 2.) to response function 1, the next four response levels (.1, .2, .3, .4) to response function 2, and the final three response levels (10., 20., 30.) to response function 3. If the `num_response_levels` key were omitted from this example, then the response levels would be evenly distributed among the response functions (three levels each in this case).
Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function. In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

A forward mapping involves computing the belief and plausibility probability level for a specified response level.

**num_response_levels**

- **Keywords Area**
- **method**
- **global_evidence**
- **response_levels**
- **num_response_levels**

Number of values at which to estimate desired statistics for each response

Specification

**Alias:** none  
**Argument(s):** INTEGERLIST  
**Default:** response_levels evenly distributed among response functions

Description

The num_response_levels keyword allows the user to specify the number of response values, for each response, at which estimated statistics are of interest. Statistics that can be computed are probabilities and reliabilities, both according to either a cumulative distribution function or a complementary cumulative distribution function.

**Default Behavior**

If num_response_levels is not specified, the response_levels will be evenly distributed among the responses.

**Expected Outputs**

The specific output will be determined by the type of statistics that are specified. In a general sense, the output will be a list of response level-statistic pairs that show the estimated value of the desired statistic for each response level specified.

Examples

```plaintext
method sampling
  samples = 100
  seed = 34785
  num_response_levels = 1 1 1
  response_levels = 0.5 0.5 0.5
```

- compute

Selection of statistics to compute at each response level

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** probabilities

<table>
<thead>
<tr>
<th>Required/-Optional Required (Choose One)</th>
<th>Description of Group 1</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>gen_reliabilities</td>
<td>probabilities</td>
<td>Computes generalized reliabilities associated with response levels</td>
</tr>
<tr>
<td>Optional</td>
<td>system</td>
<td></td>
<td>Compute system reliability (series or parallel)</td>
</tr>
</tbody>
</table>

**Description**

The `compute` keyword is used to select which forward statistical mapping is calculated at each response level.

**Default Behavior**

If `response_levels` is not specified, no statistics are computed. If `response_levels` is specified but `compute` is not, probabilities will be computed by default. If both `response_levels` and `compute` are specified, then one of the following must be specified: `probabilities`, `reliabilities`, or `gen_reliabilities`.

**Expected Output**

The type of statistics specified by `compute` will be reported for each response level.

**Usage Tips**

CDF/CCDF probabilities are calculated for specified response levels using a simple binning approach.

CDF/CCDF reliabilities are calculated for specified response levels by computing the number of sample standard deviations separating the sample mean from the response level.
6.2. METHOD

Examples

method
  sampling
    sample_type random
    samples = 100 seed = 1
  complementary distribution
  response_levels = 3.6e+11 4.0e+11 4.4e+11
                  6.0e+04 6.5e+04 7.0e+04
                  3.5e+05 4.0e+05 4.5e+05
  compute reliabilities

probabilities

- Keywords Area
- method
- global_evidence
- response_levels
- compute
- probabilities

Computes probabilities associated with response levels

Specification

Alias: none
  Argument(s): none

Description

The probabilities keyword directs Dakota to compute the probability that the model response will be below (cumulative) or above (complementary cumulative) a specified response value. This is done for every response level designated for each response.

Default Behavior

If response_levels is specified, the probabilities are computed by default. To explicitly specify it in the Dakota input file, though, the probabilities keyword should be specified in conjunction with the compute keyword.

Expected Outputs

The Dakota output is a set of response level-probability pairs that give the probability that the model response will be below or above the corresponding response level, depending on the distribution defined.

Examples

method
  sampling
    sample_type random
    samples = 100 seed = 1
  complementary distribution
  response_levels = 3.6e+11 4.0e+11 4.4e+11
                  6.0e+04 6.5e+04 7.0e+04
                  3.5e+05 4.0e+05 4.5e+05
  compute probabilities
CHAPTER 6. KEYWORDS AREA

```
gen_reliabilities
  • Keywords Area
  • method
  • global_evidence
  • response_levels
  • compute
  • gen_reliabilities

Computes generalized reliabilities associated with response levels

Specification

Alias: none
  Argument(s): none

Description

The `gen_reliabilities` keyword directs Dakota to compute generalized reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the generalized reliabilities are not computed by default. To change this behavior, the `gen_reliabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-generalized reliability pairs according to the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
  complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
    6.0e+04 6.5e+04 7.0e+04
    3.5e+05 4.0e+05 4.5e+05
  compute gen_reliabilities
```

```
compute gen_reliabilities
```

system

<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>series</td>
<td>Aggregate response statistics assuming a series system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>parallel</td>
<td>Aggregate response statistics assuming a parallel system</td>
</tr>
</tbody>
</table>

Description

With the system probability/reliability option, statistics for specified response_levels are calculated and reported assuming the response functions combine either in series or parallel to produce a total system response.

For a series system, the system fails when any one component (response) fails. The probability of failure is the complement of the product of the individual response success probabilities.

For a parallel system, the system fails only when all components (responses) fail. The probability of failure is the product of the individual response failure probabilities.

<td></td>
<td></td>
<td>cumulative</td>
<td>Computes statistics according to cumulative functions</td>
</tr>
<tr>
<td></td>
<td></td>
<td>complementary</td>
<td>Computes statistics according to complementary cumulative functions</td>
</tr>
</tbody>
</table>
Description

The `distribution` keyword allows the user to select between a cumulative distribution/belief/plausibility function and a complementary cumulative distribution/belief/plausibility function. This choice affects how probabilities and reliability indices are reported.

**Default Behavior**

If the `distribution` keyword is present, it must be accompanied by either `cumulative` or `complementary`. Otherwise, a cumulative distribution will be used by default.

**Expected Outputs**

Output will be a set of model response-probability pairs determined according to the choice of distribution. The choice of distribution also defines the sign of the reliability or generalized reliability indices.

Examples

```dakota
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

cumulative

- **cumulative**

  Computes statistics according to cumulative functions

**Specification**

**Alias:** none

**Argument(s):** none

Description

Statistics on model responses will be computed according to a cumulative distribution/belief/plausibility function.

**Default Behavior**

By default, a cumulative distribution/belief/plausibility function will be used. To explicitly specify it in the Dakota input file, however, the `cumulative` keyword must be appear in conjunction with the `distribution` keyword.

**Expected Outputs**

Output will be a set of model response-probability pairs determined according to a cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls below given response thresholds.
Examples

```
method sampling
  sample_type lhs
  samples = 10
  distribution complementary
```

Complements statistics according to complementary cumulative functions

Specification

Alias: none
Argument(s): none

Description

Statistics on model responses will be computed according to a complementary cumulative distribution/belief/plausibility function.

Default Behavior

By default, a complementary cumulative distribution/belief/plausibility function will not be used. To change that behavior, the `complementary` keyword must be appear in conjunction with the `distribution` keyword.

Expected Outputs

Output will be a set of model response-probability pairs determined according to a complementary cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls above given response thresholds.

Examples

```
method sampling
  sample_type lhs
  samples = 10
  distribution complementary
```

Specify probability levels at which to estimate the corresponding response value
6.2. METHOD

Specification

Alias: none

Argument(s): REALLIST

Default: No CDF/CCDF response levels to compute

| Required/- | Description of | Dakota Keyword | Dakota Keyword |
| Optional  | Group          |               | Description   |
| Optional  |               | num_probability_levels | Specify which probability_levels correspond to which response |

Description

Response levels are calculated for specified CDF/CCDF probabilities by indexing into a sorted samples array (the response levels computed are not interpolated and will correspond to one of the sampled values).

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function. In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).

</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td>Generates random numbers using the Mersenne twister</td>
</tr>
</tbody>
</table>

Description

The rng keyword is used to indicate a choice of random number generator.

Default Behavior

If specified, the rng keyword must be accompanied by either rnum2 (pseudo-random numbers) or mt19937 (random numbers generated by the Mersenne twister). Otherwise, mt19937, the Mersenne twister is used by default.

Usage Tips

The default is recommended, as the Mersenne twister is a higher quality random number generator.
Examples

method	sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2

mt19937

- Keywords Area
- method
- global_evidence
- rng
- mt19937

Generates random numbers using the Mersenne twister

Specification

Alias: none

Argument(s): none

Description

The mt19937 keyword directs Dakota to use the Mersenne twister to generate random numbers. Additional information can be found on wikipedia: http://en.wikipedia.org/wiki/Mersenne_twister.

Default Behavior

mt19937 is the default random number generator. To specify it explicitly in the Dakota input file, however, it must be specified in conjunction with the rng keyword.

Usage Tips

Use of the Mersenne twister random number generator (mt19937) is recommended.

Examples

method	sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng mt19937

rnum2

6.2. METHOD

- **rnum2**
  Generates pseudo-random numbers using the Pecos package

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The **rnum2** keyword directs Dakota to use pseudo-random numbers generated by the Pecos package.

**Default Behavior**

**rnum2** is not used by default. To change this behavior, it must be specified in conjunction with the **rng** keyword.

**Usage Tips**

Use of the Mersenne twister random number generator (**mt19937**) is recommended over **rnum2**.

**Examples**

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2

samples

- Keywords Area
- method
- global_evidence
- samples
```

Number of samples for sampling-based methods

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** method-dependent

**Description**

The **samples** keyword is used to define the number of samples (i.e., randomly chosen sets of variable values) at which to execute a model.

**Default Behavior**

By default, Dakota will use the minimum number of samples required by the chosen method.

**Usage Tips**
To obtain linear sensitivities or to construct a linear response surface, at least \( \text{dim}+1 \) samples should be used, where “\( \text{dim} \)” is the number of variables. For sensitivities to quadratic terms or quadratic response surfaces, at least \( (\text{dim}+1)(\text{dim}+2)/2 \) samples are needed. For uncertainty quantification, we recommend at least \( 10+\text{dim} \) samples. For \texttt{variance\_based\_decomp}, we recommend hundreds to thousands of samples. Note that for \texttt{variance\_based\_decomp}, the number of simulations performed will be \( N(\text{dim}+2) \).

**Examples**

```plaintext
method
  sampling
    sample_type lhs
    samples = 20

seed

- Keywords Area
- method
- global\_evidence
- seed

Seed of the random number generator
```

**Specification**

Alias: none

**Argument(s):** INTEGER

**Default:** system-generated (non-repeatable)

**Description**

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

**Default Behavior**

If not specified, the seed is randomly generated.

**Expected Output**

If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

**Usage Tips**

If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

**Examples**

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```
6.2. METHOD

model_pointer

- Keywords Area
- method
- global_evidence
- model_pointer

Identifier for model block to be used by a method

Topics
This keyword is related to the topics:
- block_pointer

Specification

Alias: none
Argument(s): STRING
Default: method use of last model parsed (or use of default model if none parsed)

Description
The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior
If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips
When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.
See block_pointer for details about pointers.

Examples

environment
  tabular_graphics_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'

6.2.60 global_interval_est

- Keywords Area
- method
- global_interval_est

Interval analysis using global optimization methods

Topics

This keyword is related to the topics:

- uncertainty_quantification
- epistemic_uncertainty_quantification_methods
- interval_estimation

Specification

Alias: nond_global_interval_est
Argument(s): none
### Description

In the global approach to interval estimation, one uses either a global optimization method or a sampling method to assess the bounds of the responses.

`global_interval_est` allows the user to specify several approaches to calculate interval bounds on the output responses.

- `lhs` - note: this takes the minimum and maximum of the samples as the bounds
- `ego`
- `sbo`
- `ea`

### Additional Resources

Refer to `variable_support` for information on supported variable types.

</tr>
</tbody>
</table>

Description
A surrogate-based optimization method will be used. The surrogate employed in sbo is a Gaussian process surrogate.

The main difference between ego and the sbo approach is the objective function being optimized. ego relies on an expected improvement function, while in sbo, the optimization proceeds using an evolutionary algorithm (coliny_ea) on the Gaussian process surrogate: it is a standard surrogate-based optimization. Also note that the sbo option can support optimization over discrete variables (the discrete variables are relaxed) while ego cannot. This is not the same as surrogate_based_global.

**Description**

Use the Gaussian process (GP) surrogate from Surfpack, which is specified using the `surfpack` keyword.

An alternate version of GP surrogates was available in prior versions of Dakota. **For now, both versions are supported but the dakota version is deprecated and intended to be removed in a future release.**

surfpack

- **Keywords Area**
- **method**
- **global_interval_est**
- **sbo**
- **gaussian_process**
- **surfpack**

Use the Surfpack version of Gaussian Process surrogates

**Specification**

**Alias:** none

**Argument(s):** none
Description

This keyword specifies the use of the Gaussian process that is incorporated in our surface fitting library called Surfpack.

Several user options are available:

1. Optimization methods:
   Maximum Likelihood Estimation (MLE) is used to find the optimal values of the hyper-parameters governing the trend and correlation functions. By default the global optimization method DIRECT is used for MLE, but other options for the optimization method are available. See optimization_method.
   The total number of evaluations of the likelihood function can be controlled using the max_trials keyword followed by a positive integer. Note that the likelihood function does not require running the “truth” model, and is relatively inexpensive to compute.

2. Trend Function:
   The GP models incorporate a parametric trend function whose purpose is to capture large-scale variations. See trend.

3. Correlation Lengths:
   Correlation lengths are usually optimized by Surfpack, however, the user can specify the lengths manually. See correlation_lengths.

4. Ill-conditioning
   One of the major problems in determining the governing values for a Gaussian process or Kriging model is the fact that the correlation matrix can easily become ill-conditioned when there are too many input points close together. Since the predictions from the Gaussian process model involve inverting the correlation matrix, ill-conditioning can lead to poor predictive capability and should be avoided.
   Note that a sufficiently bad sample design could require correlation lengths to be so short that any interpolatory GP model would become inept at extrapolation and interpolation.
   The surfpack model handles ill-conditioning internally by default, but behavior can be modified using

5. Gradient Enhanced Kriging (GEK).
   The use_derivatives keyword will cause the Surfpack GP to be constructed from a combination of function value and gradient information (if available).
   See notes in the Theory section.

Theory

Gradient Enhanced Kriging

Incorporating gradient information will only be beneficial if accurate and inexpensive derivative information is available, and the derivatives are not infinite or nearly so. Here “inexpensive” means that the cost of evaluating a function value plus gradient is comparable to the cost of evaluating only the function value, for example gradients computed by analytical, automatic differentiation, or continuous adjoint techniques. It is not cost effective to use derivatives computed by finite differences. In tests, GEK models built from finite difference derivatives were also significantly less accurate than those built from analytical derivatives. Note that GEK’s correlation matrix tends to have a significantly worse condition number than Kriging for the same sample design.

This issue was addressed by using a pivoted Cholesky factorization of Kriging’s correlation matrix (which is a small sub-matrix within GEK’s correlation matrix) to rank points by how much unique information they contain. This reordering is then applied to whole points (the function value at a point immediately followed by gradient
information at the same point) in GEK’s correlation matrix. A standard non-pivoted Cholesky is then applied to the reordered GEK correlation matrix and a bisection search is used to find the last equation that meets the constraint on the (estimate of) condition number. The cost of performing pivoted Cholesky on Kriging’s correlation matrix is usually negligible compared to the cost of the non-pivoted Cholesky factorization of GEK’s correlation matrix. In tests, it also resulted in more accurate GEK models than when pivoted Cholesky or whole-point-block pivoted Cholesky was performed on GEK’s correlation matrix.

- **dakota**

Select the built in Gaussian Process surrogate

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

A second version of GP surrogates was available in prior versions of Dakota. **For now, both versions are supported but the dakota version is deprecated and intended to be removed in a future release.**

Historically these models were drastically different, but in Dakota 5.1, they became quite similar. They now differ in that the Surfpack GP has a richer set of features/options and tends to be more accurate than the Dakota version. Due to how the Surfpack GP handles ill-conditioned correlation matrices (which significantly contributes to its greater accuracy), the Surfpack GP can be a factor of two or three slower than Dakota’s. As of Dakota 5.2, the Surfpack implementation is the default in all contexts except Bayesian calibration.

More details on the `gaussian_process` dakota model can be found in [58].

Dakota’s GP deals with ill-conditioning in two ways. First, when it encounters a non-invertible correlation matrix it iteratively increases the size of a “nugget,” but in such cases the resulting approximation smooths rather than interpolates the data. Second, it has a `point_selection` option (default off) that uses a greedy algorithm to select a well-spaced subset of points prior to the construction of the GP. In this case, the GP will only interpolate the selected subset. Typically, one should not need point selection in trust-region methods because a small number of points are used to develop a surrogate within each trust region. Point selection is most beneficial when constructing with a large number of points, typically more than order one hundred, though this depends on the number of variables and spacing of the sample points.

This differs from the `point_selection` option of the Dakota GP which initially chooses a well-spaced subset of points and finds the correlation parameters that are most likely for that one subset.
use_derivatives

- Keywords Area
- method
- global_interval_est
- sbo
- use_derivatives

Use derivative data to construct surrogate models

**Specification**

*Alias*: none

*Argument(s)*: none

*Default*: use function values only

**Description**

The `use_derivatives` flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, it’s use with Surfpack Gaussian process is not recommended.

**import_points_file**

<td>Selects freeform file format</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
</tr>
<tr>
<td>active_only</td>
<td>Import only active variables from tabular data file</td>
</tr>
</tbody>
</table>

**Description**

The `import_points_file` allows the user to specify a file that contains a list of variable values and the model responses computed at those values. These can be used by a number of methods in place of model evaluations. When used to construct surrogate models or emulators these are often called build points or training data.

**Default Behavior**

Be default, methods do not import points from a file.

**Usage Tips**

Dakota parses input files without regard to whitespace, but the `import_points_file` must be in one of three formats:

- annotated (default)
- custom_annotated
- freeform

**Examples**

```plaintext
method
  list_parameter_study
  import_points_file = 'dakota_pstudy.3.dat'

annotated
  - Keywords Area
  - method
  - global_interval_est
  - sbo

  - annotated
    Selects annotated tabular file format
```

**Topics**

This keyword is related to the topics:

- file_formats
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

• To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id

• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
annotated```

Resulting tabular file:

```
%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 NO_ID 0.9 1.1 0.0002 0.26 0.76
2 NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 NO_ID 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...```

<td>interface_id</td>
<td>Enable interface ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:
chapter 6. keywords area

environment
  tabular_data
  tabular_data_file = 'dakota_summary.dat'
  custom_annotated header eval_id

resulting tabular file:

%eval_id   x1   x2   obj_fn  nln_ineq_con_1  nln_ineq_con_2

CHAPTER 6. KEYWORDS AREA

Topics
This keyword is related to the topics:

- file_formats

Specification
Alias: none
Argument(s): none
Default: annotated format

Description
A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior
The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples
Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
freeform```

Resulting tabular file:

```
0.9 1.1 0.0002 0.26 0.76
0.90009 1.1 0.0001996404857 0.2601620081 0.759955

active_only

- Keywords Area
- method
- global_interval_est
- sbo
- import_points_file
- active_only

Import only active variables from tabular data file

Topics
This keyword is related to the topics:
- file_formats

Specification
Alias: none
Argument(s): none

Description
By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables. This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

export_points_file

- Keywords Area
- method
- global_interval_est

### Description

In the case of `ego`, the efficient global optimization (EGO) method is used to calculate bounds. By default, the Surfpack GP (Kriging) model is used, but the Dakota implementation may be selected instead. If `use_derivatives` is specified the GP model will be built using available derivative data (Surfpack GP only).

See `efficient_global` for more information.

</tbody>
</table>

**Description**

Use the Gaussian process (GP) surrogate from Surfpack, which is specified using the `surfpack` keyword.

An alternate version of GP surrogates was available in prior versions of Dakota. For now, both versions are supported but the `dakota` version is deprecated and intended to be removed in a future release.

`surfpack`

- Keywords Area
- method
- `global_interval_est`
- ego
- `gaussian_process`
- surfpack

Use the Surfpack version of Gaussian Process surrogates

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

This keyword specifies the use of the Gaussian process that is incorporated in our surface fitting library called Surfpack.

Several user options are available:

1. Optimization methods:

   Maximum Likelihood Estimation (MLE) is used to find the optimal values of the hyper-parameters governing the trend and correlation functions. By default the global optimization method DIRECT is used for MLE, but other options for the optimization method are available. See `optimization_method`. 
CHAPTER 6. KEYWORDS AREA

The total number of evaluations of the likelihood function can be controlled using the \texttt{max\_trials} keyword followed by a positive integer. Note that the likelihood function does not require running the “truth” model, and is relatively inexpensive to compute.

2. Trend Function:
   The GP models incorporate a parametric trend function whose purpose is to capture large-scale variations. See \texttt{trend}.

3. Correlation Lengths:
   Correlation lengths are usually optimized by Surfpack, however, the user can specify the lengths manually. See \texttt{correlation\_lengths}.

4. Ill-conditioning
   One of the major problems in determining the governing values for a Gaussian process or Kriging model is the fact that the correlation matrix can easily become ill-conditioned when there are too many input points close together. Since the predictions from the Gaussian process model involve inverting the correlation matrix, ill-conditioning can lead to poor predictive capability and should be avoided.

   Note that a sufficiently bad sample design could require correlation lengths to be so short that any interpolatory GP model would become inept at extrapolation and interpolation.

   The \texttt{surfpack} model handles ill-conditioning internally by default, but behavior can be modified using

5. Gradient Enhanced Kriging (GEK).
   The \texttt{use\_derivatives} keyword will cause the Surfpack GP to be constructed from a combination of function value and gradient information (if available).

   See notes in the Theory section.

\textbf{Theory}

\textbf{Gradient Enhanced Kriging}

Incorporating gradient information will only be beneficial if accurate and inexpensive derivative information is available, and the derivatives are not infinite or nearly so. Here “inexpensive” means that the cost of evaluating a function value plus gradient is comparable to the cost of evaluating only the function value, for example gradients computed by analytical, automatic differentiation, or continuous adjoint techniques. It is not cost effective to use derivatives computed by finite differences. In tests, GEK models built from finite difference derivatives were also significantly less accurate than those built from analytical derivatives. Note that GEK’s correlation matrix tends to have a significantly worse condition number than Kriging for the same sample design.

This issue was addressed by using a pivoted Cholesky factorization of Kriging’s correlation matrix (which is a small sub-matrix within GEK’s correlation matrix) to rank points by how much unique information they contain. This reordering is then applied to whole points (the function value at a point immediately followed by gradient information at the same point) in GEK’s correlation matrix. A standard non-pivoted Cholesky is then applied to the reordered GEK correlation matrix and a bisection search is used to find the last equation that meets the constraint on the (estimate of) condition number. The cost of performing pivoted Cholesky on Kriging’s correlation matrix is usually negligible compared to the cost of the non-pivoted Cholesky factorization of GEK’s correlation matrix. In tests, it also resulted in more accurate GEK models than when pivoted Cholesky or whole-point-block pivoted Cholesky was performed on GEK’s correlation matrix.
6.2. METHOD

The Dakota package provides a built-in Gaussian Process surrogate model. The alias is `gaussian_process`. This surrogate can be selected using the `dakota` keyword.

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

A second version of GP surrogates was available in prior versions of Dakota. **For now, both versions are supported but the dakota version is deprecated and intended to be removed in a future release.** Historically these models were drastically different, but in Dakota 5.1, they became quite similar. They now differ in that the Surfpack GP has a richer set of features/options and tends to be more accurate than the Dakota version. Due to how the Surfpack GP handles ill-conditioned correlation matrices (which significantly contributes to its greater accuracy), the Surfpack GP can be a factor of two or three slower than Dakota’s. As of Dakota 5.2, the Surfpack implementation is the default in all contexts except Bayesian calibration.

More details on the **gaussian_process** dakota model can be found in[58]. Dakota’s GP deals with ill-conditioning in two ways. First, when it encounters a non-invertible correlation matrix it iteratively increases the size of a “nugget,” but in such cases the resulting approximation smooths rather than interpolates the data. Second, it has a **point_selection** option (default off) that uses a greedy algorithm to select a well-spaced subset of points prior to the construction of the GP. In this case, the GP will only interpolate the selected subset. Typically, one should not need point selection in trust-region methods because a small number of points are used to develop a surrogate within each trust region. Point selection is most beneficial when constructing with a large number of points, typically more than order one hundred, though this depends on the number of variables and spacing of the sample points.

This differs from the **point_selection** option of the Dakota GP which initially chooses a well-spaced subset of points and finds the correlation parameters that are most likely for that one subset.

**use_derivatives**

**Alias:** none  
**Argument(s):** none

Use derivative data to construct surrogate models.
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none
Argument(s): none
Default: use function values only

Description

The use_derivatives flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, it’s use with Surfpack Gaussian process is not recommended.

import_points_file

<td>Selects freeform file format</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>active_only</td>
<td>Import only active variables from tabular data file</td>
</tr>
</tbody>
</table>
6.2. METHOD

Description

The `import_points_file` allows the user to specify a file that contains a list of variable values and the model responses computed at those values. These can be used by a number of methods in place of model evaluations. When used to construct surrogate models or emulators these are often called build points or training data.

Default Behavior

Be default, methods do not import points from a file.

Usage Tips

Dakota parses input files without regard to whitespace, but the `import_points_file` must be in one of three formats:

- annotated (default)
- custom.annotated
- freeform

Examples

```
method
  list_parameter_study

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format
Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated

Resulting tabular file:
```

<table>
<thead>
<tr>
<th>%eval_id</th>
<th>interface</th>
<th>x1</th>
<th>x2</th>
<th>obj_fn</th>
<th>nln_ineq_con_1</th>
<th>nln_ineq_con_2</th>

</tr>
</tbody>
</table>

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:
Resulting tabular file:

```
%eval_id  x1   x2   obj_fn  nln_ineq_con_1  nln_ineq_con_2

Selects freeform file format
CHAPTER 6. KEYWORDS AREA

Topics
This keyword is related to the topics:

- file_formats

Specification
Alias: none
Argument(s): none
Default: annotated format

Description
A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior
The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips
- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples
Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    freeform

Resulting tabular file:
```

```
0.9  1.1  0.0002  0.26  0.76
0.90009 1.1 0.0001996404857  0.2601620081  0.759955
0.89991 1.1 0.0002003604863  0.2598380081  0.760045

active_only

- Keywords Area
- method
- global_interval_est
- ego
- import_points_file
- active_only

Import only active variables from tabular data file

Topics
This keyword is related to the topics:
- file_formats

Specification

Alias: none
Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword active_only indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

eexport_points_file

6.2. METHOD

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```plaintext
environment
tagular_data
tabular_data_file = 'dakota_summary.dat'
freeform
```

Resulting tabular file:

```
0.9 1.1 0.0002 0.26 0.76
0.90009 1.1 0.0001996404857 0.2601620081 0.759955
0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...
```
ea

- Keywords Area
- method
- global_interval_est
- ea

Use an evolutionary algorithm

**Specification**

Alias: none

**Argument(s):** none

**Description**

In this approach, the evolutionary algorithm from Coliny, coliny_ea, is used to perform the interval optimization with no surrogate model involved. Again, this option of ea can support interval optimization over discrete variables.

lhs

- Keywords Area
- method
- global_interval_est
- lhs

Uses Latin Hypercube Sampling (LHS) to sample variables

**Specification**

Alias: none

**Argument(s):** none

**Description**

The lhs keyword invokes Latin Hypercube Sampling as the means of drawing samples of uncertain variables according to their probability distributions. This is a stratified, space-filling approach that selects variable values from a set of equi-probable bins.

**Default Behavior**

By default, Latin Hypercube Sampling is used. To explicitly specify this in the Dakota input file, however, the lhs keyword must appear in conjunction with the sample_type keyword.

**Usage Tips**

Latin Hypercube Sampling is very robust and can be applied to any problem. It is fairly effective at estimating the mean of model responses and linear correlations with a reasonably small number of samples relative to the number of variables.
6.2. METHOD

Examples

```plaintext
method
  sampling
    sample_type lhs
    samples = 20
```

rng
- Keywords Area
- method
- global_interval_est
- rng

Selection of a random number generator

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** Mersenne twister (mt19937)

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Group</th>
<th>Description of Group 1</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mt19937</td>
<td></td>
<td></td>
<td></td>
<td>Generates random numbers using the Mersenne twister</td>
</tr>
<tr>
<td>rnum2</td>
<td></td>
<td></td>
<td></td>
<td>Generates pseudo-random numbers using the Pecos package</td>
</tr>
</tbody>
</table>

**Description**

The `rng` keyword is used to indicate a choice of random number generator.

**Default Behavior**

If specified, the `rng` keyword must be accompanied by either `rnum2` (pseudo-random numbers) or `mt19937` (random numbers generated by the Mersenne twister). Otherwise, `mt19937`, the Mersenne twister is used by default.

**Usage Tips**

The default is recommended, as the Mersenne twister is a higher quality random number generator.

**Examples**

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2
```
**mt19937**

- Keywords Area
- method
- global_interval_est
- rng
- mt19937

Generates random numbers using the Mersenne twister

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The `mt19937` keyword directs Dakota to use the Mersenne twister to generate random numbers. Additional information can be found on wikipedia: [http://en.wikipedia.org/wiki/Mersenne_twister](http://en.wikipedia.org/wiki/Mersenne_twister).

**Default Behavior**

`mt19937` is the default random number generator. To specify it explicitly in the Dakota input file, however, it must be specified in conjunction with the `rng` keyword.

**Usage Tips**

Use of the Mersenne twister random number generator (`mt19937`) is recommended.

**Examples**

```python
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng mt19937
```

**rnum2**

- Keywords Area
- method
- global_interval_est
- rng
- rnum2

Generates pseudo-random numbers using the Pecos package

**Specification**

**Alias:** none

**Argument(s):** none
6.2. METHOD

Description

The `rnum2` keyword directs Dakota to use pseudo-random numbers generated by the Pecos package.

**Default Behavior**

`rnum2` is not used by default. To change this behavior, it must be specified in conjunction with the `rng` keyword.

**Usage Tips**

Use of the Mersenne twister random number generator (`mt19937`) is recommended over `rnum2`.

Examples

```plaintext
method sampling
  sample_type lhs
  samples = 10
  seed = 98765
  rng rnum2
```

**samples**

- **Keywords Area**
- **method**
- **global_interval_est**
- **samples**

Number of samples for sampling-based methods

Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** method-dependent

Description

The `samples` keyword is used to define the number of samples (i.e., randomly chosen sets of variable values) at which to execute a model.

**Default Behavior**

By default, Dakota will use the minimum number of samples required by the chosen method.

**Usage Tips**

To obtain linear sensitivities or to construct a linear response surface, at least `dim+1` samples should be used, where "dim" is the number of variables. For sensitivities to quadratic terms or quadratic response surfaces, at least `(dim+1)(dim+2)/2` samples are needed. For uncertainty quantification, we recommend at least `10*dim` samples. For `variance_based_decomp`, we recommend hundreds to thousands of samples. Note that for `variance_based_decomp`, the number of simulations performed will be `N*(dim+2)`.

Examples

```plaintext
method sampling
  sample_type lhs
  samples = 20
```
seed

- Keywords Area
- method
- global_interval_est
- seed

Seed of the random number generator

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** system-generated (non-repeatable)

**Description**

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

**Default Behavior**

If not specified, the seed is randomly generated.

**Expected Output**

If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

**Usage Tips**

If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

**Examples**

```dakota
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

**model_pointer**

- Keywords Area
- method
- global_interval_est
- model_pointer

Identifier for model block to be used by a method
6.2. METHOD

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

Examples

```plaintext
environment
    tabular_graphics_data
    method_pointer = 'UQ'

method
    id_method = 'UQ'
    model_pointer = 'Surr'

### Description

Bayesian calibration methods take prior information on parameter values (in the form of prior distributions) and observational data (e.g. from experiments) and produce posterior distributions on the parameter values. When the computational simulation is then executed with samples from the posterior parameter distributions, the results that are produced are consistent with ("agree with") the experimental data. Calibrating parameters from a computational simulation model requires a "likelihood function" that specifies the likelihood of observing a particular observation given the model and its associated parameterization; Dakota assumes a Gaussian likelihood function currently. The algorithms that produce the posterior distributions on model parameters are Monte Carlo Markov Chain Monte Carlo algorithm with Gaussian Process Surrogate (GPMSA) or DiffeRential Evolution Adaptive Metropolis (DREAM) in a standardized probability space.

CHAPTER 6. KEYWORDS AREA

Chain (MCMC) sampling algorithms. MCMC methods require many samples, often tens of thousands, so in the case of model calibration, often emulators of the computational simulation are used. For more details on the algorithms underlying the methods, see the Dakota User’s manual.

Dakota has three Bayesian calibration methods: QUESO, DREAM, and GPMSA, specified with `bayes_calibration queso`, `bayes_calibration dream`, or `bayes_calibration gpmsa`, respectively. The QUESO method uses components from the QUESO library (Quantification of Uncertainty for Estimation, Simulation, and Optimization) developed at The University of Texas at Austin. Dakota uses its DRAM (Delayed Rejected Adaptive Metropolis) algorithm, and variants, for the MCMC sampling. DREAM (DiffeRential Evolution Adaptive Metropolis) is a method that runs multiple different chains simultaneously for global exploration, and automatically tunes the proposal covariance during the process by a self-adaptive randomized subspace sampling[86]. GPMSA (Gaussian Process Models for Simulation Analysis) is an approach developed at Los Alamos National Laboratory. It constructs Gaussian process models to emulate the expensive computational simulation as well as model discrepancy. GPMSA also has extensive features for calibration, such as the capability to include a ”model discrepancy” term and the capability to model functional data such as time series data.

The Bayesian capabilities are under active development. At this stage, the QUESO methods in Dakota are the most advanced and robust, followed by DREAM, followed by GPMSA, which is in prototype form at this time. Note that as of Dakota 6.2, the field responses and associated field data may be used with QUESO and DREAM. That is, the user can specify field simulation data and field experiment data, and Dakota will interpolate and provide the proper residuals to the Bayesian calibration.

Markov Chain Monte Carlo algorithms from the QUESO package

Topics

This keyword is related to the topics:

- bayesian_calibration
- package_queso

Specification

Alias: none

Argument(s): none
### Description

For the QUESO method, one can use an emulator in the MCMC sampling. This will greatly improve the speed, since the Monte Carlo Markov Chain will generate thousands of samples on the emulator instead of the real simulation code. However, in the case of fast running evaluations, we recommend the use of no emulator. An emulator may be specified with the keyword `emulator`, followed by a *gaussian process* emulator, a *pce* emulator (polynomial chaos expansion), or a *sc* emulator (stochastic collocation). For the *gaussian process* emulator, one can use an emulator or surrogate model to evaluate the likelihood function. Utilize the logit transformation to reduce sample rejection for bounded domains. Use the DRAM MCMC algorithm. Use the Delayed Rejection MCMC algorithm. Use the Adaptive Metropolis MCMC algorithm. Use the Metropolis--Hastings MCMC algorithm. Use the multilevel MCMC algorithm.
emulator, the user must specify whether to use the surfpack or dakota version of the Gaussian process. The user can define the number of samples emulator_samples from which the emulator should be built. It is also possible to build the Gaussian process from points read in from the import_points_file and to export approximation-based sample evaluations using export_points_file. For pce or sc, the user can define a sparse_grid_level.

In terms of the MCMC sampling, one can specify one of the following MCMC algorithms to use: dram for D-RAM (Delayed Rejection Adaptive Metropolis), delayed_rejection for delayed_rejection only, adaptive_metropolis for adaptive metropolis only, metropolis_hastings for Metropolis Hastings, and multilevel for the multilevel MCMC algorithm.

There are a variety of ways the user can specify the proposal covariance matrix which is very important in governing the samples generated in the chain. The proposal covariance specifies the covariance structure of a multivariate normal distribution. The user can specify proposal_covariance, followed by derivatives, prior, values, or filename. The derivative specification involves forming the Hessian of the misfit function (the negative log likelihood). When derivative information is available inexpensively (e.g. from an emulator), the derived-based proposal covariance forms a more accurate proposal distribution, resulting in lower rejection rates and faster chain mixing. The prior setting involves constructing the proposal from the variance of the prior distributions of the parameters being calibrated. When specifying the proposal covariance with values or from a file, the user can choose to specify only the diagonals of the covariance matrix with diagonal or to specify the full covariance matrix with matrix.

There are two other controls for QUESO. The likelihood_scale is a number which scales the likelihood by dividing the log of the likelihood (e.g. dividing the sum of squared differences between the experimental data and simulation data or SSE). This is useful for situations with very small likelihoods (e.g. the model is either very far away from the data or there is a lot of data so the likelihood function involves multiplying many likelihoods together, where the SSE term is large and the likelihood becomes very small). In some respects, the likelihood_scale can be seen as a normalizing factor for the SSE. If the SSE is large, the likelihood_scale should be large. The second factor is a logit_transform, which performs an internal variable transformation from bounded domains to unbounded domains in order to reduce sample rejection due to an out-of-bounds condition.

Finally, we offer the option to calibrate the sigma terms with the calibrate_sigma flag. The sigma terms refer to the variance/covariance of the measurement error. If experimental measurement error is available to inform sigma, that is very useful, but often measurement uncertainty is not available. Note that if calibrate_sigma is specified, a separate sigma term will be calibrated for each calibration term. Thus, if there are 50 calibration terms (e.g. experimental points against which we are trying to match the model), 50 sigma values will be added to the calibration process. Calibration of the sigma values is turned off by default: only the design parameters are calibrated in default mode. Currently, calibrate_sigma is only applicable to scalar responses.

Note that as of Dakota 6.2, the field data capability may be used with QUESO. That is, the user can specify field simulation data and field experiment data, and Dakota will interpolate and provide the proper residuals to the Bayesian calibration.

- surfpack

Use the Surfpack version of Gaussian Process surrogates
6.2. METHOD

Specification

Alias: none

Argument(s): none

Description

This keyword specifies the use of the Gaussian process that is incorporated in our surface fitting library called Surfpack.

Several user options are available:

1. Optimization methods:

   Maximum Likelihood Estimation (MLE) is used to find the optimal values of the hyper-parameters governing the trend and correlation functions. By default the global optimization method DIRECT is used for MLE, but other options for the optimization method are available. See `optimization_method`.

   The total number of evaluations of the likelihood function can be controlled using the `max_trials` keyword followed by a positive integer. Note that the likelihood function does not require running the "truth" model, and is relatively inexpensive to compute.

2. Trend Function:

   The GP models incorporate a parametric trend function whose purpose is to capture large-scale variations. See `trend`.

3. Correlation Lengths:

   Correlation lengths are usually optimized by Surfpack, however, the user can specify the lengths manually. See `correlation_lengths`.

4. Ill-conditioning

   One of the major problems in determining the governing values for a Gaussian process or Kriging model is the fact that the correlation matrix can easily become ill-conditioned when there are too many input points close together. Since the predictions from the Gaussian process model involve inverting the correlation matrix, ill-conditioning can lead to poor predictive capability and should be avoided.

   Note that a sufficiently bad sample design could require correlation lengths to be so short that any interpolatory GP model would become inept at extrapolation and interpolation.

   The `surfpack` model handles ill-conditioning internally by default, but behavior can be modified using

5. Gradient Enhanced Kriging (GEK).

   The `use_derivatives` keyword will cause the Surfpack GP to be constructed from a combination of function value and gradient information (if available).

   See notes in the Theory section.

Theory

Gradient Enhanced Kriging

Incorporating gradient information will only be beneficial if accurate and inexpensive derivative information is available, and the derivatives are not infinite or nearly so. Here "inexpensive" means that the cost of evaluating a function value plus gradient is comparable to the cost of evaluating only the function value, for example gradients computed by analytical, automatic differentiation, or continuous adjoint techniques. It is not cost effective to use derivatives computed by finite differences. In tests, GEK models built from finite difference derivatives were also
significantly less accurate than those built from analytical derivatives. Note that GEK’s correlation matrix tends to have a significantly worse condition number than Kriging for the same sample design.

This issue was addressed by using a pivoted Cholesky factorization of Kriging’s correlation matrix (which is a small sub-matrix within GEK’s correlation matrix) to rank points by how much unique information they contain. This reordering is then applied to whole points (the function value at a point immediately followed by gradient information at the same point) in GEK’s correlation matrix. A standard non-pivoted Cholesky is then applied to the reordered GEK correlation matrix and a bisection search is used to find the last equation that meets the constraint on the (estimate of) condition number. The cost of performing pivoted Cholesky on Kriging’s correlation matrix is usually negligible compared to the cost of the non-pivoted Cholesky factorization of GEK’s correlation matrix. In tests, it also resulted in more accurate GEK models than when pivoted Cholesky or whole-point-block pivoted Cholesky was performed on GEK’s correlation matrix.

Select the built in Gaussian Process surrogate

Specification
Alias: none
Argument(s): none

Description
A second version of GP surrogates was available in prior versions of Dakota. For now, both versions are supported but the dakota version is deprecated and intended to be removed in a future release.

Historically these models were drastically different, but in Dakota 5.1, they became quite similar. They now differ in that the Surfpack GP has a richer set of features/options and tends to be more accurate than the Dakota version. Due to how the Surfpack GP handles ill-conditioned correlation matrices (which significantly contributes to its greater accuracy), the Surfpack GP can be a factor of two or three slower than Dakota’s. As of Dakota 5.2, the Surfpack implementation is the default in all contexts except Bayesian calibration.

More details on the gaussian process dakota model can be found in[58].

Dakota’s GP deals with ill-conditioning in two ways. First, when it encounters a non-invertible correlation matrix it iteratively increases the size of a "nugget," but in such cases the resulting approximation smooths rather than interpolates the data. Second, it has a point_selection option (default off) that uses a greedy algorithm to select a well-spaced subset of points prior to the construction of the GP. In this case, the GP will only interpo- late the selected subset. Typically, one should not need point selection in trust-region methods because a small number of points are used to develop a surrogate within each trust region. Point selection is most beneficial when constructing with a large number of points, typically more than order one hundred, though this depends on the number of variables and spacing of the sample points.
This differs from the point_selection option of the Dakota GP which initially chooses a well-spaced subset of points and finds the correlation parameters that are most likely for that one subset.

emulator_samples

- Keywords Area
- method
- bayes_calibration
- queso
- emulator
- gaussian_process
- emulator_samples

Number of data points used to train the surrogate model or emulator

**Specification**

**Alias:** none  
**Argument(s):** INTEGER

**Description**

This keyword refers to the number of build points or training points used to construct a Gaussian process emulator. If the user specifies a number of emulator_samples that is less than the minimum number of points required to build the GP surrogate, Dakota will augment the samples to obtain the minimum required.

posterior_adaptive

- Keywords Area
- method
- bayes_calibration
- queso
- emulator
- gaussian_process
- posterior_adaptive

Adapt the emulator model to achieve greater accuracy in regions of high posterior probability.

**Specification**

**Alias:** none  
**Argument(s):** none
CHAPTER 6. KEYWORDS AREA

Description

Following an emulator-based MCMC process, this option refines the emulator by selecting points in regions of high posterior probability, performing truth evaluations at these points, updating the emulator, and reperforming the MCMC process. The adaptation is continued until the maximum number of iterations is exceeded or the convergence tolerance is met.

Examples

```plaintext
bayes_calibration queso
    samples = 2000 seed = 348
    delayed_rejection
    emulator
        gaussian_process surfpack emulator_samples = 30
        posterior_adaptive max_iterations = 10
        proposal_covariance derivatives
```

</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>active_only</td>
</tr>
<tr>
<td></td>
<td>Import only active variables from tabular data file</td>
</tr>
</tbody>
</table>

**Description**

The `import_points_file` allows the user to specify a file that contains a list of variable values and the model responses computed at those values. These can be used by a number of methods in place of model evaluations. When used to construct surrogate models or emulators these are often called build points or training data.

**Default Behavior**

Default, methods do not import points from a file.

**Usage Tips**

Dakota parses input files without regard to whitespace, but the `import_points_file` must be in one of three formats:

- **annotated** (default)
- **custom_annotated**
- **freeform**

**Examples**

```plaintext
method
  list_parameter_study
  import_points_file = 'dakota_pstudy.3.dat'

  Selects annotated tabular file format
```

**Topics**

This keyword is related to the topics:

- **file Formats**
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated
```

Resulting tabular file:

```
%eval_id  interface    x1    x2    obj_fn  nln_ineq_con_1  nln_ineq_con_2
1    NO_ID         0.9    1.1    0.0002    0.26    0.76
2    NO_ID  0.90009    1.1  0.0001996404857    0.2601620081    0.759955
3    NO_ID  0.89991    1.1  0.0002003604863    0.2598380081    0.760045

</tr>
<tr>
<td>Enable header row in custom-annotated tabular file</td>
<td>Enable evaluation ID column in custom-annotated tabular file</td>
<td>Enable interface ID column in custom-annotated tabular file</td>
<td></td>
</tr>
</tbody>
</table>

**Description**

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

**Default Behavior**

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom.annotated, followed by options, in the relevant export/import context.

**Usage Tips**

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples
Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id  x1  x2  obj_fn  nln_ineq_con_1  nln_ineq_con_2

• freeform

Selects freeform file format

Topics

This keyword is related to the topics:

• file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

• Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.
6.2. METHOD

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    freeform

Resulting tabular file:

| 0.9  | 1.1  | 0.0002 | 0.26  | 0.76 |
| 0.90009 | 1.1  | 0.0001996404857 | 0.2601620081 | 0.759955 |

- custom_annotated

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none
Default: annotated format
### Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

**Default Behavior**

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

**Usage Tips**

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

### Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```plaintext
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id   x1    x2    obj_fn  nln_ineq_con_1  nln_ineq_con_2
1         0.9    1.1    0.0002   0.26         0.76
2     0.90009  1.1  0.0001996404857  0.2601620081  0.759955
3     0.89991  1.1  0.0002003604863  0.2598380081  0.760045
...```
header

- method
- bayes_calibration
- queso
- emulator
- gaussian_process
• export_points_file
• freeform

Selects freeform file format

Topics
This keyword is related to the topics:

• file_formats

Specification
Alias: none
Argument(s): none
Default: annotated format

Description
A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior
The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips
• Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples
Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
freeform
```

Resulting tabular file:

```
0.9 1.1 0.0002 0.26 0.76
0.90009 1.1 0.0001996404857 0.2601620081 0.759955

</tr>
</tbody>
</table>

**Description**

Selects a polynomial chaos expansion (PCE) surrogate model to use in the Bayesian likelihood calculations. When using PCE as a surrogate within the Bayesian framework, the PCE coefficients can be computed either from integration using a sparse grid or from regression using a random/unstructured data set.

**See Also**

- sparse_grid_level
- Keywords Area
- method
- bayes_calibration
Set the sparse grid level to be used when performing sparse grid integration or sparse grid interpolation.

**Specification**

*Alias:* none

*Argument(s):* INTEGERLIST

**Description**

Multi-dimensional integration by the Smolyak sparse grid method (specified with `sparse_grid_level` and, optionally, `dimension_preference`). The underlying one-dimensional integration rules are the same as for the tensor-product quadrature case; however, the default rule selection is nested for sparse grids (Genz-Keister for normals/transformed normals and Gauss-Patterson for uniforms/transformed uniforms). This default can be overridden with an explicit non_nested specification (resulting in Gauss-Hermite for normals/transformed normals and Gauss-Legendre for uniforms/transformed uniforms). As for tensor quadrature, the `dimension_preference` specification enables the use of anisotropic sparse grids (refer to the PCE description in the User’s Manual for the anisotropic index set constraint definition). Similar to anisotropic tensor grids, the dimension with greatest preference will have resolution at the full `sparse_grid_level` and all other dimension resolutions will be reduced in proportion to their reduced preference. For PCE with either isotropic or anisotropic sparse grids, a summation of tensor-product expansions is used, where each anisotropic tensor-product quadrature rule underlying the sparse grid construction results in its own anisotropic tensor-product expansion as described in case 1. These anisotropic tensor-product expansions are summed into a sparse PCE using the standard Smolyak summation (again, refer to the User’s Manual for additional details). As for `quadrature_order`, the `sparse_grid_level` specification admits an array input for enabling specification of multiple grid resolutions used by certain advanced solution methodologies.

This keyword can be used when using sparse grid integration to calculate PCE coefficients or when generating samples for sparse grid collocation.

</tbody>
</table>

**Description**

When the expansion_order for a polynomial chaos expansion is specified, the coefficients may be computed by integration based on random samples or by regression using either random or sub-sampled tensor product quadrature points.

Multidimensional integration by Latin hypercube sampling (specified with expansion_samples). In this case, the expansion order $p$ cannot be inferred from the numerical integration specification and it is necessary to provide an expansion_order to specify $p$ for a total-order expansion.

Linear regression (specified with either collocation_points or collocation_ratio). A total-order expansion is used and must be specified using expansion_order as described in the previous option. To avoid requiring the user to calculate $N$ from $n$ and $p$), the collocation_ratio allows for specification of a constant factor applied to $N$ (e.g., collocation_ratio = 2, produces samples = 2N). In addition, the default linear relationship with $N$ can be overridden using a real-valued exponent specified using ratio_order. In this case, the number of samples becomes $cN^o$ where $c$ is the collocation_ratio and $o$ is the ratio_order. The use_derivatives flag informs the regression approach to include derivative matching equations (limited to gradients at present) in the least squares solutions, enabling the use of fewer collocation points for a given expansion order and dimension (number of points required becomes $\frac{cN^o}{n^p+1}$). When admissible, a constrained least squares approach is employed in which response values are first reproduced exactly and error in reproducing response derivatives is minimized. Two collocation grid options are supported: the default is Latin hypercube sampling ("point collocation"), and an alternate approach of "probabilistic collocation" is also available through inclusion of the tensor_grid keyword. In this alternate case, the collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

If collocation_points or collocation_ratio is specified, the PCE coefficients will be determined by regression. If no regression specification is provided, appropriate defaults are defined. Specifically SVD-based least-squares will be used for solving over-determined systems and under-determined systems will be solved using LASSO. For the situation when the number of function values is smaller than the number of terms in a
PCE, but the total number of samples including gradient values is greater than the number of terms, the resulting over-determined system will be solved using equality constrained least squares. Technical information on the various methods listed below can be found in the Linear regression section of the Theory Manual. Some of the regression methods (OMP, LASSO, and LARS) are able to produce a set of possible PCE coefficient vectors (see the Linear regression section in the Theory Manual). If cross validation is inactive, then only one solution, consistent with the noise_tolerance, will be returned. If cross validation is active, Dakota will choose between possible coefficient vectors found internally by the regression method across the set of expansion orders \((1,...,\text{expansion\_order})\) and the set of specified noise tolerances and return the one with the lowest cross validation error indicator.

**collocation\_ratio**

- Keywords Area
- method
- bayes\_calibration
- queso
- emulator
- pce
- expansion\_order
- collocation\_ratio

Set the number of points used to build a PCE via regression to be proportional to the number of terms in the expansion.

**Specification**

*Alias:* none

*Argument(s):* REAL

**Description**

Set the number of points used to build a PCE via regression to be proportional to the number of terms in the expansion. To avoid requiring the user to calculate \(N\) from \(n\) and \(p\), the collocation\_ratio allows for specification of a constant factor applied to \(N\) (e.g., collocation\_ratio = 2, produces samples = 2\(N\)). In addition, the default linear relationship with \(N\) can be overridden using a real-valued exponent specified using ratio\_order. In this case, the number of samples becomes \(cN^o\) where \(c\) is the collocation\_ratio and \(o\) is the ratio\_order. The use\_derivatives flag informs the regression approach to include derivative matching equations (limited to gradients at present) in the least squares solutions, enabling the use of fewer collocation points for a given expansion order and dimension (number of points required becomes \(\frac{cN^o}{n+1}\)).
6.2. METHOD

- queso
- emulator
- pce
- expansion_order
- posterior_adaptive

Adapt the emulator model to achieve greater accuracy in regions of high posterior probability.

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

Following an emulator-based MCMC process, this option refines the emulator by selecting points in regions of high posterior probability, performing truth evaluations at these points, updating the emulator, and reperforming the MCMC process. The adaptation is continued until the maximum number of iterations is exceeded or the convergence tolerance is met.

**Examples**

```
bayes_calibration queso  
samples = 2000 seed = 348  
delayed_rejection  
emulator  
  gaussian_process surfpack emulator_samples = 30  
  posterior_adaptive max_iterations = 10  
  proposal_covariance derivatives

• method

• bayes_calibration

• queso

• emulator

• use_derivatives

Use derivative data to construct surrogate models

Specification

Alias: none

Argument(s): none

Default: use function values only

Description

The use_derivatives flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process). However, it’s use with Surfpack Gaussian process is not recommended.

logit_transform

• Keywords Area

• method

• bayes_calibration

• queso

• logit_transform

Utilize the logit transformation to reduce sample rejection for bounded domains
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none
  Argument(s): none

Description

The logit transformation performs an internal variable transformation from bounded domains to unbounded domains in order to reduce sample rejection due to an out-of-bounds condition.

Default Behavior
This option is experimental at present, and is therefore defaulted off.

Usage Tips
This option can be helpful when regions of high posterior density exist in the corners of a multi-dimensional bounded domain. In these cases, it may be difficult to generate feasible samples from the proposal density, such that transformation to unbounded domains may greatly reduce sample rejection rates.

Examples

method,
  bayes_calibration queso
  samples = 2000 seed = 348
  dram
  logit_transform

dram

Use the DRAM MCMC algorithm

Topics

This keyword is related to the topics:

  • bayesian_calibration

Specification

Alias: none
  Argument(s): none
  Default: dram
Description
The type of Markov Chain Monte Carlo used. This keyword specifies the use of DRAM, (Delayed Rejection Adaptive Metropolis)[39].

Default Behavior
Five MCMC algorithm variants are supported: dram, delayed_rejection, adaptive_metropolis, metropolis_hastings, and multilevel. The default is dram.

Usage Tips
If the user knows very little about the proposal covariance, using dram is a recommended strategy. The proposal covariance is adaptively updated, and the delayed rejection may help improve low acceptance rates.

Examples
```
method,
   bayes_calibration queso
dram
   samples = 10000 seed = 348
```

delayed_rejection

- Keywords Area
- method
- bayes_calibration
- queso
- delayed_rejection

Use the Delayed Rejection MCMC algorithm

Topics
This keyword is related to the topics:

- bayesian_calibration

Specification
Alias: none
   Argument(s): none
   Default: dram

Description
This keyword specifies the use of the Delayed Rejection algorithm in which there can be a delay in rejecting samples from the chain. That is, the "DR" part of DRAM is used but the "AM" part is not, rather a regular Metropolis-Hastings algorithm is used.

Default Behavior
Five MCMC algorithm variants are supported: dram, delayed_rejection, adaptive_metropolis, metropolis_hastings, and multilevel. The default is dram.

Usage Tips
If the user knows something about the proposal covariance or the proposal covariance is informed through derivative information, using delayed_rejection is preferred over dram: the proposal covariance is already being informed by derivative information and the adaptive metropolis is not necessary.

**Examples**

```plaintext
method,
  bayes_calibration queso
delayed_rejection
samples = 10000 seed = 348
```

**See Also**

These keywords may also be of interest:

- proposal_covariance

**adaptive_metropolis**

- Keywords Area
- method
- bayes_calibration
- queso
- adaptive_metropolis

Use the Adaptive Metropolis MCMC algorithm

**Topics**

This keyword is related to the topics:

- bayesian_calibration

**Specification**

*Alias: none*

*Argument(s): none*

*Default: dram*

**Description**

This keyword specifies the use of the Adaptive Metropolis algorithm. That is, the "AM" part of DRAM is used but the "DR" part is not: specifying this keyword activates only the Adaptive Metropolis part of the MCMC algorithm, in which the covariance of the proposal density is updated adaptively.

**Default Behavior**

Five MCMC algorithm variants are supported: dram, delayed_rejection, adaptive_metropolis, metropolis_hastings, and multilevel. The default is dram.

**Usage Tips**

If the user knows very little about the proposal covariance, but doesn’t want to incur the cost of using full dram with both delayed rejection and adaptive metropolis, specifying only adaptive_metropolis offers a good strategy.
6.2. METHOD

Examples

```
method,
    bayes_calibration queso
    adaptive_metropolis
    samples = 10000 seed = 348
```

```
metropolis_hastings
```

- Keywords Area
- method
- bayes_calibration
- queso
- metropolis_hastings

Use the Metropolis-Hastings MCMC algorithm

Topics

This keyword is related to the topics:

- bayesian_calibration

Specification

Alias: none

Argument(s): none

Default: dram

Description

This keyword specifies the use of a Metropolis-Hastings algorithm for the MCMC chain generation. This means there is no delayed rejection and no adaptive proposal covariance updating as in DRAM.

