Abstract

The Dakota toolkit provides a flexible and extensible interface between simulation codes and iterative analysis methods. Dakota contains algorithms for optimization with gradient and nongradient-based methods; uncertainty quantification with sampling, reliability, and stochastic expansion methods; parameter estimation with nonlinear least squares methods; and sensitivity/variance analysis with design of experiments and parameter study methods. These capabilities may be used on their own or as components within advanced strategies such as surrogate-based optimization, mixed integer nonlinear programming, or optimization under uncertainty. By employing object-oriented design to implement abstractions of the key components required for iterative systems analyses, the Dakota toolkit provides a flexible and extensible problem-solving environment for design and performance analysis of computational models on high performance computers.

This report serves as a reference manual for the commands specification for the Dakota software, providing input overviews, option descriptions, and example specifications.

Chapter 1

Main Page

The Dakota software (<http://dakota.sandia.gov/>) delivers advanced parametric analysis techniques enabling quantification of margins and uncertainty, risk analysis, model calibration, and design exploration with computational models. Its methods include optimization, uncertainty quantification, parameter estimation, and sensitivity analysis, which may be used individually or as components within surrogate-based and other advanced strategies.

Brian M. Adams, William J. Bohnhoff, Keith R. Dalbey, Mohamed S. Ebeida, John P. Eddy, Michael S. Eldred, Gianluca Geraci, Russell W. Hooper, Patricia D. Hough, Kenneth T. Hu, John D. Jakeman, Mohammad Khalil, Kathryn A. Maupin, Jason A. Monschke, Elliott M. Ridgway, Ahmad A. Rushdi, J. Adam Stephens, Laura P. Swiler, Dena M. Vigil, Timothy M. Wildey

The Reference Manual documents all the input keywords that can appear in a Dakota input file to configure a Dakota study. Its organization closely mirrors the structure of `dakota.input.summary`. For more information see [Dakota Input Specification](#). For information on software structure, refer to the Developers Manual [3], and for a tour of Dakota features and capabilities, including a tutorial, refer to the User's Manual[4].

1.1 How to Use this Manual

- To learn how to run Dakota from the command line, see [Running Dakota](#)
- To learn to how to restart Dakota studies, see [Restarting Dakota Studies](#)
- To learn about the Dakota restart utility, see [The Dakota Restart Utility](#)

To find more information about a specific keyword

1. Use the search box at the top right (currently only finds keyword names)
2. Browse the Keywords tree on the left navigation pane
3. Look at the [Dakota Input Specification](#)
4. Navigate through the keyword pages, starting from the [Keywords Area](#)

To find more information about a Dakota related topic

1. Browse the Topics Area on the left navigation pane

2. Navigate through the topics pages, starting from the [Topics Area](#)

A small number of examples are included (see [Sample Input Files](#)) along with a description of the test problems (see [Test Problems](#)).

A bibliography for the Reference Manual is provided in [Bibliographic References](#)

Chapter 2

Running Dakota

The Dakota executable file is named `dakota` (`dakota.exe` on Windows) and is most commonly run from a terminal or command prompt.

2.1 Usage

If the `dakota` command is entered at the command prompt without any arguments, a usage message similar to the following appears:

```
usage: dakota [options and <args>]
  -help (Print this summary)
  -version (Print DAKOTA version number)
  -input <$val> (REQUIRED DAKOTA input file $val)
  -preproc [$val] (Pre-process input file with pyprepro or tool $val)
  -output <$val> (Redirect DAKOTA standard output to file $val)
  -error <$val> (Redirect DAKOTA standard error to file $val)
  -parser <$val> (Parsing technology: nidr[strict][:dumpfile])
  -no_input_echo (Do not echo DAKOTA input file)
  -check (Perform input checks)
  -pre_run [$val] (Perform pre-run (variables generation) phase)
  -run [$val] (Perform run (model evaluation) phase)
  -post_run [$val] (Perform post-run (final results) phase)
  -read_restart [$val] (Read an existing DAKOTA restart file $val)
  -stop_restart <$val> (Stop restart file processing at evaluation $val)
  -write_restart [$val] (Write a new DAKOTA restart file $val)
```

Of these command line options, only `input` is required, and the `-input` switch can be omitted if the input file name is the final item appearing on the command line (see Examples); all other command-line inputs are optional.

- `help` prints the usage message above.
- `version` prints version information for the executable.
- `check` invokes a dry-run mode in which the input file is processed and checked for errors, but the study is not performed.
- `input` provides the name of the Dakota input file, which can optionally be pre-processed as a template using the `preproc` option.
- `output` and `error` options provide file names for redirection of the Dakota standard output (`stdout`) and standard error (`stderr`), respectively.