Default Behavior

Five MCMC algorithm variants are supported: dram, delayed_rejection, adaptive_metropolis, metropolis_hastings, and multilevel. The default is dram.

Usage Tips

If the user wants to use Metropolis-Hastings, possibly as a comparison to the other methods which involve more chain adaptation, this is the MCMC type to use.

Examples

```
method,
    bayes_calibration queso
    metropolis_hastings
    samples = 10000 seed = 348
```
Use the multilevel MCMC algorithm.

**Topics**

This keyword is related to the topics:

- bayesian_calibration

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** dram

**Description**

Selects the multilevel algorithm described in[70].

**Default Behavior**

Five MCMC algorithm variants are supported: dram, delayed_rejection, adaptive_metropolis, metropolis_hastings, and multilevel. The default is dram.

**Usage Tips**

The multilevel algorithm is a more experimental algorithm than the other MCMC approaches mentioned above. It works well in cases where the prior can be “evolved” to a posterior in a structured way.

**Examples**

```plaintext
method, bayes_calibration queso
    multilevel
    samples = 10000  seed = 348
```

**rng**

<td>Generates random numbers using the Mersenne twister</td>
</tr>
<tr>
<td>rnum2</td>
<td>Generates pseudo-random numbers using the Pecos package</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Description

The *rng* keyword is used to indicate a choice of random number generator.

Default Behavior

If specified, the *rng* keyword must be accompanied by either *rnum2* (pseudo-random numbers) or *mt19937* (random numbers generated by the Mersenne twister). Otherwise, *mt19937*, the Mersenne twister is used by default.

Usage Tips

The default is recommended, as the Mersenne twister is a higher quality random number generator.

Examples

```
method sampling
  sample_type lhs
  samples = 10
  seed = 98765
  rng rnum2

mt19937

  • Keywords Area

  • method

  • bayes_calibration

  • queso

  • rng

  • mt19937

Generates random numbers using the Mersenne twister
```
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none
Argument(s): none

Description

The mt19937 keyword directs Dakota to use the Mersenne twister to generate random numbers. Additional information can be found on wikipedia: http://en.wikipedia.org/wiki/Mersenne_twister.

Default Behavior

mt19937 is the default random number generator. To specify it explicitly in the Dakota input file, however, it must be specified in conjunction with the rng keyword.

Usage Tips

Use of the Mersenne twister random number generator (mt19937) is recommended.

Examples

method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng mt19937

rnum2

- Keywords Area
- method
- bayes_calibration

<th>values</th>
<th>Specifies matrix values to use as the MCMC proposal covariance.</th>
</tr>
</thead>
<tbody>
<tr>
<td>filename</td>
<td>Uses a file to import a user-specified MCMC proposal covariance.</td>
</tr>
</tbody>
</table>

**Description**

The proposal covariance is used to define a multivariate normal (MVN) jumping distribution used to create new points within a Markov chain. That is, a new point in the chain is determined by sampling within a MVN probability density with prescribed covariance that is centered at the current chain point. The accuracy of the proposal covariance has a significant effect on rejection rates and the efficiency of chain mixing.

**Default Behavior**

If the proposal covariance keyword is specified by the user, then one of the four options must be specified. If the proposal covariance block is omitted, then the prior covariance option is used as the default.

**Expected Output**

The effect of the proposal covariance is reflected in the MCMC chain values and the rejection rates, which can be seen in the diagnostic outputs from the QUESO solver within the outputData directory.

**Usage Tips**

When derivative information is available inexpensively (e.g., from an emulator model), the derived-based proposal covariance forms a more accurate proposal distribution, resulting in lower rejection rates and faster chain mixing.

**derivatives**

- **Keywords Area**
- **method**

- **proposal_covariance**
- **derivatives**

Uses derivatives to inform the MCMC proposal covariance.

**Topics**

This keyword is related to the topics:

- **bayesian_calibration**
6.2. METHOD

Specification

Alias: none
  Argument(s): none
### Description

This keyword selection results in definition of the MCMC proposal covariance from the Hessian of the misfit function (negative log likelihood), where this Hessian is defined from either a Gauss-Newton approximation (using only first derivatives of the calibration terms) or a full Hessian (using values, first derivatives, and second derivatives of the calibration terms).

**Default Behavior**

This is not the default, but rather a more advanced option that exploits structure in the form of the likelihood.

**Expected Output**

When derivatives are specified for defining the proposal covariance, the misfit Hessian and its inverse (the MVN proposal covariance) will be output to the standard output stream.

**Usage Tips**

The full Hessian of the misfit is used when either supported by the emulator in use (for PCE and surfpack GP, but not SC or dakota GP) or by the user’s response specification (Hessian type is not "no_hessians"), in the case of no emulator. When this full Hessian is indefinite and cannot be inverted to form the proposal covariance, fallback to the positive semi-definite Gauss-Newton Hessian is employed.

Since this proposal covariance is locally accurate, it should be updated periodically using the proposal_updates option. While the adaptive metropolis option can be used in combination with derivative-based preconditioning, it is generally preferable to instead increase the proposal update frequency due to the improved local accuracy of this approach.

### Examples

```plaintext
method,
        bayes_calibration queso
        samples = 2000 seed = 348
        delayed_rejection
        emulator pce sparse_grid_level = 2
        proposal_covariance derivatives # default proposal_updates

        method
        bayes_calibration
        queso
        proposal_covariance
        derivatives
```
6.2. METHOD

- proposal_updates
  Restarts the MCMC chain with updated derivative-based proposal covariance.

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Description**

When employing derivative-based proposal covariance, this specification defines the number of restarts that are performed during the course of the total sample size of the MCMC chain. For each restart, a new chain is initiated from the final point in the previous acceptance chain using updated proposal covariance corresponding to the derivatives values at the new starting point.

**Default Behavior**

If proposal_updates is not specified, then the default frequency for restarting the chain with updated proposal covariance is every 100 samples.

**Expected Output**

Each restarted chain will generate a new QUESO header and sampling summary, and the chain diagnostics will be appended within the outputData directory.

**Usage Tips**

proposal_updates should be tailored to the size of the total chain, accounting for the relative expense of derivative-based proposal updates.

**Examples**

```
method,
bayes_calibration queso
  samples = 2000 seed = 348
delayed_rejection
  emulator pce sparse_grid_level = 2
  proposal_covariance derivatives
  proposal_updates = 50 # restarted chains, each with 40 new points
```

**prior**

- Keywords Area
- method
- bayes_calibration
- queso
- proposal_covariance
- prior

Uses the covariance of the prior distributions to define the MCMC proposal covariance.

**Topics**

This keyword is related to the topics:

- bayesian_calibration
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none

Argument(s): none

Description

This keyword selection results in definition of the MCMC proposal covariance from the covariance of the prior distributions. This covariance is currently assumed to be diagonal without correlation.

Default Behavior

This is the default proposal covariance option.

Usage Tips

Since this proposal covariance is defined globally, the chain does not need to be periodically restarted using local updates to this proposal. However, it is usually effective to adapt the proposal using one of the adaptive metropolis MCMC options.

Examples

```plaintext
method,
    bayes_calibration queso
    samples = 2000 seed = 348
    dram
    proposal_covariance prior

values

• Keywords Area

• method

• bayes_calibration

• queso

• proposal_covariance

• values

Specifies matrix values to use as the MCMC proposal covariance.

Specification

Alias: none

Argument(s): REALLIST
## Description

This keyword selection results in definition of the MCMC proposal covariance from user-specified matrix values. The matrix input format must be declared as either a full matrix or a matrix diagonal.

### Default Behavior

This option is not the default, and generally implies special a priori knowledge from the user.

### Usage Tips

This option is not supported for the case of transformations to standardized probability space.

## Examples

```plaintext
method,
    bayes_calibration queso
    samples = 1000 seed = 348
    dram
    proposal_covariance
        values ... # See leaf nodes for required format option
```

**diagonal**

- Keywords Area
- method
- bayes_calibration
- queso
- proposal_covariance
- values
- diagonal

Specifies the diagonal matrix format when specifying a user-specified proposal covariance.
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none

Argument(s): none

Description

When specifying the MCMC proposal covariance in an input file, this keyword declares the use of a diagonal matrix format, i.e., the user only provides the values along the diagonal.

Examples

```
method,
    bayes_calibration queso
    samples = 1000 seed = 348
dram
    proposal_covariance
diagonal values 1.0e6 1.0e-1
```

```
matrix
```

- Keywords Area
- method
- bayes_calibration
- queso
- proposal_covariance
- values
- matrix

Specifies the full matrix format when specifying a user-specified proposal covariance.

Specification

Alias: none

Argument(s): none

Description

When specifying the MCMC proposal covariance in an input file, this keyword declares the use of a full matrix format, i.e., the user provides all values of the matrix, not just the diagonal.

Examples

```
method,
    bayes_calibration queso
    samples = 1000 seed = 348
dram
    proposal_covariance
    matrix values 1.0 0.1
    0.1 2.0
```
6.2. METHOD

filename

- Keywords Area
- method
- bayes_calibration
- queso
- proposal_covariance
- filename

Uses a file to import a user-specified MCMC proposal covariance.

Specification

Alias: none
Argument(s): STRING

| Required/- | Description of | Dakota Keyword | Dakota Keyword |
| Optional Required (Choose One) | Group 1 | diagonal | Description |
| | | | Specifies the diagonal matrix format when importing a user-specified proposal covariance. |
| | | matrix | Specifies the full matrix format when importing a user-specified proposal covariance. |

Description

This keyword selection results in definition of the MCMC proposal covariance from importing data a user-specified filename. This import must be declared as either a full matrix or a matrix diagonal.

Default Behavior

This option is not the default, and generally implies special a priori knowledge from the user.

Usage Tips

This option is not supported for the case of transformations to standardized probability space.

Examples

```
method,
bayes_calibration queso
samples = 1000 seed = 348
dram
proposal_covariance
   filename ... # See leaf nodes for required format option
```
diagonal

<td>Required</td>
<td></td>
<td>emulator_samples</td>
<td>Number of data points used to train the surrogate model or emulator</td>
</tr>
</tbody>
</table>
GPMSA (Gaussian Process Models for Simulation Analysis) is another approach that provides the capability for Bayesian calibration. The GPMSA implementation currently is an experimental capability and not ready for production use at this time. A key part of GPMSA is the construction of an emulator from simulation runs collected at various settings of input parameters. The emulator is a statistical model of the system response, and it is used to incorporate the observational data to improve system predictions and constrain or calibrate the unknown parameters. The GPMSA code draws heavily on the theory developed in the seminal Bayesian calibration paper by Kennedy and O’Hagan[55]. The particular approach in GPMSA has been developed by the Los Alamos group and document in[48]. GPMSA uses Gaussian process models in the emulation, but the emulator is actually a set of basis functions (e.g. from a singular value decomposition) which have GPs as the coefficients.

<td>proposal_-covariance</td>
<td>Defines the technique used to generate the MCMC proposal covariance.</td>
</tr>
</tbody>
</table>
For the GPMSA method, one can define the number of samples which will be used in construction of the emulator, `emulator_samples`. The emulator involves Gaussian processes in GPMSA, so the user does not specify anything about emulator type. At this point, the only controls active for GPMSA are `emulator_samples`, `seed` and `rng`, and `samples` (the number of MCMC samples) and the type of MCMC algorithm (e.g. `dram`, `delayed_rejection`, `adaptive_metropolis`, `metropolis_hastings`, or `multilevel`).

**NOTE:** the GPMSA method is in a very preliminary, prototype state at this time. The user will need to modify certain data structures in the code for their particular application and recompile to run with GPMSA.

### emulator_samples

- **Keywords Area**
- **method**
- **bayes_calibration**
- **gpmsa**
- **emulator_samples**

Number of data points used to train the surrogate model or emulator

**Specification**

**Alias:** none  
**Argument(s):** INTEGER

**Description**

This keyword refers to the number of build points or training points used to construct a Gaussian process emulator. If the user specifies a number of `emulator_samples` that is less than the minimum number of points required to build the GP surrogate, Dakota will augment the samples to obtain the minimum required.

### import_points_file

- **Keywords Area**
- **method**
- **bayes_calibration**
- **gpmsa**
- **import_points_file**

File containing variable values and corresponding responses

**Specification**

**Alias:** none  
**Argument(s):** STRING  
**Default:** no point import from a file
### Description

The `import_points_file` allows the user to specify a file that contains a list of variable values and the model responses computed at those values. These can be used by a number of methods in place of model evaluations. When used to construct surrogate models or emulators these are often called build points or training data.

#### Default Behavior

By default, methods do not import points from a file.

#### Usage Tips

Dakota parses input files without regard to whitespace, but the `import_points_file` must be in one of three formats:

- annotated (default)
- custom_annotated
- freeform

#### Examples

```plaintext
method
list_parameter_study
  import_points_file = 'dakota_pstudy.3.dat'
```

- annotated
  - Keywords Area
  - method
  - bayes_calibration
  - gpmsa
  - import_points_file
  - annotated

Selects annotated tabular file format
6.2. METHOD

Topics
This keyword is related to the topics:

- file formats

Specification

Alias: none

Argument(s): none

Default: annotated format

Description
An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior
By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```environment
tabular_data
  tabular_data_file = 'dakota_summary.dat'
annotated
```

Resulting tabular file:

```
%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 NO_ID 0.9 1.1 0.0002 0.26 0.76
2 NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 NO_ID 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...```
custom_annotated

- Keywords Area
- method
- bayes_calibration
- gpmsa
- import_points_file
- custom_annotated

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none
Default: annotated format

<table>
<thead>
<tr>
<th>Required/-Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>header</td>
<td>Enable header row in custom-annotated tabular file</td>

<tr>
<td>Optional</td>
<td></td>
<td>eval_id</td>
<td>Enable evaluation ID column in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>interface_id</td>
<td>Enable interface ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior
6.2. **METHOD**

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify *custom_annotated*, followed by options, in the relevant export/import context.

**Usage Tips**

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

**Examples**

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id x1  x2  obj_fn nln_ineq_con_1 nln_ineq_con_2
1  0.9  1.1  0.0002  0.26  0.76
2  0.90009  1.1  0.0001996404857  0.2601620081  0.759955
3  0.89991  1.1  0.0002003604863  0.2598380081  0.760045

- import_points_file
- freeform

Selects freeform file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.
Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```python
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
  freeform
Resulting tabular file:

<table>

active_only

- Keywords Area
- method
- bayes_calibration
- gpmsa
- import_points_file
- active_only

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
  Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.
6.2. METHOD

export_points_file

Dram

- Keywords Area
- method
- bayes_calibration
- gpmsa
- dram

Use the DRAM MCMC algorithm

Topics
This keyword is related to the topics:

- bayesian_calibration

Specification

Alias: none
Argument(s): none
Default: dram

Description
The type of Markov Chain Monte Carlo used. This keyword specifies the use of DRAM, (Delayed Rejection Adaptive Metropolis)[39].

Default Behavior
Five MCMC algorithm variants are supported: dram, delayed_rejection, adaptive_metropolis, metropolis_hastings, and multilevel. The default is dram.

Usage Tips
If the user knows very little about the proposal covariance, using dram is a recommended strategy. The proposal covariance is adaptively updated, and the delayed rejection may help improve low acceptance rates.
Examples

```plaintext
method, bayes_calibration queso
dram
samples = 10000 seed = 348
```

delayed_rejection

- Keywords Area
- method
- bayes_calibration
- gpmsa
- delayed_rejection

Use the Delayed Rejection MCMC algorithm

Topics

This keyword is related to the topics:

- bayesian_calibration

Specification

Alias: none
Argument(s): none
Default: dram

Description

This keyword specifies the use of the Delayed Rejection algorithm in which there can be a delay in rejecting samples from the chain. That is, the "DR" part of DRAM is used but the "AM" part is not, rather a regular Metropolis-Hastings algorithm is used.

Default Behavior

Five MCMC algorithm variants are supported: dram, delayed_rejection, adaptive_metropolis, metropolis_hastings, and multilevel. The default is dram.

Usage Tips

If the user knows something about the proposal covariance or the proposal covariance is informed through derivative information, using delayed_rejection is preferred over dram: the proposal covariance is already being informed by derivative information and the adaptive metropolis is not necessary.

Examples

```plaintext
method, bayes_calibration queso
delayed_rejection
samples = 10000 seed = 348
```
6.2. METHOD

See Also
These keywords may also be of interest:

- proposal_covariance

adaptive_metropolis

- Keywords Area
- method
- bayes_calibration
- gpmsa
- adaptive_metropolis

Use the Adaptive Metropolis MCMC algorithm

Topics
This keyword is related to the topics:

- bayesian_calibration

Specification
Alias: none
Argument(s): none
Default: dram

Description
This keyword specifies the use of the Adaptive Metropolis algorithm. That is, the "AM" part of DRAM is used but the "DR" part is not: specifying this keyword activates only the Adaptive Metropolis part of the MCMC algorithm, in which the covariance of the proposal density is updated adaptively.

Default Behavior
Five MCMC algorithm variants are supported: dram, delayed_rejection, adaptive_metropolis, metropolis_hastings, and multilevel. The default is dram.

Usage Tips
If the user knows very little about the proposal covariance, but doesn’t want to incur the cost of using full dram with both delayed rejection and adaptive metropolis, specifying only adaptive_metropolis offers a good strategy.

Examples
method,
  bayes_calibration queso
  adaptive_metropolis
  samples = 10000 seed = 348
**metropolis_hastings**

- Keywords Area
- method
- bayes_calibration
- gpmsa
- metropolis_hastings

Use the Metropolis-Hastings MCMC algorithm

**Topics**

This keyword is related to the topics:

- bayesian_calibration

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** dram

**Description**

This keyword specifies the use of a Metropolis-Hastings algorithm for the MCMC chain generation. This means there is no delayed rejection and no adaptive proposal covariance updating as in DRAM.

**Default Behavior**

Five MCMC algorithm variants are supported: dram, delayed_rejection, adaptive_metropolis, metropolis_hastings, and multilevel. The default is dram.

**Usage Tips**

If the user wants to use Metropolis-Hastings, possibly as a comparison to the other methods which involve more chain adaptation, this is the MCMC type to use.

**Examples**

```
method,
bayes_calibration queso
metropolis_hastings
samples = 10000 seed = 348
```

**multilevel**

- Keywords Area
- method
- bayes_calibration
- gpmsa
- multilevel

Use the multilevel MCMC algorithm.
6.2. METHOD

Topics
This keyword is related to the topics:

- bayesian_calibration

Specification
Alias: none
Argument(s): none
Default: dram

Description
Selects the multilevel algorithm described in [70].

Default Behavior
Five MCMC algorithm variants are supported: dram, delayed_rejection, adaptive_metropolis, metropolis_hastings, and multilevel. The default is dram.

Usage Tips
The multilevel algorithm is a more experimental algorithm than the other MCMC approaches mentioned above. It works well in cases where the prior can be "evolved" to a posterior in a structured way.

Examples

```plaintext
method, bayes_calibration queso
    multilevel
    samples = 10000 seed = 348
```

rng

- Keywords Area
- method
- bayes_calibration
- gpmsa
- rng

Selection of a random number generator

Specification
Alias: none
Argument(s): none
Default: Mersenne twister ( mt19937 )

<table>
<thead>
<tr>
<th>Required/-Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
</table>
### Description

The `rng` keyword is used to indicate a choice of random number generator.

**Default Behavior**

If specified, the `rng` keyword must be accompanied by either `rnum2` (pseudo-random numbers) or `mt19937` (random numbers generated by the Mersenne twister). Otherwise, `mt19937`, the Mersenne twister is used by default.

**Usage Tips**

The default is recommended, as the Mersenne twister is a higher quality random number generator.

### Examples

```plaintext
method
sampling
  sample_type lhs
  samples = 10
  seed = 98765
  rng rnum2

mt19937

- Keywords Area
- method
- bayes_calibration
- gpmsa
- rng
- mt19937

Generates random numbers using the Mersenne twister
```

### Specification

**Alias:** none

**Argument(s):** none
6.2. METHOD

Description

The `mt19937` keyword directs Dakota to use the Mersenne twister to generate random numbers. Additional information can be found on Wikipedia: [http://en.wikipedia.org/wiki/Mersenne_twister](http://en.wikipedia.org/wiki/Mersenne_twister).

Default Behavior

`mt19937` is the default random number generator. To specify it explicitly in the Dakota input file, however, it must be specified in conjunction with the `rng` keyword.

Usage Tips

Use of the Mersenne twister random number generator (`mt19937`) is recommended.

Examples

```dakota
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng mt19937

rnum2

• Keywords Area

• method

• bayes_calibration

• gpmsa

• rng

• rnum2

Generates pseudo-random numbers using the Pecos package

Specification

Alias: none

Argument(s): none

Description

The `rnum2` keyword directs Dakota to use pseudo-random numbers generated by the Pecos package.

Default Behavior

`rnum2` is not used by default. To change this behavior, it must be specified in conjunction with the `rng` keyword.

Usage Tips

Use of the Mersenne twister random number generator (`mt19937`) is recommended over `rnum2`.```
**Examples**

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2
```

<tbody>
<tr>
<td><strong>Required (Choose One)</strong></td>
<td><strong>Group 1</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>prior</td>
<td>Uses the covariance of the prior distributions to define the MCMC proposal covariance.</td>
</tr>
</tbody>
</table>
### Description

The proposal covariance is used to define a multivariate normal (MVN) jumping distribution used to create new points within a Markov chain. That is, a new point in the chain is determined by sampling within a MVN probability density with prescribed covariance that is centered at the current chain point. The accuracy of the proposal covariance has a significant effect on rejection rates and the efficiency of chain mixing.

#### Default Behavior

If the proposal covariance keyword is specified by the user, then one of the four options must be specified. If the proposal covariance block is omitted, then the prior covariance option is used as the default.

#### Expected Output

The effect of the proposal covariance is reflected in the MCMC chain values and the rejection rates, which can be seen in the diagnostic outputs from the QUESO solver within the outputData directory.

#### Usage Tips

When derivative information is available inexpensively (e.g., from an emulator model), the derived-based proposal covariance forms a more accurate proposal distribution, resulting in lower rejection rates and faster chain mixing.

**derivatives**

- Keywords Area
- method
- bayes_calibration
- gpmsa
- proposal_covariance
- derivatives

Uses derivatives to inform the MCMC proposal covariance.

### Topics

This keyword is related to the topics:

- bayesian_calibration
Specification

Alias: none

Argument(s): none
### Description

This keyword selection results in definition of the MCMC proposal covariance from the Hessian of the misfit function (negative log likelihood), where this Hessian is defined from either a Gauss-Newton approximation (using only first derivatives of the calibration terms) or a full Hessian (using values, first derivatives, and second derivatives of the calibration terms).

**Default Behavior**

This is not the default, but rather a more advanced option that exploits structure in the form of the likelihood.

**Expected Output**

When derivatives are specified for defining the proposal covariance, the misfit Hessian and its inverse (the MVN proposal covariance) will be output to the standard output stream.

**Usage Tips**

The full Hessian of the misfit is used when either supported by the emulator in use (for PCE and surfpack GP, but not SC or dakota GP) or by the user’s response specification (Hessian type is not “no_hessians”), in the case of no emulator. When this full Hessian is indefinite and cannot be inverted to form the proposal covariance, fallback to the positive semi-definite Gauss-Newton Hessian is employed.

Since this proposal covariance is locally accurate, it should be updated periodically using the proposal_updates option. While the adaptive metropolis option can be used in combination with derivative-based preconditioning, it is generally preferable to instead increase the proposal update frequency due to the improved local accuracy of this approach.

### Examples

```plaintext
method,
  bayes_calibration queso
  samples = 2000 seed = 348
delayed_rejection
  emulator pce sparse_grid_level = 2
  proposal_covariance derivatives # default proposal_updates

proposal_updates
  • Keywords Area
  • method
  • bayes_calibration
  • gpmsa
  • proposal_covariance
  • derivatives
```
• proposal_updates

Restarts the MCMC chain with updated derivative-based proposal covariance.

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Description**

When employing derivative-based proposal covariance, this specification defines the number of restarts that are performed during the course of the total sample size of the MCMC chain. For each restart, a new chain is initiated from the final point in the previous acceptance chain using updated proposal covariance corresponding to the derivatives values at the new starting point.

**Default Behavior**

If proposal_updates is not specified, then the default frequency for restarting the chain with updated proposal covariance is every 100 samples.

**Expected Output**

Each restarted chain will generate a new QUESO header and sampling summary, and the chain diagnostics will be appended within the outputData directory.

**Usage Tips**

proposal_updates should be tailored to the size of the total chain, accounting for the relative expense of derivative-based proposal updates.

**Examples**

```
method,
    bayes_calibration queso
    samples = 2000 seed = 348
    delayed_rejection
    emulator pce sparse_grid_level = 2
    proposal_covariance derivatives
    proposal_updates = 50 # restarted chains, each with 40 new points
```

**prior**

This keyword is related to the topics:

• bayesian_calibration
6.2. METHOD

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

This keyword selection results in definition of the MCMC proposal covariance from the covariance of the prior distributions. This covariance is currently assumed to be diagonal without correlation.

**Default Behavior**

This is the default proposal covariance option.

**Usage Tips**

Since this proposal covariance is defined globally, the chain does not need to be periodically restarted using local updates to this proposal. However, it is usually effective to adapt the proposal using one of the adaptive metropolis MCMC options.

**Examples**

```plaintext
method, bayes_calibration queso
  samples = 2000 seed = 348
dram
  proposal_covariance prior

<td></td>
<td>Number of candidate points for each crossover.</td>
</tr>
</tbody>
</table>
Description

The DiffeRential Evolution Adaptive Metropolis algorithm is described in [86]. For the DREAM method, one can define the number of chains used with `chains` (minimum 3). The total number of generations per chain in DREAM is the number of samples (`samples`) divided by the number of chains (`chains`). The number of chains randomly selected to be used in the crossover each time a crossover occurs is `crossover_chain_pairs`. There is an extra adaptation during burn-in, in which DREAM estimates a distribution of crossover probabilities that favors large jumps over smaller ones in each of the chains. Normalization is required to ensure that all of the input dimensions contribute equally. In this process, a discrete number of candidate points for each crossover value is generated. This parameter is `num_cr`. The `gr_threshold` is the convergence tolerance for the Gelman-Rubin statistic which will govern the convergence of the multiple chain process. The integer `jump_step` forces a long jump every `jump_step` generations. For more details about these parameters, see [86].

  - surfpack

Use the Surfpack version of Gaussian Process surrogates

### Specification

**Alias:** none  
**Argument(s):** none

### Description

This keyword specifies the use of the Gaussian process that is incorporated in our surface fitting library called Surfpack. Several user options are available:

1. **Optimization methods:**

   Maximum Likelihood Estimation (MLE) is used to find the optimal values of the hyper-parameters governing the trend and correlation functions. By default the global optimization method DIRECT is used for MLE, but other options for the optimization method are available. See `optimization_method`.

   The total number of evaluations of the likelihood function can be controlled using the `max_trials` keyword followed by a positive integer. Note that the likelihood function does not require running the "truth" model, and is relatively inexpensive to compute.
2. Trend Function:
   The GP models incorporate a parametric trend function whose purpose is to capture large-scale variations. See trend.

3. Correlation Lengths:
   Correlation lengths are usually optimized by Surfpack, however, the user can specify the lengths manually. See correlation lengths.

4. Ill-conditioning
   One of the major problems in determining the governing values for a Gaussian process or Kriging model is the fact that the correlation matrix can easily become ill-conditioned when there are too many input points close together. Since the predictions from the Gaussian process model involve inverting the correlation matrix, ill-conditioning can lead to poor predictive capability and should be avoided.
   
   Note that a sufficiently bad sample design could require correlation lengths to be so short that any interpolatory GP model would become inept at extrapolation and interpolation.
   
   The surfpack model handles ill-conditioning internally by default, but behavior can be modified using 5. Gradient Enhanced Kriging (GEK).

   The use_derivatives keyword will cause the Surfpack GP to be constructed from a combination of function value and gradient information (if available).

   See notes in the Theory section.

**Theory**

**Gradient Enhanced Kriging**

Incorporating gradient information will only be beneficial if accurate and inexpensive derivative information is available, and the derivatives are not infinite or nearly so. Here "inexpensive" means that the cost of evaluating a function value plus gradient is comparable to the cost of evaluating only the function value, for example gradients computed by analytical, automatic differentiation, or continuous adjoint techniques. It is not cost effective to use derivatives computed by finite differences. In tests, GEK models built from finite difference derivatives were also significantly less accurate than those built from analytical derivatives. Note that GEK’s correlation matrix tends to have a significantly worse condition number than Kriging for the same sample design.

This issue was addressed by using a pivoted Cholesky factorization of Kriging’s correlation matrix (which is a small sub-matrix within GEK’s correlation matrix) to rank points by how much unique information they contain. This reordering is then applied to whole points (the function value at a point immediately followed by gradient information at the same point) in GEK’s correlation matrix. A standard non-pivoted Cholesky is then applied to the reordered GEK correlation matrix and a bisection search is used to find the last equation that meets the constraint on the (estimate of) condition number. The cost of performing pivoted Cholesky on Kriging’s correlation matrix is usually negligible compared to the cost of the non-pivoted Cholesky factorization of GEK’s correlation matrix. In tests, it also resulted in more accurate GEK models than when pivoted Cholesky or whole-point-block pivoted Cholesky was performed on GEK’s correlation matrix.

Select the built in Gaussian Process surrogate

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

A second version of GP surrogates was available in prior versions of Dakota. **For now, both versions are supported but the dakota version is deprecated and intended to be removed in a future release.**

Historically these models were drastically different, but in Dakota 5.1, they became quite similar. They now differ in that the Surfpack GP has a richer set of features/options and tends to be more accurate than the Dakota version. Due to how the Surfpack GP handles ill-conditioned correlation matrices (which significantly contributes to its greater accuracy), the Surfpack GP can be a factor of two or three slower than Dakota’s. As of Dakota 5.2, the Surfpack implementation is the default in all contexts except Bayesian calibration.

More details on the gaussian_process dakota model can be found in[58].

Dakota’s GP deals with ill-conditioning in two ways. First, when it encounters a non-invertible correlation matrix it iteratively increases the size of a “nugget,” but in such cases the resulting approximation smooths rather than interpolates the data. Second, it has a point_selection option (default off) that uses a greedy algorithm to select a well-spaced subset of points prior to the construction of the GP. In this case, the GP will only interpolate the selected subset. Typically, one should not need point selection in trust-region methods because a small number of points are used to develop a surrogate within each trust region. Point selection is most beneficial when constructing with a large number of points, typically more than order one hundred, though this depends on the number of variables and spacing of the sample points.

This differs from the point_selection option of the Dakota GP which initially chooses a well-spaced subset of points and finds the correlation parameters that are most likely for that one subset.

**emulator_samples**

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- gaussian_process
- emulator_samples

Number of data points used to train the surrogate model or emulator
6.2. METHOD

Specification

Alias: none

Description

This keyword refers to the number of build points or training points used to construct a Gaussian process emulator. If the user specifies a number of emulator_samples that is less than the minimum number of points required to build the GP surrogate, Dakota will augment the samples to obtain the minimum required.

posterior_adaptive

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- gaussian_process
- posterior_adaptive

Adapt the emulator model to achieve greater accuracy in regions of high posterior probability.

Examples

bayes_calibration queso
samples = 2000 seed = 348
delayed_rejection
emulator
gaussian_process surfpack emulator_samples = 30
posterior_adaptive max_iterations = 10
proposal_covariance derivatives
import_points_file

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- gaussian_process
- import_points_file

File containing variable values and corresponding responses

**Specification**

**Alias:** none

**Argument(s):** STRING

**Default:** no point import from a file

<table>

<td>freeform</td>
<td>Selects freeform file format</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>active_only</td>
<td>Import only active variables from tabular data file</td>
</tr>
</tbody>
</table>

**Description**

The *import_points_file* allows the user to specify a file that contains a list of variable values and the model responses computed at those values. These can be used by a number of methods in place of model evaluations. When used to construct surrogate models or emulators these are often called build points or training data.

**Default Behavior**

By default, methods do not import points from a file.

**Usage Tips**

Dakota parses input files without regard to whitespace, but the *import_points_file* must be in one of three formats:

- annotated (default)
- custom_annotated
- freeform
6.2. METHOD

Examples

```python
method
    list_parameter_study
    import_points_file = 'dakota_pstudy.3.dat'

annotated

    • gaussian_process
    • import_points_file
    • annotated
Selects annotated tabular file format
```

Topics

This keyword is related to the topics:

• file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

• To specify pre-Dakota 6.1 tabular format, which did not include interface id, specify custom_annotated header eval_id

• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.
**Examples**

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```python
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
annotated
```

Resulting tabular file:

```plaintext
%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 NO_ID 0.9 1.1 0.0002 0.26 0.76
2 NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 NO_ID 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...
```

</tr>
<tr>
<td>Optional</td>
<td></td>
<td>interface_id</td>
<td>Enable interface ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

**Description**

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

**Default Behavior**

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

**Usage Tips**

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

**Examples**

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id  x1    x2    obj_fn  nln_ineq_con_1  nln_ineq_con_2

Selects freeform file format

Topics
This keyword is related to the topics:
• file_formats

Specification
Alias: none
Argument(s): none
Default: annotated format

Description
A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior
The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips
• Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples
Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```environment
  tabular_data
      tabular_data_file = 'dakota_summary.dat'
      freeform
```

Resulting tabular file:

```
  0.9  1.1  0.0002  0.26  0.76

- bayes_calibration
- dream
- emulator
- gaussian_process
- import_points_file
- active_only

Import only active variables from tabular data file

Topics
This keyword is related to the topics:

- file_formats

Specification
Alias: none
Argument(s): none

Description
By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword active_only indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

</tr>
</tbody>
</table>
Description

Selects a polynomial chaos expansion (PCE) surrogate model to use in the Bayesian likelihood calculations. When using PCE as a surrogate within the Bayesian framework, the PCE coefficients can be computed either from integration using a sparse grid or from regression using a random/unstructured data set.

See Also

Set the sparse grid level to be used when performing sparse grid integration or sparse grid interpolation.

Specification

Alias: none

Argument(s): INTEGERLIST

Description

Multi-dimensional integration by the Smolyak sparse grid method (specified with sparse_grid_level and, optionally, dimension_preference). The underlying one-dimensional integration rules are the same as for the tensor-product quadrature case; however, the default rule selection is nested for sparse grids (Genz-Keister for normals/transformed normals and Gauss-Patterson for uniforms/transformed uniforms). This default can be overridden with an explicit non_nested specification (resulting in Gauss-Hermite for normals/transformed normals and Gauss-Legendre for uniforms/transformed uniforms). As for tensor quadrature, the dimension_preference specification enables the use of anisotropic sparse grids (refer to the PCE description in the User’s Manual for the anisotropic index set constraint definition). Similar to anisotropic tensor grids, the dimension with greatest preference will have resolution at the full sparse_grid_level and all other dimension resolutions will be reduced in proportion to their reduced preference. For PCE with either isotropic or anisotropic sparse grids, a summation of tensor-product expansions is used, where each anisotropic tensor-product quadrature rule underlying the sparse grid construction results in its own anisotropic tensor-product expansion as described in case 1. These anisotropic tensor-product expansions are summed into a sparse PCE using the standard Smolyak summation (again, refer to the User’s Manual for additional details). As for quadrature_order, the sparse_grid_level specification admits an array input for enabling specification of multiple grid resolutions used by certain advanced solution methodologies.

This keyword can be used when using sparse grid integration to calculate PCE coefficients or when generating samples for sparse grid collocation.

**Description**

When the expansion_order for a polynomial chaos expansion is specified, the coefficients may be computed by integration based on random samples or by regression using either random or sub-sampled tensor product quadrature points.

Multidimensional integration by Latin hypercube sampling (specified with expansion_samples). In this case, the expansion order $p$ cannot be inferred from the numerical integration specification and it is necessary to provide an expansion_order to specify $p$ for a total-order expansion.

Linear regression (specified with either collocation_points or collocation_ratio). A total-order expansion is used and must be specified using expansion_order as described in the previous option. To avoid requiring the user to calculate $N$ from $n$ and $p$, the collocation_ratio allows for specification of a constant factor applied to $N$ (e.g., collocation_ratio = 2. produces samples = 2N). In addition, the default linear relationship with $N$ can be overridden using a real-valued exponent specified using ratio_order. In this
case, the number of samples becomes $cN^o$ where $c$ is the \texttt{collocation\_ratio} and $o$ is the \texttt{ratio\_order}. The \texttt{use\_derivatives} flag informs the regression approach to include derivative matching equations (limited to gradients at present) in the least squares solutions, enabling the use of fewer collocation points for a given expansion order and dimension (number of points required becomes $\frac{cN^o}{o+1}$). When admissible, a constrained least squares approach is employed in which response values are first reproduced exactly and error in reproducing response derivatives is minimized. Two collocation grid options are supported: the default is Latin hypercube sampling ("point collocation"), and an alternate approach of "probabilistic collocation" is also available through inclusion of the \texttt{tensor\_grid} keyword. In this alternate case, the collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

If \texttt{collocation\_points} or \texttt{collocation\_ratio} is specified, the PCE coefficients will be determined by regression. If no regression specification is provided, appropriate defaults are defined. Specifically SVD-based least-squares will be used for solving over-determined systems and under-determined systems will be solved using LASSO. For the situation when the number of function values is smaller than the number of terms in a PCE, but the total number of samples including gradient values is greater than the number of terms, the resulting over-determined system will be solved using equality constrained least squares. Technical information on the various methods listed below can be found in the Linear regression section of the Theory Manual. Some of the regression methods (OMP, LASSO, and LARS) are able to produce a set of possible PCE coefficient vectors (see the Linear regression section in the Theory Manual). If cross validation is inactive, then only one solution, consistent with the \texttt{noise\_tolerance}, will be returned. If cross validation is active, Dakota will choose between possible coefficient vectors found internally by the regression method across the set of expansion orders (1,...,\texttt{expansion\_order}) and the set of specified noise tolerances and return the one with the lowest cross validation error indicator.

\texttt{collocation\_ratio}

- Keywords Area
- method
- bayes\_calibration
- dream
- emulator
- pce
- expansion\_order
- collocation\_ratio

Set the number of points used to build a PCE via regression to be proportional to the number of terms in the expansion.

CHAPTER 6. KEYWORDS AREA

Description

Set the number of points used to build a PCE via regression to be proportional to the number of terms in the expansion. To avoid requiring the user to calculate N from n and p, the collocation_ratio allows for specification of a constant factor applied to N (e.g., collocation_ratio = 2 produces samples = 2N). In addition, the default linear relationship with N can be overridden using a real-valued exponent specified using ratio_order. In this case, the number of samples becomes $cn^o$ where $c$ is the collocation_ratio and $o$ is the ratio_order. The use_derivatives flag informs the regression approach to include derivative matching equations (limited to gradients at present) in the least squares solutions, enabling the use of fewer collocation points for a given expansion order and dimension (number of points required becomes $\frac{cN^o}{n+1}$).

Posterior adaptive

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- pce
- expansion_order
- posterior_adaptive

Adapt the emulator model to achieve greater accuracy in regions of high posterior probability.

Specification

Alias: none

Argument(s): none

Description

Following an emulator-based MCMC process, this option refines the emulator by selecting points in regions of high posterior probability, performing truth evaluations at these points, updating the emulator, and reperforming the MCMC process. The adaptation is continued until the maximum number of iterations is exceeded or the convergence tolerance is met.

Examples

```
bayes_calibration queso
  samples = 2000 seed = 348
delayed_rejection
emulator
  gaussian_process surfpack emulator_samples = 30
  posterior_adaptive max_iterations = 10
  proposal_covariance derivatives
```

- emulator
CHAPTER 6. KEYWORDS AREA

- sc
- sparse_grid_level

Set the sparse grid level to be used when performing sparse grid integration or sparse grid interpolation

**Specification**

**Alias:** none  
**Argument(s):** INTEGERLIST

**Description**

Multi-dimensional integration by the Smolyak sparse grid method (specified with sparse_grid_level and, optionally, dimension_preference). The underlying one-dimensional integration rules are the same as for the tensor-product quadrature case; however, the default rule selection is nested for sparse grids (Genz-Keister for normals/transformed normals and Gauss-Patterson for uniforms/transformed uniforms). This default can be overridden with an explicit non_nested specification (resulting in Gauss-Hermite for normals/transformed normals and Gauss-Legendre for uniforms/transformed uniforms). As for tensor quadrature, the dimension_preference specification enables the use of anisotropic sparse grids (refer to the PCE description in the User’s Manual for the anisotropic index set constraint definition). Similar to anisotropic tensor grids, the dimension with greatest preference will have resolution at the full sparse_grid_level and all other dimension resolutions will be reduced in proportion to their reduced preference. For PCE with either isotropic or anisotropic sparse grids, a summation of tensor-product expansions is used, where each anisotropic tensor-product quadrature rule underlying the sparse grid construction results in its own anisotropic tensor-product expansion as described in case 1. These anisotropic tensor-product expansions are summed into a sparse PCE using the standard Smolyak summation (again, refer to the User’s Manual for additional details). As for quadrature_order, the sparse_grid_level specification admits an array input for enabling specification of multiple grid resolutions used by certain advanced solution methodologies.

This keyword can be used when using sparse grid integration to calculate PCE coefficients or when generating samples for sparse grid collocation.

**use_derivatives**

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- use_derivatives

Use derivative data to construct surrogate models

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** use function values only
**Description**

The `use_derivatives` flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, its use with Surfpack Gaussian process is not recommended.

**standardized_space**

- **Keywords** Area
- **method**
- **bayes_calibration**
- **standardized_space**

Perform the MCMC process in a standardized probability space.

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

This option transforms the inference process (the MCMC sampling and any emulator model management) into a standardized probability space.

The variable transformations performed are as described in `askey`.

**Default Behavior**

The default for the Gaussian process and no emulator options is to perform the MCMC process in the original probability space (no transformation). Polynomial chaos and stochastic collocation emulators, on the other hand, are always formed in standardized probability space, such that the MCMC process is also performed in this standardized space.

**Expected Output**

The user will see the truth model evaluations performed in the original space, whereas any diagnostics relating to the MCMC samples (e.g., QUESO data in the `outputData` directory) will report points and response data (response gradients and Hessians, if present, will differ but response values will not) that correspond to the transformed space.

**Usage Tips**

Selecting `standardized_space` generally has the effect of scaling the random variables to be of equal magnitude, which can improve the efficiency of the MCMC process.

**Examples**

```
method, bayes_calibration queso
  samples = 2000 seed = 348
dram
  standardized_space
```
likelihood_scale

- Keywords Area
- method
- bayes_calibration
- likelihood_scale

Scale the log-likelihood function

**Specification**

Alias: none

- **Argument(s):** REAL
- **Default:** none

**Description**

The `likelihood_scale` is applied to the weighted sum-squared error term of the log-likelihood function. The log-likelihood is \(-0.5 \times \frac{\text{weighted sum-squared errors}}{\text{likelihood scale}}\). Thus, if the sum-squared errors is on the order of \(1E+12\), you will want to make the likelihood scale on the order of \(1E+12\) or \(1E+11\). Similarly, if the weighted sum-squared errors is very small, the likelihood scale should be very small. **Note that applying a likelihood scale changes the formulation of the calibration problem**; we only recommend using it for poorly conditioned problems where the MCMC is not working without applying scaling.

calibrate_sigma

- Keywords Area
- method
- bayes_calibration
- calibrate_sigma

Calibrate the experimental error term(s) in the likelihood function

**Specification**

Alias: none

- **Argument(s):** none
- **Default:** The sigma terms are not calibrated

**Description**

When enabled, the observational error (sigma) terms will be calibrated in addition to the model parameters.
6.2. METHOD

samples

- Keywords Area
- method
- bayes_calibration
- samples

Number of samples for sampling-based methods

Specification

Alias: none

Argument(s): INTEGER
Default: method-dependent

Description

The `samples` keyword is used to define the number of samples (i.e., randomly chosen sets of variable values) at which to execute a model.

Default Behavior
By default, Dakota will use the minimum number of samples required by the chosen method.

Usage Tips
To obtain linear sensitivities or to construct a linear response surface, at least dim+1 samples should be used, where "dim" is the number of variables. For sensitivities to quadratic terms or quadratic response surfaces, at least (dim+1)(dim+2)/2 samples are needed. For uncertainty quantification, we recommend at least 10\*dim samples. For variance-based decomp, we recommend hundreds to thousands of samples. Note that for variance-based decomp, the number of simulations performed will be N\*(dim+2).

Examples

```
method
  sampling
    sample_type lhs
    samples = 20
```

seed

- Keywords Area
- method
- bayes_calibration
- seed

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER
Default: system-generated (non-repeatable)
Description
The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior
If not specified, the seed is randomly generated.

Expected Output
If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips
If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```dakota
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

**model_pointer**

- Keywords Area
- method
- bayes_calibration
- model_pointer

Identifier for model block to be used by a method

Topics
This keyword is related to the topics:

- block_pointer

Specification

Alias: none
Argument(s): STRING
Default: method use of last model parsed (or use of default model if none parsed)

Description
The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior
If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.
6.2. METHOD

Usage Tips
When doing advanced analyses that involve using multiple methods and multiple models, defining a model-pointer for each method is imperative. See block_pointer for details about pointers.

Examples

environment

### Description

The Distributed Design and Analysis of Computer Experiments (DDACE) library provides the following DACE techniques:

1. grid sampling (*grid*)
2. pure random sampling (*random*)
3. orthogonal array sampling (*oas*)
4. latin hypercube sampling (*lhs*)
5. orthogonal array latin hypercube sampling (*oa_lhs*)
6. Box-Behnken (*box_behnken*)
7. central composite design (*central_composite*)

These methods all generate point sets that may be used to drive a set of computer experiments. Note that all of the DACE methods generated randomized designs, except for Box-Behnken and Central composite which are classical designs. That is, the grid sampling will generate a randomized grid, not what one typically thinks of as a grid of uniformly spaced points over a rectangular grid. Similar, the orthogonal array is a randomized version of an orthogonal array: it does not generate discrete, fixed levels.

In addition to the selection of the method, there are keywords that affect the method outputs:

Grid Sampling

Specification
Alias: none
Argument(s): none

Description
The grid option in DACE will produce a randomized grid of points. If you are interested in a regular grid of points, use the multidimensional parameter study (under Parameter Studies) instead. Grid Sampling

random
- Keywords Area
- method
- dace
- random
Uses purely random Monte Carlo sampling to sample variables
6.2. METHOD

Specification

Alias: none

Description

The random keyword invokes Monte Carlo sampling as the means of drawing samples of uncertain variables according to their probability distributions.

Default Behavior

Monte Carlo sampling is not used by default. To change this behavior, the random keyword must be specified in conjuction with the sample_type keyword.

Usage Tips

Monte Carlo sampling is more computationally expensive than Latin Hypercube Sampling as it requires a larger number of samples to accurately estimate statistics.

Examples

```
method sampling
    sample_type random
    samples = 200
```

oas

- Keywords Area
- method
- dace
- oas

Orthogonal Array Sampling

Specification

Alias: none

Description

Orthogonal array sampling (OAS) is a widely used technique for running experiments and systematically testing factor effects. An orthogonal array sample can be described as a 4-tuple \((m; n; s; r)\), where \(m\) is the number of sample points, \(n\) is the number of input variables, \(s\) is the number of symbols, and \(r\) is the strength of the orthogonal array. The number of sample points, \(m\), must be a multiple of the number of symbols, \(s\). The number of symbols refers to the number of levels per input variable. The strength refers to the number of columns where we are guaranteed to see all the possibilities an equal number of times. Note that the DACE OAS capability produces a randomized orthogonal array: the samples for a particular level are randomized within that level.

If one examines the sample sets in an orthogonal array by looking at the rows as individual samples and columns as the variables sampled, one sees that the columns are orthogonal to each other in an orthogonal array. This feature is important in main effects analysis, which is a sensitivity analysis technique that identifies which variables have the most influence on the output.
**lhs**
- **Keywords Area**
- **method**
- **dace**
- **lhs**

Uses Latin Hypercube Sampling (LHS) to sample variables

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The `lhs` keyword invokes Latin Hypercube Sampling as the means of drawing samples of uncertain variables according to their probability distributions. This is a stratified, space-filling approach that selects variable values from a set of equi-probable bins.

**Default Behavior**

By default, Latin Hypercube Sampling is used. To explicitly specify this in the Dakota input file, however, the `lhs` keyword must appear in conjunction with the `sample_type` keyword.

**Usage Tips**

Latin Hypercube Sampling is very robust and can be applied to any problem. It is fairly effective at estimating the mean of model responses and linear correlations with a reasonably small number of samples relative to the number of variables.

**Examples**

```
method
  sampling
    sample_type lhs
    samples = 20
```

**oa_lhs**

- **Keywords Area**
- **method**
- **dace**
- **oa_lhs**

Orthogonal Array Latin Hypercube Sampling

**Specification**

**Alias:** none

**Argument(s):** none
6.2. METHOD

Description
The Orthogonal Array Latin Hypercube Sampling option in DACE produces a “latinized” version of an orthogonal array. That is, after the orthogonal array is generated, the samples go through a stratification process to produce samples that have been both orthogonalized and stratified.

See Also
These keywords may also be of interest:

- oas

box_behnken

- Keywords Area
- method
- dace
- box_behnken

Box-Behnken Design

Specification
Alias: none
Argument(s): none

Description
The Box-Behnken design is similar to a Central Composite design, with some differences. The Box-Behnken design is a quadratic design in that it does not contain an embedded factorial or fractional factorial design. In this design the treatment combinations are at the midpoints of edges of the process space and at the center, as compared with CCD designs where the extra points are placed at star points on a circle outside of the process space. Box-Behnken designs are rotatable (or near rotatable) and require 3 levels of each factor.

centralComposite

- Keywords Area
- method
- dace
- centralComposite

Central Composite Design

Specification
Alias: none
Argument(s): none
Description

A central composite design (CCD), contains an embedded factorial or fractional factorial design with a center points that is augmented with a group of “star points” that allow estimation of curvature.

Examples

See the User’s Manual for an example.

main_effects

- Keywords Area
- method
- dace
- main_effects

ANOVA

Specification

Alias: none
Argument(s): none
Default: No main_effects

Description

The main_effects control prints Analysis-of-Variance main effects results (e.g. ANOVA tables with p-values per variable). The main_effects control is only operational with the orthogonal arrays or Latin Hypercube designs, not for Box Behnken or Central Composite designs.

Main effects is a sensitivity analysis method which identifies the input variables that have the most influence on the output. In main effects, the idea is to look at the mean of the response function when variable A (for example) is at level 1 vs. when variable A is at level 2 or level 3. If these mean responses of the output are statistically significantly different at different levels of variable A, this is an indication that variable A has a significant effect on the response. The orthogonality of the columns is critical in performing main effects analysis, since the column orthogonality means that the effects of the other variables “cancel out” when looking at the overall effect from one variable at its different levels.

quality_metrics

- Keywords Area
- method
- dace
- quality_metrics

Calculate metrics to assess the quality of quasi-Monte Carlo samples
6.2. METHOD

Topics
This keyword is related to the topics:

- package_fsudace

Specification
Alias: none
Argument(s): none
Default: No quality_metrics

Description
quality_metrics calculates four quality metrics relating to the volumetric spacing of the samples. The four quality metrics measure different aspects relating to the uniformity of point samples in hypercubes. Desirable properties of such point samples are:

- are the points equally spaced
- do the points cover the region
- and are they isotropically distributed
- with no directional bias in the spacing

The four quality metrics we report are:

- h: the point distribution norm, which is a measure of uniformity of the point distribution
- chi: a regularity measure, and provides a measure of local uniformity of a set of points
- tau: the second moment trace measure
- d: the second moment determinant measure

All of these values are scaled so that smaller is better (the smaller the metric, the better the uniformity of the point distribution).

Examples
Complete explanation of these measures can be found in [38].

variance_based_decomp

- Keywords Area
- method
- dace
- variance_based_decomp

Activates global sensitivity analysis based on decomposition of response variance into contributions from variables
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none
Argument(s): none
Default: no variance-based decomposition

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>drop_tolerance</td>
<td>Suppresses output of sensitivity indices with values lower than this tolerance</td>
</tr>
</tbody>
</table>

Description

Dakota can calculate sensitivity indices through variance based decomposition using the keyword variance-based_decomp. These indicate how important the uncertainty in each input variable is in contributing to the output variance.

Default Behavior

Because of the computational cost, variance_based_decomp is turned off as a default.

If the user specified a number of samples, N, and a number of nondeterministic variables, M, variance-based decomposition requires the evaluation of N*(M+2) samples. Note that specifying this keyword will increase the number of function evaluations above the number requested with the samples keyword since replicated sets of sample values are evaluated.

Expected Outputs

When variance_based_decomp is specified, sensitivity indices for main effects and total effects will be reported. Main effects (roughly) represent the percent contribution of each individual variable to the variance in the model response. Total effects represent the percent contribution of each individual variable in combination with all other variables to the variance in the model response.

Usage Tips

To obtain sensitivity indices that are reasonably accurate, we recommend that N, the number of samples, be at least one hundred and preferably several hundred or thousands.

Examples

```plaintext
method,
sampling
  sample_type lhs
  samples = 100
  variance_based_decomp
```

Theory

In this context, we take sensitivity analysis to be global, not local as when calculating derivatives of output variables with respect to input variables. Our definition is similar to that of[73]: “The study of how uncertainty in the output of a model can be apportioned to different sources of uncertainty in the model input.”

Variance based decomposition is a way of using sets of samples to understand how the variance of the output behaves, with respect to each input variable. A larger value of the sensitivity index, $S_i$, means that the uncertainty in the input variable $i$ has a larger effect on the variance of the output. More details on the calculations and interpretation of the sensitivity indices can be found in[73] and[87].
6.2. METHOD

drop_tolerance

- **Keywords Area**
- **method**
- **dace**
- **variance_based_decomp**
- **drop_tolerance**

Suppresses output of sensitivity indices with values lower than this tolerance

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** All VBD indices displayed

**Description**

The drop_tolerance keyword allows the user to specify a value below which sensitivity indices generated by variance_based_decomp are not displayed.

**Default Behavior**

By default, all sensitivity indices generated by variance_based_decomp are displayed.

**Usage Tips**

For polynomial_chaos, which outputs main, interaction, and total effects by default, the univariate_effects may be a more appropriate option. It allows suppression of the interaction effects since the output volume of these results can be prohibitive for high dimensional problems. Similar to suppression of these interactions is the covariance control, which can be selected to be diagonal_covariance or full_covariance, with the former supporting suppression of the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

**Examples**

```plaintext
method,
sampling
    sample_type lhs
    samples = 100
    variance_based_decomp
drop_tolerance = 0.001
```

**fixed_seed**

- **Keywords Area**
- **method**
- **dace**
- **fixed_seed**

Reuses the same seed value for multiple random sampling sets
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none
  Argument(s): none
  Default: not fixed; pattern varies run-to-run

Description

The fixed_seed flag is relevant if multiple sampling sets will be generated over the course of a Dakota analysis. This occurs when using advance methods (e.g., surrogate-based optimization, optimization under uncertainty). The same seed value is reused for each of these multiple sampling sets, which can be important for reducing variability in the sampling results.

Default Behavior

The default behavior is to not use a fixed seed, as the repetition of the same sampling pattern can result in a modeling weakness that an optimizer could potentially exploit (resulting in actual reliabilities that are lower than the estimated reliabilities). For repeatable studies, the seed must also be specified.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    fixed_seed
```

symbols

- Keywords Area
- method
- dace
- symbols

Number of replications in the sample set

Specification

Alias: none
  Argument(s): INTEGER
  Default: default for sampling algorithm

Description

symbols is related to the number of levels per variable in the sample set (a larger number of symbols equates to more stratification and fewer replications). For example, if symbols = 7, each variable would be divided into seven levels.
6.2. METHOD

samples

- Keywords Area
- method
- dace
- samples

Number of samples for sampling-based methods

Specification

Alias: none
- Argument(s): INTEGER
- Default: method-dependent

Description

The `samples` keyword is used to define the number of samples (i.e., randomly chosen sets of variable values) at which to execute a model.

Default Behavior
- By default, Dakota will use the minimum number of samples required by the chosen method.

Usage Tips
- To obtain linear sensitivities or to construct a linear response surface, at least dim+1 samples should be used, where "dim" is the number of variables. For sensitivities to quadratic terms or quadratic response surfaces, at least (dim+1)(dim+2)/2 samples are needed. For uncertainty quantification, we recommend at least 10*dim samples. For variance-based_decomp, we recommend hundreds to thousands of samples. Note that for variance-based_decomp, the number of simulations performed will be N*(dim+2).

Examples

```
method sampling
  sample_type lhs
  samples = 20
```

seed

- Keywords Area
- method
- dace
- seed

Seed of the random number generator

Specification

Alias: none
- Argument(s): INTEGER
- Default: system-generated (non-repeatable)
**Description**

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

**Default Behavior**
If not specified, the seed is randomly generated.

**Expected Output**
If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

**Usage Tips**
If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

**Examples**

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

**model_pointer**

- Keywords Area
- method
- dace
- model_pointer

Identifier for model block to be used by a method

**Topics**

This keyword is related to the topics:

- block_pointer

**Specification**

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

**Description**

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.
Usage Tips
When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.
See `block_pointer` for details about pointers.

### Description

The FSU Centroidal Voronoi Tessellation method (fsu_cvt) produces a set of sample points that are (approximately) a Centroidal Voronoi Tessellation. The primary feature of such a set of points is that they have good volumetric spacing; the points tend to arrange themselves in a pattern of cells that are roughly the same shape.

To produce this set of points, an almost arbitrary set of initial points is chosen, and then an internal set of iterations is carried out. These iterations repeatedly replace the current set of sample points by an estimate of the centroids of the corresponding Voronoi subregions. [18].

The user may generally ignore the details of this internal iteration. If control is desired, however, there are a few variables with which the user can influence the iteration. The user may specify:

- **max_iterations**, the number of iterations carried out (this is a method independent control, see max_iterations)
- **num_trials**, the number of secondary sample points generated to adjust the location of the primary sample points
- **trial_type**, which controls how these secondary sample points are generated

This method generates sets of uniform random variables on the interval [0,1]. If the user specifies lower and upper bounds for a variable, the [0,1] samples are mapped to the [lower, upper] interval.
Theory

This method is designed to generate samples with the goal of low discrepancy. Discrepancy refers to the nonuniformity of the sample points within the hypercube.

Discrepancy is defined as the difference between the actual number and the expected number of points one would expect in a particular set B (such as a hyper-rectangle within the unit hypercube), maximized over all such sets. Low discrepancy sequences tend to cover the unit hypercube reasonably uniformly.

Centroidal Voronoi Tessellation does very well volumetrically: it spaces the points fairly equally throughout the space, so that the points cover the region and are isotropically distributed with no directional bias in the point placement. There are various measures of volumetric uniformity which take into account the distances between pairs of points, regularity measures, etc. Note that Centroidal Voronoi Tessellation does not produce low-discrepancy sequences in lower dimensions. The lower-dimension (such as 1-D) projections of Centroidal Voronoi Tessellation can have high discrepancy.

latinize

- Keywords Area
- method
- fsu_cvt
- latinize

Adjust samples to improve the discrepancy of the marginal distributions

Specification

Alias: none

Argument(s): none

Default: No latinization

Description

The *latinize* control takes the samples and "latinizes" them, meaning that each original sample is moved so that it falls into one strata or bin in each dimension as in Latin Hypercube sampling. The default setting is NOT to latinize. However, one may be interested in doing this in situations where one wants better discrepancy of the 1-dimensional projections (the marginal distributions).
quality_metrics

- Keywords Area
- method
- fsu_cvt
- quality_metrics

Calculate metrics to assess the quality of quasi-Monte Carlo samples

Topics

This keyword is related to the topics:

- package_fsudace

Specification

Alias: none

Argument(s): none

Default: No quality_metrics

Description

quality_metrics calculates four quality metrics relating to the volumetric spacing of the samples. The four quality metrics measure different aspects relating to the uniformity of point samples in hypercubes. Desirable properties of such point samples are:

- are the points equally spaced
- do the points cover the region
- and are they isotropically distributed
- with no directional bias in the spacing

The four quality metrics we report are:

- h: the point distribution norm, which is a measure of uniformity of the point distribution
- chi: a regularity measure, and provides a measure of local uniformity of a set of points
- tau: the second moment trace measure
- d: the second moment determinant measure

All of these values are scaled so that smaller is better (the smaller the metric, the better the uniformity of the point distribution).

Examples

Complete explanation of these measures can be found in [38].
variance_based_decomp

- Keywords Area
- method
- fsu_cvt
- variance_based_decomp

Activates global sensitivity analysis based on decomposition of response variance into contributions from variables

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** no variance-based decomposition

<table>
<thead>
<tr>
<th>Required/-</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>drop_tolerance</td>
<td></td>
<td>Suppresses output of sensitivity indices with values lower than this tolerance</td>
</tr>
</tbody>
</table>

**Description**

Dakota can calculate sensitivity indices through variance based decomposition using the keyword `variance_based_decomp`. These indicate how important the uncertainty in each input variable is in contributing to the output variance.

**Default Behavior**

Because of the computational cost, `variance_based_decomp` is turned off as a default.

If the user specified a number of samples, N, and a number of nondeterministic variables, M, variance-based decomposition requires the evaluation of N*(M+2) samples. **Note that specifying this keyword will increase the number of function evaluations above the number requested with the `samples` keyword since replicated sets of sample values are evaluated.**

**Expected Outputs**

When `variance_based_decomp` is specified, sensitivity indices for main effects and total effects will be reported. Main effects (roughly) represent the percent contribution of each individual variable to the variance in the model response. Total effects represent the percent contribution of each individual variable in combination with all other variables to the variance in the model response.

**Usage Tips**

To obtain sensitivity indices that are reasonably accurate, we recommend that N, the number of samples, be at least one hundred and preferably several hundred or thousands.

**Examples**

```
method,
sampling
  sample_type lhs
```
6.2. METHOD

samples = 100
calculate invariance

Theory

In this context, we take sensitivity analysis to be global, not local as when calculating derivatives of output variables with respect to input variables. Our definition is similar to that of [73]: "The study of how uncertainty in the output of a model can be apportioned to different sources of uncertainty in the model input."

Variance based decomposition is a way of using sets of samples to understand how the variance of the output behaves, with respect to each input variable. A larger value of the sensitivity index, $S_i$, means that the uncertainty in the input variable $i$ has a larger effect on the variance of the output. More details on the calculations and interpretation of the sensitivity indices can be found in [73] and [87].

drop_tolerance

- **Keywords** Area
- method
- fsu_cvt
- variance_based_decomp
- drop_tolerance

Suppresses output of sensitivity indices with values lower than this tolerance

Specification

**Alias:** none

**Argument(s):** REAL

**Default:** All VBD indices displayed

Description

The `drop_tolerance` keyword allows the user to specify a value below which sensitivity indices generated by `variance_based_decomp` are not displayed.

**Default Behavior**

By default, all sensitivity indices generated by `variance_based_decomp` are displayed.

**Usage Tips**

For `polynomial_chaos`, which outputs main, interaction, and total effects by default, the `univariate_effects` may be a more appropriate option. It allows suppression of the interaction effects since the output volume of these results can be prohibitive for high dimensional problems. Similar to suppression of these interactions is the covariance control, which can be selected to be diagonal_covariance or full_covariance, with the former supporting suppression of the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).
Examples
method,
  sampling
    sample_type lhs
    samples = 100
    variance_based_decomp
    drop_tolerance = 0.001

fixed_seed
  - Keywords Area
  - method
  - fsu_cvt
  - fixed_seed

Reuses the same seed value for multiple random sampling sets

Specification
Alias: none
  Argument(s): none
  Default: not fixed; pattern varies run-to-run

Description
The fixed_seed flag is relevant if multiple sampling sets will be generated over the coarse of a Dakota analysis. This occurs when using advance methods (e.g., surrogate-based optimization, optimization under uncertainty). The same seed value is reused for each of these multiple sampling sets, which can be important for reducing variability in the sampling results.

Default Behavior
The default behavior is to not use a fixed seed, as the repetition of the same sampling pattern can result in a modeling weakness that an optimizer could potentially exploit (resulting in actual reliabilities that are lower than the estimated reliabilities). For repeatable studies, the seed must also be specified.

Examples
method
  sampling
    sample_type lhs
    samples = 10
    fixed_seed

trial_type
  - Keywords Area
  - method
  - fsu_cvt
  - trial_type

Specify how the trial samples are generated
6.2. METHOD

halton

- Keywords Area
- method
- fsu_cvt
- trial_type
- halton

Generate samples from a Halton sequence

Topics
This keyword is related to the topics:

- package_fsudace

Specification
Alias: none
Argument(s): none

Description
The quasi-Monte Carlo sequences of Halton are deterministic sequences determined by a set of prime bases. These sequences generate random numbers with the goal of filling a unit hypercube uniformly.

Generally, we recommend that the user leave the default setting for the bases, which are the lowest primes. Thus, if one wants to generate a sample set for 3 random variables, the default bases used are 2, 3, and 5 in the Halton sequence. To give an example of how these sequences look, the Halton sequence in base 2 starts with points 0.5, 0.25, 0.75, 0.125, 0.625, etc. The first few points in a Halton base 3 sequence are 0.33333, 0.66667, 0.11111, 0.44444, 0.77777, etc. Notice that the Halton sequence tends to alternate back and forth, generating a point closer to zero then a point closer to one. An individual sequence is based on a radix inverse function defined on a prime base. The prime base determines how quickly the [0,1] interval is filled in.

Theory
For more information about these sequences, see[43], [44], and [1].
random

- Keywords Area
- method
- fsu_cvt
- trial_type
- random

Uses purely random Monte Carlo sampling to sample variables

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

The `random` keyword invokes Monte Carlo sampling as the means of drawing samples of uncertain variables according to their probability distributions.

**Default Behavior**

Monte Carlo sampling is not used by default. To change this behavior, the `random` keyword must be specified in conjunction with the `sample_type` keyword.

**Usage Tips**

Monte Carlo sampling is more computationally expensive than Latin Hypercube Sampling as it requires a larger number of samples to accurately estimate statistics.

**Examples**

```
method
  sampling
    sample_type random
    samples = 200
```

**num_trials**

- Keywords Area
- method
- fsu_cvt
- num_trials

The number of secondary sample points generated to adjust the location of the primary sample points

**Specification**

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** 10000
CHAPTER 6. KEYWORDS AREA

Description

In general, the variable with the most influence on the quality of the final sample set is `num_trials`, which determines how well the Voronoi subregions are sampled.

Generally, `num_trials` should be "large", certainly much bigger than the number of sample points being requested; a reasonable value might be 10,000, but values of 100,000 or 1 million are not unusual.

**samples**

- Keywords Area
- method
- fsu_cvt
- samples

  Number of samples for sampling-based methods

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** method-dependent

**Description**

The `samples` keyword is used to define the number of samples (i.e., randomly chosen sets of variable values) at which to execute a model.

**Default Behavior**

By default, Dakota will use the minimum number of samples required by the chosen method.

**Usage Tips**

To obtain linear sensitivities or to construct a linear response surface, at least \(dim+1\) samples should be used, where "dim" is the number of variables. For sensitivities to quadratic terms or quadratic response surfaces, at least \((dim+1)(dim+2)/2\) samples are needed. For uncertainty quantification, we recommend at least 10*dim samples. For variance_based_decomp, we recommend hundreds to thousands of samples. Note that for variance_based_decomp, the number of simulations performed will be \(N*(dim+2)\).

**Examples**

```
method
sampling
  sample_type lhs
  samples = 20
```

**seed**

- Keywords Area
- method
- fsu_cvt
- seed

  Seed of the random number generator
6.2. METHOD

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)

Description

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior
If not specified, the seed is randomly generated.

Expected Output
If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips
If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347

model_pointer

Description

The Morris One-At-A-Time (MOAT) method, originally proposed by Morris [62], is a screening method, designed to explore a computational model to distinguish between input variables that have negligible, linear and additive, or nonlinear or interaction effects on the output. The computer experiments performed consist of individually randomized designs which vary one input factor at a time to create a sample of its elementary effects.
The number of samples (samples) must be a positive integer multiple of (number of continuous design variable + 1) and will be automatically adjusted if misspecified.

The number of partitions (partitions) applies to each variable being studied and must be odd (the number of MOAT levels per variable is partitions + 1). This will also be adjusted at runtime as necessary.

For information on practical use of this method, see [73].

Theory

With MOAT, each dimension of a $k$-dimensional input space is uniformly partitioned into $p$ levels, creating a grid of $p^k$ points $x \in \mathbb{R}^k$ at which evaluations of the model $y(x)$ might take place. An elementary effect corresponding to input $i$ is computed by a forward difference

$$d_i(x) = \frac{y(x + \Delta e_i) - y(x)}{\Delta},$$

where $e_i$ is the $i$th coordinate vector, and the step $\Delta$ is typically taken to be large (this is not intended to be a local derivative approximation). In the present implementation of MOAT, for an input variable scaled to $[0, 1]$, $\Delta = \frac{p}{2(p-1)}$, so the step used to find elementary effects is slightly larger than half the input range.

The distribution of elementary effects $d_i$ over the input space characterizes the effect of input $i$ on the output of interest. After generating $r$ samples from this distribution, their mean,

$$\mu_i = \frac{1}{r} \sum_{j=1}^{r} d^{(j)}_i$$

modified mean

$$\mu^*_i = \frac{1}{r} \sum_{j=1}^{r} |d^{(j)}_i|,$$

(using absolute value) and standard deviation

$$\sigma_i = \sqrt{\frac{1}{r} \sum_{j=1}^{r} \left( d^{(j)}_i - \mu_i \right)^2}$$

are computed for each input $i$. The mean and modified mean give an indication of the overall effect of an input on the output. Standard deviation indicates nonlinear effects or interactions, since it is an indicator of elementary effects varying throughout the input space.

Uses a sequential quadratic programming method for underlying optimization
CHAPTER 6. KEYWORDS AREA

Specification
Alias: none
  Argument(s): none

Description
Many uncertainty quantification methods solve a constrained optimization problem under the hood. The sqp keyword directs Dakota to use a sequential quadratic programming method to solve that problem. A sequential quadratic programming solves a sequence of linearly constrained quadratic optimization problems to arrive at the solution to the optimization problem.

nip
  • Keywords Area
  • method
  • local_evidence
  • nip

Uses a nonlinear interior point method for underlying optimization

Specification
Alias: none
  Argument(s): none

Description
Many uncertainty quantification methods solve a constrained optimization problem under the hood. The nip keyword directs Dakota to use a nonlinear interior point to solve that problem. A nonlinear interior point method traverses the interior of the feasible region to arrive at the solution to the optimization problem.

response_levels
  • Keywords Area
  • method
  • local_evidence
  • response_levels

Values at which to estimate desired statistics for each response

Specification
Alias: none
  Argument(s): REALLIST
  Default: No CDF/CCDF probabilities/reliabilities to compute
### Description

The `response_levels` specification provides the target response values for which to compute probabilities, reliabilities, or generalized reliabilities (forward mapping).

**Default Behavior**

If `response_levels` are not specified, no statistics will be computed. If they are, probabilities will be computed by default.

**Expected Outputs**

The particular statistics reported for each response level depend on the method, and they include:

1. Reliabilities
2. CDF probabilities
3. CCDF probabilities

**Usage Tips**

The `num_response_levels` is used to specify which arguments of the `response_level` correspond to which response.

**Examples**

For example, specifying a `response_level` of 52.3 followed with `compute probabilities` will result in the calculation of the probability that the response value is less than or equal to 52.3, given the uncertain distributions on the inputs.

For an example with multiple responses, the following specification

```plaintext
response_levels = 1. 2. .1 .2 .3 .4 10. 20. 30.
num_response_levels = 2 4 3
```

would assign the first two response levels (1., 2.) to response function 1, the next four response levels (.1, .2, .3, .4) to response function 2, and the final three response levels (10., 20., 30.) to response function 3. If the `num_response_levels` key were omitted from this example, then the response levels would be evenly distributed among the response functions (three levels each in this case).
Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

A forward mapping involves computing the belief and plausibility probability level for a specified response level.

**num_response_levels**

- Keywords Area
- method
- local_evidence
- response_levels
- num_response_levels

Number of values at which to estimate desired statistics for each response

Specification

Alias: none

Argument(s): INTEGERLIST

Default: response_levels evenly distributed among response functions

Description

The num_response_levels keyword allows the user to specify the number of response values, for each response, at which estimated statistics are of interest. Statistics that can be computed are probabilities and reliabilities, both according to either a cumulative distribution function or a complementary cumulative distribution function.

**Default Behavior**

If num_response_levels is not specified, the response_levels will be evenly distributed among the responses.

**Expected Outputs**

The specific output will be determined by the type of statistics that are specified. In a general sense, the output will be a list of response level-statistic pairs that show the estimated value of the desired statistic for each response level specified.

Examples

```plaintext
method
  sampling
    samples = 100
    seed = 34785
    num_response_levels = 1 1 1
    response_levels = 0.5 0.5 0.5
```
compute

- Keywords Area
- method
- local_evidence
- response_levels
- compute

Selection of statistics to compute at each response level

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** probabilities

<table>
<thead>
<tr>

<td>gen_reliabilities</td>
<td>Computes generalized reliabilities associated with response levels</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>system</td>
<td>Compute system reliability (series or parallel)</td>
</tr>
</tbody>
</table>

**Description**

The `compute` keyword is used to select which forward statistical mapping is calculated at each response level.

**Default Behavior**

If `response_levels` is not specified, no statistics are computed. If `response_levels` is specified but `compute` is not, probabilities will be computed by default. If both `response_levels` and `compute` are specified, then one of the following must be specified: `probabilities`, `reliabilities`, or `gen_reliabilities`.

**Expected Output**

The type of statistics specified by `compute` will be reported for each response level.

**Usage Tips**

CDF/CCDF probabilities are calculated for specified response levels using a simple binning approach. CDF/CCDF reliabilities are calculated for specified response levels by computing the number of sample standard deviations separating the sample mean from the response level.
Examples

method
sampling
   sample_type random
   samples = 100 seed = 1
complementary distribution
   response_levels = 3.6e+11 4.0e+11 4.4e+11

   3.5e+05 4.0e+05 4.5e+05
compute reliabilities

probabilities
   - Keywords Area
   - method
   - local Evidence
   - response Levels
   - compute
   - probabilities
Computes probabilities associated with response levels

Specification

Alias: none
   Argument(s): none

Description

The probabilities keyword directs Dakota to compute the probability that the model response will be below (cumulative) or above (complementary cumulative) a specified response value. This is done for every response level designated for each response.

Default Behavior
   If response_levels is specified, the probabilities are computed by default. To explicitly specify it in the Dakota input file, though, the probabilities keyword should be specified in conjunction with the compute keyword.

Expected Outputs
   The Dakota output is a set of response level-probability pairs that give the probability that the model response will be below or above the corresponding response level, depending on the distribution defined.

Examples

method
sampling
   sample_type random
   samples = 100 seed = 1
complementary distribution
   response_levels = 3.6e+11 4.0e+11 4.4e+11
   6.0e+04 6.5e+04 7.0e+04
   3.5e+05 4.0e+05 4.5e+05
compute probabilities
6.2. METHOD

\textbf{gen\_reliabilities}
- Keywords Area

- local\_evidence
- response\_levels
- compute
- gen\_reliabilities

Computes generalized reliabilities associated with response levels

\textbf{Specification}

\textbf{Alias:} none
\textbf{Argument(s):} none

\textbf{Description}

The \texttt{gen\_reliabilities} keyword directs Dakota to compute generalized reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

\textbf{Default Behavior}

If \texttt{response\_levels} is specified, the generalized reliabilities are not computed by default. To change this behavior, the \texttt{gen\_reliabilities} keyword should be specified in conjunction with the \texttt{compute} keyword.

\textbf{Expected Outputs}

The Dakota output is a set of response level-generalized reliability pairs according to the distribution defined.

\textbf{Examples}

\texttt{method}
\texttt{  sampling}
\texttt{    sample\_type random}
\texttt{    samples = 100 seed = 1}
\texttt{    complementary distribution}
\texttt{    response\_levels = 3.6e+11 4.0e+11 4.4e+11 6.0e+04 6.5e+04 7.0e+04 3.5e+05 4.0e+05 4.5e+05}
\texttt{    compute gen\_reliabilities}

\texttt{system}

<td></td>
<td><strong>series</strong></td>
<td>Aggregate response statistics assuming a series system</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>parallel</strong></td>
<td>Aggregate response statistics assuming a parallel system</td>
</tr>
</tbody>
</table>

Description

With the system probability/reliability option, statistics for specified response levels are calculated and reported assuming the response functions combine either in series or parallel to produce a total system response.

For a series system, the system fails when any one component (response) fails. The probability of failure is the complement of the product of the individual response success probabilities.

For a parallel system, the system fails only when all components (responses) fail. The probability of failure is the product of the individual response failure probabilities.

<td></td>
<td>cumulative</td>
<td>Computes statistics according to cumulative functions</td>
</tr>
<tr>
<td></td>
<td></td>
<td>complementary</td>
<td>Computes statistics according to complementary cumulative functions</td>
</tr>
</tbody>
</table>

Description

The distribution keyword allows the user to select between a cumulative distribution/belief/plausibility function and a complementary cumulative distribution/belief/plausibility function. This choice affects how probabilities and reliability indices are reported.

Default Behavior

If the distribution keyword is present, it must be accompanied by either cumulative or complementary. Otherwise, a cumulative distribution will be used by default.

Expected Outputs

Output will be a set of model response-probability pairs determined according to the choice of distribution. The choice of distribution also defines the sign of the reliability or generalized reliability indices.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```
cumulative

- complementary

Computes statistics according to complementary cumulative functions
6.2. METHOD

Specification

Alias: none
  Argument(s): none

Description

Statistics on model responses will be computed according to a complementary cumulative distribution/belief/plausibility function.

  Default Behavior
  
  By default, a complementary cumulative distribution/belief/plausibility function will not be used. To change that behavior, the complementary keyword must appear in conjunction with the distribution keyword.

  Expected Outputs
  
  Output will be a set of model response-probability pairs determined according to a complementary cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls above given response thresholds.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    distribution complementary
```

model_pointer

- Keywords Area
- method
- local_evidence
- model_pointer

  Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none
  Argument(s): none
  Default: method use of last model parsed (or use of default model if none parsed)
CHAPTER 6. KEYWORDS AREA

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

</tr>
</tbody>
</table>
Optional  model_pointer  Identifier for model block to be used by a method

Description
Interval analysis using local methods (local_interval_est). If the problem is amenable to local optimization methods (e.g. can provide derivatives or use finite difference method to calculate derivatives), then one can use one of two local methods to calculate these bounds.

- sqp
- nip

Additional Resources
Refer to variable_support for information on supported variable types.

Theory
In interval analysis, one assumes that nothing is known about an epistemic uncertain variable except that its value lies somewhere within an interval. In this situation, it is NOT assumed that the value has a uniform probability of occurring within the interval. Instead, the interpretation is that any value within the interval is a possible value or a potential realization of that variable. In interval analysis, the uncertainty quantification problem is one of determining the resulting bounds on the output (defining the output interval) given interval bounds on the inputs. Again, any output response that falls within the output interval is a possible output with no frequency information assigned to it.

| Optional | gen_reliability_levels | Specify generalized reliability levels at which to estimate the corresponding response value |
| Optional | model_pointer | Identifier for model block to be used by a method |

**Description**

Local reliability methods compute approximate response function distribution statistics based on specified uncertain variable probability distributions. Each of the local reliability methods can compute forward and inverse mappings involving response, probability, reliability, and generalized reliability levels.

The forward reliability analysis algorithm of computing reliabilities/probabilities for specified response levels is called the Reliability Index Approach (RIA), and the inverse reliability analysis algorithm of computing response levels for specified probability levels is called the Performance Measure Approach (PMA).

The different RIA/PMA algorithm options are specified using the `mpp_search` specification which selects among different limit state approximations that can be used to reduce computational expense during the MPP searches.

**Theory**

The Mean Value method (MV, also known as MVFOSM in [42]) is the simplest, least-expensive method in that it estimates the response means, response standard deviations, and all CDF/CCDF forward/inverse mappings from a single evaluation of response functions and gradients at the uncertain variable means. This approximation can have acceptable accuracy when the response functions are nearly linear and their distributions are approximately Gaussian, but can have poor accuracy in other situations.

All other reliability methods perform an internal nonlinear optimization to compute a most probable point (MPP) of failure. A sign convention and the distance of the MPP from the origin in the transformed standard normal space (“u-space”) define the reliability index, as explained in the section on Reliability Methods in the Uncertainty Quantification chapter of the Users Manual [4]. Also refer to `variable_support` for additional information on supported variable types for transformations to standard normal space. The reliability can then be converted to a probability using either first- or second-order integration, may then be refined using importance sampling, and finally may be converted to a generalized reliability index.

**Description**

The `x_taylor_mean` MPP search option performs a single Taylor series approximation in the space of the original uncertain variables ("x-space") centered at the uncertain variable means, searches for the MPP for each response/probability level using this approximation, and performs a validation response evaluation at each predicted MPP. This option is commonly known as the Advanced Mean Value (AMV) method. The `u_taylor_mean` option is identical to the `x_taylor_mean` option, except that the approximation is performed in u-space. The `x_taylor_mpp` approach starts with an x-space Taylor series at the uncertain variable means, but iteratively updates the Taylor series approximation at each MPP prediction until the MPP converges. This option is commonly known as the AMV+ method. The `u_taylor_mpp` option is identical to the `x_taylor_mpp` option, except that all approximations are performed in u-space. The order of the Taylor-series approximation is determined by the corresponding `responses` specification and may be first or second-order. If second-order (methods named
6.2. METHOD

$AMV^2$ and $AMV^2+$ in [22]), the series may employ analytic, finite difference, or quasi Hessians (BFGS or S-R1). The $x_{two\_point}$ MPP search option uses an x-space Taylor series approximation at the uncertain variable means for the initial MPP prediction, then utilizes the Two-point Adaptive Nonlinear Approximation (TANA) outlined in [91] for all subsequent MPP predictions. The $u_{two\_point}$ approach is identical to $x_{two\_point}$, but all the approximations are performed in u-space. The $x_{taylor\_mpp}$ and $u_{taylor\_mpp}$, $x_{two\_point}$ and $u_{two\_point}$ approaches utilize the max_iterations and convergence_tolerance method independent controls to control the convergence of the MPP iterations (the maximum number of MPP iterations per level is limited by max_iterations, and the MPP iterations are considered converged when $\|u^{(k+1)} - u^{(k)}\|_2 < \text{convergence}\_\text{tolerance}$). And, finally, the no_approx option performs the MPP search on the original response functions without the use of any approximations. The optimization algorithm used to perform these MPP searches can be selected to be either sequential quadratic programming (uses the npsol_sqp optimizer) or nonlinear interior point (uses the optpp_q_newton optimizer) algorithms using the sqp or nip keywords.

In addition to the MPP search specifications, one may select among different integration approaches for computing probabilities at the MPP by using the integration keyword followed by either first_order or second_order. Second-order integration employs the formulation of [50] (the approach of [13] and the correction of [51] are also implemented, but are not active). Combining the no_approx option of the MPP search with first- and second-order integrations results in the traditional first- and second-order reliability methods (FORM and SORM). These integration approximations may be subsequently refined using importance sampling. The refinement specification allows the selection of basic importance sampling (import), adaptive importance sampling (adapt_import), or multimodal adaptive importance sampling (mm_adapt_import), along with the specification of number of samples (samples) and random seed (seed). Additional details on these methods are available in [24] and [22] and in the Uncertainty Quantification Capabilities chapter of the Users Manual [4].

x_taylor_mean

- integration
- probability_refinement
Allow refinement of probability and generalized reliability results using importance sampling

**Topics**
This keyword is related to the topics:
- reliability_methods

**Specification**
**Alias:** sample_refinement
**Argument(s):** none
Description

The `probability.refinement` allows refinement of probability and generalized reliability results using importance sampling. If one specifies `probability.refinement`, there are some additional options. One can specify which type of importance sampling to use (import, adapt import, or mm_adapt_import). Additionally, one can specify the number of refinement samples to use with `refinement.samples` and the seed to use with `seed`.

The `probability.refinement` density reweighting accounts originally was developed based on Gaussian distributions. It now accounts for additional non-Gaussian cases.

import

- Keywords Area
- method
- local_reliability
- mpp_search
- integration
- probability.refinement
- import

Sampling option

Specification

Alias: none
Argument(s): none

Description

import centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level).
6.2. METHOD

**adapt_import**
- Keywords Area
- method
- local_reliability
- mpp_search
- integration
- probability_refinement
- adapt_import

Importance sampling option

**Specification**

*Alias:* none

*Argument(s):* none

**Description**

*adapt_import* centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level). This continues iteratively until the failure probability estimate converges.

**mm_adapt_import**
- Keywords Area
- method
- local_reliability
- mpp_search
- integration
- probability_refinement
- mm_adapt_import

Sampling option

**Specification**

*Alias:* none

*Argument(s):* none
Description

_mmadaptimport_ starts with all of the samples located in the failure region to build a multimodal sampling density. First, it uses a small number of samples around each of the initial samples in the failure region. Note that these samples are allocated to the different points based on their relative probabilities of occurrence: more probable points get more samples. This early part of the approach is done to search for “representative” points. Once these are located, the multimodal sampling density is set and then _mmadaptimport_ proceeds similarly to _adaptimport_ (sample until convergence).

**refinement_samples**

- Keywords Area
- method
- local_reliability
- mpp_search
- integration
- probability_refinement
- refinement_samples

Specify the number of samples used to improve a probabilty estimate.

Specification

Alias: none

Argument(s): INTEGER

Description

Specify the number of samples used to improve a probabilty estimate. If using uni-modal sampling all samples are assigned to the sampling center. If using multi-modal sampling the samples are split between multiple samples according to some internally computed weights.

**seed**

- Keywords Area
- method
- local_reliability
- mpp_search
- integration
- probability_refinement
- seed

Seed of the random number generator
6.2. METHOD

Specification

Alias: none

Argument(s): INTEGER
Default: system-generated (non-repeatable)

Description

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior
If not specified, the seed is randomly generated.

Expected Output
If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips
If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method sampling
  sample_type lhs
  samples = 10
  seed = 15347

response_levels
```

Values at which to estimate desired statistics for each response

Specification

Alias: none

Argument(s): REALLIST
Default: No CDF/CCDF probabilities/reliabilities to compute
CHAPTER 6. KEYWORDS AREA

<table>
<thead>
<tr>
<th>Required/-</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>num_response_levels</td>
<td></td>
<td>Number of values at which to estimate desired statistics for each response</td>
</tr>
<tr>
<td>Optional</td>
<td>compute</td>
<td></td>
<td>Selection of statistics to compute at each response level</td>
</tr>
</tbody>
</table>

Description

The `response_levels` specification provides the target response values for which to compute probabilities, reliabilities, or generalized reliabilities (forward mapping).

Default Behavior

If `response_levels` are not specified, no statistics will be computed. If they are, probabilities will be computed by default.

Expected Outputs

The particular statistics reported for each response level depend on the method, and they include:

1. Reliabilities
2. CDF probabilities
3. CCDF probabilities

Usage Tips

The `num_response_levels` is used to specify which arguments of the `response_level` correspond to which response.

Examples

For example, specifying a `response_level` of 52.3 followed with `compute probabilities` will result in the calculation of the probability that the response value is less than or equal to 52.3, given the uncertain distributions on the inputs.

For an example with multiple responses, the following specification

```plaintext
response_levels = 1. 2. .1 .2 .3 .4 10. 20. 30.
num_response_levels = 2 4 3
```

would assign the first two response levels (1., 2.) to response function 1, the next four response levels (.1, .2, .3, .4) to response function 2, and the final three response levels (10., 20., 30.) to response function 3. If the `num_response_levels` key were omitted from this example, then the response levels would be evenly distributed among the response functions (three levels each in this case).
6.2. METHOD

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

A forward mapping involves computing the belief and plausibility probability level for a specified response level.

num_response_levels

- **Keywords Area**
- method
- local_reliability
- response_levels
- num_response_levels

Number of values at which to estimate desired statistics for each response

Specification

**Alias:** none

**Argument(s):** INTEGERLIST

**Default:** response_levels evenly distributed among response functions

Description

The `num_response_levels` keyword allows the user to specify the number of response values, for each response, at which estimated statistics are of interest. Statistics that can be computed are probabilities and reliabilities, both according to either a cumulative distribution function or a complementary cumulative distribution function.

**Default Behavior**

If `num_response_levels` is not specified, the response_levels will be evenly distributed among the responses.

**Expected Outputs**

The specific output will be determined by the type of statistics that are specified. In a general sense, the output will be a list of response level-statistic pairs that show the estimated value of the desired statistic for each response level specified.

Examples

```method
sampling
  samples = 100
  seed = 34785
  num_response_levels = 1 1 1
  response_levels = 0.5 0.5 0.5```
compute

- Keywords Area
- method
- local_reliability
- response_levels
- compute

Selection of statistics to compute at each response level

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** probabilities

<p>| Required/- | Description of | Dakota Keyword Description |</p>

</tr>
<tr>
<td></td>
<td><strong>gen_reliabilities</strong></td>
<td>Computes generalized reliabilities associated with response levels</td>
</tr>
</tbody>
</table>

| Optional | **system** | Compute system reliability (series or parallel) |

**Description**

The `compute` keyword is used to select which forward statistical mapping is calculated at each response level.

**Default Behavior**

If `response_levels` is not specified, no statistics are computed. If `response_levels` is specified but `compute` is not, probabilities will be computed by default. If both `response_levels` and `compute` are specified, then one of the following must be specified: `probabilities`, `reliabilities`, or `gen_reliabilities`.

**Expected Output**

The type of statistics specified by `compute` will be reported for each response level.
6.2. METHOD

Usage Tips
CDF/CCDF probabilities are calculated for specified response levels using a simple binning approach.
CDF/CCDF reliabilities are calculated for specified response levels by computing the number of sample standard deviations separating the sample mean from the response level.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
      6.0e+04 6.5e+04 7.0e+04
      3.5e+05 4.0e+05 4.5e+05
  compute reliabilities

probabilities
```

**Keywords Area**

- method
- local_reliability
- response_levels
- compute
- probabilities

Computes probabilities associated with response levels

Specification

**Alias:** none

**Argument(s):** none

Description

The `probabilities` keyword directs Dakota to compute the probability that the model response will be below (cumulative) or above (complementary cumulative) a specified response value. This is done for every response level designated for each response.

**Default Behavior**

If `response_levels` is specified, the probabilities are computed by default. To explicitly specify it in the Dakota input file, though, the `probabilities` keyword should be specified in conjunction with the `compute` keyword.

**Expected Outputs**

The Dakota output is a set of response level-probability pairs that give the probability that the model response will be below or above the corresponding response level, depending on the distribution defined.
Examples

```plaintext
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                     6.0e+04 6.5e+04 7.0e+04
                     3.5e+05 4.0e+05 4.5e+05
    compute probabilities
```

**reliabilities**

- **local_reliability**
- **response_levels**
- **compute**
- **reliabilities**

Computes reliabilities associated with response levels

**Specification**

*Alias:* none

*Argument(s):* none

**Description**

The `reliabilities` keyword directs Dakota to compute reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

**Default Behavior**

If `response_levels` is specified, the reliabilities are not computed by default. To change this behavior, the `reliabilities` keyword should be specified in conjunction with the `compute` keyword.

**Expected Outputs**

The Dakota output is a set of response level-reliability pairs according to the distribution defined.

**Examples**

```plaintext
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                     6.0e+04 6.5e+04 7.0e+04
                     3.5e+05 4.0e+05 4.5e+05
    compute reliabilities
```

<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>num_reliability_levels</td>
<td>Specify which reliability_levels correspond to which response</td>
</tr>
</tbody>
</table>
Description
Response levels are calculated for specified CDF/CCDF reliabilities by projecting out the prescribed number of sample standard deviations from the sample mean.

Theory
Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).

**num_reliability_levels**

- Keywords Area

<td></td>
<td>cumulative</td>
<td>Computes statistics according to cumulative functions</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>complementary</td>
<td>Computes statistics according to complementary cumulative functions</td>
</tr>
</tbody>
</table>

### Description

The `distribution` keyword allows the user to select between a cumulative distribution/belief/plausibility function and a complementary cumulative distribution/belief/plausibility function. This choice affects how probabilities and reliability indices are reported.

**Default Behavior**

If the `distribution` keyword is present, it must be accompanied by either `cumulative` or `complementary`. Otherwise, a cumulative distribution will be used by default.

**Expected Outputs**

Output will be a set of model response-probability pairs determined according to the choice of distribution. The choice of distribution also defines the sign of the reliability or generalized reliability indices.

### Examples

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

### cumulative

- Keywords Area
- method
- local_reliability
- distribution
- cumulative

Computes statistics according to cumulative functions

### Specification

**Alias:** none

**Argument(s):** none
6.2. **METHOD**

### Description

Statistics on model responses will be computed according to a cumulative distribution/belief/plausibility function.

**Default Behavior**

By default, a cumulative distribution/belief/plausibility function will be used. To explicitly specify it in the Dakota input file, however, the `cumulative` keyword must be appear in conjunction with the `distribution` keyword.

**Expected Outputs**

Output will be a set of model response-probability pairs determined according to a cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls below given response thresholds.

### Examples

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

### complementary

- **Keywords Area**
- **method**
- **local_reliability**
- **distribution**
- **complementary**

Computes statistics according to complementary cumulative functions

### Specification

**Alias:** none

**Argument(s):** none

### Description

Statistics on model responses will be computed according to a complementary cumulative distribution/belief/plausibility function.

**Default Behavior**

By default, a complementary cumulative distribution/belief/plausibility function will not be used. To change that behavior, the `complementary` keyword must be appear in conjunction with the `distribution` keyword.

**Expected Outputs**

Output will be a set of model response-probability pairs determined according to a complementary cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls above given response thresholds.
Examples

```
method
    sampling
        sample_type lhs
        samples = 10
        distribution complementary
```

probability_levels

- **Keywords Area**
- **method**
- **local_reliability**
- **probability_levels**

Specify probability levels at which to estimate the corresponding response value

Specification

**Alias:** none

**Argument(s):** REALLIST

**Default:** No CDF/CCDF response levels to compute

<table>
<thead>
<tr>
<th>Required/- Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword num_probability_levels</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Description**

Response levels are calculated for specified CDF/CCDF probabilities by indexing into a sorted samples array (the response levels computed are not interpolated and will correspond to one of the sampled values).

**Theory**

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).
6.2. METHOD

- model_pointer

Identifier for model block to be used by a method

**Topics**

This keyword is related to the topics:

- block_pointer
6.2. METHOD

Specification

Alias: none
  Argument(s): STRING
  Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations
needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model
block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model-
_pointer for each method is imperative.

See block_pointer for details about pointers.

Examples

evironment
  tabular_graphics_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'

Use the Surfpack version of Gaussian Process surrogates

**Description**

This keyword specifies the use of the Gaussian process that is incorporated in our surface fitting library called Surfpack.

 Several user options are available:
1. Optimization methods:
   Maximum Likelihood Estimation (MLE) is used to find the optimal values of the hyper-parameters governing the trend and correlation functions. By default the global optimization method DIRECT is used for MLE, but other options for the optimization method are available. See optimization_method.
   The total number of evaluations of the likelihood function can be controlled using the max_trials keyword followed by a positive integer. Note that the likelihood function does not require running the “truth” model, and is relatively inexpensive to compute.

2. Trend Function:
   The GP models incorporate a parametric trend function whose purpose is to capture large-scale variations. See trend.

3. Correlation Lengths:
   Correlation lengths are usually optimized by Surfpack, however, the user can specify the lengths manually. See correlation_lengths.

4. Ill-conditioning
   One of the major problems in determining the governing values for a Gaussian process or Kriging model is the fact that the correlation matrix can easily become ill-conditioned when there are too many input points close together. Since the predictions from the Gaussian process model involve inverting the correlation matrix, ill-conditioning can lead to poor predictive capability and should be avoided.
   Note that a sufficiently bad sample design could require correlation lengths to be so short that any interpolatory GP model would become inept at extrapolation and interpolation.
   The surfpack model handles ill-conditioning internally by default, but behavior can be modified using

5. Gradient Enhanced Kriging (GEK).
   The use_derivatives keyword will cause the Surfpack GP to be constructed from a combination of function value and gradient information (if available).
   See notes in the Theory section.

Theory

Gradient Enhanced Kriging
Incorporating gradient information will only be beneficial if accurate and inexpensive derivative information is available, and the derivatives are not infinite or nearly so. Here “inexpensive” means that the cost of evaluating a function value plus gradient is comparable to the cost of evaluating only the function value, for example gradients computed by analytical, automatic differentiation, or continuous adjoint techniques. It is not cost effective to use derivatives computed by finite differences. In tests, GEK models built from finite difference derivatives were also significantly less accurate than those built from analytical derivatives. Note that GEK’s correlation matrix tends to have a significantly worse condition number than Kriging for the same sample design.

This issue was addressed by using a pivoted Cholesky factorization of Kriging’s correlation matrix (which is a small sub-matrix within GEK’s correlation matrix) to rank points by how much unique information they contain. This reordering is then applied to whole points (the function value at a point immediately followed by gradient information at the same point) in GEK’s correlation matrix. A standard non-pivoted Cholesky is then applied to the reordered GEK correlation matrix and a bisection search is used to find the last equation that meets the constraint on the (estimate of) condition number. The cost of performing pivoted Cholesky on Kriging’s correlation matrix is usually negligible compared to the cost of the non-pivoted Cholesky factorization of GEK’s correlation matrix. In tests, it also resulted in more accurate GEK models than when pivoted Cholesky or whole-point-block pivoted Cholesky was performed on GEK’s correlation matrix.

- method
- global_reliability
- dakota

Select the built in Gaussian Process surrogate

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

A second version of GP surrogates was available in prior versions of Dakota. For now, both versions are supported but the **dakota** version is deprecated and intended to be removed in a future release.

Historically these models were drastically different, but in Dakota 5.1, they became quite similar. They now differ in that the Surfpack GP has a richer set of features/options and tends to be more accurate than the Dakota version. Due to how the Surfpack GP handles ill-conditioned correlation matrices (which significantly contributes to its greater accuracy), the **Surfpack** GP can be a factor of two or three slower than Dakota’s. As of Dakota 5.2, the Surfpack implementation is the default in all contexts except Bayesian calibration.

More details on the **gaussian_process** dakota model can be found in[58].

Dakota’s GP deals with ill-conditioning in two ways. First, when it encounters a non-invertible correlation matrix it iteratively increases the size of a “nugget,” but in such cases the resulting approximation smooths rather than interpolates the data. Second, it has a **point_selection** option (default off) that uses a greedy algorithm to select a well-spaced subset of points prior to the construction of the GP. In this case, the GP will only interpolate the selected subset. Typically, one should not need point selection in trust-region methods because a small number of points are used to develop a surrogate within each trust region. Point selection is most beneficial when constructing with a large number of points, typically more than order one hundred, though this depends on the number of variables and spacing of the sample points.

This differs from the **point_selection** option of the Dakota GP which initially chooses a well-spaced subset of points and finds the correlation parameters that are most likely for that one subset.

**import_points_file**

- Keywords Area
- method
- global_reliability
- import_points_file

File containing variable values and corresponding responses
**Specification**

**Alias:** none

**Argument(s):** STRING  
**Default:** no point import from a file
### Description

The `import_points_file` allows the user to specify a file that contains a list of variable values and the model responses computed at those values. These can be used by a number of methods in place of model evaluations. When used to construct surrogate models or emulators these are often called build points or training data.

#### Default Behavior

By default, methods do not import points from a file.

#### Usage Tips

Dakota parses input files without regard to whitespace, but the `import_points_file` must be in one of three formats:

- annotated (default)
- custom_annotated
- freeform

#### Examples

```plaintext
method
  list_parameter_study
  import_points_file = 'dakota_pstudy.3.dat'
```

  - `annotated`

Selects annotated tabular file format
CHAPTER 6. KEYWORDS AREA

Topics
This keyword is related to the topics:

- file_formats

Specification
Alias: none
  Argument(s): none
  Default: annotated format

Description
An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior
By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips
- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom.annotated header eval_id
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples
Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

export
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated

Resulting tabular file:

%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 NO_ID 0.9 1.1 0.0002 0.26 0.76
2 NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955

</tr>
<tr>
<td>Optional</td>
<td>interface_id</td>
<td>Enable interface ID column in custom-annotated tabular file</td>
<td></td>
</tr>
</tbody>
</table>

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

Usage Tips
• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```plaintext
evironment
tabular_data
tabular_data_file = 'dakota_summary.dat'
custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id x1   x2     obj_fn nln_ineq_con_1 nln_ineq_con_2
1   0.9   1.1     0.0002   0.26       0.76

- import_points_file
- freeform

Selects freeform file format

Topics
This keyword is related to the topics:

- file_formats

Specification
Alias: none
Argument(s): none
Default: annotated format

Description
A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior
The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips
- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.
6.2. METHOD

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```python
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
freeform
```

Resulting tabular file:

```
  0.9       1.1  0.0002  0.26      0.76
0.90009    1.1  0.0001996404857  0.2601620081   0.759955

...
```

**active_only**

- Keywords Area
- method
- global_reliability
- import_points_file
- active_only

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- file_formats

Specification

**Alias:** none

**Argument(s):** none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.
export_points_file

- Keywords Area
- method
- global_reliability
- export_points_file

Output file for evaluations of a surrogate model

Usage Tips

6.2. METHOD

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```plaintext
environment
tabular_data
  tabular_data_file = 'dakota_summary.dat'
custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id x1  x2  obj_fn nln_ineq_con_1 nln_ineq_con_2
1  0.9 1.1  0.0002  0.26  0.76
2 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...
```

6.2. METHOD

freeform

- Keywords Area
- method
- global_reliability
- export_points_file
- freeform

Selects freeform file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none
Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.
Examples
Export a freeform tabular file containing only data for variables and responses. Input file fragment:

    environment
    tabular_data
    tabular_data_file = 'dakota_summary.dat'
    freeform

Resulting tabular file:

    0.9  1.1  0.0002  0.26  0.76
    0.90009  1.1  0.0001996404857  0.2601620081  0.759955
    0.89991  1.1  0.0002003604863  0.2598380081  0.760045
    ...

use_derivatives

- Keywords Area
- method
- global_reliability
- use_derivatives

Use derivative data to construct surrogate models

Specification

Alias: none

Argument(s): none

Default: use function values only

Description

The use_derivatives flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, its use with Surfpack Gaussian process is not recommended.

seed

- Keywords Area
- method
- global_reliability
- seed

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)
Description

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

**Default Behavior**
- If not specified, the seed is randomly generated.

**Expected Output**
- If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

**Usage Tips**
- If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```dakota
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347

rng

- Keywords Area
- method
- global_reliability
- rng

```

Selection of a random number generator

**Specification**

Alias: none

Argument(s): none

Default: Mersenne twister (mt19937)

<td>Generates random numbers using the Mersenne twister</td>
</tr>
</tbody>
</table>
CHAPTER 6. KEYWORDS AREA

| rnum2 | Generates pseudo-random numbers using the Pecos package |

Description

The `rng` keyword is used to indicate a choice of random number generator.

**Default Behavior**

If specified, the `rng` keyword must be accompanied by either `rnum2` (pseudo-random numbers) or `mt19937` (random numbers generated by the Mersenne twister). Otherwise, `mt19937`, the Mersenne twister is used by default.

**Usage Tips**

The default is recommended, as the Mersenne twister is a higher quality random number generator.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2
```

**mt19937**

- Keywords Area
- method
- global_reliability
- rng
- mt19937

Generates random numbers using the Mersenne twister

Specification

Alias: none

**Argument(s):** none

Description

The `mt19937` keyword directs Dakota to use the Mersenne twister to generate random numbers. Additional information can be found on wikipedia: [http://en.wikipedia.org/wiki/Mersenne_twister](http://en.wikipedia.org/wiki/Mersenne_twister).

**Default Behavior**

`mt19937` is the default random number generator. To specify it explicitly in the Dakota input file, however, it must be specified in conjunction with the `rng` keyword.

**Usage Tips**

Use of the Mersenne twister random number generator (`mt19937`) is recommended.
6.2. METHOD

Examples

method
  sampling
  sample_type lhs
  samples = 10
  seed = 98765
  rng mt19937

rnum2

• Keywords Area
• method
• global_reliability
• rng
• rnum2

Generates pseudo-random numbers using the Pecos package

Specification

Alias: none

Argument(s): none

Description

The rnum2 keyword directs Dakota to use pseudo-random numbers generated by the Pecos package.

Default Behavior

rnum2 is not used by default. To change this behavior, it must be specified in conjunction with the rng keyword.

Usage Tips

Use of the Mersenne twister random number generator (mt19937) is recommended over rnum2.

Examples

method
  sampling
  sample_type lhs
  samples = 10
  seed = 98765
  rng rnum2

response_levels

• Keywords Area
• method
• global_reliability
• response_levels

Values at which to estimate desired statistics for each response
CHAPTER 6. KEYWORDS AREA

Speciation

Alias: none

Argument(s): REALLIST

Default: No CDF/CCDF probabilities/reliabilities to compute

| Required/- | Description of | Dakota Keyword | Dakota Keyword |
| Optional | Group | num_response_levels | Description |
| Optional | | compute | Number of values at which to estimate desired statistics for each response |
| Optional | | | Selection of statistics to compute at each response level |

Description

The `response_levels` specification provides the target response values for which to compute probabilities, reliabilities, or generalized reliabilities (forward mapping).

Default Behavior
If `response_levels` are not specified, no statistics will be computed. If they are, probabilities will be computed by default.

Expected Outputs
The particular statistics reported for each response level depend on the method, and they include:

1. Reliabilities
2. CDF probabilities
3. CCDF probabilities

Usage Tips
The `num_response_levels` is used to specify which arguments of the `response_level` correspond to which response.

Examples

For example, specifying a `response_level` of 52.3 followed with `compute probabilities` will result in the calculation of the probability that the response value is less than or equal to 52.3, given the uncertain distributions on the inputs.

For an example with multiple responses, the following specification

```
response_levels = 1. 2. .1 .2 .3 .4 10. 20. 30.
num_response_levels = 2 4 3
```

would assign the first two response levels (1., 2.) to response function 1, the next four response levels (.1, .2, .3, .4) to response function 2, and the final three response levels (10., 20., 30.) to response function 3. If the `num_response_levels` key were omitted from this example, then the response levels would be evenly distributed among the response functions (three levels each in this case).
6.2. METHOD

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

A forward mapping involves computing the belief and plausibility probability level for a specified response level.

\texttt{num\_response\_levels}

- Keywords Area
- method
- global\_reliability
- response\_levels
- num\_response\_levels

Number of values at which to estimate desired statistics for each response

Specification

Alias: none

Argument(s): INTEGERLIST

Default: response\_levels evenly distributed among response functions

Description

The \texttt{num\_response\_levels} keyword allows the user to specify the number of response values, for each response, at which estimated statistics are of interest. Statistics that can be computed are probabilities and reliabilities, both according to either a cumulative distribution function or a complementary cumulative distribution function.

Default Behavior

If \texttt{num\_response\_levels} is not specified, the response\_levels will be evenly distributed among the responses.

Expected Outputs

The specific output will be determined by the type of statistics that are specified. In a general sense, the output will be a list of response level-statistic pairs that show the estimated value of the desired statistic for each response level specified.

Examples

\begin{verbatim}
method
    sampling
        samples = 100
        seed = 34785
        num\_response\_levels = 1 1 1
        response\_levels = 0.5 0.5 0.5
\end{verbatim}
compute

<td>gen_reliabilities</td>
<td>Computes generalized reliabilities associated with response levels</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td></td>
<td>system</td>
<td>Compute system reliability (series or parallel)</td>
</tr>
</tbody>
</table>

**Description**

The `compute` keyword is used to select which forward statistical mapping is calculated at each response level.

**Default Behavior**

If `response_levels` is not specified, no statistics are computed. If `response_levels` is specified but `compute` is not, probabilities will be computed by default. If both `response_levels` and `compute` are specified, then one of the following must be specified: `probabilities`, `reliabilities`, or `gen_reliabilities`.

**Expected Output**

The type of statistics specified by `compute` will be reported for each response level.

**Usage Tips**

CDF/CCDF probabilities are calculated for specified response levels using a simple binning approach.

CDF/CCDF reliabilities are calculated for specified response levels by computing the number of sample standard deviations separating the sample mean from the response level.
6.2. METHOD

Examples

method
    sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                     6.0e+04 6.5e+04 7.0e+04
                     3.5e+05 4.0e+05 4.5e+05
    compute reliabilities

probabilities

- Keywords Area
- method
- global_reliability
- response_levels
- compute
- probabilities

Computes probabilities associated with response levels

Specification

Alias: none
    Argument(s): none

Description

The probabilities keyword directs Dakota to compute the probability that the model response will be below (cumulative) or above (complementary cumulative) a specified response value. This is done for every response level designated for each response.

Default Behavior

If response_levels is specified, the probabilities are computed by default. To explicitly specify it in the Dakota input file, though, the probabilities keyword should be specified in conjunction with the compute keyword.

Expected Outputs

The Dakota output is a set of response level-probability pairs that give the probability that the model response will be below or above the corresponding response level, depending on the distribution defined.

Examples

method
    sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                     6.0e+04 6.5e+04 7.0e+04
                     3.5e+05 4.0e+05 4.5e+05
    compute probabilities
**gen_reliabilities**
- Keywords Area
- method
- global_reliability
- response_levels
- compute
- gen_reliabilities

Computes generalized reliabilities associated with response levels

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The `gen_reliabilities` keyword directs Dakota to compute generalized reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

**Default Behavior**

If `response_levels` is specified, the generalized reliabilities are not computed by default. To change this behavior, the `gen_reliabilities` keyword should be specified in conjunction with the `compute` keyword.

**Expected Outputs**

The Dakota output is a set of response level-generalized reliability pairs according to the distribution defined.

**Examples**

```plaintext
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
      6.0e+04 6.5e+04 7.0e+04
      3.5e+05 4.0e+05 4.5e+05
    compute gen_reliabilities

system

<td></td>
<td>series</td>
<td>Aggregate response statistics assuming a series system</td>
</tr>
<tr>
<td>parallel</td>
<td></td>
<td>parallel</td>
<td>Aggregate response statistics assuming a parallel system</td>
</tr>
</tbody>
</table>

Description

With the system probability/reliability option, statistics for specified response levels are calculated and reported assuming the response functions combine either in series or parallel to produce a total system response.

For a series system, the system fails when any one component (response) fails. The probability of failure is the complement of the product of the individual response success probabilities.

For a parallel system, the system fails only when all components (responses) fail. The probability of failure is the product of the individual response failure probabilities.

6.2. METHOD

| complementary | Computes statistics according to complementary cumulative functions |

**Description**

The `distribution` keyword allows the user to select between a cumulative distribution/belief/plausibility function and a complementary cumulative distribution/belief/plausibility function. This choice affects how probabilities and reliability indices are reported.

**Default Behavior**

If the `distribution` keyword is present, it must be accompanied by either `cumulative` or `complementary`. Otherwise, a cumulative distribution will be used by default.

**Expected Outputs**

Output will be a set of model response-probability pairs determined according to the choice of distribution. The choice of distribution also defines the sign of the reliability or generalized reliability indices.

**Examples**

```
method sampling
  sample_type lhs
  samples = 10
  distribution cumulative
```

**cumulative**

- **Keywords Area**
- **method**
- **global_reliability**
- **distribution**
- **cumulative**

Computes statistics according to cumulative functions

**Specification**

- **Alias**: none
- **Argument(s)**: none

**Description**

Statistics on model responses will be computed according to a cumulative distribution/belief/plausibility function.

**Default Behavior**

By default, a cumulative distribution/belief/plausibility function will be used. To explicitly specify it in the Dakota input file, however, the `cumulative` keyword must appear in conjunction with the `distribution` keyword.
**Expected Outputs**

Output will be a set of model response-probability pairs determined according to a cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls below given response thresholds.

**Examples**

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative

<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>num_probability_levels</td>
<td></td>
<td>Specify which probability_levels correspond to which response</td>
</tr>
</tbody>
</table>

Description

Response levels are calculated for specified CDF/CCDF probabilities by indexing into a sorted samples array (the response levels computed are not interpolated and will correspond to one of the sampled values).

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).

- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none

Argument(s): STRING
Default: method use of last model parsed (or use of default model if none parsed)
Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

**Usage Tips**

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

**Examples**

```plaintext
environment
  tabular_graphics_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'

<td>latimize</td>
<td></td>
<td>Adjust samples to improve the discrepancy of the marginal distributions</td>
</tr>
<tr>
<td>Optional</td>
<td>quality_metrics</td>
<td></td>
<td>Calculate metrics to assess the quality of quasi-Monte Carlo samples</td>
</tr>
</tbody>
</table>
### Description

Quasi-Monte Carlo methods produce low discrepancy sequences, especially if one is interested in the uniformity of projections of the point sets onto lower dimensional faces of the hypercube (usually 1-D: how well do the marginal distributions approximate a uniform?)