- The `parser` option is for debugging and will not be further described here.
- By default, Dakota will echo the input file to the output stream, but `no_input_echo` can override this behavior.
- `read_restart` and `write_restart` commands provide the names of restart databases to read from and write to, respectively.
- `stop_restart` command limits the number of function evaluations read from the restart database (the default is all the evaluations) for those cases in which some evaluations were erroneous or corrupted. Restart management is an important technique for retaining data from expensive engineering applications.
- `-pre_run`, `-run`, and `-post_run` instruct Dakota to run one or more execution phases, excluding others. The commands must be followed by filenames as described in [Execution Phases](#).

Command line switches can be abbreviated so long as the abbreviation is unique, so the following are valid, unambiguous specifications: `-h`, `-v`, `-c`, `-i`, `-o`, `-e`, `-s`, `-w`, `-re`, `-ru`, and `-po` and can be used in place of the longer forms of the command line options.

For information on restarting Dakota, see [Restarting Dakota Studies](#) and [The Dakota Restart Utility](#).

2.2 Examples

To run Dakota with a particular input file, the following syntax can be used:

```
dakota -i dakota.in
```

or more simply

```
dakota dakota.in
```

This will echo the standard output (stdout) and standard error (stderr) messages to the terminal. To redirect stdout and stderr to separate files, the `-o` and `-e` command line options may be used:

```
dakota -i dakota.in -o dakota.out -e dakota.err
```

or

```
dakota -o dakota.out -e dakota.err dakota.in
```

Alternatively, any of a variety of Unix redirection variants can be used. Refer to [\[7\]](#) for more information on Unix redirection. The simplest of these redirects stdout to another file:

```
dakota dakota.in > dakota.out
```

The specified Dakota input file may instead be an `dprepro/aprepro`-style template file to be pre-processed prior to running Dakota. For example it might contain template expressions in curly braces:

```
# {MyLB = 2.0} {MyUB = 8.6}
variables
  uniform_uncertain 3
  upper_bounds {MyUB} {MyUB} {MyUB}
  lower_bounds {MyLB} {MyLB} {MyLB}
```

(See the Interfaces chapter in the Dakota User's Manual [\[?\]](#) for more information and use cases.) To pre-process the input file, specify the `preproc` flag which generates an intermediate temporary input file for use in Dakota. If Dakota's `pyprepro.py` utility is not available on the execution PATH and/or additional pre-processing options are needed, the tool location and syntax can be specified, for example:

```
# Assumes pyprepro.py is on PATH:
dakota -i dakota_rosen.tpl -preproc

# Specify path/name of pre-processor:
dakota -i dakota_rosen.tpl \
  -preproc "/home/user/dakota/bin/pyprepro"

# Specify Python interpreter to use, for example on Windows
dakota -i dakota_rosen.tpl -preproc "C:/python27/python.exe \
  C:/dakota/6.10/bin/pyprepro/pyprepro.py"

# Specify additional options to pyprepro, e.g., include file:
dakota -i dakota_rosen.tpl -preproc "pyprepro.py -I default.params"
```

2.3 Execution Phases

Dakota has three execution phases: `pre-run`, `run`, and `post-run`.

- `pre-run` can be used to generate variable sets
- `run` (core run) invokes the simulation to evaluate variables, producing responses
- `post-run` accepts variable/response sets and analyzes the results (for example, calculate correlations from a set of samples). Currently only two modes are supported and only for sampling, parameter study, and DACE methods:

(1) `pre-run` only with optional tabular output of variables:

```
dakota -i dakota.in -pre_run [::myvariables.dat]
```

(2) `post-run` only with required tabular input of variables/responses:

```
dakota -i dakota.in -post_run myvarsresponses.dat::
```

2.4 Restarting Dakota Studies

Dakota is often used to solve problems that require repeatedly running computationally expensive simulation codes. In some cases you may want to repeat an optimization study, but with a tighter final convergence tolerance. This would be costly if the entire optimization analysis had to be repeated. Interruptions imposed by computer usage policies, power outages, and system failures could also result in costly delays. However, Dakota automatically records the variable and response data from all function evaluations so that new executions of Dakota can pick up where previous executions left off. The Dakota restart file (`dakota.rst` by default) archives the tabulated interface evaluations in a binary format. The primary restart commands at the command line are `-read_restart`, `-write_restart`, and `-stop_restart`.

2.4.1 Writing Restart Files

To write a restart file using a particular name, the `-write_restart` command line input (may be abbreviated as `-w`) is used:

```
dakota -i dakota.in -write_restart my_restart_file
```

If no `-write_restart` specification is used, then Dakota will still write a restart file, but using the default name `dakota.rst` instead of a user-specified name.