This method generates sets of uniform random variables on the interval [0,1]. If the user specifies lower and upper bounds for a variable, the [0,1] samples are mapped to the [lower, upper] interval.

The user must first choose the sequence type:

- halton or
- hammersley

Then three keywords are used to define the sequence and how it is sampled:

- prime_base
- sequence_start

<table>

Description: Quasi-Monte Carlo methods produce low discrepancy sequences, especially if one is interested in the uniformity of projections of the point sets onto lower dimensional faces of the hypercube (usually 1-D: how well do the marginal distributions approximate a uniform?)

This method generates sets of uniform random variables on the interval [0,1]. If the user specifies lower and upper bounds for a variable, the [0,1] samples are mapped to the [lower, upper] interval.

The user must first choose the sequence type:

- halton or
- hammersley

Then three keywords are used to define the sequence and how it is sampled:

- prime_base
- sequence_start
6.2. METHOD

- sequence_leap

Each of these has defaults, so specification is optional.

Theory

The quasi-Monte Carlo sequences of Halton and Hammersley are deterministic sequences determined by a set of prime bases. Generally, we recommend that the user leave the default setting for the bases, which are the lowest primes. Thus, if one wants to generate a sample set for 3 random variables, the default bases used are 2, 3, and 5 in the Halton sequence. To give an example of how these sequences look, the Halton sequence in base 2 starts with points 0.5, 0.25, 0.75, 0.125, 0.625, etc. The first few points in a Halton base 3 sequence are 0.33333, 0.66667, 0.11111, 0.44444, 0.77777, etc. Notice that the Halton sequence tends to alternate back and forth, generating a point closer to zero then a point closer to one. An individual sequence is based on a radix inverse function defined on a prime base. The prime base determines how quickly the [0,1] interval is filled in. Generally, the lowest primes are recommended.

The Hammersley sequence is the same as the Halton sequence, except the values for the first random variable are equal to 1/N, where N is the number of samples. Thus, if one wants to generate a sample set of 100 samples for 3 random variables, the first random variable has values 1/100, 2/100, 3/100, etc. and the second and third variables are generated according to a Halton sequence with bases 2 and 3, respectively.

For more information about these sequences, see [43], [44], and [1].

latinize

- Keywords Area
- method
- fsu_quasi_mc
- latinize

Adjust samples to improve the discrepancy of the marginal distributions

Specification

Alias: none

Argument(s): none

Default: No latinization

Description

The latinize control takes the samples and "latinizes" them, meaning that each original sample is moved so that it falls into one strata or bin in each dimension as in Latin Hypercube sampling. The default setting is NOT to latinize. However, one may be interested in doing this in situations where one wants better discrepancy of the 1-dimensional projections (the marginal distributions).

quality_metrics

- Keywords Area
- method
- fsu_quasi_mc
- quality_metrics

Calculate metrics to assess the quality of quasi-Monte Carlo samples

Topics

This keyword is related to the topics:

- package_fsudace

Specification

Alias: none

Argument(s): none

Default: No quality_metrics
Description

Quality metrics calculates four quality metrics relating to the volumetric spacing of the samples. The four quality metrics measure different aspects relating to the uniformity of point samples in hypercubes. Desirable properties of such point samples are:

- are the points equally spaced
- do the points cover the region
- and are they isotropically distributed
- with no directional bias in the spacing

The four quality metrics we report are:

- \( h \): the point distribution norm, which is a measure of uniformity of the point distribution
- \( \chi \): a regularity measure, and provides a measure of local uniformity of a set of points
- \( \tau \): the second moment trace measure
- \( d \): the second moment determinant measure

All of these values are scaled so that smaller is better (the smaller the metric, the better the uniformity of the point distribution).

Examples

Complete explanation of these measures can be found in [38].

variance_based_decomp

- Keywords Area
- method
- fsu_quasi_mc
- variance_based_decomp

Activates global sensitivity analysis based on decomposition of response variance into contributions from variables.

Specification

Alias: none

Argument(s): none

Default: no variance-based decomposition

<tbody>
<tr>
<td>Optional</td>
<td>Group</td>
<td>Description</td>
<td>Description</td>
</tr>
</tbody>
</table>

6.2. METHOD

| Optional | drop_tolerance | Suppresses output of sensitivity indices with values lower than this tolerance |

**Description**

Dakota can calculate sensitivity indices through variance based decomposition using the keyword `variance_based_decomp`. These indicate how important the uncertainty in each input variable is in contributing to the output variance.

**Default Behavior**

Because of the computational cost, `variance_based_decomp` is turned off as a default. If the user specified a number of samples, N, and a number of nondeterministic variables, M, variance-based decomposition requires the evaluation of \(N \times (M+2)\) samples. **Note that specifying this keyword will increase the number of function evaluations above the number requested with the `samples` keyword since replicated sets of sample values are evaluated.**

**Expected Outputs**

When `variance_based_decomp` is specified, sensitivity indices for main effects and total effects will be reported. Main effects (roughly) represent the percent contribution of each individual variable to the variance in the model response. Total effects represent the percent contribution of each individual variable in combination with all other variables to the variance in the model response.

**Usage Tips**

To obtain sensitivity indices that are reasonably accurate, we recommend that N, the number of samples, be at least one hundred and preferably several hundred or thousands.

**Examples**

```plaintext
method,
  sampling
    sample_type lhs
    samples = 100
    variance_based_decomp
```

**Theory**

In this context, we take sensitivity analysis to be global, not local as when calculating derivatives of output variables with respect to input variables. Our definition is similar to that of [73]: “The study of how uncertainty in the output of a model can be apportioned to different sources of uncertainty in the model input.”

Variance based decomposition is a way of using sets of samples to understand how the variance of the output behaves, with respect to each input variable. A larger value of the sensitivity index, \(S_i\), means that the uncertainty in the input variable i has a larger effect on the variance of the output. More details on the calculations and interpretation of the sensitivity indices can be found in [73] and [87].

**drop_tolerance**

- **Keywords Area**
- **method**
- **fsu_quasi_mca**
• variance_based_decomp

• drop_tolerance

Suppresses output of sensitivity indices with values lower than this tolerance

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** All VBD indices displayed

**Description**

The drop_tolerance keyword allows the user to specify a value below which sensitivity indices generated by variance_based_decomp are not displayed.

**Default Behavior**

By default, all sensitivity indices generated by variance_based_decomp are displayed.

**Usage Tips**

For polynomial_chaos, which outputs main, interaction, and total effects by default, the univariate_effects may be a more appropriate option. It allows suppression of the interaction effects since the output volume of these results can be prohibitive for high dimensional problems. Similar to suppression of these interactions is the covariance control, which can be selected to be diagonal_covariance or full_covariance, with the former supporting suppression of the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

**Examples**

```plaintext
method,
  sampling
    sample_type lhs
    samples = 100
    variance_based_decomp
    drop_tolerance = 0.001

samples

• Keywords Area

• method

• fsu_quasi_mc

• samples

  Number of samples for sampling-based methods
```

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 0 (or min req for surrogate build)
6.2. METHOD

Description

The samples keyword is used to define the number of samples (i.e., randomly chosen sets of variable values) at which to execute a model.

Default Behavior

By default, Dakota will use the minimum number of samples required by the chosen method.

Usage Tips

To obtain linear sensitivities or to construct a linear response surface, at least \( \text{dim} + 1 \) samples should be used, where "\( \text{dim} \)" is the number of variables. For sensitivities to quadratic terms or quadratic response surfaces, at least \((\text{dim}+1)(\text{dim}+2)/2\) samples are needed. For uncertainty quantification, we recommend at least \(10 \times \text{dim}\) samples. For variance_based_decomp, we recommend hundreds to thousands of samples. Note that for variance_based_decomp, the number of simulations performed will be \(N \times (\text{dim}+2)\).

Examples

```
method sampling
  sample_type lhs
  samples = 20
```

fixed_sequence

- Keywords Area
- method
- fsu_quasi_mc
- fixed_sequence

Reuse the same sequence and samples for multiple sampling sets

Specification

Alias: none

Argument(s): none

Default: sequence not fixed: sampling patterns are variable among multiple QMC runs

Description

The fixed_sequence control is similar to fixed_seed for other sampling methods. If fixed_sequence is specified, the user will get the same sequence (meaning the same set of samples) for subsequent calls of the QMC sampling method (for example, this might be used in a surrogate based optimization method or a parameter study where one wants to fix the uncertain variables).

sequence_start

- Keywords Area
- method
- fsu_quasi_mc
- sequence_start

Choose where to start sampling the sequence
Speciation

Alias: none
Argument(s): INTEGERLIST
Default: Vector of zeroes

Description

sequence_start determines where in the sequence the samples will start.

The default sequence_start is a vector with 0 for each variable, specifying that each sequence start with
the first term.

Examples

For example, for the Halton sequence in base 2, if the user specifies sequence_start = 2, the sequence would not
include 0.5 and 0.25, but instead would start at 0.75.

sequence_leap

- Keywords Area
- method
- fsu_quasi_mc
- sequence_leap

Specify how often the sequence is sampled

Specification

Alias: none
Argument(s): INTEGERLIST
Default: Vector of ones

Description

sequence_leap controls the "leaping" of terms in the sequence. The default is 1 for each variable, meaning
that each term in the sequence be returned.

Examples

If the user specifies a sequence_leap of 2 for a variable, the points returned would be every other term from the
QMC sequence.

Theory

The advantage to using a leap value greater than one is mainly for high-dimensional sets of random deviates. In
this case, setting a leap value to the next prime number larger than the largest prime base can help maintain
uniformity when generating sample sets for high dimensions. For more information about the efficacy of leaped
Halton sequences, see[71].
6.2. METHOD

prime_base
- Keywords Area
- method
- fsu_quasi_mc
- prime_base

The prime numbers used to generate the sequence

**Specification**

**Alias:** none

**Argument(s):** INTEGERLIST

**Default:** Vector of the first s primes for s-dimensions in Halton, First (s-1) primes for Hammersley

**Description**

It is recommended that the user not specify this and use the default values.

- For the Halton sequence, the default bases are primes in increasing order, starting with 2, 3, 5, etc.
- For the Hammersley sequence, the user specifies (s-1) primes if one is generating an s-dimensional set of random variables.

**model_pointer**

- Keywords Area
- method
- fsu_quasi_mc
- model_pointer

Identifier for model block to be used by a method

**Topics**

This keyword is related to the topics:

- block_pointer

**Specification**

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)
CHAPTER 6. KEYWORDS AREA

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model-pointer` for each method is imperative.

See `block_pointer` for details about pointers.

Examples

```plaintext
environment
    tabular_graphics_data
    method_pointer = 'UQ'

method
    id_method = 'UQ'
    model_pointer = 'SURR'
    sampling,
        samples = 10
        seed = 98765 rng rnum2
        response_levels = 0.1 0.2 0.6
        0.1 0.2 0.6
        0.1 0.2 0.6
    sample_type lhs
    distribution cumulative

CHAPTER 6. KEYWORDS AREA

| Optional | model_pointer | Identifier for model block to be used by a method |

### Description

Dakota’s vector parameter study computes response data sets at selected intervals along a vector in parameter space. It is often used for single-coordinate parameter studies (to study the effect of a single variable on a response set), but it can be used more generally for multiple coordinate vector studies (to investigate the response variations along some $n$-dimensional vector such as an optimizer search direction).

**Default Behavior**
- By default, the multidimensional parameter study operates over all types of variables.

**Expected Outputs**
- A multidimensional parameter study produces a set of responses for each parameter set that is generated.

**Usage Tips**
- **Group 1** is used to define the vector along which the parameters are varied. Both cases also rely on the variables specification of an initial value, through:
  - the `initial_point` keyword
  - the `initial_state` keyword
  - relying on the default initial value, based on the rest of the variables specification

From the initial value, the vector can be defined using one of the two keyword choices.

Once the vector is defined, the samples are then fully specified by `num_steps`.

### Examples

The following example is a good comparison to the examples on `multidim.parameter_study` and `centered.parameter_study`.

```plaintext
# tested on Dakota 6.0 on 140501
environment
  tabular_data
    tabular_data_file = 'rosen_vector.dat'

method
  vector_parameter_study
    num_steps = 10
    final_point = 2.0 2.0

model
  single

variables
  continuous_design = 2
    initial_point = -2.0 -2.0
    descriptors = 'x1' "x2"

interface
  analysis_driver = 'rosenbrock'
    fork

responses
  response_functions = 1
    no_gradients
    no_hessians
```
See Also
These keywords may also be of interest:
  • centered_parameter_study
  • multidim_parameter_study
  • list_parameter_study

final_point
  • Keywords Area
  • method
  • vector_parameter_study
  • final_point

  Final variable values defining vector in vector parameter study

Specification
Alias: none
  Argument(s): REALLIST

Description
The final_point keyword is used to define the final values for each variable on the vector to be used in the vector parameter study. The vector’s direction and magnitude are determined by the initial value from the variables specification, and the final_point.

  Default Behavior
  The user is required to specify either final_point or step_vector. There is no default definition for the vector.

  Usage Tips
  The actual points are determined based on this vector and the number of points chosen is given in num_points.

Examples
  method
  vector_parameter_study
    num_steps = 10
    final_point = 2.0 2.0

step_vector
  • Keywords Area
  • method
  • vector_parameter_study
  • step_vector

  Number of sampling steps along the vector in a vector parameter study
### Specification

**Alias:** none

**Argument(s):** REALLIST

### Description

`num_steps` defines the number of steps that are taken in the direction of the vector. The magnitude of each step is determined in conjunction with the rest of the method specification.

**Default Behavior**

The user is required to specify `num_steps` for a vector parameter study. There is no default value.

This study performs function evaluations at both ends, making the total number of evaluations equal to `num_steps + 1`.

**Usage Tips**

The study has stringent requirements on performing appropriate steps with any discrete range and discrete set variables. A `num_steps` specification must result in discrete range and set index steps that are integers: no remainder is currently permitted in the integer step calculation and no rounding to integer steps will occur.

### Examples

```
method vector_parameter_study
  num_steps = 10
  final_point = 2.0 2.0
```

### Specifying

- **Keywords Area**
- **method**
- **vector_parameter_study**
- **num_steps**

Number of sampling steps along the vector in a vector parameter study

### Specification

**Alias:** none

**Argument(s):** INTEGER

### Description

`num_steps` defines the number of steps that are taken in the direction of the vector. The magnitude of each step is determined in conjunction with the rest of the method specification.

**Default Behavior**

The user is required to specify `num_steps` for a vector parameter study. There is no default value.

This study performs function evaluations at both ends, making the total number of evaluations equal to `num_steps + 1`.

**Usage Tips**

The study has stringent requirements on performing appropriate steps with any discrete range and discrete set variables. A `num_steps` specification must result in discrete range and set index steps that are integers: no remainder is currently permitted in the integer step calculation and no rounding to integer steps will occur.
6.2. METHOD

<td>File containing variable values and corresponding responses</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>model_pointer</td>
<td>Identifier for model block to be used by a method</td>
</tr>
</tbody>
</table>

### Description

Dakota’s list parameter study allows for evaluations at user selected points of interest.

**Default Behavior**

By default, the list parameter study operates over all types of variables.

The number of real values in the `list_of_points` specification or file referenced by `import_points_file` must be a multiple of the total number of variables (including continuous and discrete types) contained in the variables specification.

**Expected Outputs**

A list parameter study produces a set of responses for each parameter set that is specified.

**Usage Tips**

- This parameter study simply performs simulations for the first parameter set (the first \( n \) entries in the list), followed by the next parameter set (the next \( n \) entries), and so on, until the list of points has been exhausted.

- Since the initial values from the variables specification will not be used, they need not be specified.

- For discrete set types, the actual values should be specified, not the set indices, although the values will be validated for membership within the set value specifications.

### Examples

This shows the method and variables block of a Dakota input file that runs a `list_parameter_study`.

```dakota
method
  list_parameter_study
      list_of_points =
        3.1e6 0.0029 0.31
        3.2e6 0.0028 0.32
        3.3e6 0.0027 0.34
        3.3e6 0.0026 0.36
variables
  continuous_design = 3
  descriptors = 'E' 'MASS' 'DENSITY'
```

Note that because of the way Dakota treats whitespace, the above example is equivalent to:
method list_parameter_study
list_of_points =
3.1e6  0.0029  0.31  3.2e6  0.0028
0.32  3.3e6  0.0027
0.34  3.3e6  0.0026  0.36

variables
continuous_design = 3
  descriptors = 'E' 'MASS' 'DENSITY'

Although the first example is much more readable.
And here's a full input file:

```plaintext
# tested on Dakota 6.0 on 140501
environment
tabular_data
tabular_data_file 'List_param_study.dat'

method
list_parameter_study
list_of_points = 0.1 0.1
0.2 0.1
0.3 0.0
0.3 1.0

model
single

variables
active design
continuous_design = 2
  descriptors = 'x1' 'x2'
continuous_state = 1
  descriptors = 'constant1'
  initial_state = 100

interface
analysis_drivers 'text_book'
fork
asynchronous
  evaluation_concurrency 2

responses
response_functions = 1
no_gradients
no_hessians

This example illustrates the list_parameter_study.

- The function evaluations are independent, so any level of evaluation_concurrency can be used
- Default behavior for parameter studies is to iterate on all variables. However, because active design is specified, this study will only iterate on the continuous_design variables.

These keywords may also be of interest:

- centered_parameter_study
6.2. METHOD

- multidim_parameter_study
- vector_parameter_study

list_of_points

- Keywords Area
- method
- list_parameter_study
- list_of_points

List of variable values to evaluate in a list parameter study

Specification

Alias: none
Argument(s): REALLIST

Description
The list_of_points keyword allows the user to specify, in a freeform format, a list of variable values at which to compute a model response.

Default Behavior
The user is required to provide a list of points for a list parameter study either by specifying it with list_of_points or by providing a file from which such a list can be read via import_points_file. There is no default list of points.

Usage Tips
The number of values in the list must be an integer multiple of the number of variables. Dakota will verify that this condition is met.

Examples

```plaintext
method
list_parameter_study
list_of_points =
  3.1e6  0.0029  0.31
  3.2e6  0.0028  0.32
  3.3e6  0.0027  0.34
  3.3e6  0.0026  0.36
```

import_points_file

| Optional | active_only | Import only active variables from tabular data file |

Description

The `import_points_file` allows the user to specify a file that contains a list of variable values and the model responses computed at those values. These can be used by a number of methods in place of model evaluations. When used to construct surrogate models or emulators these are often called build points or training data.

**Default Behavior**

By default, methods do not import points from a file.

**Usage Tips**

Dakota parses input files without regard to whitespace, but the `import_points_file` must be in one of three formats:

- `annotated` (default)
- `custom.annotated`
- `freeform`

**Examples**

```
method
list_parameter_study
import_points_file = 'dakota_pstudy.3.dat'
```

annotated

- **method**
- **list_parameter_study**
6.2. METHOD

- import_points_file
- annotated

Selects annotated tabular file format

Topics
This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none
Default: annotated

Description
An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior
By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples
Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
  annotated

Resulting tabular file:

%eval_id interface  x1    x2    obj_fn  nln_ineq_con_1  nln_ineq_con_2
1 NO_ID 0.9  1.1  0.0002  0.26  0.76
2 NO_ID 0.90009 1.1  0.0001996404857 0.2601620081 0.759955
3 NO_ID 0.89991 1.1  0.0002003604863 0.2598380081 0.760045
...```
custom_annotated

- Keywords Area
- method
- list_parameter_study
- import_points_file
- custom_annotated

Selects custom-annotated tabular file format

**Topics**
This keyword is related to the topics:
- file_formats

**Specification**

**Alias:** none  
**Argument(s):** none

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>header</td>
<td>Enable header row in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td>eval_id</td>
<td>Enable evaluation ID column in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td>interface_id</td>
<td>Enable interface ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

**Description**
A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

**Default Behavior**  
The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

**Usage Tips**
• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples
Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```
environment
tabular_data
    tabular_data_file = 'dakota_summary.dat'
custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 0.9 1.1 0.0002 0.26 0.76

6.2. METHOD

freeform

- Keywords Area
- method
- list_parameter_study
- import_points_file
- freeform

Selects freeform file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.
Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
tabular_data
  tabular_data_file = 'dakota_summary.dat'
freeform
```

Resulting tabular file:

```
  0.9  1.1  0.0002  0.26  0.76
  0.90009  1.1  0.0001996404857  0.2601620081  0.759955
  0.89991  1.1  0.0002003604863  0.2598380081  0.760045
  ...
```

**active_only**

- Keywords Area
- method
- list_parameter_study
- import_points_file
- active_only

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.
6.2. METHOD

model_pointer

- Keywords Area
- method
- list_parameter_study
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior
If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips
When doing advanced analyses that involve using multiple methods and multiple models, defining a model-pointer for each method is imperative.
See block_pointer for details about pointers.

Examples

environment
  tabular_graphics_data

6.2.72 centered_parameter_study

• Keywords Area

• method

• centered_parameter_study

Samples variables along points moving out from a center point

Topics
This keyword is related to the topics:

• parameter_studies

Specification
Alias: none
Argument(s): none

<table>
<thead>
<tr>
<th>Required/-Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword Description</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
</table>

Description

Dakota’s centered parameter study computes response data sets along multiple coordinate-based vectors, one per parameter, centered about the initial values from the variables specification. This is useful for investigation of function contours with respect to each parameter individually in the vicinity of a specific point (e.g., post-optimality analysis for verification of a minimum), thereby avoiding the cost associated with a multidimensional grid.

Default Behavior

By default, the centered parameter study operates over all types of variables.

The centered_parameter_study takes steps along each orthogonal dimension. Each dimension is treated independently. The number of steps are taken in each direction, so that the total number of points in the parameter study is \(1 + 2 \sum n\).

Expected Outputs

A centered parameter study produces a set of responses for each parameter set that is generated.

Examples

The following example is a good comparison to the examples on multidim_parameter_study and vector_parameter_study.

```bash
# tested on Dakota 6.0 on 140501
environment
    tabular_data
        tabular_data_file = 'rosen_centered.dat'

method
    centered_parameter_study
        steps_per_variable = 5 4
        step_vector = 0.4 0.5

model
    single

variables
    continuous_design = 2
    initial_point = 0 0
    descriptors = 'x1' "x2"
```
interface
  analysis_driver = 'rosenbrock'

step_vector

- Keywords Area
- method
- centered_parameter_study
- step_vector

Size of steps to be taken in each dimension of a centered parameter study

Specification

Alias: none

Argument(s): REALLIST

Description

The step_vector keyword defines the individual step size in each dimension, treated separately.

Default Behavior

The user is required to define the number of step sizes for a centered parameter study. There are no default values.

Steps are taken in the plus and minus directions, and are defined in either actual values (continuous and discrete range) or index offsets (discrete set).

Examples

method
  centered_parameter_study
  steps_per_variable = 5 4
  step_vector = 0.4 0.5
6.2. METHOD

steps_per_variable

- Keywords Area
- method
- centered_parameter_study
- steps_per_variable

Number of steps to take in each dimension of a centered parameter study

Specification

Alias: deltas_per_variable

Argument(s): INTEGERLIST

Description

The `steps_per_variable` keyword allows the user to define the number of steps in each dimension of a centered parameter study. Because they are taken independently, the number of steps can be specified for each.

Default Behavior

The user is required to define the number of steps per variable for a centered parameter study. There are no default values.

Steps are taken in the plus and minus directions, and are defined in either actual values (continuous and discrete range) or index offsets (discrete set).

Examples

```
method
  centered_parameter_study
  steps_per_variable = 5 4
  step_vector = 0.4 0.5
```

Samples variables on full factorial grid of study points

Topics

This keyword is related to the topics:
- parameter_studies

Specification

Alias: none
Argument(s): none

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required</td>
<td>partitions</td>
<td>partitions</td>
<td>Samples variables on full factorial grid of study points</td>
</tr>
<tr>
<td>Optional</td>
<td>model_pointer</td>
<td>model_pointer</td>
<td>Identifier for model block to be used by a method</td>
</tr>
</tbody>
</table>

Description

Dakota’s multidimensional parameter study computes response data sets for an n-dimensional grid of points. Each continuous and discrete range variable is partitioned into equally spaced intervals between its upper and lower bounds, each discrete set variable is partitioned into equally spaced index intervals. The partition boundaries in n-dimensional space define a grid of points, and every point is evaluated.

Default Behavior
By default, the multidimensional parameter study operates over all types of variables.

Expected Outputs
A multidimensional parameter study produces a set of responses for each parameter set that is generated.

Usage Tips
Since the initial values from the variables specification will not be used, they need not be specified.
Examples
This example is taken from the Users Manual and is a good comparison to the examples on centered\_parameter\_study and vector\_parameter\_study.

```plaintext
# tested on Dakota 6.0 on 140501
environment
tabular\_data
tabular\_data\_file = 'rosen\_multidim.dat'
method
multidim\_parameter\_study
partitions = 10 8
model
single
variables
  continuous\_design = 2
  lower\_bounds -2.0 -2.0
  upper\_bounds 2.0 2.0
  descriptors 'x1' "x2"
interface
analysis\_driver = 'rosenbrock'
fork
responses
  response\_functions = 1
  no\_gradients
  no\_hessians
```

This example illustrates the full factorial combinations of parameter values created by the multidim\_parameter\_study. With 10 and 8 partitions, there are actually 11 and 9 values for each variable. This means that $11 \times 9 = 99$ function evaluations will be required.

</tr>
</tbody>
</table>

Description

Solution verification procedures estimate the order of convergence of the simulation response data during the course of a refinement study. This branch of methods is new and currently only contains one algorithm: Richardson extrapolation.

Refinement of the model

The model fidelity must be parameterized by one or more continuous state variable(s).

The refinement path is determined from the initial state of the continuous state variables specification in combination with the refinement rate, where each of the state variables is treated as an independent refinement factor and each of the initial state values is repeatedly divided by the refinement rate value to define new discretization states.

Results

Three algorithm options are currently provided:

1. estimate_order
2. converge_order
3. converge_qoi

Stopping Criteria

The method employs the max_iterations and convergence_tolerance method independent controls as stopping criteria.
Theory

In each of these cases, convergence order for a response quantity of interest (QoI) is estimated from

$$p = \ln \left( \frac{QoI_3 - QoI_2}{QoI_2 - QoI_1} \right) / \ln(r)$$

where $r$ is the uniform refinement rate specified by `refinement_rate`.

`estimate_order`

- **Keywords** Area
- **method**
- **richardson_extrap**
- **estimate_order**

Compute the best estimate of the convergence order from three points

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

The `estimate_order` option is the simplest option. For each of the refinement factors, it evaluates three points along the refinement path and uses these results to perform an estimate of the convergence order for each response function.

`converge_order`

- **Keywords** Area
- **method**
- **richardson_extrap**
- **converge_order**

Refine until the estimated coverage order converges

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

The `converge_order` option is initialized using the `estimate_order` approach, and additional refinements are performed along the refinement path until the convergence order estimates converge (two-norm of the change in response orders is less than the convergence tolerance).
converge_qoi

- Keywords Area
- method
- richardson_extrap
- converge_qoi

Refine until the response converges

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The `converge_qoi` option is similar to the `converge_order` option, except that the convergence criterion is that the two-norm of the response discretization errors (computed from extrapolation) must be less than the convergence tolerance.

refinement_rate

- Keywords Area
- method

**Default:** method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

**Usage Tips**

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

Examples

</tr>
<tr>
<td>Optional</td>
<td>variables_pointer</td>
<td></td>
<td>Specify which variables block will be included with this model block</td>
</tr>
</tbody>
</table>
### Description

A model is comprised of a mapping from variables, through an interface, to responses.

**Model Group 1** The type of model can be:

1. **single**
2. **nested**
3. **surrogate**

The input file must specify one of these types. If the type is not specified, Dakota will assume a single model.

**Block Pointers and ID**

Each of these model types supports `variables_pointer` and `responses_pointer` strings for identifying the variables and responses specifications used in constructing the model by cross-referencing with `id-variables` and `id-responses` strings from particular variables and responses keyword specifications.

These pointers are valid for each model type since each model contains a set of variables that is mapped into a set of responses – only the specifics of the mapping differ.

Additional pointers are used for each model type for constructing the components of the variable to response mapping. As an environment specification identifies a top-level method and a method specification identifies a model, a model specification identifies variables, responses, and (for some types) interface specifications. This top-down flow specifies all of the object interrelationships.

### Examples

The next example displays a surrogate model specification which selects a quadratic polynomial from among the global approximation methods. It uses a pointer to a design of experiments method for generating the data needed for building the global approximation, reuses any old data available for the current approximation region, and employs the first-order multiplicative approach to correcting the approximation each time correction is requested.
This example demonstrates the use of identifiers and pointers. It provides the optional model independent specifications for model identifier, variables pointer, and responses pointer as well as model dependent specifications for global surrogates (see \texttt{global}).

Finally, an advanced nested model example would be

\begin{verbatim}
model
  id_model = 'M1'
  variables_pointer = 'V1'
  responses_pointer = 'R1'
  nested
    optional_interface_pointer = 'OI1'
    optional_interface_responses_pointer = 'OIR1'
    sub_method_pointer = 'SM1'
    primary_variable_mapping = '' 'X' 'Y'
    secondary_variable_mapping = '' 'mean' 'mean'
    primary_response_mapping = 1.0 0.0 0.0 0.0 0.0 0.0 0.0
    secondary_response_mapping = 0.0 0.0 1.3 0.0 0.0 0.0 1.3 0.0
\end{verbatim}

This example also supplies model independent controls for model identifier, variables pointer, and responses pointer and supplies model dependent controls for specifying details of the nested mapping.

\section{id\_model}

- Keywords Area
- model
- id\_model

Give the model block an identifying name, in case of multiple model blocks

\section*{Topics}

This keyword is related to the topics:

- block\_identifier

\section*{Specification}

\textbf{Alias:} none
\textbf{Argument(s):} STRING
\textbf{Default:} method use of last model parsed
6.3. **MODEL**

**Description**

The model identifier string is supplied with *id_model* and is used to provide a unique identifier string for use within method specifications (refer to any of the keywords: *model_pointer* in under one of the methods in the *method* block, for example: *model_pointer*)

This is used to determine which model the method will run.

**See Also**

These keywords may also be of interest:

- *model_pointer*

6.3.2 **variables_pointer**

- **Keywords Area**
- *model*
- *variables_pointer*

Specify which variables block will be included with this model block

**Topics**

This keyword is related to the topics:

- *block_pointer*

**Specification**

Alias: none

**Argument(s):** STRING

**Default:** model use of last variables parsed

**Description**

The *variables_pointer* is used to specify which variables block will be used by the model, by cross-referencing with *id_variables* keyword in the *variables* block.

See *block_pointer* for details about pointers.

6.3.3 **responses_pointer**

- **Keywords Area**
- *model*
- *responses_pointer*

Specify which responses block will be used by this model block
CHAPTER 6. KEYWORDS AREA

Topics
This keyword is related to the topics:

- block_pointer

Specification
Alias: none
Argument(s): STRING
Default: model use of last responses parsed

Description
The responses_pointer is used to specify which responses block will be used by the model, by cross-referencing with id_responses keyword in the responses block.
See block_pointer for details about pointers.

6.3.4 hierarchical_tagging

- Keywords Area
- model
- hierarchical_tagging

Enables hierarchical evaluation tagging

Specification
Alias: none
Argument(s): none
Default: no hierarchical tagging

Description
The hierarchical tagging option is useful for studies involving multiple models with a nested or hierarchical relationship. For example a nested model has a sub-method, which itself likely operates on a sub-model, or a hierarchical approximation involves coordination of low and high fidelity models. Specifying hierarchical_tagging will yield function evaluation identifiers (“tags”) composed of the evaluation IDs of the models involved, e.g., outermodel.innermodel.interfaceid = 4.9.2. This communicates the outer contexts to the analysis driver when performing a function evaluation.

Examples
test/dakota_uq_timeseries_ivp_optinterf.in test/dakota_uq_timeseries_sop_optinterf.in

See Also
These keywords may also be of interest:

- file_tag model-nested
6.3.5 single

- **Keywords Area**
- **model**
- **single**

A model with one of each block: variable, interface, and response

### Specification

**Alias:** none

- **Argument(s):** none
- **Default:** N/A (single if no model specification)

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>interface_pointer</td>
<td>Interface block pointer for the single model type</td>
</tr>
</tbody>
</table>

### Description

The single model is the simplest model type. It uses a single interface instance to map variables into responses. There is no recursion in this case.

The optional `interface_pointer` specification identifies the interface block by cross-referencing with the `id_interface` string input from a particular interface keyword specification. This is only necessary when the input file has multiple interface blocks, and you wish to explicitly point to the desired block. The same logic follows for responses and variables blocks and pointers.

### Examples

The example shows a minimal specification for a single model, which is the default model when no models are specified by the user.

```plaintext
model
  single
```

This example does not provide any pointer strings and therefore relies on the default behavior of constructing the model with the last variables, interface, and responses specifications parsed.

### See Also

These keywords may also be of interest:

- **surrogate**
- **nested**
interface_pointer

• Keywords Area

• model

• single

• interface_pointer

Interface block pointer for the single model type

Topics

This keyword is related to the topics:

• block_pointer

Specification

Alias: none

Argument(s): STRING

Default: model use of last interface parsed

Description

In the single model case, a single interface is used to map the variables into responses. The optional interface-pointer specification identifies this interface by cross-referencing with the id_interface string input from a particular interface keyword specification.

See block_pointer for details about pointers.

6.3.6 surrogate

• Keywords Area

• model

• surrogate

An empirical model that is created from data or the results of a submodel

Specification

Alias: none

Argument(s): none
### Description

Surrogate models are inexpensive approximate models that are intended to capture the salient features of an expensive high-fidelity model. They can be used to explore the variations in response quantities over regions of the parameter space, or they can serve as inexpensive stand-ins for optimization or uncertainty quantification studies (see, for example, the surrogate-based optimization methods, surrogate_based_global and surrogate_based_local).

Surrogate models supported in Dakota are categorized as Data Fitting or Hierarchical, as shown below. Each of these surrogate types provides an approximate representation of a "truth" model which is used to perform the parameter to response mappings. This approximation is built and updated using results from the truth model, called the "training data".

- **Data fits:**
  
  Data fitting methods involve construction of an approximation or surrogate model using data (response values, gradients, and Hessians) generated from the original truth model. Data fit methods can be further categorized as local, multipoint, and global approximation techniques, based on the number of points used in generating the data fit.

1. **Local:** built from response data from a single point in parameter space
   
   - Taylor series expansion: taylor_series

### Dakota Supported Surrogate Types

<table>
<thead>

<td>hierarchical</td>
<td>Hierarchical approximations use corrected results from a low fidelity model as an approximation to the results of a high fidelity &quot;truth&quot; model.</td>
</tr>
</tbody>
</table>
Training data consists of a single point, plus gradient and Hessian information.

2. Multipoint: built from two or more points in parameter space, often involving the current and previous iterates of a minimization algorithm.
   - TANA-3: `tana`
     Training Data comes from a few previously evaluated points

3. Global full space response surface methods:
   - Polynomial regression: `polynomial`
   - Gaussian process (Kriging): `gaussian_process`
   - Artificial neural network: `neural_network`
   - MARS: `mars`
   - Radial Basis Functions: `radial_basis`
   - Orthogonal polynomials (only supported in PCE/SC for now): `polynomial_chaos` and `stoch_collocation`

   Training data is generated using either a design of experiments method applied to the truth model (specified by `dace_method_pointer`), or from saved data (specified by `reuse_points`) in a restart database, or an import file.

- Multiplicity/hierarchical:

  Multifidelity modeling involves the use of a low-fidelity physics-based model as a surrogate for the original high-fidelity model. The low-fidelity model typically involves a coarser mesh, looser convergence tolerances, reduced element order, or omitted physics.

  See `hierarchical`.

The global and hierarchical surrogates have a correction feature in order to improve the local accuracy of the surrogate models. The correction factors force the surrogate models to match the true function values and possibly true function derivatives at the center point of each trust region. Details can be found on global correction or hierarchical correction.

Theory

Surrogate models are used extensively in the surrogate-based optimization and least squares methods, in which the goals are to reduce expense by minimizing the number of truth function evaluations and to smooth out noisy data with a global data fit. However, the use of surrogate models is not restricted to optimization techniques; uncertainty quantification and optimization under uncertainty methods are other primary users.

Data Fit Surrogate Models

A surrogate of the `{data fit}` type is a non-physics-based approximation typically involving interpolation or regression of a set of data generated from the original model. Data fit surrogates can be further characterized by the number of data points used in the fit, where a local approximation (e.g., first or second-order Taylor series) uses data from a single point, a multipoint approximation (e.g., two-point exponential approximations (TPEA) or two-point adaptive nonlinearity approximations (TANA)) uses a small number of data points often drawn from the previous iterates of a particular algorithm, and a global approximation (e.g., polynomial response surfaces, kriging/gaussian_process, neural networks, radial basis functions, splines) uses a set of data points distributed over the domain of interest, often generated using a design of computer experiments.

Dakota contains several types of surface fitting methods that can be used with optimization and uncertainty quantification methods and strategies such as surrogate-based optimization and optimization under uncertainty. These are: polynomial models (linear, quadratic, and cubic), first-order Taylor series expansion, kriging spatial interpolation, artificial neural networks, multivariate adaptive regression splines, radial basis functions, and moving
least squares. With the exception of Taylor series methods, all of the above methods listed in the previous sentence are accessed in Dakota through the Surfpack library. All of these surface fitting methods can be applied to problems having an arbitrary number of design parameters. However, surface fitting methods usually are practical only for problems where there are a small number of parameters (e.g., a maximum of somewhere in the range of 30-50 design parameters). The mathematical models created by surface fitting methods have a variety of names in the engineering community. These include surrogate models, meta-models, approximation models, and response surfaces. For this manual, the terms surface fit model and surrogate model are used.

The data fitting methods in Dakota include software developed by Sandia researchers and by various researchers in the academic community.

Multifidelity Surrogate Models

A second type of surrogate is the \{model hierarchy\} type (also called multifidelity, variable fidelity, variable complexity, etc.). In this case, a model that is still physics-based but is of lower fidelity (e.g., coarser discretization, reduced element order, looser convergence tolerances, omitted physics) is used as the surrogate in place of the high-fidelity model. For example, an inviscid, incompressible Euler CFD model on a coarse discretization could be used as a low-fidelity surrogate for a high-fidelity Navier-Stokes model on a fine discretization.

Surrogate Model Selection

This section offers some guidance on choosing from among the available surrogate model types.

- For Surrogate Based Local Optimization, using the surrogate_based_local method with a trust region:
  
  using the keywords:
  
  1. surrogate local taylor_series or
  2. surrogate multipoint tana

  will probably work best.

  If for some reason you wish or need to use a global surrogate (not recommended) then the best of these options is likely to be either:

  1. surrogate global gaussian_process surfpack or
  2. surrogate global moving_least_squares.

- For Efficient Global Optimization (EGO), the efficient_global method:

  the default surrogate is: gaussian_process surfpack which is likely to find a more optimal value and/or require fewer true function evaluations than the alternative, gaussian_process dakota. However, the surfpack will likely take more time to build than the dakota version. Note that currently the use_derivatives keyword is not recommended for use with EGO based methods.

- For EGO based global interval estimation, the global_interval_est ego method:

  the default gaussian_process surfpack will likely work better than the alternative gaussian_process dakota.

- For Efficient Global Reliability Analysis (EGRA), the global_reliability method:

  the surfpack and dakota versions of the gaussian process tend to give similar answers with the dakota version tending to use fewer true function evaluations. Since this is based on EGO, it is likely that the default surfpack is more accurate, although this has not been rigorously demonstrated.

- For EGO based Dempster-Shafer Theory of Evidence, i.e. the global_evidence ego method, the default gaussian_process surfpack often use significantly fewer true function evaluations than the alternative gaussian_process dakota.

- When using a global surrogate to extrapolate, any of the surrogates:
- `gaussian_process surfpack`
- `polynomial quadratic`
- `polynomial cubic`

are recommended.

- When there is over roughly two or three thousand data points and you wish to interpolate (or approximately interpolate) then a Taylor series, Radial Basis Function Network, or Moving Least Squares fit is recommended. The only reason that the `gaussian_process surfpack` is not recommended is that it can take a considerable amount of time to construct when the number of data points is very large. Use of the third party MARS package included in Dakota is generally discouraged.

- In other situations that call for a global surrogate, the `gaussian_process surfpack` is generally recommended. The `use_derivatives` keyword will only be useful if accurate and inexpensive derivatives are available. Finite difference derivatives are disqualified on both counts. However, derivatives generated by analytical, automatic differentiation, or continuous adjoint techniques can be appropriate. Currently, first order derivatives, i.e. gradients, are the highest order derivatives that can be used to construct the `gaussian_process surfpack` model; Hessians will not be used even if they are available.

- `nested`

**id_surrogates**

- `Keywords Area`
- `model`
- `surrogate`
- `id_surrogates`

Identifies the subset of the response functions by number that are to be approximated (the default is all functions).

**Specification**

**Alias**: none  
**Argument(s)**: INTEGERLIST  
**Default**: All response functions are approximated

**Description**

In the `surrogate` model case, the specification first allows a mixture of surrogate and actual response mappings through the use of the optional `id_surrogates` specification. This identifies the subset of the response functions by number that are to be approximated (the default is all functions). The valid response function identifiers range from 1 through the total number of response functions (see `response_functions`).
6.3. MODEL

Select a surrogate model with global support

**Specification**

### Description

The global surrogate model requires specification of one of the following approximation types:

1. Polynomial
2. Gaussian process (Kriging interpolation)
3. Layered perceptron artificial neural network approximation
4. MARS
5. Moving least squares
6. Radial basis function
7. Voronoi Piecewise Surrogate (VPS)

All these approximations are implemented in SurfPack[36], except for VPS. In addition, a second version of Gaussian process is implemented directly in Dakota.

### Training Data

Training data can be taken from prior runs, stored in a datafile, or by running a Design of Experiments method. The keywords listed below are used to determine how to collect training data:

- `dace_method_pointer`
- `reuse_points`
- `import_points_file`
- `use_derivatives`

The source of training data is determined by the contents of a provided `import_points_file`, whether `reuse_points` and `use_derivatives` are specified, and the contents of the method block specified by `dace_method_pointer`. `use_derivatives` is a special case, the other keywords are discussed below.

The number of training data points used in building a global approximation is determined by specifying one of three point counts:

1. **minimum_points**: minimum required or minimum "reasonable" amount of training data. Defaults to `d+1` for `d` input dimensions for most models, e.g., polynomials override to the number of coefficients required to estimate the requested order.
2. **recommended_points**: recommended number of training data, (this is the default option, if none of the keywords is specified). Defaults to `5*d`, except for polynomials where it’s equal to the minimum.
3. total_points: specify the number of training data points. However, if the total_points value is less than the default minimum_points value, the minimum_points value is used.

The sources of training data depend on the number of training points, \(N_{tp}\), the number of points in the import file, \(N_{if}\), and the value of reuse_points.

- If there is no import file, all training data come from the DACE method
- If there is an import file, all \(N_{if}\) points from the file are used, and the remaining \(N_{tp} - N_{if}\) points come from the DACE method
- If there is an import file and reuse_points is:
  - none - all \(N_{tp}\) points from DACE method
  - region - only the points within a trust region are taken from the import file, and all remaining points are from the DACE method.
  - all - (Default) all \(N_{if}\) points from the file are used, and the remaining \(N_{tp} - N_{if}\) points come from the DACE method

**Surrogate Correction**
A correction model can be added to the constructed surrogate in order to better match the training data. The specified correction method will be applied to the surrogate, and then the corrected surrogate model is used by the method.

Finally, the quality of the surrogate can be tested using the metrics and challenge_points_file keywords.

**Theory**
Global methods, also referred to as response surface methods, involve many points spread over the parameter ranges of interest. These surface fitting methods work in conjunction with the sampling methods and design of experiments methods.

**Procedures for Surface Fitting**
The surface fitting process consists of three steps:

1. selection of a set of design points
2. evaluation of the true response quantities (e.g., from a user-supplied simulation code) at these design points,
3. using the response data to solve for the unknown coefficients (e.g., polynomial coefficients, neural network weights, kriging correlation factors) in the surface fit model.

In cases where there is more than one response quantity (e.g., an objective function plus one or more constraints), then a separate surface is built for each response quantity. Currently, the surface fit models are built using only 0\(^{th}\)-order information (function values only), although extensions to using higher-order information (gradients and Hessians) are possible.

Each surface fitting method employs a different numerical method for computing its internal coefficients. For example, the polynomial surface uses a least-squares approach that employs a singular value decomposition to compute the polynomial coefficients, whereas the kriging surface uses Maximum Likelihood Estimation to compute its correlation coefficients. More information on the numerical methods used in the surface fitting codes is provided in the Dakota Developers Manual.

- dakota

Select the built in Gaussian Process surrogate
A second version of GP surrogates was available in prior versions of Dakota. **For now, both versions are supported but the **dakota** version is deprecated and intended to be removed in a future release.**

Historically these models were drastically different, but in Dakota 5.1, they became quite similar. They now differ in that the Surfpack GP has a richer set of features/options and tends to be more accurate than the Dakota version. Due to how the Surfpack GP handles ill-conditioned correlation matrices (which significantly contributes to its greater accuracy), the Surfpack GP can be a factor of two or three slower than Dakota’s. As of Dakota 5.2, the Surfpack implementation is the default in all contexts except Bayesian calibration.

More details on the **gaussian_process** dakota model can be found in[58].

Dakota’s GP deals with ill-conditioning in two ways. First, when it encounters a non-invertible correlation matrix it iteratively increases the size of a “nugget,” but in such cases the resulting approximation smooths rather than interpolates the data. Second, it has a **point_selection** option (default off) that uses a greedy algorithm to select a well-spaced subset of points prior to the construction of the GP. In this case, the GP will only interpolate the selected subset. Typically, one should not need point selection in trust-region methods because a small number of points are used to develop a surrogate within each trust region. Point selection is most beneficial when constructing with a large number of points, typically more than order one hundred, though this depends on the number of variables and spacing of the sample points.

This differs from the **point_selection** option of the Dakota GP which initially chooses a well-spaced subset of points and finds the correlation parameters that are most likely for that one subset.

**point_selection**

6.3. MODEL

<table>
<thead>
<tr>
<th>Optional</th>
<th>export_model_file</th>
<th>Export surrogate to Surfpack model file</th>
</tr>
</thead>
</table>

**Description**

This keyword specifies the use of the Gaussian process that is incorporated in our surface fitting library called Surfpack.

Several user options are available:

1. **Optimization methods:**
   
   Maximum Likelihood Estimation (MLE) is used to find the optimal values of the hyper-parameters governing the trend and correlation functions. By default, the global optimization method DIRECT is used for MLE, but other options for the optimization method are available. See `optimization_method`.

   The total number of evaluations of the likelihood function can be controlled using the `max_trials` keyword followed by a positive integer. Note that the likelihood function does not require running the "truth" model, and is relatively inexpensive to compute.

2. **Trend Function:**
   
   The GP models incorporate a parametric trend function whose purpose is to capture large-scale variations. See `trend`.

3. **Correlation Lengths:**
   
   Correlation lengths are usually optimized by Surfpack, however, the user can specify the lengths manually. See `correlation_lengths`.

4. **Ill-conditioning**
   
   One of the major problems in determining the governing values for a Gaussian process or Kriging model is the fact that the correlation matrix can easily become ill-conditioned when there are too many input points close together. Since the predictions from the Gaussian process model involve inverting the correlation matrix, ill-conditioning can lead to poor predictive capability and should be avoided.

   Note that a sufficiently bad sample design could require correlation lengths to be so short that any interpolatory GP model would become inept at extrapolation and interpolation.

   The `surfpack` model handles ill-conditioning internally by default, but behavior can be modified using `surfpack_model`.

5. **Gradient Enhanced Kriging (GEK).**
   
   The `use_derivatives` keyword will cause the Surfpack GP to be constructed from a combination of function value and gradient information (if available).

   See notes in the Theory section.

**Theory**

**Gradient Enhanced Kriging**

Incorporating gradient information will only be beneficial if accurate and inexpensive derivative information is available, and the derivatives are not infinite or nearly so. Here "inexpensive" means that the cost of evaluating a function value plus gradient is comparable to the cost of evaluating only the function value, for example gradients computed by analytical, automatic differentiation, or continuous adjoint techniques. It is not cost effective to use derivatives computed by finite differences. In tests, GEK models built from finite difference derivatives were also
significantly less accurate than those built from analytical derivatives. Note that GEK’s correlation matrix tends to have a significantly worse condition number than Kriging for the same sample design.

This issue was addressed by using a pivoted Cholesky factorization of Kriging’s correlation matrix (which is a small sub-matrix within GEK’s correlation matrix) to rank points by how much unique information they contain. This reordering is then applied to whole points (the function value at a point immediately followed by gradient information at the same point) in GEK’s correlation matrix. A standard non-pivoted Cholesky is then applied to the reordered GEK correlation matrix and a bisection search is used to find the last equation that meets the constraint on the (estimate of) condition number. The cost of performing pivoted Cholesky on Kriging’s correlation matrix is usually negligible compared to the cost of the non-pivoted Cholesky factorization of GEK’s correlation matrix. In tests, it also resulted in more accurate GEK models than when pivoted Cholesky or whole-point-block pivoted Cholesky was performed on GEK’s correlation matrix.

```

Change the optimization method used to compute hyperparameters

**Specification**

**Alias:** none

**Argument(s):** STRING

**Default:** global

**Description**

Select the optimization method to compute hyperparameters of the Gaussian Process by specifying one of these arguments:

- global (default) - DIRECT method
- local - CONMIN method
- sampling - generates several random guesses and picks the candidate with greatest likelihood
- none - no optimization, pick the center of the feasible region

The none option, and the starting location of the local optimization, default to the center, in log(correlation length) scale, of the of feasible region.

Surfpack picks a small feasible region of correlation parameters.

Note that we have found the global optimization method to be the most robust.
max_trials

- gaussian_process
- surfpack
- nugget

Specify a nugget to handle ill-conditioning

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** None
Description

By default, the Surfpack GP handles ill-conditioning and does not use a nugget. If the user wishes to specify a nugget, there are two approaches.

- The user can specify the value of a nugget with `nugget`.
- Have Surfpack find the optimal value of the nugget. This is specified by `find_nugget`. There are two options for `find_nugget`.
  - `find_nugget = 1`: assume that the reciprocal condition number of the correlation matrix R, rcondR, is zero and calculate the nugget needed to make the worst case of R not ill-conditioned.
  - `find_nugget = 2`: calculate rcondR, which requires a Cholesky factorization. If rcondR indicates that R is not ill-conditioned, then kriging uses the Cholesky factorization. Otherwise, if rcondR says R is ill conditioned, then kriging will calculate the nugget needed to make the worst case of R not ill-conditioned.

`find_nugget = 1` and `2` are similar, the second option just takes more computation (the initial Cholesky factorization) for larger problems.

`find_nugget`

CHAPTER 6. KEYWORDS AREA

Description
This surface fitting method uses multivariate adaptive regression splines from the MARS3.5 package[27] developed at Stanford University.

The MARS reference material does not indicate the minimum number of data points that are needed to create a MARS surface model. However, in practice it has been found that at least $n_{\text{quad}}$, and sometimes as many as 2 to 4 times $n_{\text{quad}}$, data points are needed to keep the MARS software from terminating. Provided that sufficient data samples can be obtained, MARS surface models can be useful in SBO and OUU applications, as well as in the prediction of global trends throughout the parameter space.

Theory
The form of the MARS model is based on the following expression:

$$\hat{f}(x) = \sum_{m=1}^{M} a_m B_m(x)$$

where the $a_m$ are the coefficients of the truncated power basis functions $B_m$, and $M$ is the number of basis functions. The MARS software partitions the parameter space into subregions, and then applies forward and backward regression methods to create a local surface model in each subregion. The result is that each subregion contains its own basis functions and coefficients, and the subregions are joined together to produce a smooth, $C^2$-continuous surface model.

MARS is a nonparametric surface fitting method and can represent complex multimodal data trends. The regression component of MARS generates a surface model that is not guaranteed to pass through all of the response data values. Thus, like the quadratic polynomial model, it provides some smoothing of the data.

max.bases

</tr>
</tbody>
</table>

Description

Moving least squares is a further generalization of weighted least squares where the weighting is "moved" or recalculated for every new point where a prediction is desired[64].

**The implementation of moving least squares is still under development.** It tends to work well in trust region optimization methods where the surrogate model is constructed in a constrained region over a few points. The present implementation may not work as well globally.
CHAPTER 6. KEYWORDS AREA

Theory

Moving Least Squares can be considered a more specialized version of linear regression models. In linear regression, one usually attempts to minimize the sum of the squared residuals, where the residual is defined as the difference between the surrogate model and the true model at a fixed number of points.

In weighted least squares, the residual terms are weighted so the determination of the optimal coefficients governing the polynomial regression function, denoted by \( \hat{f}(x) \), are obtained by minimizing the weighted sum of squares at \( N \) data points:

\[
\sum_{n=1}^{N} w_n (\| \hat{f}(x_n) - f(x_n) \|)
\]

poly_order

</table>

**Description**

Dakota’s artificial neural network surrogate is a stochastic layered perceptron network, with a single hidden layer. Weights for the input layer are chosen randomly, while those in the hidden layer are estimated from data using a variant of the Zimmerman direct training approach[92].

This typically yields lower training cost than traditional neural networks, yet good out-of-sample performance. This is helpful in surrogate-based optimization and optimization under uncertainty, where multiple surrogates may be repeatedly constructed during the optimization process, e.g., a surrogate per response function, and a new surrogate for each optimization iteration.

The neural network is a non parametric surface fitting method. Thus, along with Kriging (Gaussian Process) and MARS, it can be used to model data trends that have slope discontinuities as well as multiple maxima and minima. However, unlike Kriging, the neural network surrogate is not guaranteed to interpolate the data from which it was constructed.

This surrogate can be constructed from fewer than $n_{\text{quad}}$ data points, however, it is a good rule of thumb to use at least $n_{\text{quad}}$ data points when possible.
6.3. MODEL

Theory

The form of the neural network model is

\[ \hat{f}(x) \approx \tanh \left\{ A_1 \tanh \left( A_0^T x + \theta_0^T \right) + \theta_1 \right\} \]

where \( x \) is the evaluation point in \( n \)-dimensional parameter space; the terms \( A_0, \theta_0 \) are the random input layer weight matrix and bias vector, respectively; and \( A_1, \theta_1 \) are a weight vector and bias scalar, respectively, estimated from training data. These coefficients are analogous to the polynomial coefficients obtained from regression to training data. The neural network uses a cross validation-based orthogonal matching pursuit solver to determine the optimal number of nodes and to solve for the weights and offsets.

**max_nodes**

- Keywords Area
- model
- surrogate
- global
- neural_network
- max_nodes

Maximum number of hidden layer nodes

Topics

This keyword is related to the topics:

- surrogate_models

Specification

**Alias:** nodes

**Argument(s):** INTEGER

**Default:** numTrainingData - 1

Description

Limits the maximum number of hidden layer nodes in the neural network model. The default is to use one less node than the number of available training data points yielding a fully-determined linear least squares problem. However, reducing the number of nodes can help reduce overfitting and more importantly, can drastically reduce surrogate construction time when building from a large data set. (Historically, Dakota limited the number of nodes to 100.)

The keyword `max_nodes` provides an upper bound. Dakota’s orthogonal matching pursuit algorithm may further reduce the effective number of nodes in the final model to achieve better generalization to unseen points.

### Description

Radial basis functions $\phi$ are functions whose value typically depends on the distance from a center point, called the centroid, $c$.

The surrogate model approximation comprises a sum of $K$ weighted radial basis functions:

$$\hat{f}(x) = \sum_{k=1}^{K} w_k \phi(\|x - c_k\|)$$

These basis functions take many forms, but Gaussian kernels or splines are most common. The Dakota implementation uses a Gaussian radial basis function. The weights are determined via a linear least squares solution approach. See[67] for more details.

**Description**

Linear, quadratic, and cubic polynomial surrogate models are available in Dakota. The utility of the simple polynomial models stems from two sources:

- over a small portion of the parameter space, a low-order polynomial model is often an accurate approximation to the true data trends
- the least-squares procedure provides a surface fit that smooths out noise in the data.

Local surrogate-based optimization methods ([surrogate_based_local](#)) are often successful when using polynomial models, particularly quadratic models. However, a polynomial surface fit may not be the best choice for modeling data trends globally over the entire parameter space, unless it is known a priori that the true data trends are close to linear, quadratic, or cubic. See [63](#) for more information on polynomial models.

**Theory**

The form of the linear polynomial model is

\[
\hat{f}(\mathbf{x}) \approx c_0 + \sum_{i=1}^n c_i x_i
\]

the form of the quadratic polynomial model is:

\[
\hat{f}(\mathbf{x}) \approx c_0 + \sum_{i=1}^n c_i x_i + \sum_{i=1}^n \sum_{j \geq i} c_{ij} x_i x_j
\]

and the form of the cubic polynomial model is:

\[
\hat{f}(\mathbf{x}) \approx c_0 + \sum_{i=1}^n c_i x_i + \sum_{i=1}^n \sum_{j \geq i} c_{ij} x_i x_j + \sum_{i=1}^n \sum_{j \geq i} \sum_{k \geq j} c_{ijk} x_i x_j x_k
\]
In all of the polynomial models, $\hat{f}(x)$ is the response of the polynomial model; the $x_i, x_j, x_k$ terms are the components of the $n$-dimensional design parameter values; the $c_0, c_i, c_{ij}, c_{ijk}$ terms are the polynomial coefficients, and $n$ is the number of design parameters. The number of coefficients, $n_c$, depends on the order of polynomial model and the number of design parameters. For the linear polynomial:

$$n_{c_{\text{linear}}} = n + 1$$

for the quadratic polynomial:

$$n_{c_{\text{quad}}} = \frac{(n + 1)(n + 2)}{2}$$

and for the cubic polynomial:

$$n_{c_{\text{cubic}}} = \frac{(n^3 + 6n^2 + 11n + 6)}{6}$$

There must be at least $n_c$ data samples in order to form a fully determined linear system and solve for the polynomial coefficients. In Dakota, a least-squares approach involving a singular value decomposition numerical method is applied to solve the linear system.

<td></td>
<td>cell.type</td>
<td>Type of the Geometric Cells Used for the Piecewise Decomposition Option of Global Surrogates</td>
</tr>
</tbody>
</table>
### Description

Most regression techniques use all available sample points to approximate the underlying function anywhere in the domain. An alternative option is to use piecewise decomposition to locally approximate the function at some point using a few sample points from its neighborhood.

This option currently supports Polynomial Regression, Gaussian Process (GP) Interpolation, and Radial Basis Functions (RBF) Regression. It requires a decomposition cell type (currently set to be Voronoi cells), an optional number of support layers of neighbors, and optional discontinuity detection parameters (jump/gradient).

**cell_type**

- Keywords Area
- model
- surrogate
- global
- piecewise_decomposition
- cell_type

Type of the Geometric Cells Used for the Piecewise Decomposition Option of Global Surrogates

### Specification

Alias: none

**Argument(s):** STRING

### Description

The piecewise decomposition option for global surrogates is used to locally approximate a function at some point using a few sample points from its neighborhood.

This option requires a decomposition cell type that can vary from structured grid boxes, to geometric Voronoi cells. Currently, this option only supports Voronoi cells.
6.3. MODEL

**support_layers**
- Keywords Area
- model
- surrogate
- global
- piecewise_decomposition
- support_layers

Optional Number of Support Layers for the Piecewise Decomposition Option of Global Surrogates

**Specification**

*Alias:* none

*Argument(s):* INTEGER

**Description**

The piecewise decomposition option for global surrogates is used to locally approximate a function at some point using a few sample points from its neighborhood.

The neighborhood of a cell is parameterized via a number of support layers. The (default) 0th layer contains only the direct neighbors of the cell. The 1st layer includes neighbors of the direct neighbors, etc.

**discontinuity_detection**

## Description

The piecewise decomposition option for global surrogates is used to locally approximate a function at some point using a few sample points from its neighborhood.

The domain decomposition algorithm supports an optional discontinuity detection capability where seeds across a user-input discontinuity threshold can not be considered neighbors, splitting the domain into patches that trap discontinuities between their edges. This capability is specified by either a jump threshold value or a gradient threshold one.

### jump_threshold

Gradient Threshold Parameter of the Optional Discontinuity Detection Capability for the Piecewise Decomposition Option of Global Surrogates
6.3. MODEL

Specification

Alias: none
    Argument(s): REAL

Description

The piecewise decomposition option for global surrogates is used to locally approximate a function at some point using a few sample points from its neighborhood.

The domain decomposition algorithm supports an optional discontinuity detection capability where seeds across a user-input discontinuity threshold can not be considered neighbors, splitting the domain into patches that trap discontinuities between their edges. This capability can be specified using a gradient threshold value.

gradient_threshold

- Keywords Area
- model
- surrogate
- global
- piecewise_decomposition
- discontinuity_detection
- gradient_threshold

Gradient Threshold Parameter of the Optional Discontinuity Detection Capability for the Piecewise Decomposition Option of Global Surrogates

Specification

Alias: none
    Argument(s): REAL

Description

The piecewise decomposition option for global surrogates is used to locally approximate a function at some point using a few sample points from its neighborhood.

The domain decomposition algorithm supports an optional discontinuity detection capability where seeds across a user-input discontinuity threshold can not be considered neighbors, splitting the domain into patches that trap discontinuities between their edges. This capability can be specified using a gradient threshold value.

total_points

- Keywords Area
- model
- surrogate
- global
- total_points

Specified number of training points
**Specification**

*Alias*: none

*Argument(s)*: INTEGER

*Default*: recommended_points

**Description**

See parent page.

**minimum_points**

- Keywords Area
- model
- surrogate
- global
- minimum_points

Construct surrogate with minimum number of points

**Specification**

*Alias*: none

*Argument(s)*: none

**Description**

The minimum is d+1, for d input dimensions, except for polynomials. See parent page.

**recommended_points**

- Keywords Area
- model
- surrogate
- global
- recommended_points

Construct surrogate with recommended number of points

**Specification**

*Alias*: none

*Argument(s)*: none
6.3. MODEL

Description
This is the default option. It requires 5*d build points for d input dimensions, except for polynomial models. See parent page.

dace_method_pointer
- Keywords Area
- model
- surrogate
- global
- dace_method_pointer
  Specify a method to gather training data

Topics
This keyword is related to the topics:
- block_pointer

Specification
Alias: none
Argument(s): STRING
Default: no design of experiments data

Description
The number of training points and the sources are specified on global, as well as the number of new training points required.
New training points are gathered by running the “truth” model using the method specified by dace_method_pointer. The DACE method will only be invoked if it has new samples to perform, and if new samples are required and no DACE iterator has been provided, an error will result.
The dace_method_pointer points to design of experiments method block used to generate truth model data.
Permissible methods include: Monte Carlo (random) sampling, Latin hypercube sampling, orthogonal array sampling, central composite design sampling, and Box-Behnken sampling.
Note that the number of samples specified in the method block may be overwritten, if the requested number of samples is less than minimum_points.

actual_model_pointer
- Keywords Area
- model
- surrogate
- global
• actual_model_pointer

A surrogate model pointer that guides a method to whether it should use a surrogate model or compute truth function evaluations

**Specification**

**Alias:** none

**Argument(s):** STRING

**Description**

Dakota methods use global surrogate models to compute surrogate function approximations. They also need to know the true function evaluations. A global surrogate model now must have an actual_model_pointer keyword to decide for the method whether to evaluate the global surrogate model, or compute the true function evaluations if actual_model_pointer = TRUTH.

**reuse_points**

• Keywords Area

• model

• surrogate

• global

• reuse_points

Surrogate model training data reuse control

**Topics**

This keyword is related to the topics:

• surrogate_models

**Specification**

**Alias:** reuse_samples

**Argument(s):** none

**Default:** all for import; none otherwise

<table>
<thead>
<tr>
<th>Required/-Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required (Choose One)</td>
<td>all</td>
<td>region</td>
<td>Option for reuse_points</td>
</tr>
</tbody>
</table>
Description

Dakota’s global surrogate methods rely on training data, which can either come from evaluation of a “truth” model, which is generated by the method specified with dace_method_pointer, from a file of existing training data, identified by import_points_file, or both.

The reuse_points keyword controls the amount of training data used in building a surrogate model, either initially, or during iterative rebuild, as in surrogate-based optimization. If import_points_file is specified, reuse_points controls how the file contents are used. If used during iterative rebuild, it controls what data from previous surrogate builds is reused in building the current model.

- all (default for file import) - use all points in the file or available from previous builds
- region - use only the points falling in the current trust region (see surrogate_based_local)
- none (default when no import) - ignore the contents of the file or previous build points, and gather new training data using the specified DACE method

Specification

Alias: none

Argument(s): none

Description

This is described on the parent page.
• reuse_points
• region

Option for reuse_points

**Specification**

import_points_file

• Keywords Area
• model
• surrogate
• global
• import_points_file

File containing variable values and corresponding responses
6.3. MODEL

Specification

Alias: samples_file
  Argument(s): STRING
  Default: no point import from a file
### Description

The `import_points_file` allows the user to specify a file that contains a list of variable values and the model responses computed at those values. These can be used by a number of methods in place of model evaluations. When used to construct surrogate models or emulators these are often called build points or training data.

**Default Behavior**

Be default, methods do not import points from a file.

**Usage Tips**

Dakota parses input files without regard to whitespace, but the `import_points_file` must be in one of three formats:

- `annotated` (default)
- `custom_annotated`
- `freeform`

### Examples

```dakota
method
  list_parameter_study
    import_points_file = 'dakota_pstudy.3.dat'
```

- `annotated`
  - Keywords Area
  - model
  - surrogate
  - global
  - `import_points_file`
  - `annotated`
    Selects annotated tabular file format
6.3. MODEL

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Default: annotated

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```environment
tabular_data
  tabular_data_file = 'dakota_summary.dat'
annotated
```

Resulting tabular file:

```
%eval_id interface x1   x2  obj_fn nln_ineq_con_1 nln_ineq_con_2
1  NO_ID 0.9   1.1   0.0002 0.26   0.76
2  NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3  NO_ID 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...```
custom.annotated

- Keywords Area
- model
- surrogate
- global
- import.points_file
- custom.annotated

Selects custom-annotated tabular file format

**Topics**

This keyword is related to the topics:

- file.formats

**Specification**

Alias: none

Argument(s): none

<table>
<thead>
<tr>
<th>Required/-</th>
<th>Description of</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>Group</td>
<td>header</td>
<td>Description</td>
</tr>
</tbody>
</table>

| Optional | eval.id | Enable evaluation ID column in custom-annotated tabular file |
| Optional | interface.id | Enable interface ID column in custom-annotated tabular file |

**Description**

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval.id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

**Default Behavior**

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom.annotated, followed by options, in the relevant export/import context.

**Usage Tips**
Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```plaintext
environment
    tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id  x1  x2  obj_fn  nln_ineq_con_1  nln_ineq_con_2
1  0.9  1.1  0.0002  0.26  0.76
2  0.90009  1.1  0.0001996404857  0.2601620081  0.759955

freeform

- Keywords Area
- model
- surrogate
- global
- import_points_file
- freeform

Selects freeform file format

Topics
This keyword is related to the topics:

- fileFormats

Specification

Alias: none
Argument(s): none
Default: annotated

Description
A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior
The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.
Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```python
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
freeform

Resulting tabular file:

<p>| | | | |</p>

```

active_only

- Keywords Area
- model
- surrogate
- global
- import_points_file
- active_only

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

Description
A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior
The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips
• Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.
6.3. **MODEL**

**Examples**

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```python
environment
    tabular_data
        tabular_data_file = 'dakota_summary.dat'
freeform
```

Resulting tabular file:

<table>

- **surrogate**
- **global**
- **use_derivatives**

Use derivative data to construct surrogate models

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** use function values only

**Description**

The **use_derivatives** flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, it’s use with Surfpack Gaussian process is not recommended.

**Correction**

Correction approaches for surrogate models
**Specification**

**Alias:** none

- **Argument(s):** none
- **Default:** no surrogate correction
### Description

Some of the surrogate model types support the use of correction factors that improve the local accuracy of the surrogate models.

The correction specification specifies that the approximation will be corrected to match truth data, either matching truth values in the case of zeroth order matching, matching truth values and gradients in the case of first order matching, or matching truth values, gradients, and Hessians in the case of second order matching. For additive and multiplicative corrections, the correction is local in that the truth data is matched at a single point, typically the center of the approximation region. The additive correction adds a scalar offset (zeroth order), a linear function (first order), or a quadratic function (second order) to the approximation to match the truth data at the point, and the multiplicative correction multiplies the approximation by a scalar (zeroth order), a linear function (first order), or a quadratic function (second order) to match the truth data at the point. The additive first order case is due to [57] and the multiplicative first order case is commonly known as beta correction [40]. For the combined correction, the use of both additive and multiplicative corrections allows the satisfaction of an additional matching condition, typically the truth function values at the previous correction point (e.g., the center of the previous trust region). The combined correction is then a multipoint correction, as opposed to the local additive and multiplicative corrections. Each of these correction capabilities is described in detail in [24].

The correction factors force the surrogate models to match the true function values and possibly true function

derivatives at the center point of each trust region. Currently, Dakota supports either zeroth-, first-, or second-order accurate correction methods, each of which can be applied using either an additive, multiplicative, or combined correction function. For each of these correction approaches, the correction is applied to the surrogate model and the corrected model is then interfaced with whatever algorithm is being employed. The default behavior is that no correction factor is applied.

The simplest correction approaches are those that enforce consistency in function values between the surrogate and original models at a single point in parameter space through use of a simple scalar offset or scaling applied to the surrogate model. First-order corrections such as the first-order multiplicative correction (also known as beta correction[15]) and the first-order additive correction[57] also enforce consistency in the gradients and provide a much more substantial correction capability that is sufficient for ensuring provable convergence in SBO algorithms. SBO convergence rates can be further accelerated through the use of second-order corrections which also enforce consistency in the Hessians[24], where the second-order information may involve analytic, finite-difference, or quasi-Newton Hessians.

Correcting surrogate models with additive corrections involves

$$\hat{f}_{hi}(x) = f_{lo}(x) + \alpha(x)$$

(6.1)

where multifidelity notation has been adopted for clarity. For multiplicative approaches, corrections take the form

$$\hat{f}_{hi,i}(x) = f_{lo}(x)\beta(x)$$

(6.2)

where, for local corrections, $\alpha(x)$ and $\beta(x)$ are first or second-order Taylor series approximations to the exact correction functions:

$$\alpha(x) = A(x_c) + \nabla A(x_c)^T(x - x_c) + \frac{1}{2}(x - x_c)^T\nabla^2 A(x_c)(x - x_c)$$

(6.3)

$$\beta(x) = B(x_c) + \nabla B(x_c)^T(x - x_c) + \frac{1}{2}(x - x_c)^T\nabla^2 B(x_c)(x - x_c)$$

(6.4)

where the exact correction functions are

$$A(x) = f_{hi}(x) - f_{lo}(x)$$

(6.5)

$$B(x) = \frac{f_{hi}(x)}{f_{lo}(x)}$$

(6.6)

Refer to[24] for additional details on the derivations.

A combination of additive and multiplicative corrections can provide for additional flexibility in minimizing the impact of the correction away from the trust region center. In other words, both additive and multiplicative corrections can satisfy local consistency, but through the combination, global accuracy can be addressed as well. This involves a convex combination of the additive and multiplicative corrections:

$$\hat{f}_{hi,i}(x) = \gamma \hat{f}_{hi,\alpha}(x) + (1 - \gamma) \hat{f}_{hi,\beta}(x)$$

where $\gamma$ is calculated to satisfy an additional matching condition, such as matching values at the previous design iterate.

It should be noted that in both first order correction methods, the function $\hat{f}(x)$ matches the function value and gradients of $f_{i}(x)$ at $x = x_c$. This property is necessary in proving that the first order-corrected SBO algorithms are provably convergent to a local minimum of $f_{i}(x)$. However, the first order correction methods are significantly more expensive than the zeroth order correction methods, since the first order methods require computing both $\nabla f_{i}(x_c)$ and $\nabla f_{s}(x_c)$. When the SBO strategy is used with either of the zeroth order correction methods, or
with no correction method, convergence is not guaranteed to a local minimum of $f_i(x)$. That is, the SBO strategy becomes a heuristic optimization algorithm. From a mathematical point of view this is undesirable, but as a practical matter, the heuristic variants of SBO are often effective in finding local minima.

**Usage guidelines**

- Both the additive zeroth order and multiplicative zeroth order correction methods are "free" since they use values of $f_i(x_c)$ that are normally computed by the SBO strategy.
- The use of either the additive first order method or the multiplicative first order method does not necessarily improve the rate of convergence of the SBO algorithm.
- When using the first order correction methods, the gradient-related response keywords must be modified to allow either analytic or numerical gradients to be computed. This provides the gradient data needed to compute the correction function.
- For many computationally expensive engineering optimization problems, gradients often are too expensive to obtain or are discontinuous (or may not exist at all). In such cases the heuristic SBO algorithm has been an effective approach at identifying optimal designs[35].

**zeroth order**

- Keywords Area

<tr>
<td>Optional</td>
<td></td>
<td>press</td>
<td>Leave-one-out cross validation</td>
</tr>
</tbody>
</table>

Description

A variety of diagnostic metrics are available to assess the goodness of fit of a global surrogate to its training data. The default diagnostics are:

- root_mean_squared
- mean_abs
- rsquared

Additional available diagnostics include
6.3. MODEL

- sum_squared
- mean_squared
- sum_abs
- max_abs

The keywords press and cross_validation further specify leave-one-out or k-fold cross validation, respectively, for all of the active metrics from above.

Theory

Most of these diagnostics refer to some operation on the residuals (the difference between the surrogate model and the truth model at the data points upon which the surrogate is built).

For example, sum_squared refers to the sum of the squared residuals, and mean_abs refers to the mean of the absolute value of the residuals. rsquared refers to the R-squared value typically used in regression analysis (the proportion of the variability in the response that can be accounted for by the surrogate model). Care should be taken when interpreting metrics, for example, errors may be near zero for interpolatory models or rsquared may not be applicable for non-polynomial models.

cross_validation

- Keywords Area
- model
- surrogate
- global
- metrics
- cross_validation

Perform k-fold cross validation

Topics

</table>

## Description

General k-fold cross validation may be performed by specifying `cross_validation`. The cross-validation statistics will be calculated for all metrics.

Cross validation may further specify:

- `folds`, the number of folds into which to divide the build data (between 2 and number of data points) or
- `percent`, the fraction of data (between 0 and 0.5) to use in each fold.

These will be adjusted as needed based on the number of available training points. The default number of folds $k = 10$, or 0.1

### folds

- **Keywords Area**

**Description**

Specifies a data file containing variable and response (truth) values, in one of three formats:

- annotated (default)
- custom_annotated
- freeform

The surrogate is evaluated at the points in the file, and the surrogate (approximate) responses are compared against the truth results from the file. All metrics specified with metrics will be computed for the challenge data.
annotated

- **Keywords Area**
- **model**
- **surrogate**
- **global**
- **challenge_points_file**
- **annotated**

Selects annotated tabular file format

**Topics**

This keyword is related to the topics:

- **file_formats**

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** annotated

**Description**

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

**Default Behavior**

By default, Dakota imports and exports tabular files in annotated format. The `annotated` keyword can be used to explicitly specify this.

**Usage Tips**

- To specify pre-Dakota 6.1 tabular format, which did not include `interface_id`, specify `custom_annotated header eval_id`

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to `annotated format`, though `freeform` remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.
Examples
Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```python
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
annotated

Resulting tabular file:
%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1  NO_ID  0.9 1.1 0.0002 0.26 0.76
2  NO_ID  0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3  NO_ID  0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...

custom_annotated
```

- Keywords Area
- model
- surrogate
- global
- challenge_points_file
- custom_annotated

Selects custom-annotated tabular file format

Topics
This keyword is related to the topics:

- file_formats

Specification
Alias: none

<table>
<thead>
<tr>

<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>header</td>
<td></td>
<td>Enable header row in custom-annotated tabular file</td>
</tr>
</tbody>
</table>
A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

**Default Behavior**

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

**Usage Tips**

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

**Examples**

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```plaintext
evironment
  tabular_data
  tabular_data_file = 'dakota_summary.dat'
custom_annotated header eval_id
```

Resulting tabular file:

<table>
<thead>
<tr>
<th>eval_id</th>
<th>x1</th>
<th>x2</th>

Import only active variables from tabular data file

**Topics**

This keyword is related to the topics:

- **file_formats**
6.3. MODEL

Specification

Alias: none  
Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

multipoint

<td>actual_model_pointer</td>
<td>Pointer to specify a &quot;truth&quot; model, from which to construct a surrogate</td>
</tr>
</tbody>
</table>

Description

Multipoint approximations use data from previous design points to improve the accuracy of local approximations. The data often comes from the current and previous iterates of a minimization algorithm.

Currently, only the Two-point Adaptive Nonlinearity Approximation (TANA-3) method of [91] is supported with the `tana` keyword.

The truth model to be used to generate the value/gradient data used in the approximation is identified through the required `actual_model_pointer` specification.

- multipoint
- tana

Local multi-point model via two-point nonlinear approximation

Specification
Alias: none

Argument(s): none

Description
TANA stands for Two Point Adaptive Nonlinearity Approximation. The TANA-3 method\[91\] is a multipoint approximation method based on the two point exponential approximation\[25\]. This approach involves a Taylor series approximation in intermediate variables where the powers used for the intermediate variables are selected to match information at the current and previous expansion points.

Theory
The form of the TANA model is:

\[
\hat{f}(x) \approx f(x_2) + \sum_{i=1}^{n} \frac{\partial f}{\partial x_i}(x_2) \frac{x_i^{1-p_i}}{p_i} (x_i^{p_i} - x_{i,2}^{p_i}) + \frac{1}{2} \epsilon(x) \sum_{i=1}^{n} (x_i^{p_i} - x_{i,2}^{p_i})^2
\]

where \( n \) is the number of variables and:

\[
p_i = 1 + \ln \left( \frac{\frac{\partial f}{\partial x_2}(x_1)}{\frac{\partial f}{\partial x_1}(x_2)} \right) \ln \left( \frac{x_{i,1}}{x_{i,2}} \right) \epsilon(x) = \frac{H}{\sum_{i=1}^{n} (x_i^{p_i} - x_{i,1}^{p_i})^2 + \sum_{i=1}^{n} (x_i^{p_i} - x_{i,2}^{p_i})^2} H = 2 \left[ f(x_1) - f(x_2) - \sum_{i=1}^{n} \frac{\partial f}{\partial x_i}(x_2) x_{i,2}^{1-p_i} (x_i^{1-p_i} - x_{i,2}^{p_i}) \right]
\]

and \( x_2 \) and \( x_1 \) are the current and previous expansion points. Prior to the availability of two expansion points, a first-order Taylor series is used.
actual_model_pointer

- Keywords Area
- model
- surrogate
- multipoint
- actual_model_pointer

Pointer to specify a "truth" model, from which to construct a surrogate

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none
Argument(s): STRING

Description

This must point to a model block, identified by id_model. That model will be run to generate training data, from which a surrogate model will be constructed.

See block_pointer for details about pointers.

Argument(s): none
**Description**

Local approximations use value, gradient, and possibly Hessian data from a single point to form a series expansion for approximating data in the vicinity of this point.

The currently available local approximation is the `taylor_series` selection.

The truth model to be used to generate the value/gradient/Hessian data used in the series expansion is identified through the required `actual_model_pointer` specification. The use of a model pointer (as opposed to an interface pointer) allows additional flexibility in defining the approximation. In particular, the derivative specification for the truth model may differ from the derivative specification for the approximation, and the truth model results being approximated may involve a model recursion (e.g., the values/gradients from a nested model).

- model
- surrogate
- local
- `taylor_series`

Construct a Taylor Series expansion around a point

**Specification**

Alias: none

Argument(s): none
Description

The Taylor series model is purely a local approximation method. That is, it provides local trends in the vicinity of a single point in parameter space.

The order of the Taylor series may be either first-order or second-order, which is automatically determined from the gradient and Hessian specifications in the responses specification (see responses for info on how to specify gradients and Hessians) for the truth model.

Theory

The first-order Taylor series expansion is:

\[ \hat{f}(x) \approx f(x_0) + \nabla_x f(x_0)^T (x - x_0) \]  \hspace{1cm} (6.7)

and the second-order expansion is:

\[ \hat{f}(x) \approx f(x_0) + \nabla_x f(x_0)^T (x - x_0) + \frac{1}{2} (x - x_0)^T \nabla^2_x f(x_0) (x - x_0) \]  \hspace{1cm} (6.8)

where \( x_0 \) is the expansion point in \( n \)-dimensional parameter space and \( f(x_0) \), \( \nabla_x f(x_0) \), and \( \nabla^2_x f(x_0) \) are the computed response value, gradient, and Hessian at the expansion point, respectively.

As dictated by the responses specification used in building the local surrogate, the gradient may be analytic or numerical and the Hessian may be analytic, numerical, or based on quasi-Newton secant updates.

In general, the Taylor series model is accurate only in the region of parameter space that is close to \( x_0 \). While the accuracy is limited, the first-order Taylor series model reproduces the correct value and gradient at the point \( x_0 \), and the second-order Taylor series model reproduces the correct value, gradient, and Hessian. This consistency is useful in provably-convergent surrogate-based optimization. The other surface fitting methods do not use gradient information directly in their models, and these methods rely on an external correction procedure in order to satisfy the consistency requirements of provably-convergent SBO.

Description

Hierarchical approximations use corrected results from a low fidelity model as an approximation to the results of a high fidelity "truth" model. These approximations are also known as model hierarchy, multifidelity, variable fidelity, and variable complexity approximations. The required `low_fidelity_model_pointer` specification points to the low fidelity model specification. This model is used to generate low fidelity responses which are then corrected and returned to an iterator. The required `high_fidelity_model_pointer` specification points to the specification for the high fidelity truth model. This model is used only for verifying low fidelity results and updating low fidelity corrections. The correction specification specifies which correction technique will be applied to the low fidelity results in order to match the high fidelity results at one or more points. In the hierarchical case (as compared to the global case), the correction specification is required, since the omission of a correction technique would effectively eliminate the purpose of the high fidelity model. If it is desired to use a low fidelity model without corrections, then a hierarchical approximation is not needed and a single model should be used. Refer to global for additional information on available correction approaches.
Theory

Multifidelity Surrogates: Multifidelity modeling involves the use of a low-fidelity physics-based model as a surrogate for the original high-fidelity model. The low-fidelity model typically involves a coarser mesh, looser convergence tolerances, reduced element order, or omitted physics. It is a separate model in its own right and does not require data from the high-fidelity model for construction. Rather, the primary need for high-fidelity evaluations is for defining correction functions that are applied to the low-fidelity results.

Multifidelity Surrogate Models

A second type of surrogate is the \{model hierarchy\} type (also called multifidelity, variable fidelity, variable complexity, etc.). In this case, a model that is still physics-based but is of lower fidelity (e.g., coarser discretization, reduced element order, looser convergence tolerances, omitted physics) is used as the surrogate in place of the high-fidelity model. For example, an inviscid, incompressible Euler CFD model on a coarse discretization could be used as a low-fidelity surrogate for a high-fidelity Navier-Stokes model on a fine discretization.

Correction approaches for surrogate models

**Specification**

Alias: none

**Argument(s):** none

**Default:** no surrogate correction
Description

Some of the surrogate model types support the use of correction factors that improve the local accuracy of the surrogate models.

The correction specification specifies that the approximation will be corrected to match truth data, either matching truth values in the case of zeroth_order matching, matching truth values and gradients in the case of first_order matching, or matching truth values, gradients, and Hessians in the case of second_order matching. For additive and multiplicative corrections, the correction is local in that the truth data is matched at a single point, typically the center of the approximation region. The additive correction adds a scalar offset (zeroth_order), a linear function (first_order), or a quadratic function (second_order) to the approximation to match the truth data at the point, and the multiplicative correction multiplies the approximation by a scalar (zeroth_order), a linear function (first_order), or a quadratic function (second_order) to match the truth data at the point. The additive first_order case is due to[57] and the multiplicative first_order case is commonly known as beta correction[40]. For the combined correction, the use of both additive and multiplicative corrections allows the satisfaction of an additional matching condition, typically the truth function values at the previous correction point (e.g., the center of the previous trust region). The combined correction is then a multipoint correction, as opposed to the local additive and multiplicative corrections. Each of these correction capabilities is described in detail in[24].

The correction factors force the surrogate models to match the true function values and possibly true function derivatives at the center point of each trust region. Currently, Dakota supports either zeroth-, first-, or second-order accurate correction methods, each of which can be applied using either an additive, multiplicative, or combined
correction function. For each of these correction approaches, the correction is applied to the surrogate model and the corrected model is then interfaced with whatever algorithm is being employed. The default behavior is that no correction factor is applied.

The simplest correction approaches are those that enforce consistency in function values between the surrogate and original models at a single point in parameter space through use of a simple scalar offset or scaling applied to the surrogate model. First-order corrections such as the first-order multiplicative correction (also known as beta correction\[15\]) and the first-order additive correction\[57\] also enforce consistency in the gradients and provide a much more substantial correction capability that is sufficient for ensuring provable convergence in SBO algorithms. SBO convergence rates can be further accelerated through the use of second-order corrections which also enforce consistency in the Hessians\[24\], where the second-order information may involve analytic, finite-difference, or quasi-Newton Hessians.

Correcting surrogate models with additive corrections involves

\[
\hat{f}_{hi}(\mathbf{x}) = f_{lo}(\mathbf{x}) + \alpha(\mathbf{x})
\]

(6.9)

where multifidelity notation has been adopted for clarity. For multiplicative approaches, corrections take the form

\[
\hat{f}_{hi}(\mathbf{x}) = f_{lo}(\mathbf{x}) \beta(\mathbf{x})
\]

(6.10)

where, for local corrections, \(\alpha(\mathbf{x})\) and \(\beta(\mathbf{x})\) are first or second-order Taylor series approximations to the exact correction functions:

\[
\alpha(\mathbf{x}) = A(\mathbf{x}_c) + \nabla A(\mathbf{x}_c)^T (\mathbf{x} - \mathbf{x}_c) + \frac{1}{2} (\mathbf{x} - \mathbf{x}_c)^T \nabla^2 A(\mathbf{x}_c)(\mathbf{x} - \mathbf{x}_c)
\]

(6.11)

\[
\beta(\mathbf{x}) = B(\mathbf{x}_c) + \nabla B(\mathbf{x}_c)^T (\mathbf{x} - \mathbf{x}_c) + \frac{1}{2} (\mathbf{x} - \mathbf{x}_c)^T \nabla^2 B(\mathbf{x}_c)(\mathbf{x} - \mathbf{x}_c)
\]

(6.12)

where the exact correction functions are

\[
A(\mathbf{x}) = f_{hi}(\mathbf{x}) - f_{lo}(\mathbf{x})
\]

(6.13)

\[
B(\mathbf{x}) = \frac{f_{hi}(\mathbf{x})}{f_{lo}(\mathbf{x})}
\]

(6.14)

Refer to\[24\] for additional details on the derivations.

A combination of additive and multiplicative corrections can provide for additional flexibility in minimizing the impact of the correction away from the trust region center. In other words, both additive and multiplicative corrections can satisfy local consistency, but through the combination, global accuracy can be addressed as well. This involves a convex combination of the additive and multiplicative corrections:

\[
f_{hi,\gamma}(\mathbf{x}) = \gamma f_{hi}(\mathbf{x}) + (1 - \gamma) f_{hi,\beta}(\mathbf{x})
\]

where \(\gamma\) is calculated to satisfy an additional matching condition, such as matching values at the previous design iterate.

It should be noted that in both first order correction methods, the function \(\hat{f}(\mathbf{x})\) matches the function value and gradients of \(f_{lo}(\mathbf{x})\) at \(x = x_c\). This property is necessary in proving that the first order-corrected SBO algorithms are provably convergent to a local minimum of \(f_{lo}(\mathbf{x})\). However, the first order correction methods are significantly more expensive than the zeroth order correction methods, since the first order methods require computing both \(\nabla f_{lo}(x_c)\) and \(\nabla f_{lo}(x_c)\). When the SBO strategy is used with either of the zeroth order correction methods, or with no correction method, convergence is not guaranteed to a local minimum of \(f_{lo}(\mathbf{x})\). That is, the SBO strategy becomes a heuristic optimization algorithm. From a mathematical point of view this is undesirable, but as a practical matter, the heuristic variants of SBO are often effective in finding local minima.

**Usage guidelines**
Both the additive zeroth order and multiplicative zeroth order correction methods are “free” since they use values of \( f_i(x_c) \) that are normally computed by the SBO strategy.

The use of either the additive first order method or the multiplicative first order method does not necessarily improve the rate of convergence of the SBO algorithm.

When using the first order correction methods, the gradient-related response keywords must be modified to allow either analytic or numerical gradients to be computed. This provides the gradient data needed to compute the correction function.

For many computationally expensive engineering optimization problems, gradients often are too expensive to obtain or are discontinuous (or may not exist at all). In such cases the heuristic SBO algorithm has been an effective approach at identifying optimal designs[35].

<td>Pointer to interface that provides non-nested responses</td>
</tr>
<tr>
<td>Required</td>
<td></td>
<td>sub_method_pointer</td>
<td>The sub_method_pointer specifies the method block for the sub-iterator</td>
</tr>
</tbody>
</table>

**Description**

Instead of appealing directly to a primary interface, a nested model maps variables to responses by executing a secondary iterator, or a "sub-iterator". In other words, a function evaluation of the primary study consists of a solution of an entire secondary study - potentially many secondary function evaluations.

The sub-iterator in turn operates on a sub-model. The sub-iterator responses may be combined with non-nested contributions from an optional interface specification.

A **sub_method_pointer** must be provided in order to specify the method block describing the sub-iterator. The remainder of the model is specified under that keyword.

A **optional_interface_pointer points** to the interface specification and **optional_interface_responses_pointer points** to a responses specification describing the data to be returned by this interface). This interface is used to provide non-nested data, which is then combined with data from the nested iterator using the **primary_response_mapping** and **secondary_response_mapping** inputs (see mapping discussion below).

**Examples**

An example of variable and response mappings is provided below:

```plaintext
primary_variable_mapping = ' ' ' ' ' X ' ' Y '
secondary_variable_mapping = ' ' ' ' ' mean ' mean '
primary_response_mapping = 1. 0. 0. 0. 0. 0. 0. 0. 0.
secondary_response_mapping = 0. 0. 0. 1. 3. 0. 0. 0. 0.
```
The variable mappings correspond to 4 top-level variables, the first two of which employ the default mappings from active top-level variables to sub-model variables of the same type (option 3 above) and the latter two of which are inserted into the mean distribution parameters of sub-model variables 'X' and 'Y' (option 1 above). The response mappings define a 3 by 9 matrix corresponding to 9 inner loop response attributes and 3 outer loop response functions (one primary response function and 2 secondary functions, such as one objective and two constraints). Each row of the response mapping is a vector which is multiplied (i.e., with a dot-product) against the 9 sub-iterator values to determine the outer loop function. Consider a UQ example with 3 response functions, each providing a mean, a standard deviation, and one level mapping (if no level mappings are specified, the responses would only have a mean and standard deviation). The primary response mapping can be seen to extract the first value from the inner loop, which would correspond to the mean of the first response function. This mapped sub-iterator response becomes a single objective function, least squares term, or generic response function at the outer level, as dictated by the top-level response specification. The secondary response mapping maps the fourth sub-iterator response function plus 3 times the fifth sub-iterator response function (mean plus 3 standard deviations) into one top-level nonlinear constraint and the seventh sub-iterator response function plus 3 times the eighth sub-iterator response function (mean plus 3 standard deviations) into another top-level nonlinear constraint, where these top-level nonlinear constraints may be inequality or equality, as dictated by the top-level response specification. Note that a common case is for each sub-iterator response to be mapped to a unique outer loop response (for example, in the nested UQ case where one wants to determine an interval on each inner loop statistic). In these simple cases, the response mapping would define an identity matrix.

### Description

The `sub_method_pointer` specifies the method block for the sub-iterator. See `block_pointer` for details about pointers.

Nested models may employ mappings for both the variable inputs to the sub-model and the response outputs from the sub-model. In the former case, the `primary_variable_mapping` and `secondary_variable_mapping` specifications are used to map from the active top-level variables into the sub-model variables, and in the latter case, the `primary_response_mapping` and `secondary_response_mapping` specifications are used to compute the sub-model response contributions to the top-level responses.

For the variable mappings, the primary and secondary specifications provide lists of strings which are used to target specific sub-model variables and their sub-parameters, respectively. The primary strings are matched to continuous or discrete variable labels such as `cdv_1` (either user-supplied or default labels), and the secondary strings are matched to either real or integer random variable distribution parameters such as `mean` or `num_trials` (the form of the uncertain distribution parameter keyword that is appropriate for a single variable instance) or continuous or discrete design/state variable sub-parameters such as `lower_bound` or `upper_bound` (again, keyword form appropriate for a single variable instance). No coercion of types is supported, so real-valued top-level variables should map to either real-valued sub-model variables or real-valued sub-parameters and integer-valued top-level variables should map to either integer-valued sub-model variables or integer-valued sub-parameters. As long as these real versus integer constraints are satisfied, mappings are free to cross variable types (design, aleatory uncertain, epistemic uncertain, state) and domain types (continuous, discrete). Both `primary_variable_mapping` and `secondary_variable_mapping` specifications are optional, which is designed to support the following three possibilities:

1. If both primary and secondary variable mappings are specified, then an active top-level variable value will be inserted into the identified sub-parameter (the secondary mapping) for the identified sub-model variable (the primary mapping).

2. If a primary mapping is specified but a secondary mapping is not, then an active top-level variable value will be inserted into the identified sub-model variable value (the primary mapping).

3. If a primary mapping is not specified (corresponding secondary mappings, if specified, are ignored), then an active top-level variable value will be inserted into a corresponding sub-model variable, based on matching of variable types (e.g., top-level and sub-model variable specifications both allocate a set of `continuous_design` variables which are active at the top level). Multiple sub-model variable types may be updated in this manner, provided that they are all active in the top-level variables. Since there is a direct variable correspondence for these default insertions, sub-model bounds and labels are also updated.
from the top-level bounds and labels in order to eliminate the need for redundant input file specifications. Thus, it is typical for the sub-model variables specification to only contain the minimal required information, such as the number of variables, for these insertion targets. The sub-model must allocate enough space for each of the types that will accept default insertions, and the leading set of matching sub-model variables are updated (i.e., the sub-model may allocate more than needed and the trailing set will be unmodified).

These different variable mapping possibilities may be used in any combination by employing empty strings ("") for particular omitted mappings (the number of strings in user-supplied primary and secondary variable mapping specifications must equal the total number of active top-level variables, including both continuous and discrete types). The ordering of the active variables is the same as shown in dakota.input.summary on Input Spec Summary and as presented in variables.

If inactive variables are present at the outer level, then the default type 3 mapping is used for these variables; that is, outer loop inactive variables are inserted into inner loop variables (active or inactive) based on matching of variable types, top-level bounds and labels are also propagated, the inner loop must allocate sufficient space to receive the outer loop values, and the leading subset within this inner loop allocation is updated. This capability is important for allowing nesting beyond two levels, since an active variable at the outer-most loop may become inactive at the next lower level, but still needs to be further propagated down to lower levels in the recursion.

For the response mappings, the primary and secondary specifications provide real-valued multipliers to be applied to sub-iterator response results so that the responses from the inner loop can be mapped into a new set of responses at the outer loop. For example, if the nested model is being employed within a mixed aleatory-epistemic uncertainty quantification, then aleatory statistics from the inner loop (such as moments of the response) are mapped to the outer level, where minima and maxima of these aleatory statistics are computed as functions of the epistemic parameters. The response mapping defines a matrix which scales the values from the inner loop and determines their position in the outer loop response vector. Each row of the mapping corresponds to one outer loop response, where each column of the mapping corresponds to a value from the inner loop. Depending on the number of responses and the particular attributes calculated on the inner loop, there will be a vector of inner loop response values that need to be accounted for in the mapping. This vector of inner loop response results is defined as follows for different sub-iterator types:

- optimization: the final objective function(s) and nonlinear constraints
- nonlinear least squares: the final least squares terms and nonlinear constraints
- aleatory uncertainty quantification (UQ): for each response function, a mean statistic, a standard deviation statistic, and all probability/reliability/generalized reliability/response level results for any user-specified response_levels,probability_levels,reliability_levels,and/or gen_reliability_levels, in that order.
- epistemic and mixed aleatory/epistemic UQ using interval estimation methods: lower and upper interval bounds for each response function.
- epistemic and mixed aleatory/epistemic UQ using evidence methods: for each response function, lower and upper interval bounds (belief and plausibility) for all probability/reliability/generalized reliability/response level results computed from any user-specified response_levels,probability_levels,reliability_levels,and/or gen_reliability_levels, in that order.
- parameter studies and design of experiments: for optimization and least squares response data sets, the best solution found (lowest constraint violation if infeasible, lowest composite objective function if feasible). For generic response data sets, a best solution metric is not defined, so the sub-iterator response vector is empty in this case.
The primary values map sub-iterator response results into top-level objective functions, least squares terms, or generic response functions, depending on the declared top-level response set. The secondary values map sub-iterator response results into top-level nonlinear inequality and equality constraints.

Nested models utilize a sub-iterator and a sub-model to perform a complete iterative study as part of every evaluation of the model. This sub-iteration accepts variables from the outer level, performs the sub-level analysis, and computes a set of sub-level responses which are passed back up to the outer level. Mappings are employed for both the variable inputs to the sub-model and the response outputs from the sub-model.

In the variable mapping case, primary and secondary variable mapping specifications are used to map from the top-level variables into the sub-model variables. These mappings support three possibilities in any combination: (1) insertion of an active top-level variable value into an identified sub-model distribution parameter for an identified active sub-model variable, (2) insertion of an active top-level variable value into an identified active sub-model variable value, and (3) addition of an active top-level variable value as an inactive sub-model variable, augmenting the active sub-model variables.

In the response mapping case, primary and secondary response mapping specifications are used to map from the sub-model responses back to the top-level responses. These specifications provide real-valued multipliers that are applied to the sub-iterator response results to define the outer level response set. These nested data results may be combined with non-nested data through use of the "optional interface" component within nested models.

The nested model constructs admit a wide variety of multi-iterator, multi-model solution approaches. For example, optimization within optimization (for hierarchical multidisciplinary optimization), uncertainty quantification within uncertainty quantification (for second-order probability), uncertainty quantification within optimization (for optimization under uncertainty), and optimization within uncertainty quantification (for uncertainty of optima) are all supported, with and without surrogate model indirection. Several examples of nested model usage are provided in the Users Manual, most notably mixed epistemic-aleatory UQ, optimization under uncertainty (OUU), and surrogate-based UQ.

**iterator_servers**

Specify the number of iterator servers when Dakota is run in parallel

**Topics**

This keyword is related to the topics:

- concurrency_and_parallelism

**Specification**

**Alias:** none

**Argument(s):** INTEGER
6.3. MODEL

Description
An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional iterator_servers specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, hybrid, multi_start, and pareto_set component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [4] for additional information.

iterator_scheduling
- Keywords Area
- model
- nested
- sub_method_pointer
- iterator_scheduling

Specify the scheduling of concurrent iterators when Dakota is run in parallel.

Topics
This keyword is related to the topics:
- concurrency_and_parallelism

Specification
Alias: none
Argument(s): none

| Required/- | Description of | Dakota Keyword | Dakota Keyword |
|-----------| Group 1 | master | peer |
| Optional  |     | | |
| Required(Choose One) | | Specify a dedicated master partition for parallel iterator scheduling | Specify a peer partition for parallel iterator scheduling |

Description
An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional iterator_scheduling specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, hybrid, multi_start, and pareto_set component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [4] for additional information.
master

• Keywords Area
• model
• nested
• sub_method_pointer
• iterator_scheduling
• master

Specify a dedicated master partition for parallel iterator scheduling

Topics
This keyword is related to the topics:

• concurrency_and_parallelism

Specification
Alias: none
Argument(s): none

Description
This option overrides the Dakota parallel automatic configuration, forcing the use of a dedicated master partition. In a dedicated master partition, one processor (the “master”) dynamically schedules work on the iterator servers. This reduces the number of processors available to create servers by 1.

peer

• Keywords Area
• model
• nested
• sub_method_pointer
• iterator_scheduling
• peer

Specify a peer partition for parallel iterator scheduling

Topics
This keyword is related to the topics:

• concurrency_and_parallelism
6.3. MODEL

Specification

Alias: none
Argument(s): none

Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a peer partition. In a peer partition, all processors are available to be assigned to iterator servers. Note that unlike the case of evaluation-scheduling, it is not possible to specify static or dynamic.

processors_per_iterator

- Keywords Area
- model
- nested
- sub_method_pointer
- processors_per_iterator

Specify the number of processors per iterator server when Dakota is run in parallel.

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none
Argument(s): INTEGER

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional processors_per_iterator specification supports user override of the automatic parallel configuration for the number of processors in each iterator server. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired server size at the iterator parallelism level. Currently, hybrid, multi_start, and pareto_set component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual[4] for additional information.

primary_variable_mapping

- Keywords Area
- model
- nested
Primary mapping of top-level variables to sub-model variables

**Specification**

**Alias:** none

**Argument(s):** STRINGLIST

**Default:** default variable insertions based on variable type

**Description**

The primary_variable_mapping, secondary_variable_mapping, primary_response_mapping, and secondary_response_mapping keywords control how top-level variables and responses are mapped to variables and responses in the sub-model. Their usage is explained on the parent keyword (sub_method_pointer) page.

**secondary_variable_mapping**

- Keywords Area
- model
- nested
- sub_method_pointer
- secondary_variable_mapping

Secondary mapping of top-level variables to sub-model variables

**Specification**

**Alias:** none

**Argument(s):** STRINGLIST

**Default:** primary mappings into sub-model variables are value-based

**Description**

The primary_variable_mapping, secondary_variable_mapping, primary_response_mapping, and secondary_response_mapping keywords control how top-level variables and responses are mapped to variables and responses in the sub-model. Their usage is explained on the parent keyword (sub_method_pointer) page.
6.3. MODEL

primary_response_mapping

- Keywords Area
- model
- nested
- sub_method_pointer
- primary_response_mapping

Primary mapping of sub-model responses to top-level responses

Specification

Alias: none

Argument(s): REALLIST

Default: no sub-iterator contribution to primary functions

Description

The primary_variable_mapping, secondary_variable_mapping, primary_response_mapping, and secondary_response_mapping keywords control how top-level variables and responses are mapped to variables and responses in the sub-model. Their usage is explained on the parent keyword (sub_method-pointer) page.

secondary_response_mapping

- Keywords Area
- model
- nested
- sub_method_pointer
- secondary_response_mapping

Secondary mapping of sub-model responses to top-level responses

Specification

Alias: none

Argument(s): REALLIST

Default: no sub-iterator contribution to secondary functions

Description

The primary_variable_mapping, secondary_variable_mapping, primary_response_mapping, and secondary_response_mapping keywords control how top-level variables and responses are mapped to variables and responses in the sub-model. Their usage is explained on the parent keyword (sub_method-pointer) page.
6.4 variables

- Keywords Area
- variables

Specifies the parameter set to be iterated by a particular method.

6.4. VARIABLES

| Optional | discrete_state_set | Set-valued discrete state variables |

**Description**

The variables specification in a Dakota input file specifies the parameter set to be iterated by a particular method.

In the case of

- An optimization study:
  - These variables are adjusted in order to locate an optimal design.

- Parameter studies/sensitivity analysis/design of experiments:
  - These parameters are perturbed to explore the parameter space.

- Uncertainty analysis:
  - The variables are associated with distribution/interval characterizations which are used to compute corresponding distribution/interval characterizations for response functions.

To accommodate these different studies, Dakota supports different:

- Variable types
  - design
  - aleatory uncertain
  - epistemic uncertain
  - state

- Variable domains
  - continuous
  - discrete
    - discrete range
    - discrete integer set
    - discrete string set
    - discrete real set

Use the variables page to browse the available variables by type and domain.

**Variable Types**

- Design Variables
  - Design variables are those variables which are modified for the purposes of computing an optimal design.
  - The most common type of design variables encountered in engineering applications are of the continuous type. These variables may assume any real value within their bounds.
  - All but a handful of the optimization algorithms in Dakota support continuous design variables exclusively.
• Aleatory Uncertain Variables
  – Aleatory uncertainty is also known as inherent variability, irreducible uncertainty, or randomness.
  – Aleatory uncertainty is predominantly characterized using probability theory. This is the only option implemented in Dakota.

• Epistemic Uncertain Variables
  – Epistemic uncertainty is uncertainty due to lack of knowledge.
  – In Dakota, epistemic uncertainty is characterized by interval analysis or the Dempster-Shafer theory of evidence.
  – Note that epistemic uncertainty can also be modeled with probability density functions (as done with aleatory uncertainty). Dakota does not support this capability.

• State Variables
  – State variables consist of ”other” variables which are to be mapped through the simulation interface, in that they are not to be used for design and they are not modeled as being uncertain.
  – State variables provide a convenient mechanism for managing additional model parameterizations such as mesh density, simulation convergence tolerances, and time step controls.
  – Only parameter studies and design of experiments methods will iterate on state variables.
  – The initial_value is used as the only value for the state variable for all other methods, unless active state is invoked.
  – See more details on the state_variables page.

Variable Domains
Continuous variables are defined by bounds. Discrete variables can be defined in one of three ways, which are discussed on the page discrete_variables.

Ordering of Variables
The ordering of variables is important, and a consistent ordering is employed throughout the Dakota software. The ordering is shown in dakota.input.summary and can be summarized as:

1. design
   (a) continuous
   (b) discrete integer
   (c) discrete string
   (d) discrete real

2. aleatory uncertain
   (a) continuous
   (b) discrete integer
   (c) discrete string
   (d) discrete real

3. epistemic uncertain
   (a) continuous
6.4. VARIABLES

(b) discrete integer
(c) discrete string
(d) discrete real

4. state
(a) continuous
(b) discrete integer
(c) discrete string
(d) discrete real

Ordering of variable types below this granularity (e.g., from normal to histogram bin within aleatory uncertain
- continuous ) is defined somewhat arbitrarily, but is enforced consistently throughout the code.

Active Variables
The reason variable types exist is that methods have the capability to treat variable types differently. All
methods have default behavior that determines which variable types are “active” and will be assigned values by
the method. For example, optimization methods will only vary the design variables - by default.
The default behavior should be described on each method page, or on topics pages that relate to classes of
methods. In addition, the default behavior can be modified using the active keyword.