To turn restart recording off, the user may use the [restart.file](#) keyword, in the `interface` block. This can increase execution speed and reduce disk storage requirements, but at the expense of a loss in the ability to recover

and continue a run that terminates prematurely. This option is not recommended when function evaluations are costly or prone to failure. Please note that using the `deactivate restart_file` specification will result in a zero length restart file with the default name `dakota.rst`, which can overwrite an existing file.

2.4.2 Using Restart Files

To restart Dakota from a restart file, the `-read_restart` command line input (may be abbreviated as `-r`) is used:

```
dakota -i dakota.in -read_restart my_restart_file
```

If no `-read_restart` specification is used, then Dakota will not read restart information from any file (i.e., the default is no restart processing).

To read in only a portion of a restart file, the `-stop_restart` control (may be abbreviated as `-s`) is used to specify the number of entries to be read from the database. Note that this integer value corresponds to the restart record processing counter (as can be seen when using the `print` utility (see [The Dakota Restart Utility](#)) which may differ from the evaluation numbers used in the previous run if, for example, any duplicates were detected (since these duplicates are not recorded in the restart file). In the case of a `-stop_restart` specification, it is usually desirable to specify a new restart file using `-write_restart` so as to remove the records of erroneous or corrupted function evaluations. For example, to read in the first 50 evaluations from `dakota.rst`:

```
dakota -i dakota.in -r dakota.rst -s 50 -w dakota_new.rst
```

The `dakota_new.rst` file will contain the 50 processed evaluations from `dakota.rst` as well as any new evaluations. All evaluations following the 50th in `dakota.rst` have been removed from the latest restart record.

2.4.3 Appending to a Restart File

If the `-write_restart` and `-read_restart` specifications identify the same file (including the case where `-write_restart` is not specified and `-read_restart` identifies `dakota.rst`), then new evaluations will be appended to the existing restart file.

2.4.4 Working with multiple Restart Files

If the `-write_restart` and `-read_restart` specifications identify different files, then the evaluations read from the file identified by `-read_restart` are first written to the `-write_restart` file. Any new evaluations are then appended to the `-write_restart` file. In this way, restart operations can be chained together indefinitely with the assurance that all of the relevant evaluations are present in the latest restart file.

2.4.5 How it Works

Dakota's restart algorithm relies on its duplicate detection capabilities. Processing a restart file populates the list of function evaluations that have been performed. Then, when the study is restarted, it is started from the beginning (not a warm start) and many of the function evaluations requested by the iterator are intercepted by the duplicate detection code. This approach has the primary advantage of restoring the complete state of the iteration (including the ability to correctly detect subsequent duplicates) for all methods/iterators without the need for iterator-specific restart code. However, the possibility exists for numerical round-off error to cause a divergence between the evaluations performed in the previous and restarted studies. This has been rare in practice.

2.5 The Dakota Restart Utility

The Dakota restart utility program provides a variety of facilities for managing restart files from Dakota executions. The executable program name is `dakota_restart_util` and it has the following options, as shown by the usage message returned when executing the utility without any options:

Usage:

```
dakota_restart_util command <arg1> [<arg2> <arg3> ...] --options
dakota_restart_util print <restart_file>
dakota_restart_util to_neutral <restart_file> <neutral_file>
dakota_restart_util from_neutral <neutral_file> <restart_file>
dakota_restart_util to_tabular <restart_file> <text_file>
  [--custom_annotated [header] [eval_id] [interface_id]]
  [--output_precision <int>]
dakota_restart_util remove <double> <old_restart_file> <new_restart_file>
dakota_restart_util remove_ids <int_1> ... <int_n> <old_restart_file> <new_restart_file>
dakota_restart_util cat <restart_file_1> ... <restart_file_n> <new_restart_file>
```

options:

```
--help                show dakota_restart_util help message
--custom_annotated arg tabular file options: header, eval_id,
                       interface_id
--freeform            tabular file: freeform format
--output_precision arg (=10) set tabular output precision
```

Several of these functions involve format conversions. In particular, the binary format used for restart files can be converted to ASCII text and printed to the screen, converted to and from a neutral file format, or converted to a tabular format for importing into 3rd-party plotting programs. In addition, a restart file with corrupted data can be repaired by value or id, and multiple restart files can be combined to create a master database.

2.5.1 Print Command

The `print` option is useful to show contents of a restart file, since the binary format is not convenient for direct inspection. The restart data is printed in full precision, so that exact matching of points is possible for restarted runs or corrupted data removals. For example, the following command

```
dakota_restart_util print
dakota.rst
```

results in output similar to the following:

```
-----
Restart record    1  (evaluation id    1):
-----
Parameters:
           1.8000000000000000e+00 intake_dia

...<snip>...

Restart file processing completed: 11 evaluations retrieved.