Examples
Several examples follow. In the first example, two continuous design variables are specified:

variables,
  continuous_design = 2
  initial_point 0.9 1.1
  upper_bounds 5.8 2.9
  lower_bounds 0.5 -2.9
  descriptors ‘radius’ ‘location’

In the next example, defaults are employed. In this case, initial_point will default to a vector of 0.
values, upper_bounds will default to vector values of DBL_MAX (the maximum number representable in double
precision for a particular platform, as defined in the platform’s float.h C header file), lower_bounds will
default to a vector of -DBL_MAX values, and descriptors will default to a vector of ’cdv_i’ strings, where
i ranges from one to two:

variables,
  continuous_design = 2

In the following example, the syntax for a normal-lognormal distribution is shown. One normal and one
lognormal uncertain variable are completely specified by their means and standard deviations. In addition, the
dependence structure between the two variables is specified using the uncertain_correlation_matrix.

variables,
  normal_uncertain = 1
  means = 1.0
  std_deviations = 1.0
  descriptors = ’TF1n’
  lognormal_uncertain = 1
  means = 2.0
  std_deviations = 0.5
  descriptors = ’TF2ln’
  uncertain_correlation_matrix = 1.0 0.2
                                0.2 1.0
An example of the syntax for a state variables specification follows:

```plaintext
variables,
    continuous_state = 1
    initial_state  4.0
    lower_bounds  0.0
    upper_bounds  8.0
    descriptors   'CS1'
    discrete_state_range = 1
    initial_state 104
    lower_bounds 100
    upper_bounds 110
    descriptors 'DS1'

And in a more advanced example, a variables specification containing a set identifier, continuous and discrete design variables, normal and uniform uncertain variables, and continuous and discrete state variables is shown:

```plaintext
variables,
    id_variables = 'V1'
    continuous_design = 2
        initial_point 0.9 1.1
        upper_bounds 5.8 2.9
        lower_bounds 0.5 -2.9
        descriptors 'radius' 'location'
    discrete_design_range = 1
        initial_point 2
        upper_bounds 1
        lower_bounds 3
        descriptors 'material'
    normal_uncertain = 2
        means = 248.89, 593.33
        std_deviations = 12.4, 29.7
        descriptors = 'TF1n' 'TF2n'
    uniform_uncertain = 2
        lower_bounds = 199.3, 474.63
        upper_bounds = 298.5, 712.
        descriptors = 'TF1u' 'TF2u'
    continuous_state = 2
        initial_state = 1.e-4 1.e-6
        descriptors = 'EPSIT1' 'EPSIT2'
    discrete_state_set_int = 1
        initial_state = 100
        set_values = 100 212 375
        descriptors = 'load_case'
```

**Topics**

This keyword is related to the topics:

- block_pointer
6.4. VARIABLES

Specification

Alias: none

Argument(s): STRING

Default: use of last variables parsed

Description

The optional set identifier specification uses the keyword id:variables to input a unique string for use in identifying a particular variables set. A model can then identify the use of this variables set by specifying the same string in its variables:pointer specification.

If the id:variables specification is omitted, a particular variables set will be used by a model only if that model omits specifying a variables:pointer and if the variables set was the last set parsed (or is the only set parsed). In common practice, if only one variables set exists, then id:variables can be safely omitted from the variables specification and variables:pointer can be omitted from the model specification(s), since there is no potential for ambiguity in this case.

Examples

For example, a model whose specification contains variables:pointer = 'V1' will use a variables specification containing the set identifier id:variables = 'V1'.

**Description**

There are certain situations where the user may want to explicitly control the subset of variables that is considered active for a certain Dakota method. This is done by specifying the keyword `active` in the variables specification block, followed by one of the following: `all`, `design`, `uncertain`, `aleatory`, `epistemic`, or `state`. Specifying one of these subsets of variables will allow the Dakota method to operate on the specified variable types and override the default active subset.

If the user does not specify any explicit override of the active view of the variables, Dakota first considers the response function specification.

- If the user specifies objective functions or calibration terms in the response specification block, then we can infer that the active variables should be the design variables (since design variables are used within optimization and least squares methods).
- If the user instead specifies the generic response type of `response_functions`, then Dakota cannot infer the active variable subset from the response specification and will instead infer it from the method selection.

1. If the method is a parameter study, or any of the methods available under dace, psuade, or fsu methods, the active view is set to all variables.
2. For uncertainty quantification methods, if the method is sampling, then the view is set to aleatory if only aleatory variables are present, epistemic if only epistemic variables are present, or uncertain (covering both aleatory and epistemic) if both are present.
3. If the uncertainty method involves interval estimation or evidence calculations, the view is set to epistemic.
4. For other uncertainty quantification methods not mentioned in the previous sentences (e.g., reliability methods or stochastic expansion methods), the default view is set to aleatory.
5. Finally, for verification studies using the Richardson extrapolation method, the active view is set to state.
6. Note that in surrogate-based optimization, where the surrogate is built on points defined by the method defined by the `dace_method_pointer`, the sampling used to generate the points is performed only over the design variables as a default unless otherwise specified (e.g., state variables will not be sampled for surrogate construction).

As alluded to in the previous section, the iterative method selected for use in Dakota determines what subset, or view, of the variables data is active in the iteration. The general case of having a mixture of various different types of variables is supported within all of the Dakota methods even though certain methods will only modify certain types of variables (e.g., optimizers and least squares methods only modify design variables, and uncertainty quantification methods typically only utilize uncertain variables). This implies that variables which are not under
the direct control of a particular iterator will be mapped through the interface in an unmodified state. This allows
for a variety of parameterizations within the model in addition to those which are being used by a particular
iterator, which can provide the convenience of consolidating the control over various modeling parameters in a
single file (the Dakota input file). An important related point is that the variable set that is active with a particular
iterator is the same variable set for which derivatives are typically computed.

Examples
For example, the default behavior for a nondeterministic sampling method is to sample the uncertain variables.
However, if the user specified `active all` in the variables specification block, the sampling would be performed
over all variables (e.g. design and state variables in addition to the uncertain variables). This may be desired in
situations such as surrogate-based optimization under uncertainty, where a surrogate may be constructed to span
both design and uncertain variables. This is an example where we expand the active subset beyond the default, but
in other situations, we may wish to restrict from the default. An example of this would be performing design of
experiments in the presence of multiple variable types (for which all types are active by default), but only wanting
to sample over the design variables for purposes of constructing a surrogate model for optimization.

Theory
The optional status of the different variable type specifications allows the user to specify only those variables
which are present (rather than explicitly specifying that the number of a particular type of variables is zero).
However, at least one type of variables that are active for the iterator in use must have nonzero size or an input
error message will result.

6.4.3 mixed

- Keywords Area
- variables
- mixed

Maintain continuous/discrete variable distinction
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none

Argument(s): none

Default: relaxed (branch and bound), mixed (all other methods)

Description

The variables domain specifies how the discrete variables are treated. If the user specifies mixed in the variable specification block, the continuous and discrete variables are treated separately. If the user specifies relaxed in the variable specification block, the discrete variables are relaxed and treated as continuous variables. This may be useful in optimization problems involving both continuous and discrete variables when a user would like to use an optimization method that is designed for continuous variable optimization. All Dakota methods have a default value of mixed for the domain type except for the branch-and-bound method which has a default domain type of relaxed. Note that the branch-and-bound method is under development at this time. Finally, note that the domain selection applies to all variable types: design, aleatory uncertain, epistemic uncertain, and state.

With respect to domain type, if the user does not specify an explicit override of mixed or relaxed, Dakota infers the domain type from the method. As mentioned above, all methods currently use a mixed domain as a default, except the branch-and-bound method which is under development.

Specify maximum values
6.4. VARIABLES

Specification

Alias: cdv_upper_bounds

Argument(s): REALLIST
Default: infinity

Description

Specify maximum values

scale_types

- Keywords Area
- variables
- continuous_design
- scale_types

Specify scaling for the variables

Specification

Alias: cdv_scale_types

Argument(s): STRINGLIST
Default: vector values = 'none'

Description

For continuous variables, the scale_types specification includes strings specifying the scaling type for each component of the continuous design variables vector in methods that support scaling, when scaling is enabled.

Each entry in scale_types may be selected from 'none', 'value', 'auto', or 'log', to select no, characteristic value, automatic, or logarithmic scaling, respectively. If a single string is specified it will apply to all components of the continuous design variables vector. Each entry in scales may be a user-specified nonzero real characteristic value to be used in scaling each variable component. These values are ignored for scaling type 'none', required for 'value', and optional for 'auto' and 'log'. If a single real value is specified it will apply to all components of the continuous design variables vector.

Examples

Two continuous design variables, one scaled by a value, the other log scaled,

```plaintext
continuous_design = 2
initial_point -1.2  1.0
lower_bounds  -2.0  0.001
upper_bounds   2.0   2.0
descriptors    'x1'  'x2'
scale_types    'value' 'log'
scales         4.0   0.1
```
CHAPTER 6. KEYWORDS AREA

scales
  • Keywords Area
  • variables
  • continuous_design
  • scales

Specify scaling for the variable.

Specification

Alias: cdv_scales
  Argument(s): REALLIST
  Default: vector values = 1. (no scaling)

Description

For continuous variables, the scale_types specification includes strings specifying the scaling type for each component of the continuous design variables vector in methods that support scaling, when scaling is enabled. Each entry in scale_types may be selected from 'none', 'value', 'auto', or 'log', to select no, characteristic value, automatic, or logarithmic scaling, respectively. If a single string is specified it will apply to all components of the continuous design variables vector. Each entry in scales may be a user-specified nonzero real characteristic value to be used in scaling each variable component. These values are ignored for scaling type 'none', required for 'value', and optional for 'auto' and 'log'. If a single real value is specified it will apply to all components of the continuous design variables vector.

Examples

Two continuous design variables, both scaled by the characteristic value 4.0

```plaintext
continuous_design = 2
initial_point -1.2 1.0
lower_bounds -200 0.001
upper_bounds 200 2.0
descriptors 'x1' 'x2'
scale_types = 'value' 'none'
scales = 10.0
```

descriptors
  • Keywords Area
  • variables
  • continuous_design
  • descriptors

Labels for the variables
6.4. VARIABLES

Specification

Alias: cdv_descriptors

Argument(s): STRINGLIST

Default: cdv_{i}

Description

The optional variables labels specification descriptors is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a root string plus a numeric identifier.

6.4.6 discrete_design_range

- Keywords Area
- variables
- discrete_design_range

Discrete design variables; each defined by an integer interval

Topics

This keyword is related to the topics:

- discrete_variables
- design_variables

Specification

Alias: none

Argument(s): INTEGER

Default: no discrete design variables

<table>
<thead>

<td>descriptors</td>
<td></td>
<td>Labels for the variables</td>
</tr>
</tbody>
</table>

Description

These variables take on a range of integer values from the specified lower bound to the specified upper bound. The details of how to specify this discrete variable are located on the discrete_variables page.
initial_point

- Keywords Area
- variables
- discrete_design_range
- initial_point

Initial values

Specification

Alias: ddv_initial_point
Argument(s): INTEGERLIST
Default: 0

Description

The initial_point specifications provide the point in design space (variable values) from which an iterator is started. These default to the midpoint of bounds (continuous design variables) or the middle value (discrete design variables).

lower_bounds

- Keywords Area
- variables
- discrete_design_range
- lower_bounds

Specify minimum values

Specification

Alias: ddv_lower_bounds
Argument(s): INTEGERLIST
Default: INT_MIN

Description

Specify minimum values

upper_bounds

- Keywords Area
- variables
- discrete_design_range
- upper_bounds

Specify maximum values
6.4. VARIABLES

**Specification**

Alias: ddv_upper_bounds
- Argument(s): INTEGERLIST
- Default: INT_MAX

**Description**

Specify maximum values

descriptors
- Keywords Area
- variables
- discrete_design_range
- descriptors
Labels for the variables

**Specification**

Alias: ddv_descriptors
- Argument(s): STRINGLIST
- Default: ddrv_{i}

**Description**

The optional variables labels specification descriptors is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a root string plus a numeric identifier.

**6.4.7 discrete_design_set**

- Keywords Area
- variables
- discrete_design_set
Set-valued discrete design variables

**Topics**

This keyword is related to the topics:
- discrete_variables
- design_variables

**Specification**

Alias: none
- Argument(s): none
Required/Optional | Description of Group | Dakota Keyword | Dakota Keyword Description
--- | --- | --- | ---
Optional |  | integer | Integer-valued discrete design variables
Optional |  | string | String-valued discrete design set variables
Optional |  | real | Real-valued discrete design variables

### Description

Discrete design variables whose values come from a set of admissible elements. Each variable specified must be of type integer, string, or real.

#### integer
- **Keywords Area**
- **variables**
- **discrete_design_set**
- **integer**

Integer-valued discrete design variables

### Topics

This keyword is related to the topics:
- **discrete_variables**
- **design_variables**

### Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** no discrete design set integer variables
### Description

A design variable whose values come from a specified set of admissible integers. The details of how to specify this discrete variable are located on the `discrete_variables` page.

### Examples

Four integer variables whose values will be selected from the following sets during the search for an optimal design. \(y_1 \in \{0, 1\}, y_2 \in \{0, 1\}, y_3 \in \{0, 5\}\) and \(y_4 \in \{10, 15, 20, 23\}\).

```
discrete_design_set
integer 4
descriptors 'y1' 'y2' 'y3' 'y4'
elements_per_variable 2 2 2 4
elements 0 1 0 1 0 5 10 15 20 23
```

### elements_per_variable

- Keywords Area
- variables
- discrete_design_set
- integer
- elements_per_variable

Number of admissible elements for each set variable
CHAPTER 6. KEYWORDS AREA

Specification

Alias: num_set_values
   Argument(s): INTEGERLIST
   Default: equal distribution

Description

Discrete set variables (including design, uncertain, and state) take on only a fixed set of values. For each type (integer, string, or real), this keyword specifies how many admissible values are provided for each variable. If not specified, equal apportionment of elements among variables is assumed, and the number of elements must be evenly divisible by the number of variables.

elements
   • Keywords Area
   • variables
   • discrete_design_set
   • integer
   • elements

The permissible values for each discrete variable

Specification

Alias: set_values
   Argument(s): INTEGERLIST

Description

Specify the permissible values for discrete set variables (of type integer, string, or real). See the description on the discrete_variables page.

categorical
   • Keywords Area
   • variables
   • discrete_design_set
   • integer
   • categorical

Whether the set-valued variables are categorical or relaxable

Specification

Alias: none
   Argument(s): STRINGLIST
6.4. VARIABLES

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>adjacency_matrix</td>
<td>1-0 matrix defining which categorical variable levels are related.</td>
</tr>
</tbody>
</table>

**Description**

A list of strings of length equal to the number of set (integer, string, or real) variables indicating whether they are strictly categorical, meaning may only take on values from the provided set, or relaxable, meaning may take on any integer or real value between the lowest and highest specified element. Valid categorical strings include 'yes', 'no', 'true', and 'false', or any abbreviation in [yYnNtTfF][.]*.

**Examples**

Discrete design set variable, 'rotor_blades', can take on only integer values, 2, 4, or 7 by default. Since categorical is specified to be false, the integrality can be relaxed and 'rotor_blades' can take on any value between 2 and 7, e.g., 3, 6, or 5.5.

```plaintext
discrete_design_set
integer 1
  elements 2 4 7
descriptor 'rotor_blades'
categorical 'no'
```

**adjacency_matrix**

- Keywords Area
- variables
- discrete_design_set
- integer
- categorical
- adjacency_matrix

1-0 matrix defining which categorical variable levels are related.

**Specification**

Alias: none
Argument(s): INTEGERLIST
Description

The `adjacency_matrix` keyword is associated with `discrete_design_set` variables that are specified to be categorical. Each such variable is associated with one \( k \times k \) symmetric matrix, where \( k \) is the number of values (or levels) of the variable. Entry \( i,j \) of a matrix should be 1 if level \( i \) and level \( j \) are related by some subjective criteria or if \( i = j \); it should be 0 otherwise. The matrices for all variables of the same type (string, real, or integer) are entered sequentially as a list of integers as shown in the examples below.

**Default Behavior**

The `adjacency_matrix` keyword is only relevant for `discrete_design_set` real and `discrete_design_set` integer variables if one or more of them have been specified to be categorical. It is always relevant for `discrete_design_set` string variables. If the user does not define an adjacency matrix, the default is method dependent. Currently, the only method that makes use of the adjacency matrix is `mesh_adaptive_search`, which uses a tri-diagonal adjacency matrix by default.

**Expected Output**

The expected output is method dependent.

**Usage Tips**

If an adjacency matrix is defined for one type of (categorical) `discrete_design_set` variable, it must be defined for all variables of that type, even for those not defined to be categorical. Those for the non-categorical set variables will be ignored.

**Examples**

The following example shows a variables specification where some real and some integer `discrete_design_set` variables are categorical.

```plaintext
variables
continuous_design = 3
  initial_point -1.0 1.5 2.0
  lower_bounds -10.0 -10.0 -10.0
  upper_bounds 10.0 10.0 10.0
  descriptors 'x1' 'x2' 'x3'
discrete_design_range = 2
  initial_point 2 2
  lower_bounds 1 1
  upper_bounds 4 9
  descriptors 'y1' 'y2'
discrete_design_set
  real = 2
    elements_per_variable = 4 5
    elements = 1.2 2.3 3.4 4.5 1.2 3.3 4.4 5.5 7.7
    descriptors 'y3' 'y4'
    categorical 'no' 'yes'
  adjacency_matrix 1 1 0 0 # Begin entry of 4x4 matrix for y3
    1 1 0
    0 1 1
    0 0 1
    1 0 1 0 1 # Begin entry of 5x5 matrix for y4
    1 0 1 0
    1 0 1 0
    0 1 0 1 0
    1 0 1 0 1
integer = 2
  elements_per_variable = 2 3
  elements = 4 7 8 9 12
  descriptors 'z1' 'z2'
  categorical 'yes' 'yes'
```
Note that for the real case, the user wants to define an adjacency matrix for the categorical variable, so adjacency matrices for both variables must be specified. The matrix for the first one will be ignored. Note that no adjacency matrix is specified for either integer categorical variable. The default will be used in both cases. Currently the only method taking advantage of adjacency matrices is `mesh_adaptive_search`, which uses a tri-diagonal adjacency matrix by default. Thus, the matrices used would be

\[
\begin{bmatrix}
1 & 1 \\
1 & 1 \\
1 & 1 & 0 \\
1 & 1 & 1 \\
0 & 1 & 1 \\
\end{bmatrix}
\]

The following example shows a variables specification for string variables. Note that string variables are always considered to be categorical. If an adjacency matrix is not specified, a method-dependent default matrix will be used.

```plaintext
variables,
    continuous_design = 2
    initial_point 0.5 0.5
    lower_bounds 0. 0.
    upper_bounds 1. 1.
    descriptors = 'x' 'y'
discrete_design_set string = 1
elements = 'aniso1' 'aniso2' 'iso1' 'iso2' 'iso3'
descriptors = 'ancomp'
    adjacency_matrix 1 1 0 0 0
                     1 1 0 0 0
                     0 0 1 1 1
                     0 0 1 1 1
                     0 0 1 1 1
```

### Description

Discrete design variables whose values come from a specified set of admissible strings. The details of how to specify this discrete variable are located on the discrete_variables page. Each string element value must be quoted and may contain alphanumeric, dash, underscore, and colon. White space, quote characters, and back-slash/metacharacters are not permitted.

### Examples

Two string variables whose values will be selected from the set of provided elements. The first variable, 'linear solver', takes on values from a set of three possible elements and the second variable, 'mesh_file', from a set of two possible elements.

```
discrete_design_set
  string 2
    descriptors 'linear_solver' 'mesh_file'
    elements_per_variable 3 2
    elements 'cg' 'gmres' 'direct'
      'mesh64.exo' 'mesh128.exo'
```

adjacency_matrix

- Keywords Area
- variables
- discrete_design_set
- string
- adjacency_matrix

1-0 matrix defining which categorical variable levels are related.

Specification

Alias: none
  Argument(s): INTEGERLIST
6.4. VARIABLES

Description

The adjacency_matrix keyword is associated with discrete_design_set variables that are specified to be categorical. Each such variable is associated with one $k \times k$ symmetric matrix, where $k$ is the number of values (or levels) of the variable. Entry $i,j$ of a matrix should be 1 if level $i$ and level $j$ are related by some subjective criteria or if $i = j$; it should be 0 otherwise. The matrices for all variables of the same type (string, real, or integer) are entered sequentially as a list of integers as shown in the examples below.

Default Behavior

The adjacency_matrix keyword is only relevant for discrete_design_set real and discrete_design_set integer variables if one or more of them have been specified to be categorical. It is always relevant for discrete_design_set string variables. If the user does not define an adjacency matrix, the default is method dependent. Currently, the only method that makes use of the adjacency matrix is mesh_adaptive_search, which uses a tri-diagonal adjacency matrix by default.

Expected Output

The expected output is method dependent.

Usage Tips

If an adjacency matrix is defined for one type of (categorical) discrete_design_set variable, it must be defined for all variables of that type, even for those not defined to be categorical. Those for the non-categorical set variables will be ignored.

Examples

The following example shows a variables specification where some real and some integer discrete_design_set variables are categorical.

```variables
  continuous_design = 3
  initial_point -1.0  1.5  2.0
  lower_bounds  -10.0 -10.0 -10.0
  upper_bounds   10.0  10.0  10.0
  descriptors    'x1'  'x2'  'x3'

  discrete_design_range = 2
  initial_point  2  2
  lower_bounds   1  1
  upper_bounds   4  9
  descriptors    'y1'  'y2'

  discrete_design_set
  real = 2
    elements_per_variable = 4 5
    elements            = 1.2  2.3  3.4  4.5  1.2  3.3  4.4  5.5  7.7
    descriptors        'y3'  'y4'
    categorical        'no'  'yes'

  integer = 2
    elements_per_variable = 2 3
    elements            = 4  7  8  9  12
    descriptors        'z1'  'z2'
    categorical        'yes' 'yes'
```
Note that for the real case, the user wants to define an adjacency matrix for the categorical variable, so adjacency matrices for both variables must be specified. The matrix for the first one will be ignored. Note that no adjacency matrix is specified for either integer categorical variable. The default will be used in both cases. Currently the only method taking advantage of adjacency matrices is mesh_adaptive_search, which uses a tri-diagonal adjacency matrix by default. Thus, the matrices used would be

\[
\begin{bmatrix}
1 & 1 \\
1 & \end{bmatrix}
\]

\[
\begin{bmatrix}
1 & 1 & 0 \\
1 & 1 & 1 \\
0 & 1 & 1 \\
\end{bmatrix}
\]

The following example shows a variables specification for string variables. Note that string variables are always considered to be categorical. If an adjacency matrix is not specified, a method-dependent default matrix will be used.

```plaintext
variables,
  continuous_design = 2
  initial_point 0.5 0.5
  lower_bounds 0. 0.
  upper_bounds 1. 1.
  descriptors = 'x' 'y'
 discrete_design_set string = 1
  elements = 'aniso1' 'aniso2' 'iso1' 'iso2' 'iso3'
  descriptors = 'ancomp'
  adjacency_matrix 1 1 0 0 0
                   1 1 0 0
                   0 0 1 1
                   0 0 1 1
                   0 0 1 1
```

**Description**

A list of strings of length equal to the number of set (integer, string, or real) variables indicating whether they are strictly categorical, meaning may only take on values from the provided set, or relaxable, meaning may take on any integer or real value between the lowest and highest specified element. Valid categorical strings include ‘yes’, ‘no’, ‘true’, and ‘false’, or any abbreviation in [yYnNtTfF][.]*

**Examples**

Discrete design set variable, ‘rotor.blades’, can take on only integer values, 2, 4, or 7 by default. Since categorical is specified to be false, the integrality can be relaxed and ‘rotor.blades’ can take on any value between 2 and 7, e.g., 3, 6, or 5.5.

```plaintext
discrete_design_set
    integer 1
    elements 2 4 7
descriptor ‘rotor.blades’
categorical ‘no’
```

**adjacency_matrix**

- Keywords Area
- variables
- discrete_design_set
- real
- categorical
- adjacency_matrix

1-0 matrix defining which categorical variable levels are related.

**Specification**

Alias: none

Argument(s): INTEGERLIST
Description

The adjacency_matrix keyword is associated with discrete_design_set variables that are specified to be categorical. Each such variable is associated with one \( k \times k \) symmetric matrix, where \( k \) is the number of values (or levels) of the variable. Entry \( i, j \) of a matrix should be 1 if level \( i \) and level \( j \) are related by some subjective criteria or if \( i = j \); it should be 0 otherwise. The matrices for all variables of the same type (string, real, or integer) are entered sequentially as a list of integers as shown in the examples below.

Default Behavior

The adjacency_matrix keyword is only relevant for discrete_design_set real and discrete_design_set integer variables if one or more of them have been specified to be categorical. It is always relevant for discrete_design_set string variables. If the user does not define an adjacency matrix, the default is method dependent. Currently, the only method that makes use of the adjacency matrix is mesh_adaptive_search, which uses a tri-diagonal adjacency matrix by default.

Expected Output

The expected output is method dependent.

Usage Tips

If an adjacency matrix is defined for one type of (categorical) discrete_design_set variable, it must be defined for all variables of that type, even for those not defined to be categorical. Those for the non-categorical set variables will be ignored.

Examples

The following example shows a variables specification where some real and some integer discrete_design_set variables are categorical.

```
variables
continuous_design = 3
    initial_point -1.0 1.5 2.0
    upper_bounds 10.0 10.0 10.0
    descriptors 'x1' 'x2' 'x3'
discrete_design_range = 2
    initial_point 2 2
    lower_bounds 1 1
    upper_bounds 4 9
    descriptors 'y1' 'y2'
discrete_design_set
    real = 2
        elements_per_variable = 4 5
        elements = 1.2 2.3 3.4 4.5 1.2 3.3 4.4 5.5 7.7
        descriptors 'y3' 'y4'
        categorical 'no' 'yes'
        adjacency_matrix
            1 1 0 0  # Begin entry of 4x4 matrix for y3
            1 1 1

            1 0 1 0  # Begin entry of 5x5 matrix for y4
            0 1 0 1
            1 0 1 0
            0 1 0 1
            1 0 1 0
    integer = 2
        elements_per_variable = 2 3
        elements = 4 7 8 9 12
        descriptors 'z1' 'z2'
        categorical 'yes' 'yes'
```
Note that for the real case, the user wants to define an adjacency matrix for the categorical variable, so adjacency matrices for both variables must be specified. The matrix for the first one will be ignored. Note that no adjacency matrix is specified for either integer categorical variable. The default will be used in both cases. Currently the only method taking advantage of adjacency matrices is mesh\_adaptive\_search, which uses a tri-diagonal adjacency matrix by default. Thus, the matrices used would be

\[
\begin{align*}
z_1: & \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix} \\
z_2: & \begin{bmatrix} 1 & 1 & 0 \\ 1 & 1 & 1 \\ 0 & 1 & 1 \end{bmatrix}
\end{align*}
\]

The following example shows a variables specification for string variables. Note that string variables are always considered to be categorical. If an adjacency matrix is not specified, a method-dependent default matrix will be used.

\[
\begin{array}{l}
\text{variables,} \\
\text{continuous\_design = 2} \\
\text{initial\_point 0.5 0.5} \\
\text{lower\_bounds 0. 0.} \\
\text{upper\_bounds 1. 1.} \\
\text{descriptors = 'x' 'y'} \\
\text{discrete\_design\_set string = 1} \\
\text{elements = 'aniso1' 'aniso2' 'iso1' 'iso2' 'iso3'} \\
\text{descriptors = 'ancomp'} \\
\text{adjacency\_matrix 1 1 0 0 0} \\
\hspace{1cm} 1 1 0 0 0 \\
\hspace{1cm} 0 0 1 1 1 \\
\hspace{1cm} 0 0 1 1 1 \\
\hspace{1cm} 0 0 1 1 1 \\
\end{array}
\]

- aleatory_uncertain_variables

Specification
Alias: none
Argument(s): INTEGER
Default: no normal uncertain variables
### Description

Within the normal uncertain optional group specification, the number of normal uncertain variables, the means, and standard deviations are required specifications, and the distribution lower and upper bounds and variable descriptors are optional specifications. The normal distribution is widely used to model uncertain variables such as population characteristics. It is also used to model the mean of a sample: as the sample size becomes very large, the Central Limit Theorem states that the distribution of the mean becomes approximately normal, regardless of the distribution of the original variables.

The density function for the normal distribution is:

\[
f(x) = \frac{1}{\sqrt{2\pi}\sigma_N} e^{-\frac{1}{2} \left( \frac{x - \mu_N}{\sigma_N} \right)^2}
\]

where \( \mu_N \) and \( \sigma_N \) are the mean and standard deviation of the normal distribution, respectively.

Note that if you specify bounds for a normal distribution, the sampling occurs from the underlying distribution with the given mean and standard deviation, but samples are not taken outside the bounds (see “bounded normal” distribution type in [89]). This can result in the mean and the standard deviation of the sample data being different from the mean and standard deviation of the underlying distribution. For example, if you are sampling from a normal distribution with a mean of 5 and a standard deviation of 3, but you specify bounds of 1 and 7, the resulting mean of the samples will be around 4.3 and the resulting standard deviation will be around 1.6. This is because you have bounded the original distribution significantly, and asymetrically, since 7 is closer to the original mean than 1.

### Theory

When used with design of experiments and multidimensional parameter studies, distribution bounds are inferred. These bounds are \([ \mu - 3\sigma, \mu + 3\sigma] \)

For vector and centered parameter studies, an inferred initial starting point is needed for the uncertain variables. These variables are initialized to their means for these studies.

### Description

If the logarithm of an uncertain variable $X$ has a normal distribution, that is $\log X \sim N(\mu, \sigma)$, then $X$ is distributed with a lognormal distribution. The lognormal is often used to model:

1. time to perform some task
2. variables which are the product of a large number of other quantities, by the Central Limit Theorem
3. quantities which cannot have negative values.

Within the lognormal uncertain optional group specification, the number of lognormal uncertain variables, the means, and either standard deviations or error factors must be specified, and the distribution lower and upper bounds and variable descriptors are optional specifications. These distribution bounds can be used to truncate the tails of lognormal distributions, which as for bounded normal, can result in the mean and the standard deviation of the sample data being different from the mean and standard deviation of the underlying distribution (see "bounded lognormal" and "bounded lognormal-n" distribution types in[89]).

For the lognormal variables, one may specify either the mean $\mu$ and standard deviation $\sigma$ of the actual lognormal distribution (option 1), the mean $\mu$ and error factor $\epsilon$ of the actual lognormal distribution (option 2), or the mean $\lambda$ ("lambda") and standard deviation $\zeta$ ("zeta") of the underlying normal distribution (option 3).

The conversion equations from lognormal mean $\mu$ and either lognormal error factor $\epsilon$ or lognormal standard deviation $\sigma$ to the mean $\lambda$ and standard deviation $\zeta$ of the underlying normal distribution are as follows:

\[
\zeta = \frac{\ln(\epsilon)}{1.645}
\]

\[
\zeta^2 = \ln\left(\frac{\sigma^2}{\mu^2} + 1\right)
\]

\[
\lambda = \ln(\mu) - \frac{\zeta^2}{2}
\]

Conversions from $\lambda$ and $\zeta$ back to $\mu$ and $\epsilon$ or $\sigma$ are as follows:

\[
\mu = e^{\lambda + \frac{\zeta^2}{2}}
\]
\[ \sigma^2 = e^{2\lambda+\zeta^2}(e^{\zeta^2} - 1) \]
\[ e = e^{1.645\zeta} \]

The density function for the lognormal distribution is:
\[ f(x) = \frac{1}{\sqrt{2\pi\zeta x}} e^{-\frac{1}{2} \left( \frac{\ln x - \lambda}{\zeta} \right)^2} \]

**Theory**

When used with design of experiments and multidimensional parameter studies, distribution bounds are inferred. These bounds are \([0, \mu + 3\sigma]\).

For vector and centered parameter studies, an inferred initial starting point is needed for the uncertain variables. These variables are initialized to their means for these studies.

Description

The triangular distribution is often used when one does not have much data or information, but does have an estimate of the most likely value and the lower and upper bounds. Within the triangular uncertain optional group specification, the number of triangular uncertain variables, the modes, and the distribution lower and upper bounds are required specifications, and variable descriptors is an optional specification.

The density function for the triangular distribution is:

\[ f(x) = \begin{cases} \frac{2(x - L_T)}{(U_T - L_T)(M_T - L_T)} & \text{if } L_T \leq x \leq M_T, \\ \frac{2(U_T - x)}{(U_T - L_T)(U_T - M_T)} & \text{if } M_T \leq x \leq U_T, \\ 0 & \text{elsewhere.} \end{cases} \]

In these equations, \( L_T \) is the lower bound, \( U_T \) is the upper bound, and \( M_T \) is the mode of the triangular distribution.

</tbody>
</table>
Description

Within the beta uncertain optional group specification, the number of beta uncertain variables, the alpha and beta parameters, and the distribution upper and lower bounds are required specifications, and the variable descriptors is an optional specification. The beta distribution can be helpful when the actual distribution of an uncertain variable is unknown, but the user has a good idea of the bounds, the mean, and the standard deviation of the uncertain variable. The density function for the beta distribution is

\[ f(x) = \frac{\Gamma(\alpha + \beta) (x - L_B)^{\alpha-1} (U_B - x)^{\beta-1}}{\Gamma(\alpha) \Gamma(\beta) (U_B - L_B)^{\alpha+\beta-1}} \]

where \( \Gamma(\alpha) \) is the gamma function and \( B(\alpha, \beta) = \frac{\Gamma(\alpha) \Gamma(\beta)}{\Gamma(\alpha + \beta)} \) is the beta function. To calculate the mean and standard deviation from the alpha, beta, upper bound, and lower bound parameters of the beta distribution, the following expressions may be used.

\[ \mu_B = L_B + \frac{\alpha}{\alpha + \beta} (U_B - L_B) \]

\[ \sigma_B^2 = \frac{\alpha \beta}{(\alpha + \beta)^2 (\alpha + \beta + 1)} (U_B - L_B)^2 \]

Solving these for \( \alpha \) and \( \beta \) gives:

\[ \alpha = \frac{(\mu_B - L_B) (\mu_B - L_B) (U_B - \mu_B) - \sigma_B^2}{\sigma_B^2 (U_B - L_B)} \]
\[ \beta = \frac{(U_B - \mu_B) (\mu_B - L_B) (U_B - \mu_B) - \sigma_B^2}{\sigma_B^2 (U_B - L_B)} \]

Note that the uniform distribution is a special case of this distribution for parameters \( \alpha = \beta = 1 \).

Theory

For vector and centered parameter studies, an inferred initial starting point is needed for the uncertain variables. These variables are initialized to their means for these studies.

The gamma distribution is sometimes used to model time to complete a task, such as a repair or service task. It is a very flexible distribution with its shape governed by alpha and beta.

The density function for the gamma distribution is given by:

\[
f(x) = \frac{x^{\alpha-1}e^{-\frac{x}{\beta}}}{\beta^\alpha \Gamma(\alpha)}
\]

where \(\mu_{GA} = \alpha \beta\) and \(\sigma^2_{GA} = \alpha \beta^2\). Note that the exponential distribution is a special case of this distribution for parameter \(\alpha = 1\).

**Theory**

When used with design of experiments and multidimensional parameter studies, distribution bounds are inferred. These bounds are \([0, \mu + 3\sigma]\).

For vector and centered parameter studies, an inferred initial starting point is needed for the uncertain variables. These variables are initialized to their means for these studies.

Description

The Gumbel distribution is also referred to as the Type I Largest Extreme Value distribution. The distribution of maxima in sample sets from a population with a normal distribution will asymptotically converge to this distribution. It is commonly used to model demand variables such as wind loads and flood levels.

The density function for the Gumbel distribution is given by:

\[ f(x) = \alpha e^{-\alpha(x-\beta)} \exp(-e^{-\alpha(x-\beta)}) \]

where \( \mu_{GU} = \beta + \frac{0.5772}{\alpha} \) and \( \sigma_{GU} = \frac{\pi}{\sqrt{6\alpha}} \).

Theory

When used with design of experiments and multidimensional parameter studies, distribution bounds are inferred. These bounds are \([ \mu - 3\sigma, \mu + 3\sigma ]\).

For vector and centered parameter studies, an inferred initial starting point is needed for the uncertain variables. These variables are initialized to their means for these studies.

### Description

Histogram uncertain variables are typically used to model a set of empirical data. The bin histogram (contrast: `histogram_point_uncertain`) is a continuous aleatory distribution characterized by bins of non-zero width where the uncertain variable may lie, together with the relative frequencies of each bin. Hence it can be used to specify a marginal probability density function arising from data.

The `histogram_bin_uncertain` keyword specifies the number of variables to be characterized as continuous histograms. The required sub-keywords are: `abscissas` (ranges of values the variable can take on) and either `ordinates` or `counts` (characterizing each variable’s frequency information). When using histogram bin variables, each variable must be defined by at least one bin (with two bounding value pairs). When more than one histogram bin variable is active, `pairs_per_variable` can be used to specify unequal apportionment of provided bin pairs among the variables.

The `abscissas` specification defines abscissa values (“x” coordinates) for the probability density function of each histogram variable. When paired with `counts`, the specifications provide sets of (x,c) pairs for each histogram variable where c defines a count (i.e., a frequency or relative probability) associated with a bin. If using bins of unequal width and specification of probability densities is more natural, then the `counts` specification can be replaced with an `ordinates` specification (“y” coordinates) in order to support interpretation of the input as (x,y) pairs defining the profile of a “skyline” probability density function.

Conversion between the two specifications is straightforward: a count/frequency is a cumulative probability quantity defined from the product of the ordinate density value and the x bin width. Thus, in the cases of bins of equal width, ordinate and count specifications are equivalent. In addition, ordinates and counts may be relative values; it is not necessary to scale them as all user inputs will be normalized.

To fully specify a bin-based histogram with n bins (potentially of unequal width), n+1 (x,c) or (x,y) pairs must be specified with the following features:

- x is the parameter value for the left boundary of a histogram bin and c is the corresponding count for that

<table>

6.4. VARIABLES

bin. Alternatively, \( y \) defines the ordinate density value for this bin within a skyline probability density function. The right boundary of the bin is defined by the left boundary of the next pair.

- the final pair specifies the right end of the last bin and must have a \( c \) or \( y \) value of zero.
- the \( x \) values must be strictly increasing.
- all \( c \) or \( y \) values must be positive, except for the last which must be zero.
- a minimum of two pairs must be specified for each bin-based histogram variable.

Examples

The \texttt{pairs\_per\_variable} specification provides for the proper association of multiple sets of (x,c) or (x,y) pairs with individual histogram variables. For example, in this input snippet

\begin{verbatim}
histogram\_bin\_uncertain = 2
pairs\_per\_variable = 3 4
abscissas = 5 8 10 .1 .2 .3 .4
counts = 17 21 0 12 24 12 0
descriptors = 'hbu_1' 'hbu_2'
\end{verbatim}

\texttt{pairs\_per\_variable} associates the first 3 (x,c) pairs from \texttt{abscissas} and \texttt{counts} \{(5,17),(8,21),(10,0)\} with one bin-based histogram variable, where one bin is defined between 5 and 8 with a count of 17 and another bin is defined between 8 and 10 with a count of 21. The following set of 4 (x,c) pairs \{(0.1,12),(0.2,24),(0.3,12),(0.4,0)\} defines a second bin-based histogram variable containing three equal-width bins with counts 12, 24, and 12 (middle bin is twice as probable as the other two).

These keywords may also be of interest:

- \texttt{histogram\_point\_uncertain}

FAQ

\textbf{Difference between bin and point histograms:} A (continuous) bin histogram specifies bins of non-zero width, whereas a (discrete) point histogram specifies individual point values, which can be thought of as bins with zero width. In the terminology of LHS[89], the bin pairs specification defines a "continuous linear" distribution and the point pairs specification defines a "discrete histogram" distribution (although the points are real-valued, the number of possible values is finite).

### Description

The Poisson distribution is used to predict the number of discrete events that happen in a single time interval. The random events occur uniformly and independently. The expected number of occurrences in a single time interval is \( \lambda \), which must be a positive real number. For example, if events occur on average 4 times per year and we are interested in the distribution of events over six months, \( \lambda \) would be 2. However, if we were interested in the distribution of events occurring over 5 years, \( \lambda \) would be 20.

The density function for the Poisson distribution is given by:

\[
f(x) = \frac{\lambda e^{-\lambda}}{x!}
\]

where

- \( \lambda \) is the expected number of events occurring in a single time interval
- \( x \) is the number of events that occur in this time period
- \( f(x) \) is the probability that \( x \) events occur in this time period

### Theory

When used with design of experiments and multidimensional parameter studies, distribution bounds are inferred. These bounds are \([0, \mu + 3\sigma]\).

For vector and centered parameter studies, an inferred initial starting point is needed for the uncertain variables. These variables are initialized to their means for these studies.

Description

The binomial distribution describes probabilities associated with a series of independent Bernoulli trials. A Bernoulli trial is an event with two mutually exclusive outcomes, such as 0 or 1, yes or no, success or fail. The probability of success remains the same (the trials are independent).

The density function for the binomial distribution is given by:

\[ f(x) = \binom{n}{x} p^x (1 - p)^{n-x} \]

where \( p \) is the probability of failure per trial, \( n \) is the number of trials and \( x \) is the number of successes.

Theory

The binomial distribution is typically used to predict the number of failures or defective items in a total of \( n \) independent tests or trials, where each trial has the probability \( p \) of failing or being defective.

### Description

The density function for the negative binomial distribution is given by:

\[ f(x) = \binom{n + x - 1}{x} p^n (1 - p)^x \]

where

- \( p \) is the probability of success per trial  
- \( n \) is the number of successful trials  
- \( X \) is the number of failures

### Theory

The negative binomial distribution is typically used to predict the number of failures observed when repeating a test until a total of \( n \) successes have occurred, where each test has a probability \( p \) of success.

Description
The hypergeometric probability density is used when sampling without replacement from a total population of elements where

- The resulting element of each sample can be separated into one of two non-overlapping sets
- The probability of success changes with each sample.
The density function for the hypergeometric distribution is given by:

\[ f(x) = \binom{m}{x} \binom{N - m}{n - x} \binom{N}{n} \]

where:

- 'N' is the total population
- 'm' is the number of items in the selected population (e.g., the number of white balls in the full urn of 'N' items)
- 'n' is the size of the sample drawn (e.g., number of balls drawn)
- 'x' is the number of success (e.g., drawing a white ball)
- \( \binom{a}{b} \) is a binomial coefficient

Theory

The hypergeometric is often described using an urn model. For example, say we have a total population containing 'N' balls, and we know that 'm' of the balls are white and the remaining balls are green. If we draw 'n' balls from the urn without replacement, the hypergeometric distribution describes the probability of drawing 'x' white balls.

6.4.25 histogram_point_uncertain

- Keywords Area
- variables
- histogram_point_uncertain

Aleatory uncertain variable - discrete histogram

Topics

This keyword is related to the topics:

- discrete_variables
- aleatory_uncertain_variables

Specification

Alias: none

Argument(s): none

Default: no histogram point uncertain variables
### Description

Histogram uncertain variables are typically used to model a set of empirical data. When the variables take on only discrete values or categories, a discrete, or point histogram is used to describe their probability mass function (one could think of this as a histogram_bin_uncertain variable with "bins" of zero width). Dakota supports integer-, string-, and real-valued point histograms.

Point histograms are similar to discrete_design_set and discrete_state_set, but as they are uncertain variables, include the relative probabilities of observing the different values within the set.

The histogram_point_uncertain keyword is followed by one or more of integer, string, or real, each of which specify the number of variables to be characterized as discrete histograms of that sub-type. Each discrete histogram variable is specified by one or more abscissa/count pairs. The abscissas, are the possible values the variable can take on ("x" coordinates of type integer, string, or real), and must be specified in increasing order. These are paired with counts which provide the frequency of the given value or string, relative to other possible values/strings.

Thus, to fully specify a point-based histogram with \( n \) points, \( n \) \((x,c)\) pairs must be specified with the following features:

- \( x \) is the point value (integer, string, or real) and \( c \) is the corresponding count for that value.
- the \( x \) values must be strictly increasing (lexicographically for strings).
- all \( c \) values must be positive.
- a minimum of one pair must be specified for each point-based histogram.

### Examples

The pairs_per_variable specification provides for the proper association of multiple sets of \((x,c)\) or \((x,y)\) pairs with individual histogram variables. For example, in the following specification,

```bash
histogram_point_uncertain
  integer = 2
  pairs_per_variable = 2 3
  abscissas = 3 4 100 200 300
  counts = 1 1 1 2 1
```

pairs_per_variable associates the \((x,c)\) pairs \{(3,1),(4,1)\} with one point-based histogram variable (where the values 3 and 4 are equally probable) and associates the \((x,c)\) pairs \{(100,1),(200,2),(300,1)\} with a second point-based histogram variable (where the value 200 is twice as probable as either 100 or 300).
6.4. VARIABLES

See Also
These keywords may also be of interest:

- histogram_bin_uncertain

FAQ

**Difference between bin and point histograms:** A (continuous) bin histogram specifies bins of non-zero width, whereas a (discrete) point histogram specifies individual point values, which can be thought of as bins with zero width. In the terminology of LHS[89], the bin pairs specification defines a "continuous linear" distribution and the point pairs specification defines a "discrete histogram" distribution (although the points are real-valued, the number of possible values is finite).

**integer**

- histogram_point_uncertain
- real
- initial_point

Initial values

Specification

Alias: none
Argument(s): REALLIST

Description

The initial_point specifications provide the point in design space (variable values) from which an iterator is started. These default to the midpoint of bounds (continuous design variables) or the middle value (discrete design variables).

descriptors

- Keywords Area
- variables
- histogram_point_uncertain
- real
- descriptors

Labels for the variables

Specification

Alias: none
Argument(s): STRINGLIST
Default: hpruv_\{i\}

Description

The optional variables labels specification descriptors is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a root string plus a numeric identifier.
6.4.26 uncertain_correlation_matrix

- Keywords Area
- variables
- uncertain_correlation_matrix

Correlation among aleatory uncertain variables

Specification

Alias: none

Argument(s): REALLIST
Default: identity matrix (uncorrelated)

Description

Aleatory uncertain variables may have correlations specified through use of an uncertain_correlation_matrix specification. This specification is generalized in the sense that its specific meaning depends on the nondeterministic method in use.

When the method is a nondeterministic sampling method (i.e., sampling), then the correlation matrix specifies rank correlations [52].

When the method is a reliability (i.e., local_reliability or global_reliability) or stochastic expansion (i.e., polynomial_chaos or stoch_collocation) method, then the correlation matrix specifies correlation coefficients (normalized covariance) [42].

In either of these cases, specifying the identity matrix results in uncorrelated uncertain variables (the default). The matrix input should be symmetric and have all \( n^2 \) entries where \( n \) is the total number of aleatory uncertain variables.

Ordering of the aleatory uncertain variables is:

1. normal
2. lognormal
3. uniform
4. loguniform
5. triangular
6. exponential
7. beta
8. gamma
9. gumbel
10. frechet
11. weibull
12. histogram bin
13. poisson
14. binomial
15. negative binomial
16. geometric
17. hypergeometric
18. histogram point

When additional variable types are activated, they assume uniform distributions, and the ordering is as listed on variables.

Examples
Consider the following random variables, distributions and correlations:

- $X_1$, normal, uncorrelated with others
- $X_2$, normal, correlated with $X_3$, $X_4$ and $X_5$
- $X_3$, weibull, correlated with $X_5$
- $X_4$, exponential, correlated with $X_3$, $X_4$ and $X_5$
- $X_5$, normal, correlated with $X_5$

These correlations are captured by the following commands (order of the variables is respected).

```plaintext
uncertain_correlation_matrix
# ordering normal, exponential, weibull
# $X_1$ $X_2$ $X_5$ $X_4$ $X_3$
1.00 0.00 0.00 0.00 0.00
0.00 1.00 0.50 0.24 0.78
0.00 0.50 1.00 0.00 0.20
0.00 0.24 0.00 1.00 0.49
0.00 0.78 0.20 0.49 1.0
```

### 6.4.27 continuous_interval_uncertain

- **Keywords** Area
- **variables**
- **continuous_interval_uncertain**

Epistemic uncertain variable - values from one or more continuous intervals

Topics
This keyword is related to the topics:
- **continuous_variables**
- **epistemic_uncertain_variables**

Specification
**Alias:** interval_uncertain
**Argument(s):** INTEGER
**Default:** no continuous interval uncertain variables
### Description

Continuous interval uncertain variables are epistemic types. They can specify a single interval per variable which may be used in interval analysis, where the goal is to determine the interval bounds on the output corresponding to the interval bounds on the input. All values between the bounds are permissible. More detailed continuous interval representations can specify a set of belief structures based on intervals that may be contiguous, overlapping, or disjoint. This is used in specifying the inputs necessary for an epistemic uncertainty analysis using Dempster-Shafer theory of evidence.

Other epistemic types include:

- `discrete_interval_uncertain`
- `discrete_uncertain_set integer`
- `discrete_uncertain_set string`
- `discrete_uncertain_set real`

### Examples

The following specification is for an interval analysis:

```plaintext
continuous_interval_uncertain = 2  
lower_bounds = 2.0 4.0  
upper_bounds = 2.5 5.0
```

The following specification is for a Dempster-Shafer analysis:

```plaintext
continuous_interval_uncertain = 2  
num_intervals = 3 2  
interval_probs = 0.25 0.5 0.25 0.4 0.6  
lower_bounds = 2.0 4.0 4.5 1.0 3.0  
upper_bounds = 2.5 5.0 6.0 5.0 5.0
```

Here there are 2 interval uncertain variables. The first one is defined by three intervals, and the second by two intervals. The three intervals for the first variable have basic probability assignments of 0.2, 0.5, and 0.3, respectively, while the basic probability assignments for the two intervals for the second variable are 0.4 and 0.6.
The basic probability assignments for each interval variable must sum to one. The interval bounds for the first variable are [2, 2.5], [4, 5], and [4.5, 6], and the interval bounds for the second variable are [1.0, 5.0] and [3.0, 5.0]. Note that the intervals can be overlapping or disjoint. The BPA for the first variable indicates that it is twice as likely that the value occurs on the interval [4,5] than either [2,2.5] or [4.5,6].

**Theory**

The continuous interval uncertain variable is NOT a probability distribution. Although it may seem similar to a histogram, the interpretation of this uncertain variable is different. It is used in epistemic uncertainty analysis, where one is trying to model uncertainty due to lack of knowledge. The continuous interval uncertain variable is used in both interval analysis and in Dempster-Shafer theory of evidence.

- **interval analysis** -only one interval is allowed for each `continuous_interval_uncertain` variable -the interval is defined by lower and upper bounds -the value of the random variable lies somewhere in this interval -output is the minimum and maximum function value conditional on the specified interval

- **Dempster-Shafer theory of evidence** -multiple intervals can be assigned to each `continuous_interval_uncertain` variable -a Basic Probability Assignment (BPA) is associated with each interval. The BPA represents a probability that the value of the uncertain variable is located within that interval. -each interval is defined by lower and upper bounds -outputs are called “belief” and “plausibility.” Belief represents the smallest possible probability that is consistent with the evidence, while plausibility represents the largest possible probability that is consistent with the evidence. Evidence is the intervals together with their BPA.

**num_intervals**

- **Keywords Area**
- **variables**
- **continuous_interval_uncertain**
- **num_intervals**

Specify the number of intervals for each variable

**Specification**

**Alias:** iuv_num_intervals  
**Argument(s):** INTEGERLIST  
**Default:** Equal apportionment of intervals among variables

**Description**

In Dakota, epistemic uncertainty analysis is performed using either interval estimation or Dempster-Shafer theory of evidence. In these approaches, one does not assign a probability distribution to each uncertain input variable. Rather, one divides each uncertain input variable into one or more intervals. The input parameters are only known to occur within intervals; nothing more is assumed. `num_intervals` specifies the number of such intervals associated with each interval uncertain parameter.
interval_probabilities

- Keywords Area
- variables
- continuous_interval_uncertain
- interval_probabilities

Assign probability mass to each interval

Specification

Alias: interval_probs iuv_interval_probs
Argument(s): REALLIST
Default: Equal probability assignments for each interval (1/num_intervals[i])

Description

The basic probability assignments for each interval variable must sum to one. For example, if an interval variable is defined with three intervals, the probabilities for these intervals could be 0.2, 0.5, and 0.3 which sum to one, but could not be 0.5, 0.5, and 0.5 which do not sum to one.

Description

Discrete interval uncertain variables are epistemic types. They can specify a single interval per variable which may be used in interval analysis, where the goal is to determine the interval bounds on the output corresponding to the interval bounds on the input. Permissible values are any integer within the bound. More detailed continuous
interval representations can specify a set of belief structures based on intervals that may be contiguous, overlapping, or disjoint. This is used in specifying the inputs necessary for an epistemic uncertainty analysis using Dempster-Shafer theory of evidence.

Other epistemic types include:

- `continuous_interval_uncertain`
- `discrete_uncertain_set integer`
- `discrete_uncertain_set string`
- `discrete_uncertain_set real`

### Examples

Let $d_1$ be 2, 3 or 4 with probability 0.2, 4 or 5 with probability 0.5 and 6 with probability 0.3. Let $d_2$ be 4, 5 or 6 with probability 0.4 and 6, 7 or 8 with probability 0.6. The following specification is for a Dempster-Shafer analysis:

```plaintext
discrete_interval_uncertain = 2
num_intervals = 3 2
interval_probs = 0.2 0.5 0.3 0.4 0.6
lower_bounds = 2 4 6 4 6
upper_bounds = 4 5 6 6 8
```

### Theory

- Dempster-Shafer theory of evidence - multiple intervals can be assigned to each `discrete_interval_uncertain` variable - a Basic Probability Assignment (BPA) is associated with each interval. The BPA represents a probability that the value of the uncertain variable is located within that interval. Each interval is defined by lower and upper bounds - outputs are called "belief" and "plausibility." Belief represents the smallest possible probability that is consistent with the evidence, while plausibility represents the largest possible probability that is consistent with the evidence. Evidence is the intervals together with their BPA.

### Description

Discrete set variables may be used to specify categorical choices which are epistemic. For example, if we have three possible forms for a physics model (model 1, 2, or 3) and there is epistemic uncertainty about which one is correct, a discrete uncertain set may be used to represent this type of uncertainty.

This variable is defined by a set of reals, in which the discrete variable may take any value defined within the real set (for example, a parameter may have two allowable real values, 3.285 or 4.79).

Other epistemic types include:
- `continuous_interval_uncertain`
- `discrete_interval_uncertain`
- `discrete_uncertain_set integer`
- `discrete_uncertain_set string`

### Examples

Let \( d_1 \) be 2.1 or 1.3 and \( d_2 \) be 0.4, 5 or 2.6. The following specification is for an interval analysis:

```plaintext
discrete_uncertain_set
integer
num_set_values 2 3
set_values 2.1 1.3 0.4 5 2.6
descriptors 'dri' 'dr2'
```

### Theory

The `discrete_uncertain_set_integer` variable is NOT a discrete random variable. It can be contrasted to a the histogram-defined random variables: `histogram_bin_uncertain` and `histogram_point_uncertain`. It is used in epistemic uncertainty analysis, where one is trying to model uncertainty due to lack of knowledge.
The discrete uncertain set integer variable is used in both interval analysis and in Dempster-Shafer theory of evidence.

- **interval analysis** - the values are integers, equally weighted - the true value of the random variable is one of the integers in this set - output is the minimum and maximum function value conditional on the specified inputs

- **Dempster-Shafer theory of evidence** - the values are integers, but they can be assigned different weights - outputs are called "belief" and "plausibility." Belief represents the smallest possible probability that is consistent with the evidence, while plausibility represents the largest possible probability that is consistent with the evidence. Evidence is the values together with their weights.

- variables
- continuous_state
- initial_state

Initial values for the state variables

**Specification**

Alias: csv_initial_state

Argument(s): REALLIST

Default: 0.0

**Description**

The initial_state specifications provide the initial values for the state variables.

This is an optional keyword. If it is not specified, the initial state will be inferred from the other keywords that define the state variable.

Defaults are:

- Continuous state variables - use the midpoint of the bounds
- Set variables - use the value with the index closest to the middle of the set
- Range variables - use the midpoint of the range
6.4. VARIABLES

lower_bounds

- Keywords Area
- variables
- continuous_state
- lower_bounds

Specify minimum values

Specification

Alias: csv_lower_bounds

Argument(s): REALLIST
Default: -infinity

Description

Specify minimum values

upper_bounds

- Keywords Area
- variables
- continuous_state
- upper_bounds

Specify maximum values

Specification

Alias: csv_upper_bounds

Argument(s): REALLIST
Default: infinity

Description

Specify maximum values

descriptors

- Keywords Area
- variables
- continuous_state
- descriptors

Labels for the variables
CHAPTER 6. KEYWORDS AREA

Specification
Alias: csv_descriptors
  Argument(s): STRINGLIST
  Default: csv_{i}

Description
The optional variables labels specification descriptors is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a root string plus a numeric identifier.

6.4.31 discrete_state_range

- Keywords Area
- variables
- discrete_state_range

Discrete state variables; each defined by an integer interval

Topics
This keyword is related to the topics:

- discrete_variables
- state_variables

Specification
Alias: none
Argument(s): INTEGER
Default: No discrete state variables

<table>
<thead>

Description
Discrete state variables defined by bounds.

The details of how to specify this discrete variable are located on the discrete_variables page.

See the state_variables page for details on the behavior of state variables.
6.4. VARIABLES

initial_state

- Keywords Area
- variables
- discrete_state_range
- initial_state

Initial values for the state variables

Specification

Alias: dsv_initial_state
Argument(s): INTEGERLIST
Default: 0

Description

The initial_state specifications provide the initial values for the state variables.
This is an optional keyword. If it is not specified, the initial state will be inferred from the other keywords that define the state variable.

Defaults are:
- Continuous state variables - use the midpoint of the bounds
- Set variables - use the value with the index closest to the middle of the set
- Range variables - use the midpoint of the range

lower_bounds

- Keywords Area
- variables

</tr>
</tbody>
</table>
### Description

The interface section in a Dakota input file specifies how function evaluations will be performed in order to map the variables into the responses.

In this context, a "function evaluation" is the series of operations that takes the variables and computes the responses. This can be comprised of one or many codes, scripts, and glue, which are generically referred to as "analysis drivers".

The optional `asynchronous` flag specifies use of asynchronous protocols (i.e., background system calls, nonblocking forks, POSIX threads) when evaluations or analyses are invoked. The `evaluation_concurrency` and `analysis_concurrency` specifications serve a dual purpose:

- when running Dakota on a single processor in `asynchronous` mode, the default concurrency of evaluations and analyses is all concurrency that is available. The `evaluation_concurrency` and `analysis_concurrency` specifications can be used to limit this concurrency in order to avoid machine overload or usage policy violation.

- when running Dakota on multiple processors in message passing mode, the default concurrency of evaluations and analyses on each of the servers is one (i.e., the parallelism is exclusively that of the message

| Optional | synchronous | Specify analysis driver concurrency, when Dakota is run in serial |
| Optional | evaluation_servers | Specify the number of evaluation servers when Dakota is run in parallel |
| Optional | evaluation_scheduling | Specify the scheduling of concurrent evaluations when Dakota is run in parallel |
| Optional | processors_per_evaluation | Specify the number of processors per evaluation server when Dakota is run in parallel |
| Optional | analysis_servers | Specify the number of analysis servers when Dakota is run in parallel |
| Optional | analysis_scheduling | Specify the scheduling of concurrent analyses when Dakota is run in parallel |
passing). With the evaluation_concurrency and analysis_concurrency specifications, a hybrid parallelism can be selected through combination of message passing parallelism with asynchronous parallelism on each server.

If Dakota’s automatic parallel configuration is undesirable for some reason, the user can specify overrides that enforce a desired number of partitions, a size for the partitions, and/or a desired scheduling configuration at the evaluation and analysis parallelism levels. The optional evaluation_servers and analysis_servers specifications support user overrides of the automatic parallel configuration for the number of evaluation servers and the number of analysis servers, and the optional processors_per_evaluation specification supports user overrides for the size of processor allocations for evaluation servers (Note: see direct for the processors_per_analysis specification supported for direct interfaces). Similarly, the optional evaluation_scheduling and analysis_scheduling specifications can be used to override the automatic parallel configuration at the evaluation and analysis parallelism levels to use either a dedicated master or a peer partition. In addition, the evaluation parallelism level supports an override for the scheduling algorithm used within a peer partition; this can be either dynamic or static scheduling (default configuration of a peer partition employs a dynamic scheduler when it can be supported; i.e., when the peer 1 local scheduling can be asynchronous). The ParallelLibrary class and the Parallel Computing chapter of the Users Manual[4] provide additional details on parallel configurations.

When performing asynchronous local evaluations, the local_evaluation_scheduling keyword controls how new evaluation jobs are dispatched when one completes. If the local_evaluation_scheduling is specified as dynamic (the default), each completed evaluation will be replaced by the next in the local evaluation queue. If local_evaluation_scheduling is specified as static, each completed evaluation will be replaced by an evaluation number that is congruent modulo the evaluation_concurrency. This is helpful for relative node scheduling as described in Dakota/examples/parallelism. For example, assuming only asynchronous local concurrency (no MPI), if the local concurrency is 6 and job 2 completes, it will be replaced with job 8. For the case of hybrid parallelism, static local scheduling results in evaluation replacements that are modulo the total capacity, defined as the product of the evaluation concurrency and the number of evaluation servers. Both of these cases can result in idle processors if runtimes are non-uniform, so the default dynamic scheduling is preferred when relative node scheduling is not required.

Theory

Function evaluations are performed using either interfaces to simulation codes, algebraic mappings, or a combination of the two.

When employing mappings with simulation codes, the interface invokes the simulation using either forks, direct function invocations, or computational grid invocations.

- In the fork case, Dakota will treat the simulation as a black-box and communication between Dakota and the simulation occurs through parameter and result files. This is the most common case.

- In the direct function case, the simulation is internal to Dakota and communication occurs through the function parameter list. The direct case can involve linked simulation codes or test functions which are compiled into the Dakota executable. The test functions allow for rapid testing of algorithms without process creation overhead or engineering simulation expense.

- The grid case is experimental and under development, but is intended to support simulations which are external to Dakota and geographically distributed.

When employing algebraic mappings, the AMPL solver library[29] is used to evaluate a directed acyclic graph (DAG) specification from a separate stub.nl file. Separate stub.col and stub.row files are also required to declare the string identifiers of the subset of inputs and outputs, respectively, that will be used in the algebraic mappings.
6.5. INTERFACE

6.5.1 id_interface

- Keywords Area
- interface
- id_interface

Name the interface block; helpful when there are multiple

Topics

This keyword is related to the topics:

- block_identifier

Specification

Alias: none

Argument(s): STRING
Default: use of last interface parsed

Description

The optional set identifier specification uses the keyword id_interface to input a string for use in identifying a particular interface specification. A model can then identify the use of this interface by specifying the same string in its interface_pointer specification.

If the id_interface specification is omitted, a particular interface specification will be used by a model only if that model omits specifying a interface_pointer and if the interface set was the last set parsed (or is the only set parsed). In common practice, if only one interface set exists, then id_interface can be safely omitted from the interface specification and interface_pointer can be omitted from the model specification(s), since there is no potential for ambiguity in this case.

Examples

For example, a model whose specification contains interface_pointer = 'I1' will use an interface specification with id_interface = 'I1'.

6.5.2 algebraic_mappings

- Keywords Area
- interface
- algebraic_mappings

Use AMPL to define algebraic input-output mappings

Specification

Alias: none

Argument(s): STRING
Default: no algebraic mappings
CHAPTER 6. KEYWORDS AREA

Description

If desired, one can define algebraic input-output mappings using the AMPL code[26] and save these mappings in 3 files: stub.nl, stub.col, and stub.row, where stub is a particular root name describing a particular problem. These files names can be communicated to Dakota using the algebraic_mappings input. This string may either specify the stub.nl filename, or alternatively, just the stub itself.

Dakota then uses stub.col and stub.row to extract the input and output identifier strings and employs the AMPL solver library[29] to process the DAG specification in stub.nl. The variable and objective function names declared within AMPL should be a subset of the variable descriptors and response descriptors used by Dakota (see variables and descriptors). Ordering is not important, as Dakota will reorder data as needed.

6.5.3 analysis_drivers

- Keywords Area
- interface
- analysis_drivers

Define how Dakota should run a function evaluation

Specification

Alias: none

Argument(s): STRINGLIST

| Required/- | Description of | Dakota Keyword | Dakota Keyword Description |
| Optional | Group | | |
| Optional | | analysis_components | Provide additional identifiers to analysis drivers. Run a pre-processing script before the analysis drivers |
| Optional | | input_filter | |
| Optional | | output_filter | Run a post-processing script after the analysis drivers |
| Required (Choose One) | Group 1 | system | (Not recommended) Launch analysis drivers with a system call |
The required `analysis_drivers` keyword provides the names of one or more executable analysis programs or scripts, a.k.a. “drivers” which comprise a function evaluation. The optional and required sub-keywords specify how Dakota will manage directories and files, and run the driver(s).

### Types of Interfaces
Dakota has two recommended ways of running analysis drivers:

- as an external processes (`fork`), or
- using internal code to couple to the analysis driver (`direct`)

Other options are available for advanced users, and are not as well documented, supported, or tested:

- external processes (`system`)
- internal coupling (`python`, `matlab`, `scilab`, `grid`)
**Use Cases**

The internally coupled codes have few options because many of the details are already handled with the coupling. Their behavior is described in the **direct** keyword.

For external processes using the **fork** keyword,

A function evaluation may comprise:

1. **A single analysis driver**: Function evaluation, including all pre- and post-processing is contained entirely within a single script/executable.

2. **A single analysis driver with filters**: Function evaluation is explicitly split into pre-processing (performed by the input filter), analysis, and post-processing (by the output filter).

3. **A single analysis driver with environment variables**: Function evaluation is contained within one analysis driver, but it requires environment variables to be set before running.

4. **Multiple analysis drivers**: Drivers are run sequentially or concurrently (See the **asynchronous** keyword) and can have any of the above options as well.

For fork and system interfaces, the analysis driver list contains the names of one or more executable programs or scripts taking parameters files as input and producing results files as output. The first field in each analysis driver string must be an executable program or script for Dakota to spawn to perform the function evaluation.

Drivers support:

- One set of nested quotes, for arguments with spaces
- Dakota will define special environment variables `DAKOTA_PARAMETERS_FILE` and `DAKOTA_RESULTS_FILE` which can be used in the driver script.
- Variable definitions preceding the executable program or script, such as `MY_VAR=2 run_analysis.sh` are no longer supported.

For details and examples see the Simulation Interface Components section of the Interfaces chapter of the User’s Manual; for details on the filters and environment variables, see the subsection on Syntax for Filter and Driver Strings.

**Examples**

Examples:

1. `analysis_drivers = 'run_simulation_part1.sh' 'run_simulation_part2.sh'`

2. `analysis_driver = 'run_simulation.sh -option "option 1"'`

3. `analysis_driver = 'simulation.exe -option value -dakota_params $DAKOTA_PARAMETERS_FILE -input sim.in -dakota_results_file $DAKOTA_RESULTS_FILE'`

**FAQ**

**Where will Dakota look for the analysis_driver?** Dakota will locate analysis_driver programs first in (or relative to) the present working directory (".", the interface-analysis_drivers-fork-work_directory if used, otherwise the directory in which Dakota is started), then the directory from which Dakota is started, then using the system $PATH environment variable (Path% on Windows).

**Where should the driver be located?** When the driver is a script it is most commonly placed in the same directory as the Dakota input file. When using a **work_directory**, Dakota will also look for drivers in the specified working directory, so link_files or copy_files may specify the driver to get copied or linked into the work directory.
When executable programs are used as drivers, they are often elsewhere on the filesystem. These can be specified using absolute paths, or by prepending the PATH environment variable so Dakota finds them.

**What if Dakota fails to run my analysis driver?** Prepend the absolute location of the driver to the PATH environment variable before running Dakota, or specify an absolute path to the driver in the Dakota input file.

**analysis_components**
- Keywords Area
- interface
- analysis_drivers
- analysis_components

Provide additional identifiers to analysis drivers.

**Specification**

**Alias:** none

**Argument(s):** STRINGLIST

**Default:** no additional identifiers

**Description**

The optional `analysis_components` specification allows the user to provide additional identifiers (e.g., mesh file names) for use by the analysis drivers. This is particularly useful when the same analysis driver is to be reused multiple times for slightly different analyses. The specific content within the strings is open-ended and can involve whatever syntax is convenient for a particular analysis driver. The number of analysis components $n_c$ should be an integer multiple of the number of drivers $n_d$, and the first $n_c/n_d$ component strings will be passed to the first driver, etc.

**input_filter**
- Keywords Area
- interface
- analysis_drivers
- input_filter

Run a pre-processing script before the analysis drivers.

**Specification**

**Alias:** none

**Argument(s):** STRING

**Default:** no input filter
CHAPTER 6. KEYWORDS AREA

Description

The optional \texttt{input\_filter} and \texttt{output\_filter} specifications provide the names of separate pre- and post-processing programs or scripts which assist in mapping Dakota parameters files into analysis input files and mapping analysis output files into Dakota results files, respectively.

If there is only a single analysis driver, then it is usually most convenient to combine pre- and post-processing requirements into a single analysis driver script and omit the separate input and output filters. However, in the case of multiple analysis drivers, the input and output filters provide a convenient location for non-repeated pre-and post-processing requirements. That is, input and output filters are only executed once per function evaluation, regardless of the number of analysis drivers, which makes them convenient locations for data processing operations that are shared among the analysis drivers.

output\_filter

- Keywords Area
- interface
- analysis\_drivers
- output\_filter

Run a post-processing script after the analysis drivers

Specification

Alias: none

Argument(s): STRING

Default: no output filter

Description

The optional \texttt{input\_filter} and \texttt{output\_filter} specifications provide the names of separate pre- and post-processing programs or scripts which assist in mapping Dakota parameters files into analysis input files and mapping analysis output files into Dakota results files, respectively.

If there is only a single analysis driver, then it is usually most convenient to combine pre- and post-processing requirements into a single analysis driver script and omit the separate input and output filters. However, in the case of multiple analysis drivers, the input and output filters provide a convenient location for non-repeated pre- and post-processing requirements. That is, input and output filters are only executed once per function evaluation, regardless of the number of analysis drivers, which makes them convenient locations for data processing operations that are shared among the analysis drivers.

Description

The system call interface is included in Dakota for portability and backward compatibility. Users are strongly encouraged to use the fork interface if possible, reverting to system only when necessary. To enable the system call interface, replace the fork keyword with system. All other keywords have identical meanings to those for the fork interface.

See Also

These keywords may also be of interest:

- fork
parameters_file

- Keywords Area
- interface
- analysis_drivers
- system
- parameters_file

Specify the name of the parameters file

**Specification**

Alias: none  
**Argument(s):** STRING  
**Default:** Unix temp files

**Description**

The parameters file is used by Dakota to pass the parameter values to the analysis driver. The name of the file can be optionally specified using the `parameters_file` keyword.

If this is not specified, the default data transfer files are temporary files with system-generated names (e.g., /usr/tmp/aaaa08861).

results_file

- Keywords Area
- interface
- analysis_drivers
- system
- results_file

Specify the name of the results file

**Specification**

Alias: none  
**Argument(s):** STRING  
**Default:** Unix temp files

**Description**

The results file must be written by the analysis driver. It is read by Dakota to determine the response values for each function evaluation.

The name of the file can be optionally specified using the `results_file` keyword.

If this is not specified, the default data transfer files are temporary files with system-generated names (e.g., /usr/tmp/aaaa08861).
6.5. INTERFACE

allow_existing_results

- Keywords Area
- interface
- analysis_drivers
- system
- allow_existing_results

Change how Dakota deals with existing results files

Specification

Alias: none

Argument(s): none

Default: results files removed before each evaluation

Description

By default Dakota will remove existing results files before invoking the analysis_driver to avoid problems created by stale files in the current directory. To override this behavior and not delete existing files, specify allow_existing_results.

verbatim

- Keywords Area
- interface
- analysis_drivers
- system
- verbatim

Specify the command Dakota uses to launch analysis driver(s) and filters

Specification

Alias: none

Argument(s): none

Default: driver/filter invocation syntax augmented with file names

Description

The typical commands that Dakota uses to launch analysis drivers are:

```
> analysis_driver parameters_file_name results_file_name
```

Dakota will automatically arrange the executables and file names.

If the analysis driver requires a different syntax, the entire command can be specified as the analysis driver and the verbatim keyword will tell Dakota to use this as the command.

Note, this will not allow the use of file_tag, because the exact command must be specified.

For additional information on invocation syntax, see the Interfaces chapter of the Users Manual[4].
Examples
In the following example, the analysis_driver command is run without any edits from Dakota.

```plaintext
interface
    analysis_driver = "matlab -nodesktop -nojvm -r 'MatlabDriver_hardcoded_filenames; exit’ "
fork
    parameters_file 'params.in'
    results_file 'results.out'
verbatim # this tells Dakota to fork the command exactly as written, instead of appending I/O filenames
```

The -r flag identifies the commands that will be run by matlab. The Matlab script has the parameters.file and results.file names hardcoded, so no additional arguments are required.

aprepro
- Keywords Area
- interface
- analysis_drivers
- system
- aprepro

Write parameters files in APREPRO syntax

Topics
This keyword is related to the topics:
- file_formats

Specification
Alias: dprepro
Argument(s): none
Default: standard parameters file format

Description
The format of data in the parameters files can be modified for direct usage with the APREPRO pre-processing tool [75] using the aprepro specification.

Without this keyword, the parameters file are written in DPrePro format. DPrePro is a utility included with Dakota, described in the Users Manual[4].

file_tag
- Keywords Area
- interface
- analysis_drivers
- system
- file_tag

Tag each parameters & results file name with the function evaluation number
6.5. INTERFACE

Specification

Alias: none

Argument(s): none

Default: no tagging

Description

If this keyword is used, Dakota will append a period and the function evaluation number to the names of the parameter and results files.

For example, if the following is included in the interface section of the Dakota input:

```
parameters_file = params.in
results_file = results.out
file_tag
```

Then for the 3rd evaluation, Dakota will write `params.in.3`, and will expect `results.out.3` to be written by the analysis driver.

If this keyword is omitted, the default is no file tagging.

File tagging is most useful when multiple function evaluations are running simultaneously using files in a shared disk space. The analysis driver will be able to infer the function evaluation number from the file names. Note that when the `file_save` keyword is used, Dakota renames parameters and results files, giving them tags, after execution of the analysis driver if they otherwise would be overwritten by the next evaluation.

file_save

- Keywords Area
- interface
- analysis_drivers
- system
- file_save

Keep the parameters & results files after the analysis driver completes

Specification

Alias: none

Argument(s): none

Default: file cleanup

Description

If file_save is used, Dakota will not delete the parameters and results files after the function evaluation is completed.

The default behavior is NOT to save these files.

If file_tag is not specified and the saved files would be overwritten by a future evaluation, Dakota renames them after the analysis driver has run by tagging them with the evaluation number.

File saving is most useful when debugging the data communication between Dakota and the simulation.
work_directory

- Keywords Area
- interface
- analysis_drivers
- system
- work_directory

Perform each function evaluation in a separate working directory

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** no work directory

<table>

</tbody>
</table>
6.5. INTERFACE

<table>
<thead>
<tr>
<th>Optional</th>
<th>replace</th>
<th>Overwrite existing files within a work directory</th>
</tr>
</thead>
</table>

**Description**

When performing concurrent evaluations, it is typically necessary to cloister simulation input and output files in separate directories to avoid conflicts. When the `work_directory` feature is enabled, Dakota will create a directory for each evaluation, with optional tagging (`directory_tag`) and saving (`directory_save`), as with files, and execute the analysis driver from that working directory.

The directory may be `named` with a string, or left anonymous to use an automatically-generated directory in the system's temporary file space, e.g., `/tmp/dakota_work_c93vb71z/`. The optional `link_files` and `copy_files` keywords specify files or directories which should appear in each working directory.

When using `work_directory`, the `analysis_drivers` may be given by an absolute path, located in (or relative to) the startup directory alongside the Dakota input file, in the list of template files linked or copied, or on the $PATH (Path% on Windows).

- `named`
  - Keywords Area
  - `interface`
  - `analysis_drivers`
  - `system`
  - `work_directory`
  - `named`

The base name of the work directory created by Dakota

**Specification**

**Alias:** none

**Argument(s):** STRING

**Default:** `workdir`

**Description**

The `named` keyword is followed by a string, indicating the name of the work directory created by Dakota. If relative, the work directory will be created relative to the directory from which Dakota is invoked.

If `named` is not used, the default work directory is a temporary directory with a system-generated name (e.g., `/tmp/dakota_work_c93vb71z/`).

**See Also**

These keywords may also be of interest:

- `directory_tag`
- `directory_save`
directory_tag

- **Keywords Area**
- **interface**
- **analysis_drivers**
- **system**
- **work_directory**
- **directory_tag**

Tag each work directory with the function evaluation number

### Specification

**Alias:** dir_tag  
**Argument(s):** none  
**Default:** no work directory tagging

### Description

If this keyword is used, Dakota will append a period and the function evaluation number to the work directory names.

If this keyword is omitted, the default is no tagging, and the same work directory will be used for ALL function evaluations. Tagging is most useful when multiple function evaluations are running simultaneously.

directory_save

- **Keywords Area**
- **interface**
- **analysis_drivers**
- **system**
- **work_directory**
- **directory_save**

Preserve the work directory after function evaluation completion

### Specification

**Alias:** dir_save  
**Argument(s):** none  
**Default:** remove work directory

### Description

By default, when a working directory is created by Dakota using the **work_directory** keyword, it is deleted after the evaluation is completed. The **directory_save** keyword will cause Dakota to leave (not delete) the directory.
6.5. INTERFACE

**link_files**
- Keywords Area
- interface
- analysis_drivers
- system
- work_directory
- link_files

Paths to be linked into each working directory

**Specification**
**Alias:** none
**Argument(s):** STRINGLIST
**Default:** no linked files

**Description**
Specifies the paths (files or directories) that will be symbolically linked from each working directory. Wildcards using * and ? are permitted. Linking is space-saving and useful for files not modified during the function evaluation. However, not all filesystems support linking, for example, support on Windows varies.

**Examples**
Specifying
```
link_files = 'siminput*.in' '/path/to/simdir1' 'simdir2/*'
```
will create copies
```
workdir/siminput*.in  # links to each of rundir / siminput*.in
workdir/simdir1/      # whole directory simdir1 linked
workdir/*             # each entry in directory simdir2 linked
```

**copy_files**
- Keywords Area
- interface
- analysis_drivers
- system
- work_directory
- copy_files

Files and directories to be copied into each working directory
**Specification**

*Alias:* none  
*Argument(s):* STRINGLIST  
*Default:* no copied files

**Description**

Specifies the files or directories that will be recursively copied into each working directory. Wildcards using * and ? are permitted.

**Examples**

Specifying

```plaintext
    copy_files = 'siminput*.in' '/path/to/simdir1' 'simdir2/*'
```

will create copies

```plaintext
    workdir/siminput*.in   # files rundir/siminput*.in copied  
    workdir/simdir1/      # whole directory simdir1 recursively copied  
    workdir/*             # contents of directory simdir2 recursively copied
```

where rundir is the directory in which Dakota was started.

```
    replace
```

- **Keywords Area**
- interface
- analysis_drivers
- system
- work_directory
- replace

Overwrite existing files within a work directory

**Specification**

*Alias:* none  
*Argument(s):* none  
*Default:* do not overwrite files

**Description**

By default, Dakota will not overwrite any existing files in a work directory. The `replace` keyword changes this behavior to force overwriting.
6.5. INTERFACE

fork

- Keywords Area
- interface
- analysis_drivers
- fork

Launch analysis drivers using fork command

Specification

Alias: none
Argument(s): none

</table>
CHAPTER 6. KEYWORDS AREA

<table>
<thead>
<tr>
<th>Optional</th>
<th>work_directory</th>
<th>Perform each function evaluation in a separate working directory</th>
</tr>
</thead>
</table>

**Description**

The *fork* interface is the most common means by which Dakota launches a separate application analysis process.

The *fork* interface is recommended over *system* for most analysis drivers that are external to Dakota (i.e. not using the *direct* interface).

As explained in the Users Manual, the parameters and results file names are passed on the command line to the analysis driver(s). If input/output filters are specified, they will be run before/after the analysis drivers. The *verbatim* keyword is used to modify the default driver/filter commands.

For additional information on invocation syntax, see the Interfaces chapter of the Users Manual[4].

**Examples**

```plaintext
interface
analysis_drivers = 'rosenbrock'
fork
parameters_file = 'params.in'
results_file   = 'results.out'
file_tag
file_save
```

**parameters_file**

- Keywords Area
- interface
- analysis_drivers
- fork
- parameters_file

Specify the name of the parameters file

**Specification**

Alias: none

Argument(s): STRING

Default: Unix temp files

**Description**

The parameters file is used by Dakota to pass the parameter values to the analysis driver. The name of the file can be optionally specified using the *parameters_file* keyword.

If this is not specified, the default data transfer files are temporary files with system-generated names (e.g., `/usr/tmp/aaaa08861`).
results_file

- Keywords Area
- interface
- analysis_drivers
- fork
- results_file

Specify the name of the results file

**Specification**

**Alias:** none  
**Argument(s):** STRING  
**Default:** Unix temp files

**Description**

The results file must be written by the analysis driver. It is read by Dakota to determine the response values for each function evaluation.

The name of the file can be optionally specified using the `results_file` keyword. If this is not specified, the default data transfer files are temporary files with system-generated names (e.g., `/usr/tmp/aaaa08861`).

allow_existing_results

- Keywords Area
- interface
- analysis_drivers
- fork
- allow_existing_results

Change how Dakota deals with existing results files

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** results files removed before each evaluation

**Description**

By default Dakota will remove existing results files before invoking the analysis_driver to avoid problems created by stale files in the current directory. To override this behavior and not delete existing files, specify `allow_existing_results`. 
verbatim

- Keywords Area
- interface
- analysis_drivers
- fork
- verbatim

Specify the command Dakota uses to launch analysis driver(s) and filters

Specification

Alias: none

Argument(s): none

Default: driver/filter invocation syntax augmented with file names

Description

The typical commands that Dakota uses to launch analysis drivers are:

```bash
> analysis_driver parameters_file_name results_file_name
```

Dakota will automatically arrange the executables and file names.

If the analysis driver requires a different syntax, the entire command can be specified as the analysis driver and the `verbatim` keyword will tell Dakota to use this as the command.

Note, this will not allow the use of `file_tag`, because the exact command must be specified.

For additional information on invocation syntax, see the Interfaces chapter of the Users Manual[4].

Examples

In the following example, the analysis_driver command is run without any edits from Dakota.

```bash
interface

analysis_driver = "matlab -nodesktop -nojvm -r 'MatlabDriver_hardcoded_filenames; exit' "
fork
    parameters_file 'params.in'
    results_file 'results.out'
verbatim # this tells Dakota to fork the command exactly as written, instead of appending I/O filenames
```

The `-r` flag identifies the commands that will be run by matlab. The Matlab script has the parameters_file and results_file names hardcoded, so no additional arguments are required.

aprepro

- Keywords Area
- interface
- analysis_drivers
- fork
- aprepro

Write parameters files in APREPRO syntax
6.5. INTERFACE

Topics
This keyword is related to the topics:

- file_formats

Specification
Alias: dprepro
  
  Argument(s): none
  
  Default: standard parameters file format

Description
The format of data in the parameters files can be modified for direct usage with the APREPRO pre-processing tool [75] using the aprepro specification

Without this keyword, the parameters file are written in DPrePro format. DPrePro is a utility included with Dakota, described in the Users Manual [4].

file_tag
  
  - Keywords Area
  
  - interface
  
  - analysis_drivers
  
  - fork
  
  - file_tag

Tag each parameters & results file name with the function evaluation number

Specification
Alias: none
  
  Argument(s): none
  
  Default: no tagging

Description
If this keyword is used, Dakota will append a period and the function evaluation number to the names of the parameter and results files.

For example, if the following is included in the interface section of the Dakota input:

```plaintext
parameters_file = params.in
results_file = results.out
file_tag
```

Then for the 3rd evaluation, Dakota will write `params.in.3`, and will expect `results.out.3` to be written by the analysis driver.

If this keyword is omitted, the default is no file tagging.

File tagging is most useful when multiple function evaluations are running simultaneously using files in a shared disk space. The analysis driver will be able to infer the function evaluation number from the file names. Note that when the file_save keyword is used, Dakota renames parameters and results files, giving them tags, after execution of the analysis driver if they otherwise would be overwritten by the next evaluation.
file\_save

- Keywords Area
- interface
- analysis\_drivers
- fork
- file\_save

Keep the parameters & results files after the analysis driver completes

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** file cleanup

**Description**

If *file\_save* is used, Dakota will not delete the parameters and results files after the function evaluation is completed.

The default behavior is NOT to save these files.

If *file\_tag* is not specified and the saved files would be overwritten by a future evaluation, Dakota renames them after the analysis driver has run by tagging them with the evaluation number.

File saving is most useful when debugging the data communication between Dakota and the simulation.

work\_directory

- Keywords Area
- interface
- analysis\_drivers
- fork
- work\_directory

Perform each function evaluation in a separate working directory

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** no work directory
### Description

When performing concurrent evaluations, it is typically necessary to cloister simulation input and output files in separate directories to avoid conflicts. When the `work_directory` feature is enabled, Dakota will create a directory for each evaluation, with optional tagging (directory_tag) and saving (directory_save), as with files, and execute the analysis driver from that working directory.

The directory may be named with a string, or left anonymous to use an automatically-generated directory in the system’s temporary file space, e.g., `/tmp/dakota_work_c93vb71z/`. The optional link_files and copy_files keywords specify files or directories which should appear in each working directory.

When using work_directory, the `analysis_drivers` may be given by an absolute path, located in (or relative to) the startup directory alongside the Dakota input file, in the list of template files linked or copied, or on the $PATH (Path% on Windows).

<table>
<thead>

Optional

When performing concurrent evaluations, it is typically necessary to cloister simulation input and output files in separate directories to avoid conflicts. When the `work_directory` feature is enabled, Dakota will create a directory for each evaluation, with optional tagging (directory_tag) and saving (directory_save), as with files, and execute the analysis driver from that working directory.

The directory may be named with a string, or left anonymous to use an automatically-generated directory in the system’s temporary file space, e.g., `/tmp/dakota_work_c93vb71z/`. The optional link_files and copy_files keywords specify files or directories which should appear in each working directory.

When using work_directory, the `analysis_drivers` may be given by an absolute path, located in (or relative to) the startup directory alongside the Dakota input file, in the list of template files linked or copied, or on the $PATH (Path% on Windows).

- **Keywords Area**
- interface
- analysis_drivers
- fork
- work_directory
• named

The base name of the work directory created by Dakota

**Specification**

**Alias:** none

**Argument(s):** STRING

**Default:** workdir

**Description**

The `named` keyword is followed by a string, indicating the name of the work directory created by Dakota. If relative, the work directory will be created relative to the directory from which Dakota is invoked.

If `named` is not used, the default work directory is a temporary directory with a system-generated name (e.g., `/tmp/dakota_work_c93vb71z/`).

**See Also**

These keywords may also be of interest:

• directory_tag

• directory_save

**directory_tag**

• Keywords Area

• interface

• analysis_drivers

• fork

• work_directory

• directory_tag

Tag each work directory with the function evaluation number

**Specification**

**Alias:** dir_tag

**Argument(s):** none

**Default:** no work directory tagging

**Description**

If this keyword is used, Dakota will append a period and the function evaluation number to the work directory names.

If this keyword is omitted, the default is no tagging, and the same work directory will be used for ALL function evaluations. Tagging is most useful when multiple function evaluations are running simultaneously.
directory_save
- Keywords Area
- interface
- analysis_drivers
- fork
- work_directory
- directory_save

Preserve the work directory after function evaluation completion

Specification
Alias: dir_save
- Argument(s): none
- Default: remove work directory

Description
By default, when a working directory is created by Dakota using the work_directory keyword, it is deleted after the evaluation is completed. The directory_save keyword will cause Dakota to leave (not delete) the directory.

link_files
- Keywords Area
- interface
- analysis_drivers
- fork
- work_directory
- link_files

Paths to be linked into each working directory

Specification
Alias: none
- Argument(s): STRINGLIST
- Default: no linked files

Description
Specifies the paths (files or directories) that will be symbolically linked from each working directory. Wildcards using * and ? are permitted. Linking is space-saving and useful for files not modified during the function evaluation. However, not all filesystems support linking, for example, support on Windows varies.
CHAPTER 6. KEYWORDS AREA

Examples
Specifying

    link_files = 'siminput*.in' '/path/to/simdir1' 'simdir2/*'

will create copies

    workdir/siminput*.in  # links to each of rundir / siminput*.in
    workdir/simdir1/      # whole directory simdir1 linked
    workdir/*/           # each entry in directory simdir2 linked

copy_files

  • Keywords Area
  • interface
  • analysis_drivers
  • fork
  • work_directory
  • copy_files

Files and directories to be copied into each working directory

Specification

Alias: none

  Argument(s): STRINGLIST
  Default: no copied files

Description

Specifies the files or directories that will be recursively copied into each working directory. Wildcards using * and ? are permitted.

Examples
Specifying

    copy_files = 'siminput*.in' '/path/to/simdir1' 'simdir2/*'

will create copies

    workdir/siminput*.in  # files rundir/siminput*.in copied
    workdir/simdir1/      # whole directory simdir1 recursively copied
    workdir/*/           # contents of directory simdir2 recursively copied

where rundir is the directory in which Dakota was started.
6.5. INTERFACE

replace

• Keywords Area
• interface
• analysis_drivers
• fork
• work_directory
• replace

Overwrite existing files within a work directory

Specification

Alias: none
Argument(s): none
Default: do not overwrite files

Description

By default, Dakota will not overwrite any existing files in a work directory. The replace keyword changes this behavior to force overwriting.

direct

• Keywords Area
• interface
• analysis_drivers
• direct

Run analysis drivers that are linked-to or compiled-with Dakota

Specification

Alias: none
Argument(s): none

<table>
<thead>
<tr>
<th>Required/-Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>processors_per_analysis</td>
<td>processors_per_analysis</td>
<td>Specify the number of processors per analysis when Dakota is run in parallel</td>
</tr>
</tbody>
</table>
CHAPTER 6. KEYWORDS AREA

Description
The primary use of the direct interface is to invoke internal test functions that perform parameter to response mappings for simple functions as inexpensively as possible. These problems are compiled directly into the Dakota executable as part of the direct function interface class and are used for algorithm testing.

Dakota also supports direct interfaces to a few select simulation codes. One example is ModelCenter, a commercial simulation management framework from Phoenix Integration. To utilize this interface, a user must first define the simulation specifics within a ModelCenter session and then save these definitions to a ModelCenter configuration file. The analysis_components specification provides the means to communicate this configuration file to Dakota’s ModelCenter interface.

Examples
The rosenbrock function is available as an executable, which can be launched with fork, and is also compiled with Dakota. The internal version can be launched with:

```
interface
  analysis_drivers = ‘rosenbrock’
  direct
```

### processors_per_analysis

- Keywords Area
- interface
- analysis_drivers
- direct
- processors_per_analysis

Specify the number of processors per analysis when Dakota is run in parallel.

Topics
This keyword is related to the topics:
- concurrency_and_parallelism

Specification
Alias: none
Argument(s): INTEGER
Default: no override of auto configure

Description
For direct function interfaces, processors_per_analysis is an additional optional setting within the required group which can be used to specify multiprocessor analysis partitions. As with the evaluation_servers, analysis_servers, evaluation_self_scheduling, evaluation_static_scheduling, analysis_self_scheduling, and analysis_static_scheduling specifications, processors_per_analysis provides a means for the user to override the automatic parallel configuration (refer to Parallel-Library and the Parallel Computing chapter of the Users Manual [4]) for the number of processors used for each analysis partition. Note that if both analysis_servers and processors_per_analysis are specified and they are not in agreement, then analysis_servers takes precedence.
6.5. INTERFACE

matlab

- Keywords Area
- interface
- analysis_drivers
- matlab

Run Matlab with a direct interface - requires special Dakota build

Specification

Alias: none
Argument(s): none

Description

Dakota supports library-linked interfaces to Matlab, Scilab, and Python scientific computation software, but they must be explicitly enabled when compiling Dakota from source. First consult the Users Manual[4] for discussion and examples.

Contact the Dakota users mailing list for assistance building and using Dakota with these interfaces.

In all these interfaces, the analysis_driver is used to specify a Matlab, Scilab, or Python file which implements the parameter to response mapping.

python

- Keywords Area

Run Scilab with a direct interface - requires special Dakota build

**Specification**

**Alias:** none

**Argument(s):** none
6.5. INTERFACE

Description

Dakota supports library-linked interfaces to Matlab, Scilab, and Python scientific computation software, but they must be explicitly enabled when compiling Dakota from source. First consult the Users Manual[4] for discussion and examples.

Contact the Dakota users mailing list for assistance building and using Dakota with these interfaces.

In all these interfaces, the analysis_driver is used to specify a Matlab, Scilab, or Python file which implements the parameter to response mapping.

grid

- Keywords Area
- interface
- analysis_drivers
- grid

Experimental capability

Specification

Alias: none

Argument(s): none

Description

For grid interfaces, no additional specifications are used at this time.

This capability has been used for interfaces with IDEA and JAVASpaces in the past and is currently a place-holder for future work with Condor and/or Globus services. It is not currently operational.

failure_capture

- Keywords Area
- interface
- analysis_drivers
- failure_capture

Determine how Dakota responds to analysis driver failure

Specification

Alias: none

Argument(s): none

Default: abort
Description

Dakota can deal with analysis failure in a few ways.

The first step is that Dakota must detect analysis failure. Importantly, Dakota always expects a results file to be written by the analysis driver, even when a failure has occurred. If the file does not exist when the analysis driver exits, Dakota itself terminates. The analysis driver communicates an analysis failure to Dakota by writing a results file beginning with the word "fail", which is not case sensitive. Everything after "fail" is ignored.

Once Dakota detects analysis failure, the failure can be mitigated in four ways:

- **abort** (the default)
- **retry**
- **recover**
- **continuation**

**abort**

- **Keywords Area**
- **interface**
- **analysis_drivers**
- **failure_capture**
- **abort**

(Defaults) Abort the Dakota job

**Specification**

**Alias:** none

**Argument(s):** none
6.5. INTERFACE

Description

abort will stop the Dakota job, as well as any other running analysis drivers.

retry

- Keywords Area
- interface
- analysis_drivers
- failure_capture
- retry

Rerun failed analyses

Specification

Alias: none

Argument(s): INTEGER

Description

The retry selection supports an integer input for specifying a limit on retries.

recover

- Keywords Area
- interface
- analysis_drivers
- failure_capture
- recover

Substitute dummy values for the responses

Specification

Alias: none

Argument(s): REALLIST

Description

The recover selection supports a list of reals for specifying the dummy function values (only zeroth order information is supported) to use for the failed function evaluation.
continuation

- Keywords Area
- interface
- analysis_drivers
- failure_capture
- continuation

Cause Dakota to step toward the failed “target” simulation from a nearby successful “source”

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

When `failure_capture continuation` is enabled and an evaluation fails, then Dakota will attempt to march incrementally from a previous good evaluation (the "source") toward the failing one (the "target"). Further details about the algorithm employed by Dakota are supplied in the User’s Manual [4].

**deactivate**

- Keywords Area
- interface
- analysis_drivers
- deactivate

Deactivate Dakota features to simplify interface development, increase execution speed, or reduce memory and disk requirements

**Specification**

**Alias:** none  
**Argument(s):** none

**Default:** Active set vector control, function evaluation cache, and restart file features are active

</tr>
</tbody>
</table>
6.5. INTERFACE

### Description

The optional `deactivate` specification block includes three features which a user may deactivate in order to simplify interface development, increase execution speed, and/or reduce memory and disk requirements:

- **Active set vector (ASV) control**: deactivation of this feature using a `deactivate active_set_vector` specification allows the user to turn off any variability in ASV values so that active set logic can be omitted in the user’s simulation interface. This option trades some efficiency for simplicity in interface development. The default behavior is to request the minimum amount of data required by an algorithm at any given time, which implies that the ASV values may vary from one function evaluation to the next. Since the user’s interface must return the data set requested by the ASV values, this interface must contain additional logic to account for any variations in ASV content. Deactivating this ASV control causes Dakota to always request a “full” data set (the full function, gradient, and Hessian data that is available from the interface as specified in the responses specification) on each function evaluation. For example, if ASV control has been deactivated and the responses section specifies four response functions, analytic gradients, and no Hessians, then the ASV on every function evaluation will be \{3 3 3 3\}, regardless of what subset of this data is currently needed. While wasteful of computations in many instances, this simplifies the interface and allows the user to return the same data set on every evaluation. Conversely, if ASV control is active (the default behavior), then the ASV requests in this example might vary from \{1 1 1 1\} to \{2 0 0 2\}, etc., according to the specific data needed on a particular function evaluation. This will require the user’s interface to read the ASV requests and perform the appropriate logic in conditionally returning only the data requested. In general, the default ASV behavior is recommended for the sake of computational efficiency, unless interface development time is a critical concern. Note that in both cases, the data returned to Dakota from the user’s interface must match the ASV passed in, or else a response recovery error will result. However, when the ASV control is deactivated, the ASV values are invariant and need not be checked on every evaluation. **Note:** Deactivating the ASV control can have a positive effect on load balancing for parallel Dakota executions. Thus, there is significant overlap in this ASV control option with speculative gradients. There is also overlap with the mode override approach used with certain optimizers to combine individual value, gradient, and Hessian requests.

- **Function evaluation cache**: deactivation of this feature using a `deactivate evaluation_cache` specification allows the user to avoid retention of the complete function evaluation history in memory. This can be important for reducing memory requirements in large-scale applications (i.e., applications with a large number of variables or response functions) and for eliminating the overhead of searching for duplicates within the function evaluation cache prior to each new function evaluation (e.g., for improving speed in problems with 1000’s of inexpensive function evaluations or for eliminating overhead when performing timing studies). However, the downside is that unnecessary computations may be performed since duplication in function evaluation requests may not be detected. For this reason, this option is not recommended when function evaluations are costly. **Note:** duplication detection within Dakota can be deactivated, but duplication detection features within specific optimizers may still be active.

- **Strict Cache Equality**: By default, Dakota’s evaluation cache and restart capabilities are based on strict binary equality. This provides a performance advantage, as it permits a hash-based data structure to be used
to search the evaluation cache. However, deactivating strict equality may prevent cache misses, which can occur when attempting to use a restart file on a machine different from the one on which it was generated.

- **Restart file**: deactivation of this feature using a `deactivate restart_file` specification allows the user to eliminate the output of each new function evaluation to the binary restart file. This can increase speed and reduce disk storage requirements, but at the expense of a loss in the ability to recover and continue a run that terminates prematurely (e.g., due to a system crash or network problem). This option is not recommended when function evaluations are costly or prone to failure. Please note that using the `deactivate restart_file` specification will result in a zero length restart file with the default name `dakota.rst`.

These three features may be deactivated independently and concurrently.

<tr>
<th>Optional</th>
<th>Group</th>
<th></th>
<th>Description</th>
</tr>
</thead>
</table>
### Description

The optional `asynchronous` keyword specifies use of asynchronous protocols (i.e., background system calls, nonblocking forks, POSIX threads) when evaluations or analyses are invoked. The `evaluation_concurrency` and `analysis_concurrency` specifications serve a dual purpose:

- when running Dakota on a single processor in asynchronous mode, the default concurrency of evaluations and analyses is all concurrency that is available. The `evaluation_concurrency` and `analysis_concurrency` specifications can be used to limit this concurrency in order to avoid machine overload or usage policy violation.

- when running Dakota on multiple processors in message passing mode, the default concurrency of evaluations and analyses on each of the servers is one (i.e., the parallelism is exclusively that of the message passing). With the `evaluation_concurrency` and `analysis_concurrency` specifications, a hybrid parallelism can be selected through combination of message passing parallelism with asynchronous parallelism on each server.

#### `evaluation_concurrency`

- **Keywords Area**
  - interface
  - asynchronous
  - `evaluation_concurrency`

  Determine how many concurrent evaluations Dakota will schedule

#### Topics

This keyword is related to the topics:

- `concurrency_and_parallelism`

#### Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** local: unlimited concurrency, hybrid: no concurrency
Description

When asynchronous execution is enabled, the default behavior is to launch all available evaluations simultaneously. The `evaluation_concurrency` keyword can be used to limit the number of concurrent evaluations.

**local_evaluation_scheduling**

- **Keywords Area**
- **interface**
- **asynchronous**

<td></td>
<td></td>
<td>Dynamic local scheduling (sequential)</td>
</tr>
</tbody>
</table>

Description

When performing asynchronous local evaluations, the `local_evaluation_scheduling` keyword controls how new evaluation jobs are dispatched when one completes.

The two options are:

- **dynamic**
- **static**

If the `local_evaluation_scheduling` is specified as dynamic (the default), each completed evaluation will be replaced by the next in the local evaluation queue.

If `local_evaluation_scheduling` is specified as static, each completed evaluation will be replaced by an evaluation number that is congruent modulo the `evaluation_concurrency`. This is helpful for relative node scheduling as described in Dakota/examples/parallelism. For example, assuming only asynchronous local concurrency (no MPI), if the local concurrency is 6 and job 2 completes, it will be replaced with job 8.
For the case of hybrid parallelism, static local scheduling results in evaluation replacements that are modulo the total capacity, defined as the product of the evaluation concurrency and the number of evaluation servers. Both of these cases can result in idle processors if runtimes are non-uniform, so the default dynamic scheduling is preferred when relative node scheduling is not required.

**Dynamic local scheduling (sequential)**

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

If the local_evaluation_scheduling is specified as dynamic (the default), each completed evaluation will be replaced by the next in the local evaluation queue.

**Static local scheduling (tiled)**

**Specification**

**Alias:** none

**Argument(s):** none
CHAPTER 6. KEYWORDS AREA

Description

If local_evaluation_scheduling is specified as static, each completed evaluation will be replaced by an evaluation number that is congruent modulo the evaluation_concurrency. This is helpful for relative node scheduling as described in Dakota/examples/parallelism. For example, assuming only asynchronous local concurrency (no M-P), if the local concurrency is 6 and job 2 completes, it will be replaced with job 8.

For the case of hybrid parallelism, static local scheduling results in evaluation replacements that are modulo the total capacity, defined as the product of the evaluation concurrency and the number of evaluation servers. Both of these cases can result in idle processors if runtimes are non-uniform, so the default dynamic scheduling is preferred when relative node scheduling is not required.

analysis_concurrency

- Keywords Area
- interface
- asynchronous
- analysis_concurrency

Limit the number of analysis drivers within an evaluation that Dakota will schedule

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none
Argument(s): INTEGER
Default: local: unlimited concurrency, hybrid: no concurrency

Description

When asynchronous execution is enabled and each evaluation involves multiple analysis drivers, then the default behavior is to launch all drivers simultaneously. The analysis_concurrency keyword can be used to limit the number of concurrently run drivers.

6.5.5 evaluation_servers

- Keywords Area
- interface
- evaluation_servers

Specify the number of evaluation servers when Dakota is run in parallel
6.5. INTERFACE

Topics
This keyword is related to the topics:

- concurrency and parallelism

Specification
Alias: none
Argument(s): INTEGER
Default: no override of auto configure

Description
The optional evaluation_servers specification supports user override of the automatic parallel configuration for the number of evaluation servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the evaluation parallelism level. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [4] for additional information.

6.5.6 evaluation_scheduling

- Keywords Area
- interface
- evaluation_scheduling

Specify the scheduling of concurrent evaluations when Dakota is run in parallel

Specification
Alias: none
Argument(s): none
Default: automatic (see discussion)

<table>
<thead>
<tr>
<th>Required/-Optional Required(Choose One)</th>
<th>Description of Group 1</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>master</td>
<td></td>
<td>master</td>
<td>Specify a dedicated master partition for parallel evaluation scheduling</td>
</tr>
<tr>
<td>peer</td>
<td></td>
<td>peer</td>
<td>Specify a peer partition for parallel evaluation scheduling</td>
</tr>
</tbody>
</table>

Description
When Dakota is run in parallel, the partition type and scheduling for the evaluation servers are determined automatically. If these settings are undesirable, they may be overridden by the user using the evaluation_scheduling keyword.

The partition type and scheduling are
master

- Keywords Area
- interface
- evaluation_scheduling
- master

Specify a dedicated master partition for parallel evaluation scheduling

Topics
This keyword is related to the topics:

- concurrency_and_parallelism

Specification
Alias: none
Argument(s): none

Description
This option overrides the Dakota parallel automatic configuration, forcing the use of a dedicated master partition. In a dedicated master partition, one processor (the "master") dynamically schedules work on the evaluation servers. This reduces the number of processors available to create servers by 1.

peer

- Keywords Area
- interface
- evaluation_scheduling
- peer

Specify a peer partition for parallel evaluation scheduling

Topics
This keyword is related to the topics:

- concurrency_and_parallelism

Specification
Alias: none
Argument(s): none
### Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a peer partition. In a peer partition, all processors are available to be assigned to evaluation servers. The scheduling, static or dynamic, must also be specified.

**dynamic**

- **Keywords Area**
- interface
- evaluation_scheduling
- peer
- dynamic

Specify dynamic scheduling in a peer partition when Dakota is run in parallel.

### Topics

This keyword is related to the topics:

- concurrency_and_parallelism

### Specification

**Alias:** none

**Argument(s):** none

**Default:** dynamic (see discussion)

### Description

In dynamic scheduling, evaluations are assigned to servers as earlier evaluations complete. Dynamic scheduling is advantageous when evaluations are of uneven duration.
static

- Keywords Area
- interface
- evaluation_scheduling
- peer
- static

Specify static scheduling in a peer partition when Dakota is run in parallel.

**Topics**

This keyword is related to the topics:

- concurrency_and_parallelism

**Specification**

Alias: none

Argument(s): none

**Description**

In static scheduling, all available evaluations are assigned to servers in a predetermined fashion. Each completed evaluation is replaced with one congruent modulo the evaluation concurrency. For example, with 6 servers, eval number 2 will be replaced by eval number 8.

6.5.7 processors_per_evaluation

- Keywords Area
- interface
- processors_per_evaluation

Specify the number of processors per evaluation server when Dakota is run in parallel

**Topics**

This keyword is related to the topics:

- concurrency_and_parallelism

**Specification**

Alias: none

Argument(s): INTEGER
6.5. INTERFACE

Description

The optional processors_per_evaluation specification supports user override of the automatic parallel configuration for the number of processors in each evaluation server. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired server size at the evaluation parallelism level. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [4] for additional information.

6.5.8 analysis_servers

- Keywords Area
- interface
- analysis_servers

Specify the number of analysis servers when Dakota is run in parallel

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none

Argument(s): INTEGER

Default: no override of auto configure

Description

The optional analysis_servers specification supports user override of the automatic parallel configuration for the number of analysis servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the analysis parallelism level. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [4] for additional information.

6.5.9 analysis_scheduling

- Keywords Area
- interface
- analysis_scheduling

Specify the scheduling of concurrent analyses when Dakota is run in parallel

Topics

This keyword is related to the topics:

- concurrency_and_parallelism
**Specification**

Alias: none

**Argument(s):** none

Default: no override of auto configure

<table>
<thead>
<tr>
<th>Required/-Optional Required (Choose One)</th>
<th>Description of Group 1</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>

<tbody>
<tr>
<td></td>
<td></td>
<td>master</td>
<td>Specify a dedicated master partition for parallel analysis scheduling</td>
</tr>
<tr>
<td></td>
<td></td>
<td>peer</td>
<td>Specify a peer partition for parallel analysis scheduling</td>
</tr>
</tbody>
</table>

**Description**

When Dakota is run in parallel, the partition type for the analysis servers is determined automatically. If this setting is undesirable, it may be overridden by the user using the `analysis_scheduling` keyword.

The partition type and scheduling are

- **master**
  - Keywords Area
  - interface
  - analysis_scheduling
  - master

Specify a dedicated master partition for parallel analysis scheduling

**Topics**

This keyword is related to the topics:

- concurrency_and_parallelism

**Specification**

Alias: none

**Argument(s):** none

**Description**

This option overrides the Dakota parallel automatic configuration, forcing the use of a dedicated master partition. In a dedicated master partition, one processor (the "master") dynamically schedules work on the analysis servers. This reduces the number of processors available to create servers by 1.
peer

- Keywords Area
- interface
- analysis_scheduling
- peer

Specify a peer partition for parallel analysis scheduling

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none
Argument(s): none

Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a peer partition. In a peer partition, all processors are available to be assigned to analysis servers. Note that unlike the case of evaluation_scheduling, it is not possible to specify static or dynamic.

6.6 responses

- Keywords Area
- responses

Description of the model output data returned to Dakota upon evaluation of an interface.

Topics

This keyword is related to the topics:

- block

Specification

Alias: none
Argument(s): none

</tbody>
</table>
### Description

The `responses` specification in a Dakota input file indicates the types of data that can be returned by an interface when invoked during Dakota’s execution. The specification includes three groups and two optional keywords.

**Group 1** is related to the type and number of responses expected by Dakota. The specification must be one of three types:

1. objective and constraint functions
2. calibration (least squares) terms and constraint functions
3. a generic response functions specification.

These correspond to optimization, least squares, and uncertainty quantification methods, respectively. The response type chosen from Group 1 should be consistent with the iterative technique called for in the method specification. Certain general-purpose iterative techniques, such as parameter studies and design of experiments methods, can be used with any of these data sets.

Each type of response has additional required and optional keywords.

**Group 2** is related to the availability of first derivatives (gradient vectors) for the response functions. The gradient specification also links back to the iterative method used. Gradients commonly are needed when the iterative study involves gradient-based optimization, local reliability analysis for uncertainty quantification, or local sensitivity analysis. They can optionally be used to build some types of surrogate models.

**Group 3** is related to the availability of second derivatives (Hessian matrices) for the response functions. Hessian availability for the response functions is similar to the gradient availability specifications, with the addition of support for "quasi-Hessians". The Hessian specification also links back to the iterative method in use; Hessians commonly would be used in gradient-based optimization by full Newton methods or in reliability analysis with second-order limit state approximations or second-order probability integrations.

### Examples

Several examples follow. The first example shows an optimization data set containing an objective function and two nonlinear inequality constraints. These three functions have analytic gradient availability and no Hessian availability.

```plaintext
responses
  objective_functions = 1
  nonlinear_inequality_constraints = 2
  analytic_gradients
  no_hessians
```
The next example shows a typical specification for a calibration data set. The six residual functions will have numerical gradients computed using the dakota finite differencing routine with central differences of 0.1% (plus/minus delta relative to current variables value = .001*value).

```
responses
  calibration_terms = 6
  numerical_gradients
  method_source dakota
  interval_type central
  fd_gradient_step_size = .001
  no_hessians
```

The last example shows a generic specification that could be used with a nondeterministic sampling iterator. The three response functions have no gradient or Hessian availability; therefore, only function values will be used by the iterator.

```
responses
  response_functions = 3
  no_gradients
  no_hessians
```

Parameter study and design of experiments iterators are not restricted in terms of the response data sets which may be catalogued; they may be used with any of the function specification examples shown above.

**Theory**

Responses specify the total data set that is available for use by the method over the course of iteration. This is distinguished from the data subset described by an active set vector (see Dakota File Data Formats in the Users Manual [Adams et al., 2010]) indicating the particular subset of the response data needed for a particular function evaluation. Thus, the responses specification is a broad description of the data to be used during a study whereas the active set vector indicates the subset currently needed.

### 6.6.1 id_responses

- **Keywords Area**
- **responses**
- **id_responses**

Name the response block, helpful when there are multiple

**Topics**

This keyword is related to the topics:

- **block_identifier**

**Specification**

**Alias:** none  
  **Argument(s):** STRING  
  **Default:** use of last responses parsed
6.6. RESPONSES

Description

The optional block identifier id.responses specifies a string to uniquely identify a particular responses specification (typically used when there are multiple present). A model can then specify or point to this response set by specifying the same string in its responses.pointer specification. For example, a model whose specification contains responses.pointer = 'R1' will use a responses set with id.responses = 'R1'.

If the id.responses specification is omitted, a particular responses specification will be used by a model only if that model omits specifying a responses_pointer and if the responses set was the last set parsed (or is the only set parsed). In common practice, if only one responses set exists, then id.responses can be safely omitted from the responses specification and responses_pointer can be omitted from the model specification(s), since there is no potential for ambiguity in this case.

6.6.2 descriptors

- Keywords Area
- responses
t- descriptors

Labels for the responses

Specification

Alias: response.descriptors

Argument(s): STRINGLIST

Default: root strings plus numeric identifiers

Description

The optional response labels specification descriptors is a list of strings which will be printed in Dakota output to identify the values for particular response functions.

Note that the ordering of responses and descriptors in the input currently must match the order of the values returned to Dakota in a results_file. See the example below.

The default descriptor strings use a root string plus a numeric identifier. This root string is

- "obj_fn" for objective functions
- "least_sq_term" for least squares terms
- "response_fn" for generic response functions
- "nln_iner_con" for nonlinear inequality constraints
- "nln_eq_con" for nonlinear equality constraints

Examples

Note that the descriptors currently must match the order of the values in the results file; they are not used to validate the returned data. For example, if the responses block contains:

```
c descriptors 'x1' 'x2' 'x3'
```

and the results file contains
Then Dakota will understand the returned data to be:

\[ x_1 = 4 \]
\[ x_2 = 5 \]
\[ x_3 = 6 \]

### 6.6.3 objective_functions

### Description

The `objective_functions` keyword specifies the number of objective functions returned to Dakota. The number of objective functions must be 1 or greater.

**Constraints**

The keywords `nonlinear_inequality_constraints` and `nonlinear_equality_constraints` specify the number of nonlinear inequality constraints, and nonlinear equality constraints, respectively. When interfacing to external applications, the responses must be returned to Dakota in this order: objective functions, nonlinear_inequality_constraints, then nonlinear_equality_constraints.

Any linear constraints present in an application need only be input to an optimizer at start up and do not need to be part of the data returned on every function evaluation. These are therefore specified in the `method` block.

Bounds on the design variables are specified in the `variables` block.

**Optional Keywords**

The optional keywords relate to scaling the objective functions (for better numerical results), formulating the problem as minimization or maximization, and dealing with multiple objective functions. If scaling is used, it is applied before multi-objective weighted sums are formed.

### See Also

These keywords may also be of interest:

- `calibration_terms`
- `response_functions`
- `method`
- `variables`

**sense**

- `Keywords Area`
- `responses`
- `objective_functions`
- `sense`

Whether to minimize or maximize each objective function

### Specification

**Alias:** none  
**Argument(s):** STRINGLIST  
**Default:** vector values = ‘minimize’
Description
The `sense` keyword is used to declare whether each objective function should be minimized or maximized. The argument options are:

- "minimization"
- "maximization" These can be abbreviated to "min" and "max".

The number of strings should either be equal to the number of objective functions, or one. If a single string is specified it will apply to each objective function.

`primary_scale_types`

- `Keywords Area`
- `responses`
- `objective_functions`
- `primary_scale_types`

Choose a scaling type for each response

Specification
Alias: `objective_function_scale_types`
Argument(s): STRINGLIST
Default: no scaling

Description
The `primary_scale_types` keyword specifies one of number of primary functions strings indicating the scaling type for each response value in methods that support scaling, when scaling is enabled.

See the scaling page for details on how to use this keyword. Note that primary response functions (objective, calibration, or response functions) cannot be automatically scaled due to lack of bounds, so valid scale types are ‘none’ ‘value’ and ‘log’.

`primary_scales`

- `Keywords Area`
- `responses`
- `objective_functions`
- `primary_scales`

Supply a characteristic value to scale each response

Specification
Alias: `objective_function_scales`
Argument(s): REALLIST
Default: 1.0 (no scaling)
6.6. RESPONSES

Description

Each entry in primary_scales is a user-specified nonzero characteristic value to scale each response.

The argument may be of length 1 or the number of primary response functions. See the scaling page for details on how to use this keyword.

weights

- Keywords Area
- responses
- objective_functions
- weights

Specify weights for each objective function

Specification

Alias: multi_objective_weights
Argument(s): REALLIST
Default: equal weights

Description

If the number of objective functions is greater than 1, then a weights specification provides a simple weighted-sum approach to combining multiple objectives into a single objective:

\[ f = \sum_{i=1}^{n} w_i f_i \]

If weights are not specified, then each response is given equal weighting:

\[ f = \frac{\sum_{i=1}^{n} f_i}{n} \]

where, in both of these cases, a "minimization" sense will retain a positive weighting for a minimizer and a "maximization" sense will apply a negative weighting.

nonlinear_inequality_constraints

- Keywords Area
- responses
- objective_functions
- nonlinear_inequality_constraints

Group to specify nonlinear inequality constraints

Specification

Alias: num_nonlinear_inequality_constraints
Argument(s): INTEGER
Default: 0
### Description

The `lower_bounds` and `upper_bounds` specifications provide the lower and upper bounds for 2-sided nonlinear inequalities of the form

\[ g_l \leq g(x) \leq g_u \]

The defaults for the inequality constraint bounds are selected so that one-sided inequalities of the form

\[ g(x) \leq 0.0 \]

result when there are no user constraint bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than `+bigRealBoundSize` (1.e+30, as defined in Minimizer) are treated as +infinity and any lower bound values less than `-bigRealBoundSize` are treated as -infinity. This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since `-DBL_MAX < -bigRealBoundSize`). The same approach is used for nonexistent linear inequality bounds and for nonexistent design variable bounds.

The `scale_types` and `scales` keywords are related to scaling of \( g(x) \). See the `scaling` page for details.

### lower_bounds

- **Keywords Area**
- **responses**
- **objective_functions**
- **nonlinear_inequality_constraints**
- lower_bounds

scalar_objectives

- Keywords Area
- responses
- objective_functions
- scalar_objectives

Number of scalar objective functions

Specification

Alias: num.scalar_objectives
Argument(s): INTEGER
**Description**

This keyword describes the number of scalar objective functions. It is meant to be used in conjunction with `field_objectives`, which describes the number of field objectives functions. The total number of objective functions, both scalar and field, is given by `objective_functions`. If only scalar objective functions are specified, it is not necessary to specify the number of scalar terms explicitly: one can simply say `objective_functions = 5` and get 5 scalar objectives. However, if there are three scalar objectives and 2 field objectives, then `objective_functions = 5` but `scalar_objectives = 3` and `field_objectives = 2`.

Objective functions are responses that are used with optimization methods in Dakota. Currently, each term in a field objective is added to the total objective function presented to the optimizer. For example, if you have one field objective with 100 terms (e.g., a time-temperature trace with 100 time points and 100 corresponding temperature points), the 100 temperature values will be added to create the overall objective.

**See Also**

These keywords may also be of interest:

- `field_objectives`
- `Keywords Area`
- `responses`
- `objective_functions`
- `field_objectives`

**Specification**

**Alias:** num_field_objectives

**Argument(s):** INTEGER

| Required/- | Description of | Dakota Keyword | Dakota Keyword |
| Optional | Group | Description | Description |
| Required | lengths | lengths | lengths |
| Optional | num_coordinates_per_field | num_coordinates_per_field | num_coordinates_per_field |
| Optinal (Choose One) | coordinate_list | coordinate_list | coordinate_list |
Description

This keyword describes the number of field objective functions. A field function is a set of related response values collected over a range of independent coordinate values which may or may not be specified by the user. For example, voltage over time would be a field function, where voltage is the field_objective and time is the independent coordinate. Similarly, temperature over time and space would be a field response, where the independent coordinates would be both time and spatial coordinates such as (x,y) or (x,y,z), depending on the application. The main difference between scalar objectives and field objectives is that for field data, we plan to implement methods that take advantage of the correlation or relationship between the field values.

Note that if there is one field_objective, and it has length 100 (meaning 100 values), then the user’s simulation code must return 100 values. Also, if there are both scalar and field objectives, the user should specify the number of scalar objectives as scalar_objectives. If there are only field objectives, it still is necessary to specify both objective_functions = NN and field_objectives = NN, where NN is the number of field objectives.

Objective functions are responses that are used with optimization methods in Dakota. Currently, each term in a field objective is added to the total objective function presented to the optimizer. For example, if you have one field objective with 100 terms (e.g. a time-temperature trace with 100 time points and 100 corresponding temperature points), the 100 temperature values will be added to create the overall objective.

num_coordinates_per_field

- Keywords Area
- responses
- objective_functions
- field_objectives
- num_coordinates_per_field

Number of independent coordinates for field responses

Specification

Alias: none

Argument(s): INTEGERLIST

Description

This keyword describes the number of independent coordinates for each field response. It is an integer vector of length field_responses. For example, if the field_responses = 2, an example would be num_coordinates_per_field = 2 1 means that the first field response has two sets of independent coordinates (perhaps x, y locations), but the second response only has one (for example, time where the field response is only dependent upon time). The actual coordinate values (e.g. the independent variables) corresponding to these field responses are defined either with coordinate_list or coordinate_data_file.

- coordinate_list

Values of the independent coordinates for field data

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Description**

Field data involves a field quantity or response that is dependent upon some quantity. For example, temperature (the field response) might be dependent on time (the independent coordinate). Another example is where acceleration (the field response) might be dependent on a spatial (x,y,z) location, in this case on three independent coordinates.

The `coordinate_list` specifies the actual coordinate values. Note that the number of dimensions are defined by `num_coordinates_per_field`. The length of the coordinate list is defined by `lengths`. If the length a particular field data response is very long (e.g. `lengths = 10000`), it will be easier to read the independent coordinates by reading a data file instead of specifying them with a coordinate list in the Dakota input file. For example, one could say `coordinate_data_file = 'my_coord_data.dat'` instead of the coordinate list values.

**See Also**

These keywords may also be of interest:

- field_responses

coordinate_data_file

- Keywords Area
- responses

<th>Dakota Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>scalar_calibration_terms</td>
<td>field_calibration_terms</td>
<td>primary_scale_types</td>
<td>primary_scales</td>
<td></td>
</tr>
</tbody>
</table>
Description

Responses for a calibration study are specified using `calibration_terms` and optional keywords for weighting/scaling, data, and constraints. In general when calibrating, Dakota automatically tunes parameters \( \theta \) to minimize discrepancies or residuals between the model and the data:

\[
R_i = y_{\text{Model}}^i(\theta) - y_{\text{Data}}^i.
\]

There are two use cases:

- If `calibration_data_file` is NOT specified, then each of the calibration terms returned to Dakota through the interface is a residual \( R_i \) to be driven toward zero.

- If `calibration_data_file` IS specified, then each of the calibration terms returned to Dakota must be a response \( y_{\text{Model}}^i(\theta) \), which Dakota will difference with the data in the specified data file.

Constraints

The keywords `nonlinear_inequality_constraints` and `nonlinear_equality_constraints` specify the number of nonlinear inequality constraints, and nonlinear equality constraints, respectively. When interfacing to external applications, the responses must be returned to Dakota in this order: calibration terms, nonlinear_inequality_constraints, then nonlinear_equality_constraints.

Any linear constraints present in an application need only be input to an optimizer at start up and do not need to be part of the data returned on every function evaluation. These are therefore specified in the method block.

Optional Keywords

The optional keywords relate to scaling responses (for better numerical results), dealing with multiple residuals, and importing data.

See `scaling` for more details on scaling. If scaling is specified, then it is applied to each residual prior to squaring:

\[
f = \sum_{i=1}^{n} w_i \left( \frac{y_{\text{Model}}^i(\theta) - y_{\text{Data}}^i}{s_i} \right)^2
\]
In the case where experimental data uncertainties are supplied, then the weights are automatically defined to be the inverse of the experimental variance:

\[
f = \sum_{i=1}^{n} \frac{1}{\sigma_i^2} (\frac{y_{Model} - y_{Data}}{s_i})^2
\]

Theory

Dakota calibration terms are typically used to solve problems of parameter estimation, system identification, and model calibration/inversion. Local least squares calibration problems are most efficiently solved using special-purpose least squares solvers such as Gauss-Newton or Levenberg-Marquardt; however, they may also be solved using any general-purpose optimization algorithm in Dakota. While Dakota can solve these problems with either least squares or optimization algorithms, the response data sets to be returned from the simulator are different when using objective functions versus calibration terms.

Least squares calibration involves a set of residual functions, whereas optimization involves a single objective function (sum of the squares of the residuals), i.e.,

\[
f = \sum_{i=1}^{n} R_i^2 = \sum_{i=1}^{n} \left( y_{Model}(\theta) - y_{Data} \right)^2
\]

where \( f \) is the objective function and the set of \( R_i \) are the residual functions, most commonly defined as the difference between a model response and data. Therefore, function values and derivative data in the least squares case involve the values and derivatives of the residual functions, whereas the optimization case involves values and derivatives of the sum of squares objective function. This means that in the least squares calibration case, the user must return each of \( n \) residuals separately as separate calibration terms. Switching between the two approaches sometimes requires different simulation interfaces capable of returning the different granularity of response data required, although Dakota supports automatic recasting of residuals into a sum of squares for presentation to an optimization method. Typically, the user must compute the difference between the model results and the observations when computing the residuals. However, the user has the option of specifying the observational data (e.g. from physical experiments or other sources) in a file.

**Description**

This keyword describes the number of field calibration terms. A set of field calibration terms is a set of related response values collected over a range of independent coordinate values which may or may not be specified by the user. For example, voltage over time would be a field function, where voltage is the field objective and time is the independent coordinate. Similarly, temperature over time and space would be a field response, where the independent coordinates would be both time and spatial coordinates such as (x,y) or (x,y,z), depending on the application. The main difference between scalar calibration terms and field calibration terms is that for field data, we plan to implement methods that take advantage of the correlation or relationship between the field values. For example, with calibration, if we want to calibrate parameters that result in a good model fit to a time-temperature curve, we may have to do some interpolation between the experimental data and the simulation data. That capability requires knowledge of the independent coordinates.

Note that if there is one field_calibration_terms, and it has length 100 (meaning 100 values), then the user’s simulation code must return 100 values. Also, if there are both scalar and field calibration, the user should specify the number of scalar terms as scalar_calibration_terms. If there are only field calibration terms, it still is necessary to specify both field_calibration_terms = NN and calibration_terms = NN, where NN is the number of field calibration terms.

Calibration terms are responses that are used with calibration methods in Dakota, such as least squares optimizers. Currently, each scalar term is added to the total sum-of-squares error function presented to the optimizer. However, each individual field value is added as well. For example, if you have one field calibration term with length 100 (e.g. a time-temperature trace with 100 time points and 100 temperature points), the 100 temperature values will be added to create the overall sum-of-squares error function used in calibration. We have an initial capability to interpolate the field data from the user’s simulation to the experimental data. For example, if the user has thermocouple readings at 20 time points, it will be an experimental field response with 20 time points and 20 temperature values. Dakota takes the 100 simulation time-temperature values (from the example above) and interpolates those to the 20 experimental points, to create 20 residual terms (simulation minus experimental data points) that will be used in calibration.

- responses
- calibration_terms
- primary_scale_types

Choose a scaling type for each response

**Specification**

**Alias:** calibration_term_scale_types least_squares_term_scale_types  
**Argument(s):** STRINGLIST  
**Default:** no scaling

**Description**

The primary_scale_types keyword specifies one of number of primary functions strings indicating the scaling type for each response value in methods that support scaling, when scaling is enabled.

See the scaling page for details on how to use this keyword. Note that primary response functions (objective, calibration, or response functions) cannot be automatically scaled due to lack of bounds, so valid scale types are 'none' 'value' and 'log'.
primary_scales

- Keywords Area
- responses
- calibration_terms
- primary_scales

Supply a characteristic value to scale each response

**Specification**

**Alias:** calibration_term_scales least_squares_term_scales  
**Argument(s):** REALLIST  
**Default:** 1.0 (no scaling)

**Description**

Each entry in primary_scales is a user-specified nonzero characteristic value to scale each response. The argument may be of length 1 or the number of primary response functions. See the scaling page for details on how to use this keyword.

weights

- Keywords Area
- responses
- calibration_terms
- weights

Apply different weights to each response

**Specification**

**Alias:** calibration_weights least_squares_weights  
**Argument(s):** REALLIST  
**Default:** equal weights

**Description**

The weights specification provides a means to specify a relative emphasis among the vector of squared residuals through multiplication of these squared residuals by a vector of weights:

$$f = \sum_{i=1}^{n} w_i R_i^2 = \sum_{i=1}^{n} w_i (y_i^M - y_i^O)^2$$
calibration_data

- Keywords Area
- responses
- calibration_terms
- calibration_data

Supply calibration data in the case of field data or mixed data (both scalar and field data).

### Specification

**Alias:** none  
**Argument(s):** none

6.6. RESPONSES

| Optional | read_field-coordinates | Add context to data: flag to indicate that field coordinates should be read |

Description

`calibration_data` specifies a keyword block that indicates that Dakota should read in various types of experimental data. This block is primarily to support the reading of field calibration data.

The user will specify the number of experiments, `num_experiments`. If this is not specified, it is assumed there is only one experiment.

For each experiment, there are four main types of data related to fields:

- **values.**

  These are the values of the experiment field (e.g. temperature values, voltage levels, etc.) These MUS-T be specified in a file named `response_descriptor.NUM.dat`, where NUM is replaced by the number of the experiment (1, 2, ...) and `response_descriptor` is replaced by the actual `response_descriptor` the user has specified. For example, if `response_descriptor` = voltage, then the voltage field values for experiment 1 should be in a file labeled `voltage.1.dat`. The field values should be in a column (e.g. one field value per row).

- **field coordinates.**

  Field coordinates specify independent variables (e.g. spatial or temporal coordinates) upon which the field depends. For example, the voltage level above might be a function of time, so time is the field coordinate. If the user has field coordinates to read, they need to specify `read_field_coordinates`. The field coordinates will then be read from a file named `response_descriptor.NUM.coords`, similar to the pattern for field values. The number of columns in the coords file should be equal to the number of field coordinates.

- **variance terms.**

  The user needs to specify `variance_type`, which defines the type of experimental measurement error. This is a string list, with one variance type specified for each scalar and each field. The available types are 'none' (no variance is specified), 'scalar' (one scalar value is specified which is applicable to all of the measurements in the field), 'diagonal' (a column vector is provided which contains the number of elements of the experimental data field. Each element of the vector contains the experimental measurement variance corresponding to that particular field measurement. For example, for the fifth term in the field, the fifth term in the diagonal vector would have the variance of that measurement), and 'matrix'. In the matrix case, a full covariance matrix is provided, which contains the pairwise correlations between each element in the field. For each field, if the `variance_type` is not 'none', a data file must be provided with the name `response_descriptor.NUM.sigma`, which contains the appropriate variance data for that field.

- **configuration variables.**

  Configuration variables specify the conditions corresponding to different experiments. This is used when there is more than one experiment. If `num_config_variables` is positive, the configuration variables for each experiment should be placed in a file named `experiment.NUM.config`, where the number of items in that config file are the `num_config_variables`. Currently, configuration variables are not being used. However, the intent is that they will be used as state variables for the simulation (for example) and not as variables that would be calibrated.
The above description is relevant for field data (with files for field values, field coordinates, field variances). If the user also has scalar experimental data, it may be entered in the same way (e.g. one file for a scalar experimental value named scalar_response_descriptor.NUM.dat, etc.) However, the user can choose to enter the scalar data in the format that we offer for pure scalar data, where we have just one file, with the number of rows of that file equal to the number of experiments. In that case, the scalar data is in the file given by the name scalar_data_file, and the format of that file is the same as discussed in calibration_data_file.

One important feature of field data is the capability to interpolate between points in the field. For example, we may have simulation data at a set of responses $y$ at time points $t$: $(t_{s1}, y_{s1}), (t_{s2}, y_{s2})$, etc. In this example, $t$ is the independent coordinate for the simulation, and the simulation time and response points are denoted with subscripts $s1, s2, s3$. If the user has experimental data that is taken at different time points: $(t_{e1}, y_{e1}), (t_{e2}, y_{e2}), ...$, it is necessary to interpolate the simulation data to provide estimates of the simulation response at the experimental time points to construct the residual terms (model - experiment) at the experimental time points. Dakota can perform this interpolation now. The user must specify the keyword interpolate, and also provide the field coordinates as well as field values for the experiment data. If the interpolate keyword is not specified, Dakota will assume that the simulation field data and the experiment field data is taken at the same set of independent coordinate values and simply construct the difference between these field terms to create the set of residuals for the sum-of-squares calculation. When interpolate is specified, the simulation coordinates are assumed fixed and the same for each simulation. These coordinates are provided in coordinate_data_file or coordinate_list. However, the experiment coordinates for each experiment can be different, and are provided in the files numbered by experiment with the file names given by response_descriptor.NUM.coords, as indicated above.

**num_experiments**

- **Keywords Area**
- **responses**
- **calibration_terms**
- **calibration_data**
- **num_experiments**

Add context to data: number of different experiments

**Specification**

Alias: none

Argument(s): INTEGER

Default: 1

**Description**

The number of different experiments. Dakota will expand the total number of residual terms based on the number of calibration terms and the number of experiments. For example, if the number of calibration terms are five scalars, and there are three experiments, the total number of residuals in the least squares formulation will be 15. See calibration_data or calibration_data_file.
**num_config_variables**

- Keywords Area
- responses
- calibration_terms
- calibration_data
- num_config_variables

Add context to data: number of configuration variables.

**Specification**

Alias: none

Argument(s): INTEGER

Default: 0

**Description**

This is an optional description. If there are multiple experiments, there can be different configuration variables (e.g. experimental settings, boundary conditions, etc.) per experiment. See calibration_data or calibration_data_file. Note: as of Dakota 6.2, configuration variables are not used. However, the intent is to treat them as state variables which will be passed to the simulation, and not treated as parameters which are calibrated.

**variance_type**

- Keywords Area
- responses
- calibration_terms
- calibration_data
- variance_type

Add context to experiment data description by specifying the type of experimental error.

**Specification**

Alias: none

Argument(s): STRINGLIST

Default: none
Description

There are four options for specifying the experimental error (e.g. the measurement error in the data you provide for calibration purposes): 'none', 'scalar', 'diagonal', or 'matrix.'

If the user specifies none, Dakota will calculate a variance (sigma-squared) term. This will be a constant variance term across all of the data). If the user specifies scalar, they can provide a scalar variance per calibration term. Note that for scalar calibration terms, only 'none' or 'scalar' are options for the measurement variance. However, for field calibration terms, there are two additional options. 'diagonal' allows the user to provide a vector of measurement variances (one for each term in the calibration field). This vector corresponds to the diagonal of the full covariance matrix of measurement errors. If the user specifies 'matrix', they can provide a full covariance matrix (not just the diagonal terms), where each element(i,j) of the covariance matrix represents the covariance of the measurement error between the i-th and j-th field values.

**scalar.data_file**

- **Keywords Area**
- **responses**
- **calibration_terms**
- **calibration.data**
- **scalar.data_file**

Specify a scalar data file to complement field data files (mixed case)

Specification

**Alias:** none
**Argument(s):** STRING

- **custom_annotated**
- **freeform**

Specify a scalar data file to complement field data files (mixed case)

Description

When calibrating both scalar and field calibration terms, to associated experimental data, the scalar data may be provided in the file named by **scalar.data_file**. This file follows the same format as: **calibration.data_file**.

Default Behavior
If `scalar_data_file` is omitted, all calibration data, including for scalar responses, will be read from the generic field `calibration_data` format.

**annotated**

- Keywords Area
- responses
- calibration_terms
- calibration_data
- scalar_data_file
- annotated

Selects annotated tabular file format for experiment data

**Topics**

This keyword is related to the topics:

- file_formats

**Specification**

Alias: none

Argument(s): none

Default: annotated format

**Description**

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. For experiment data files, each subsequent row contains an experiment ID, followed by data for configuration variables, observations, and/or observation errors, depending on context.

**Default Behavior**

By default, Dakota imports tabular experiment data files in annotated format. The `annotated` keyword can be used to explicitly specify this.

**Usage Tips**

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
Examples

Import an annotated experimental data file containing a header row, leading exp_id column, and experiment data in a calibration study

```plaintext
responses
  scalar_data_file 'shock_experiment.dat'
  annotated

Example data file with two measured quantities, three experiments:

%exp_id    velocity  stress
1           18.23     83.21
2           34.14     93.24
3           22.41     88.92
```

custom_annotated

**Description**

A custom-annotated tabular file is a whitespace-separated text file containing experiment data, including configuration variables, observations, and/or observation errors, depending on context. For experiment import, custom-annotated allows user options for whether header row and exp_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

**Default Behavior**

By default, Dakota imports tabular experiment data files in annotated format. The `custom_annotated` keyword, followed by options can be used to select other formats.

**Usage Tips**

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

**Examples**

Import an experimental data file containing a header row, no leading exp_id column, and experiment data in a calibration study

```plaintext
responses
...  
scalar_data_file 'shock_experiment.dat'
  custom_annotated header
```

Example data file with two measured quantities, three experiments:

```
% velocity  stress
 18.23    83.21
 34.14    93.24
 22.41    88.92
```

Selects free-form tabular file format for experiment data
6.6. RESPONSES

Topics
This keyword is related to the topics:

- file_formats

Specification
Alias: none
Argument(s): none
Default: annotated format

Description
A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. For experiment data files, each row contains data for configuration variables, observations, and/or observation errors, depending on context.

Default Behavior
By default, Dakota imports tabular experiment data files in annotated format. Specify freeform to instead select this format.

Usage Tips
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

Examples
Import a free-form experimental data file containing raw experiment data in a calibration study

```plaintext
responses
... scalar_data_file 'shock_experiment.dat'
freeform
```

Example data file with two measured quantities, three experiments:

```
18.23   83.21
34.14   93.24
22.41   88.92
```

interpolate

- Keywords Area
- responses
- calibration_terms
- calibration_data
- interpolate

Flag to indicate interpolation of simulation values.
CHAPTER 6. KEYWORDS AREA

Specification

Alias: none
  Argument(s): none

Description

If `interpolate` is specified, Dakota will interpolate between the simulation data and the experiment data to calculate the residuals for calibration methods. Specifically, the simulation data is interpolated onto the experimental data points. So, if the simulation data is a field of length 100 with one independent coordinate, and the experiment data is of length 5 with one independent coordinate, the interpolation is done between the 100 (t,f) simulation points (where t is the independent coordinate and f is the simulation field value) onto the five (t,e) points to obtain the residual differences between the simulation and experiment. See `calibration_data`.

### Description

Enables text file import of experimental observations for use in calibration, for scalar responses only. Dakota will calibrate model variables to best match these data. Key options include:

- **format**: whether the data file is in annotated, custom_annotated, or freeform format
- **content**: where num_experiments, num_config_variables, and variance_type indicate which columns appear in the data.

While some components may be omitted, the most complete version of a an annotated calibration data file could include columns corresponding to:

```
exp_id | configuration xvars | y data observations | y data variances
```

Each row in the file corresponds to an experiment or replicate observation of an experiment to be compared to the model output.

### Usage Tips

- The `calibration_data_file` used when ONLY scalar calibration terms are present. If there are field calibration terms, instead use `calibration_data`. For mixed scalar and field calibration terms, one may use the `calibration_data` specification, together with its sub-specification `scalar_data_file`, which uses the format described here.
Simple Case
In the simplest case, no data content descriptors are specified, so the data file must contain only the $y^{Data}$ observations which represent a single experimental observation. In this case, the data file should have $N_{terms}$ columns and 1 row, where $N_{terms}$ is the value of calibration_terms.

For each function evaluation, Dakota will run the analysis driver, which must return $N_{terms}$ model responses. Then the residuals are computed as:

$$R_i = y_i^{Model} - y_i^{Data}.$$  

These residuals can be weighted using weights.

With experimental variances
If information is known about the measurement error and the uncertainty in the measurement, that can be specified by sending the measurement error variance to Dakota. In this case, the keyword variance_type is added, followed by a string of variance types of length one or of length $N_{terms}$, where $N_{terms}$ is the value of calibration_terms. The variance_type for each response can be 'none' or 'scalar'. NOTE: you must specify the same variance_type for all scalar terms. That is, they will all be 'none' or all be 'scalar.'

For each response that has a 'scalar' variance type, each row of the datafile will now have $N_{terms}$ of $y$ data values followed by $N_{terms}$ columns that specify the measurement error (in units of variance, not standard deviation of the measurement error) for $y$ variances.

Dakota will run the analysis driver, which must return $N_{terms}$ responses. Then the residuals are computed as:

$$R_i = \frac{y_i^{Model} - y_i^{Data}}{\sqrt{\text{var}_i}}$$

for $i = 1 \ldots N_{terms}$.

Fully general case
In the most general case, the content of the data file is described by the arguments of three parameters. The parameters are optional, and defaults are described below.

- **num_experiments** ($N_{exp}$)
  
  Default: $N_{exp} = 1$

  This indicates that the data represents multiple experiments, where each experiment might be conducted with different values of configuration variables. An experiment can also be thought of as a replicate, where the experiments are run at the same values of the configuration variables.

- **num_config_variables** ($N_{cfg}$)

  This is not yet supported, but will specify the values of experimental conditions at which data were collected.

- **variance_type** ('none' or 'scalar')

  This indicates if the data file contains variances for measurement error of the experimental data. The default is 'none'.

If the user does not specify variance_type, or if the variance_type = 'none', only the actual observations are specified in the calibration_data_file. If the user specifies variance_type = 'scalar', then the calibration_data_file must contain two times calibration_terms. The first calibration_terms columns are the experimental data, and the second calibration_terms columns are the experimental measurement error variance. For example, if the user has three calibration_terms, and specifies variance_type = 'scalar', then the calibration data must contain six columns. The first three columns will contain the data, and the second three columns will contain the experimental error (in units of variance) for the data in the first three columns. These variances are used to weight the residuals in the sum-of-squares objective.
A more advanced use of the `calibration_data_file` might specify `num_experiments` $N_E$ indicating that there are multiple experiments. When multiple experiments are present, Dakota will expand the number of residuals for the repeat measurement data and difference with the data accordingly. For example, if the user has five experiments in the example above with three calibration terms, the `calibration_data_file` would need to contain five rows (one for each experiment), and each row should contain three experimental data values that will be differenced with respect to the appropriate model response. In this example, $N_E = 5$. To summarize, Dakota will calculate the sum of the squared residuals as:

$$ f = \sum_{i=1}^{N_E} R_i^2 $$

where the residuals now are calculated as:

$$ R_i = y_i^{Model}(\theta) - y_i^{Data}. $$

annotated

- calibration_data_file
- annotated

Selects annotated tabular file format for experiment data

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. For experiment data files, each subsequent row contains an experiment ID, followed by data for configuration variables, observations, and/or observation errors, depending on context.

Default Behavior

By default, Dakota imports tabular experiment data files in annotated format. The `annotated` keyword can be used to explicitly specify this.

Usage Tips
• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

Examples

Import an annotated experimental data file containing a header row, leading exp_id column, and experiment data in a calibration study

    responses ...
    scalar_data_file 'shock_experiment.dat'
    annotated

Example data file with two measured quantities, three experiments:

```
%exp_id  velocity  stress
1     18.23      83.21
2     34.14      93.24
3     22.41      88.92
```

Add context to experiment data description by specifying the type of experimental error.
6.6. RESPONSES

**Specification**

**Alias:** none

**Argument(s):** STRINGLIST

**Default:** none

**Description**

There are four options for specifying the experimental error (e.g. the measurement error in the data you provide for calibration purposes): 'none', 'scalar', 'diagonal', or 'matrix.'

If the user specifies none, Dakota will calculate a variance (sigma-squared) term. This will be a constant variance term across all of the data). If the user specifies scalar, they can provide a scalar variance per calibration term. Note that for scalar calibration terms, only 'none' or 'scalar' are options for the measurement variance. However, for field calibration terms, there are two additional options. 'diagonal' allows the user to provide a vector of measurement variances (one for each term in the calibration field). This vector corresponds to the diagonal of the full covariance matrix of measurement errors. If the user specifies 'matrix', they can provide a full covariance matrix (not just the diagonal terms), where each element(i,j) of the covariance matrix represents the covariance of the measurement error between the i-th and j-th field values.

</tr>
</tbody>
</table>

**Description**

The lower_bounds and upper_bounds specifications provide the lower and upper bounds for 2-sided nonlinear inequalities of the form

\[ g_l \leq g(x) \leq g_u \]
The defaults for the inequality constraint bounds are selected so that one-sided inequalities of the form
\[ g(x) \leq 0.0 \]
result when there are no user constraint bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than \( +\text{bigRealBoundSize} \) (1.e+30, as defined in Minimizer) are treated as \( +\infty \) and any lower bound values less than \( -\text{bigRealBoundSize} \) are treated as \( -\infty \). This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since \( -\text{DBL\_MAX} < -\text{bigRealBoundSize} \)). The same approach is used for nonexistent linear inequality bounds and for nonexistent design variable bounds.

The `scale_types` and `scales` keywords are related to scaling of \( g(x) \). See the `scaling` page for details.

<td>Optional</td>
<td></td>
<td>scalar_responses</td>
<td>Number of scalar response functions</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>field_responses</td>
<td>Number of field responses functions</td>
</tr>
</tbody>
</table>

Description

A generic response data set is specified using response_functions. Each of these functions is simply a response quantity of interest with no special interpretation taken by the method in use.

Whereas objective, constraint, and residual functions have special meanings for optimization and least squares algorithms, the generic response function data set need not have a specific interpretation and the user is free to define whatever functional form is convenient.

Theory

This type of data set is used by uncertainty quantification methods, in which the effect of parameter uncertainty on response functions is quantified, and can also be used in parameter study and design of experiments methods (although these methods are not restricted to this data set), in which the effect of parameter variations on response functions is evaluated.

- calibration_terms

scalar_responses

- Keywords Area
- responses
- response_functions
- scalar_responses

Number of scalar response functions

Specification

Alias: num_scalar_responses

Argument(s): INTEGER

Description

This keyword describes the number of scalar response functions. It is meant to be used in conjunction with field_responses, which describes the number of field response functions. The total number of response functions, both scalar and field, is given by response_functions. If only scalar responses functions are specified, it is not necessary to specify the number of scalar terms explicitly: one can simply say response_functions = 5 and get 5 scalar responses. However, if there are three scalar responses and 2 field responses, then response_functions = 5 but scalar_responses = 3 and field_responses = 2.

This type of data set is used by uncertainty quantification methods, in which the effect of parameter uncertainty on response functions is quantified, and can also be used in parameter study and design of experiments methods (although these methods are not restricted to this data set), in which the effect of parameter variations on response functions is evaluated.

<tr>
<td>Optional (Choose One)</td>
<td>coordinate_list</td>
<td>coordinate_data_file</td>
<td>Name of the file which stores the values of the independent coordinates for field data</td>
</tr>
</tbody>
</table>

Description

This keyword describes the number of field response functions. A field function is a set of related response values collected over a range of independent coordinate values which may or may not be specified by the user. For example, voltage over time would be a field function, where voltage is the field objective and time is the independent coordinate. Similarly, temperature over time and space would be a field response, where the independent coordinates would be both time and spatial coordinates such as (x,y) or (x,y,z), depending on the application. The main difference between scalar responses and field responses is that for field data, we plan to implement methods that take advantage of the correlation or relationship between the field values.

Note that if there is one field response, and it has length 100 (meaning 100 values), then the user’s simulation code must return 100 values. Also, if there are both scalar and field responses, the user should specify the number of scalar responses as scalar_responses. If there are only field responses, it still is necessary to specify both response_functions = NN and field_responses = NN, where NN is the number of field responses.

This type of data set is used by uncertainty quantification methods, in which the effect of parameter uncertainty on response functions is quantified, and can also be used in parameter study and design of experiments methods (although these methods are not restricted to this data set), in which the effect of parameter variations on response functions is evaluated. Currently, field response functions will be translated back to scalar responses. So, a field of length 100 will be treated as 100 separate scalar responses. However, in future versions of Dakota, we plan to implement methods which can exploit the nature of field data.

• field_responses

coordinate_list

• Keywords Area
• responses
• response_functions
• field_responses
• coordinate_list

Values of the independent coordinates for field data

Specification

Alias: none
Argument(s): REALLIST

Description

Field data involves a field quantity or response that is dependent upon some quantity. For example, temperature (the field response) might be dependent on time (the independent coordinate). Another example is where acceleration (the field response) might be dependent on a spatial (x,y,z) location, in this case on three independent coordinates.

The coordinate_list specifies the actual coordinate values. Note that the number of dimensions are defined by num_coordinates_per_field. The length of the coordinate list is defined by lengths. If the length a particular field data response is very long (e.g. lengths = 10000), it will be easier to read the independent coordinates by reading a data file instead of specifying them with a coordinate list in the Dakota input file. For example, one could say coordinate_data_file = 'my_coord_data.dat' instead of the coordinate list values.

See Also

• field_responses
coordinate_data_file

- Keywords Area
- responses
- response_functions
- field_responses
- coordinate_data_file

Name of the file which stores the values of the independent coordinates for field data

**Specification**

**Alias:** none

**Argument(s):** STRING

**Description**

Field data involves a field quantity or response that is dependent upon some quantity. For example, temperature (the field response) might be dependent on time (the independent coordinate). Another example is where acceleration (the field response) might be dependent on a spatial (x,y,z) location, in this case on three independent coordinates.

The `coordinate_data_file` specifies the file which contains the actual coordinate values. Note that the number of dimensions (the number of columns of the file) is defined by `num_coordinates_per_field`. The length of the file (e.g. the number of rows in the file) is defined by `lengths`. If the length a particular field data response is very long (e.g. `lengths = 10000`), we recommend using this option. It is easier to read the independent coordinates by reading a data file instead of specifying them with a coordinate list in the Dakota input file. However, an alternative to reading them from a file is to read them via `coordinate_list`.

Description

The *mixed_gradients* specification means that some gradient information is available directly from the simulation (analytic) whereas the rest will have to be finite differenced (numerical). This specification allows the user to make use of as much analytic gradient information as is available and then finite difference for the rest.

The *method_source, interval_type, and fd_gradient_step_size* specifications pertain to those functions listed by the *id_numerical_gradients* list.

Examples

For example, the objective function may be a simple analytic function of the design variables (e.g., weight) whereas the constraints are nonlinear implicit functions of complex analyses (e.g., maximum stress).

Specify which finite difference routine is used

Specification
Alias: none
Argument(s): none
Default: dakota

Description
The method_source setting specifies the source of the finite differencing routine that will be used to compute the numerical gradients:

- dakota (default)
- vendor
dakota denotes Dakota’s internal finite differencing algorithm and vendor denotes the finite differencing algorithm supplied by the iterator package in use (DOT, CONMIN, NPSOL, NL2SOL, NLSSOL, and OPT++ each have their own internal finite differencing routines). The dakota routine is the default since it can execute in parallel and exploit the concurrency in finite difference evaluations (see Exploiting Parallelism in the Users Manual [4]).

However, the vendor setting can be desirable in some cases since certain libraries will modify their algorithm when the finite differencing is performed internally. Since the selection of the dakota routine hides the use of finite differencing from the optimizers (the optimizers are configured to accept user-supplied gradients, which some algorithms assume to be of analytic accuracy), the potential exists for the vendor setting to trigger the use of an algorithm more optimized for the higher expense and/or lower accuracy of finite-differencing. For example, NPSOL uses gradients in its line search when in user-supplied gradient mode (since it assumes they are inexpensive), but uses a value-based line search procedure when internally finite differencing. The use of a value-based line search will often reduce total expense in serial operations. However, in parallel operations, the use of gradients in the NPSOL line search (user-supplied gradient mode) provides excellent load balancing without need to resort to speculative optimization approaches.

In summary, then, the dakota routine is preferred for parallel optimization, and the vendor routine may be preferred for serial optimization in special cases.

**Description**

The **dakota** routine is the default since it can execute in parallel and exploit the concurrency in finite difference evaluations (see Exploiting Parallelism in the Users Manual [4]).

When the **method_source** is **dakota**, the user may also specify the type of scaling desired when determining the finite difference step size. The choices are **absolute**, **bounds**, and **relative**. For **absolute**, the step size will be applied as is. For **bounds**, it will be scaled by the range of each parameter. For **relative**, it will be scaled by the parameter value.

**ignore_bounds**
- **Keywords** Area
- responses
- mixed_gradients
- **dakota**
- **ignore_bounds**

Do not respect bounds when computing gradients or Hessians

**Specification**

**Alias:** none
- **Argument(s):** none
- **Default:** bounds respected

**Description**

When Dakota computes gradients or Hessians by finite differences and the variables in question have bounds, it by default chooses finite-differencing steps that keep the variables within their specified bounds. Older versions of Dakota generally ignored bounds when computing finite differences. To restore the older behavior, one can add keyword **ignore_bounds** to the **response specification** when **method_source dakota** (or just **dakota**) is also specified.

In forward difference or backward difference computations, honoring bounds is straightforward.

To honor bounds when approximating $\frac{\partial f}{\partial x_i}$, i.e., component $i$ of the gradient of $f$, by central differences, Dakota chooses two steps $h_1$ and $h_2$ with $h_1 \neq h_2$, such that $x + h_1 e_i$ and $x + h_2 e_i$ both satisfy the bounds, and then computes

$$
\frac{\partial f}{\partial x_i} \approx \frac{h_2^2(f_1 - f_0) - h_1^2(f_2 - f_0)}{h_1 h_2 (h_2 - h_1)},
$$

with $f_0 = f(x)$, $f_1 = f(x + h_1 e_i)$, and $f_2 = f(x + h_2 e_i)$.

- responses
- mixed_gradients
- interval_type

Specify how to compute gradients and hessians

Specification

Alias: none

Argument(s): none

Default: forward
Description
The `interval_type` setting is used to select between forward and central differences in the numerical gradient calculations. The `dakota`, `DOT vendor`, and `OPT++ vendor` routines have both forward and central differences available, the `CONMIN` and `NL2SOL vendor` routines support forward differences only, and the `NP-SOL` and `NLSSOL vendor` routines start with forward differences and automatically switch to central differences as the iteration progresses (the user has no control over this). The following forward difference expression

\[ \nabla f(x) \approx \frac{f(x + h e_i) - f(x)}{h} \]

and the following central difference expression

\[ \nabla f(x) \approx \frac{f(x + h e_i) - f(x - h e_i)}{2h} \]

are used to estimate the \( i^{th} \) component of the gradient vector.

fd_step_size

- Keywords Area
- responses
- mixed_gradients
- fd_step_size

Step size used when computing gradients and Hessians

Specification

Alias: fd_gradient_step_size
Argument(s): REALLIST
Default: 0.001

Description

fd_gradient_step_size specifies the relative finite difference step size to be used in the computations. Either a single value may be entered for use with all parameters, or a list of step sizes may be entered, one for each parameter.

The latter option of a list of step sizes is only valid for use with the Dakota finite differencing routine. For Dakota with an interval scaling type of absolute, the differencing interval will be fd_gradient_step_size.

For Dakota with and interval scaling type of bounds, the differencing intervals are computed by multiplying fd_gradient_step_size with the range of the parameter. For Dakota (with an interval scaling type of relative), DOT, CONMIN, and OPT++, the differencing intervals are computed by multiplying the fd_gradient_step_size with the current parameter value. In this case, a minimum absolute differencing interval is needed when the current parameter value is close to zero. This prevents finite difference intervals for the parameter which are too small to distinguish differences in the response quantities being computed. Dakota, DOT, CONMIN, and OPT++ all use .01*fd_gradient_step_size as their minimum absolute differencing interval. With a fd_gradient_step_size = .001, for example, Dakota, DOT, CONMIN, and OPT++ will use intervals of .001+current value with a minimum interval of 1.e-5. NPSOL and NLSSOL use a different formula for their finite difference intervals: fd_gradient_step_size*(1+|current parameter value|). This definition has the advantage of eliminating the need for a minimum absolute differencing interval since the interval no longer goes to zero as the current parameter value goes to zero.

Specify which finite difference routine is used.
6.6. RESPONSES

Specification

Alias: none
- Argument(s): none
- Default: dakota

Description

The method_source setting specifies the source of the finite differencing routine that will be used to compute the numerical gradients:

- **dakota** (default)
- **vendor**

**dakota** denotes Dakota’s internal finite differencing algorithm and **vendor** denotes the finite differencing algorithm supplied by the iterator package in use (DOT, CONMIN, NPSOL, NL2SOL, NLSSOL, and OPT++ each have their own internal finite differencing routines). The **dakota** routine is the default since it can execute in parallel and exploit the concurrency in finite difference evaluations (see Exploiting Parallelism in the Users Manual [4]).

However, the **vendor** setting can be desirable in some cases since certain libraries will modify their algorithm when the finite differencing is performed internally. Since the selection of the **dakota** routine hides the use of finite differencing from the optimizers (the optimizers are configured to accept user-supplied gradients, which some algorithms assume to be of analytic accuracy), the potential exists for the **vendor** setting to trigger the use of an algorithm more optimized for the higher expense and/or lower accuracy of finite-differencing. For example, NPSOL uses gradients in its line search when in user-supplied gradient mode (since it assumes they are inexpensive), but uses a value-based line search procedure when internally finite differencing. The use of a value-based line search will often reduce total expense in serial operations. However, in parallel operations, the use of gradients in the NPSOL line search (user-supplied gradient mode) provides excellent load balancing without need to resort to speculative optimization approaches.

In summary, then, the **dakota** routine is preferred for parallel optimization, and the **vendor** routine may be preferred for serial optimization in special cases.

### Description

The dakota routine is the default since it can execute in parallel and exploit the concurrency in finite difference evaluations (see Exploiting Parallelism in the Users Manual [4]).

When the method_source is dakota, the user may also specify the type of scaling desired when determining the finite difference step size. The choices are absolute, bounds, and relative. For absolute, the step size will be applied as is. For bounds, it will be scaled by the range of each parameter. For relative, it will be scaled by the parameter value.

**ignore_bounds**

- Keywords Area
- responses
- numerical_gradients
- dakota
- ignore_bounds

Do not respect bounds when computing gradients or Hessians

### Specification

Alias: none

Argument(s): none

Default: bounds respected

### Description

When Dakota computes gradients or Hessians by finite differences and the variables in question have bounds, it by default chooses finite-differencing steps that keep the variables within their specified bounds. Older versions of Dakota generally ignored bounds when computing finite differences. To restore the older behavior, one can add keyword ignore_bounds to the response specification when method_source dakota (or just dakota) is also specified.
In forward difference or backward difference computations, honoring bounds is straightforward.

To honor bounds when approximating $\frac{\partial f}{\partial x_i}$, i.e., component $i$ of the gradient of $f$, by central differences, Dakota chooses two steps $h_1$ and $h_2$ with $h_1 \neq h_2$, such that $x + h_1 e_i$ and $x + h_2 e_i$ both satisfy the bounds, and then computes

$$
\frac{\partial f}{\partial x_i} \approx \frac{h_2^2(f_1 - f_0) - h_1^2(f_2 - f_0)}{h_1 h_2(h_2 - h_1)},
$$

with $f_0 = f(x)$, $f_1 = f(x + h_1 e_i)$, and $f_2 = f(x + h_2 e_i)$.

Specify how to compute gradients and hessians
6.6. RESPONSES

**Specification**

*Alias:* none  
*Argument(s):* none  
*Default:* forward

**Description**

The `interval_type` setting is used to select between forward and central differences in the numerical gradient calculations. The `dakota`, `DOT vendor`, and `OPT++ vendor` routines have both forward and central differences available, the `CONMIN` and `NL2SOL vendor` routines support forward differences only, and the `NP-SOL` and `NLSSOL vendor` routines start with forward differences and automatically switch to central differences as the iteration progresses (the user has no control over this). The following forward difference expression

\[
\nabla f(x) \approx \frac{f(x + h e_i) - f(x)}{h}
\]

and the following central difference expression

\[
\nabla f(x) \approx \frac{f(x + h e_i) - f(x - h e_i)}{2h}
\]

are used to estimate the \(i^{th}\) component of the gradient vector.

\texttt{fd}\_\texttt{step}\_\texttt{size}

- Keywords Area
- responses
- numerical\_gradients
- \texttt{fd}\_\texttt{step}\_\texttt{size}

Step size used when computing gradients and Hessians

Specification

Alias: \texttt{fd}\_\texttt{gradient}\_\texttt{step}\_\texttt{size}
  Argument(s): REALLIST
  Default: 0.001

Description

\texttt{fd}\_\texttt{gradient}\_\texttt{step}\_\texttt{size} specifies the relative finite difference step size to be used in the computations. Either a single value may be entered for use with all parameters, or a list of step sizes may be entered, one for each parameter.

The latter option of a list of step sizes is only valid for use with the Dakota finite differencing routine. For Dakota with an interval scaling type of \texttt{absolute}, the differencing interval will be \texttt{fd}\_\texttt{gradient}\_\texttt{step}\_\texttt{size}.

For Dakota with an interval scaling type of \texttt{bounds}, the differencing intervals are computed by multiplying \texttt{fd}\_\texttt{gradient}\_\texttt{step}\_\texttt{size} with the range of the parameter. For Dakota (with an interval scaling type of \texttt{relative}), DOT, CONMIN, and OPT++, the differencing intervals are computed by multiplying the \texttt{fd}\_\texttt{gradient}\_\texttt{step}\_\texttt{size} with the current parameter value. In this case, a minimum absolute differencing interval is needed when the current parameter value is close to zero. This prevents finite difference intervals for the parameter which are too small to distinguish differences in the response quantities being computed. Dakota, DOT, CONMIN, and OPT++ all use .01*\texttt{fd}\_\texttt{gradient}\_\texttt{step}\_\texttt{size} as their minimum absolute differencing interval. With a \texttt{fd}\_\texttt{gradient}\_\texttt{step}\_\texttt{size} = .001, for example, Dakota, DOT, CONMIN, and OPT++ will use intervals of .001*current value with a minimum interval of 1.e-5. NPSOL and NLSSOL use a different formula for their finite difference intervals: \texttt{fd}\_\texttt{gradient}\_\texttt{step}\_\texttt{size}*(1+|current parameter value|). This definition has the advantage of eliminating the need for a minimum absolute differencing interval since the interval no longer goes to zero as the current parameter value goes to zero.
6.6.10 no_hessians

- Keywords Area
- responses
- no_hessians

Hessians will not be used

Specification

Alias: none

Argument(s): none

Description

The no_hessians specification means that the method does not require Dakota to manage the computation of any Hessian information. Therefore, it will neither be retrieved from the simulation nor computed by Dakota. The no_hessians keyword is a complete specification for this case. Note that, in some cases, Hessian information may still be being approximated internal to an algorithm (e.g., within a quasi-Newton optimizer such as optpp_qnewton); however, Dakota has no direct involvement in this process and the responses specification need not include it.

**Description**

The `numerical_hessians` specification means that Hessian information is needed and will be computed with finite differences using either first-order gradient differencing (for the cases of `analytic_gradients` or for the functions identified by `id_analytic_gradients` in the case of `mixed_gradients`) or first- or second-order function value differencing (all other gradient specifications). In the former case, the following expression

\[
\nabla^2 f(x)_i \cong \frac{\nabla f(x + h e_i) - \nabla f(x)}{h}
\]

estimates the \(i^{th}\) Hessian column, and in the latter case, the following expressions

\[
\nabla^2 f(x)_{i,j} \cong \frac{f(x + h_i e_i + h_j e_j) - f(x + h_i e_i) - f(x - h_j e_j) + f(x)}{h_i h_j}
\]

and

\[
\nabla^2 f(x)_{i,j} \cong \frac{f(x + h e_i + h e_j) - f(x + h e_i - h e_j) - f(x - h e_i + h e_j) + f(x - h e_i - h e_j)}{4h^2}
\]

provide first- and second-order estimates of the \(ij^{th}\) Hessian term. Prior to Dakota 5.0, Dakota always used second-order estimates. In Dakota 5.0 and newer, the default is to use first-order estimates (which honor bounds on the variables and require only about a quarter as many function evaluations as do the second-order estimates), but specifying `central` after `numerical_hessians` causes Dakota to use the old second-order estimates, which do not honor bounds. In optimization algorithms that use Hessians, there is little reason to use second-order differences in computing Hessian approximations.

- fd_step_size

Step size used when computing gradients and Hessians

Specification

Alias: fd_hessian_step_size

Argument(s): REALLIST

Default: 0.001 (forward), 0.002 (central)

Description

fd_gradient_step_size specifies the relative finite difference step size to be used in the computations. Either a single value may be entered for use with all parameters, or a list of step sizes may be entered, one for each parameter.

The latter option of a list of step sizes is only valid for use with the Dakota finite differencing routine. For Dakota with an interval scaling type of absolute, the differencing interval will be fd_gradient_step_size.

For Dakota with and interval scaling type of bounds, the differencing intervals are computed by multiplying fd_gradient_step_size with the range of the parameter. For Dakota (with an interval scaling type of relative), DOT, CONMIN, and OPT++, the differencing intervals are computed by multiplying the fd_gradient_step_size with the current parameter value. In this case, a minimum absolute differencing interval is needed when the current parameter value is close to zero. This prevents finite difference intervals for the parameter which are too small to distinguish differences in the response quantities being computed. Dakota, DOT, CONMIN, and OPT++ all use .01*fd_gradient_step_size as their minimum absolute differencing interval. With a fd_gradient_step_size = .001, for example, Dakota, DOT, CONMIN, and OPT++ will use intervals of .001*current value with a minimum interval of 1.e-5. NPSOL and NLSSOL use a different formula for their finite difference intervals: fd_gradient_step_size*(1+|current parameter value|). This definition has the advantage of eliminating the need for a minimum absolute differencing interval since the interval no longer goes to zero as the current parameter value goes to zero.

6.6.12 quasi_hessians

- Keywords Area
- responses
- quasi_hessians

Hessians are needed and will be approximated by secant updates (BFGS or SR1) from a series of gradient evaluations
Specification

Alias: none

Argument(s): none
### Description

The `quasi_hessians` specification means that Hessian information is needed and will be approximated using secant updates (sometimes called "quasi-Newton updates", though any algorithm that approximates Newton’s method is a quasi-Newton method).

Compared to finite difference numerical Hessians, secant approximations do not expend additional function evaluations in estimating all of the second-order information for every point of interest. Rather, they accumulate approximate curvature information over time using the existing gradient evaluations.

The supported secant approximations include the Broyden-Fletcher-Goldfarb-Shanno (BFGS) update (specified with the keyword `bfgs`) and the Symmetric Rank 1 (SR1) update (specified with the keyword `sr1`).

**Argument(s):** none
CHAPTER 6. KEYWORDS AREA

Required/Optional | Description of Group | Dakota Keyword | Dakota Keyword Description
--- | --- | --- | ---
Optional |  | damped | Numerical safeguarding for BFGS updates

### Description

Broyden-Fletcher-Goldfarb-Shanno (BFGS) update will be used to compute quasi-Hessians.

\[
B_{k+1} = B_k - \frac{B_k s_k s_k^T B_k}{s_k^T B_k s_k} + \frac{y_k y_k^T}{y_k^T s_k}
\]

where \(B_k\) is the \(k^{th}\) approximation to the Hessian, \(s_k = x_{k+1} - x_k\) is the step and \(y_k = \nabla f_{k+1} - \nabla f_k\) is the corresponding yield in the gradients.

### Notes

- Initial scaling of \(y_k^T s_k I\) is used for \(B_0\) prior to the first update.
- Numerical safeguarding is used to protect against numerically small denominators within the updates.
- This safeguarding skips the update if \(|y_k^T s_k| < 10^{-6} s_k^T B_k s_k\)
- Additional safeguarding can be added using the damped option, which utilizes an alternative damped BF-GS update when the curvature condition \(y_k^T s_k > 0\) is nearly violated.

Description

Hessian availability must be specified with either no_hessians, numerical_hessians, quasi_hessians, analytic_hessians, or mixed_hessians.

The mixed_hessians specification means that some Hessian information is available directly from the simulation (analytic) whereas the rest will have to be estimated by finite differences (numerical) or approximated by secant updating. As for mixed gradients, this specification allows the user to make use of as much analytic information as is available and then estimate/approximate the rest.

The id_analytic_hessians list specifies by number the functions which have analytic Hessians, and the id_numerical_hessians and id_quasi_hessians lists specify by number the functions which must use numerical Hessians and secant Hessian updates, respectively. Each function identifier, from 1 through the total number of functions, must appear once and only once within the union of the id_analytic_hessians, id_numerical_hessians, and id_quasi_hessians lists.

The fd_hessian_step_size and bfgs, damped bfgs, or sr1 secant update selections are as described previously in responses and pertain to those functions listed by the id_numerical_hessians and id_quasi_hessians lists.

**fd_step_size**

- Keywords Area
- responses
- mixed_hessians
- `id_numerical_hessians`
- `fd_step_size`

Step size used when computing gradients and Hessians

**Specification**

Alias: `fd_hessian_step_size`

Argument(s): `REALLIST`

Default: 0.001 (forward), 0.002 (central)

**Description**

`fd_gradient_step_size` specifies the relative finite difference step size to be used in the computations. Either a single value may be entered for use with all parameters, or a list of step sizes may be entered, one for each parameter.

The latter option of a list of step sizes is only valid for use with the Dakota finite differencing routine. For Dakota with an interval scaling type of `absolute`, the differencing interval will be `fd_gradient_step_size`.

For Dakota with and interval scaling type of `bounds`, the differencing intervals are computed by multiplying `fd_gradient_step_size` with the range of the parameter. For Dakota (with an interval scaling type of
relative), DOT, CONMIN, and OPT++, the differencing intervals are computed by multiplying the \texttt{fd-gradient_step_size} with the current parameter value. In this case, a minimum absolute differencing interval is needed when the current parameter value is close to zero. This prevents finite difference intervals for the parameter which are too small to distinguish differences in the response quantities being computed. Dakota, DOT, CONMIN, and OPT++ all use \texttt{.01*fd\_gradient\_step\_size} as their minimum absolute differencing interval. With a \texttt{fd\_gradient\_step\_size = .001}, for example, Dakota, DOT, CONMIN, and OPT++ will use intervals of \texttt{.001*current value} with a minimum interval of \texttt{1.e-5}. NPSOL and NLSSOL use a different formula for their finite difference intervals: \texttt{fd\_gradient\_step\_size*(1+|current parameter value|)}. This definition has the advantage of eliminating the need for a minimum absolute differencing interval since the interval no longer goes to zero as the current parameter value goes to zero.

**Description**
Broyden-Fletcher-Goldfarb-Shanno (BFGS) update will be used to compute quasi-Hessians.

\[
B_{k+1} = B_k - \frac{B_k s_k s_k^T B_k}{s_k^T B_k s_k} + \frac{y_k y_k^T}{y_k^T s_k}
\]

where \( B_k \) is the \( k^{th} \) approximation to the Hessian, \( s_k = x_{k+1} - x_k \) is the step and \( y_k = \nabla f_{k+1} - \nabla f_k \) is the corresponding yield in the gradients.

**Notes**
- Initial scaling of \( \frac{y_k^T y_k}{y_k^T s_k} I \) is used for \( B_0 \) prior to the first update.
- Numerical safeguarding is used to protect against numerically small denominators within the updates.
- This safeguarding skips the update if \( |y_k^T s_k| < 10^{-6} s_k^T B_k s_k \)
- Additional safeguarding can be added using the damped option, which utilizes an alternative damped BFGS update when the curvature condition \( y_k^T s_k > 0 \) is nearly violated.
Numerical safeguarding for BFGS updates

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** undamped BFGS

**Description**

See parent page.

Use the Symmetric Rank 1 update method to compute quasi-Hessians

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

The Symmetric Rank 1 (SR1) update (specified with the keyword **sr1**) will be used to compute quasi-Hessians.

\[ B_{k+1} = B_k + \frac{(y_k - B_k s_k)(y_k - B_k s_k)^T}{(y_k - B_k s_k)^T s_k} \]

where \( B_k \) is the \( k^{th} \) approximation to the Hessian, \( s_k = x_{k+1} - x_k \) is the step and \( y_k = \nabla f_{k+1} - \nabla f_k \) is the corresponding yield in the gradients.

**Notes**
• Initial scaling of $\mathbf{y}_k^T \mathbf{s}_k I$ is used for $B_0$ prior to the first update.

• Numerical safeguarding is used to protect against numerically small denominators within the updates.

• This safeguarding skips the update if $|(y_k - B_k s_k)^T s_k| < 10^{-6}||s_k||_2 ||y_k - B_k s_k||_2$

id_analytic_hessians

• Keywords Area
  • responses
  • mixed_hessians
  • id_analytic_hessians

Identify which analytical Hessian corresponds to which response

Topics

This keyword is related to the topics:

• objective_function_pointer

Specification

Alias: none

Argument(s): INTEGERLIST

Description

The id_analytic_hessians list specifies by number the functions which have analytic Hessians, and the id_numerical_hessians and id_quasi_hessians lists specify by number the functions which must use numerical Hessians and secant Hessian updates, respectively. Each function identifier, from 1 through the total number of functions, must appear once and only once within the union of the id_analytic_hessians, id_numerical_hessians, and id_quasi_hessians lists.