```

2.5.2 Neutral File Format

A Dakota restart file can be converted to a neutral file format using a command like the following:

```
dakota_restart_util to_neutral dakota.rst dakota.neu
```

which results in a report similar to the following:

```

Writing neutral file dakota.neu
Restart file processing completed: 11 evaluations retrieved.

```

Similarly, a neutral file can be returned to binary format using a command like the following:

```
dakota_restart_util from_neutral dakota.neu dakota.rst
```

which results in a report similar to the following:

```

Reading neutral file dakota.neu
Writing new restart file dakota.rst
Neutral file processing completed: 11 evaluations retrieved.

```

The contents of the generated neutral file are similar to the following (from the first two records for the Cylinder example in[4]).

```

6 7 2 1.8000000000000000e+00 intake_dia 1.0000000000000000e+00 flatness 0 0 0 0
NULL 4 2 1 0 3 3 3 1 2 obj_fn nln_ineq_con_1 nln_ineq_con_2 nln_ineq_con_3
-2.4355973813420619e+00 -4.7428486677140930e-01 -4.5000000000000001e-01
1.3971143170299741e-01 -4.3644298963447897e-01 1.4999999999999999e-01
1.3855136437818300e-01 0.0000000000000000e+00 0.0000000000000000e+00
1.4999999999999999e-01 0.0000000000000000e+00 -1.9485571585149869e-01 1
6 7 2 2.1640000000000001e+00 intake_dia 1.7169994018008317e+00 flatness 0 0 0 0
NULL 4 2 1 0 3 3 3 1 2 obj_fn nln_ineq_con_1 nln_ineq_con_2 nln_ineq_con_3
-2.4869127192988878e+00 6.9256958799989843e-01 -3.4245008972987528e-01
8.7142207937157910e-03 -4.3644298963447897e-01 1.4999999999999999e-01
2.9814239699997572e+01 0.0000000000000000e+00 0.0000000000000000e+00
1.4999999999999999e-01 0.0000000000000000e+00 -1.6998301774282701e-01 2

```

This format is not intended for direct viewing (`print` should be used for this purpose). Rather, the neutral file capability has been used in the past for managing portability of restart data across platforms (recent use of more portable binary formats has largely eliminated this need) or for advanced repair of restart records (in cases where the `remove` command was insufficient).

2.5.3 Tabular Format

Conversion of a binary restart file to a tabular format enables convenient import of this data into 3rd-party post-processing tools such as Matlab, TECplot, Excel, etc. This facility is nearly identical to the output activated by the `tabular_data` keyword in the Dakota input file specification, but with two important differences:

1. No function evaluations are suppressed as they are with `tabular_data` (i.e., any internal finite difference evaluations are included).
2. The conversion can be performed later, i.e., for Dakota runs executed previously.

An example command for converting a restart file to tabular format is:

```
dakota_restart_util to_tabular dakota.rst dakota.m
```

which results in a report similar to the following:

```
Writing tabular text file dakota.m
Restart file processing completed: 10 evaluations tabulated.
```

The contents of the generated tabular file are similar to the following (from the example in the Restart section of [4]). Note that while evaluations resulting from numerical derivative offsets would be reported (as described above), derivatives returned as part of the evaluations are not reported (since they do not readily fit within a compact tabular format):

```
%eval_id interface          x1          x2          obj_fn nln_ineq_con_1 nln_ineq_con_2
1          NO_ID           0.9          1.1          0.0002      0.26          0.76
2          NO_ID           0.90009      1.1 0.0001996404857 0.2601620081 0.759955

8          NO_ID           0.5825035339 0.4772224441 0.1050725476 0.1006991449 -0.06351050577
9          NO_ID           0.58256179 0.4772701663 0.1050283245 0.100743156 -0.06349408333
10         NO_ID           0.58256179 0.4771747219 0.1050828704 0.1007908783 -0.06358517983
...
```

Controlling tabular format: The command-line options `--freeform` and `--custom_annotated` give control of headers in the resulting tabular file. Freeform will generate a tabular file with no leading row nor columns (variable and response values only). Custom annotated format accepts any or all of the options:

- `header`: include `%`-commented header row with labels
- `eval_id`: include leading column with evaluation ID
- `interface_id`: include leading column with interface ID

For example, to recover Dakota 6.0 tabular format, which contained a header row, leading column with evaluation ID, but no interface ID:

```
dakota_restart_util to_tabular dakota.rst dakota.m --custom_annotated header eval_id
```

Resulting in

```
%eval_id          x1          x2          obj_fn nln_ineq_con_1 nln_ineq_con_2
1          0.9          1.1          0.0002      0.26          0.76
2          0.90009      1.1 0.0001996404857 0.2601620081 0.759955
3          0.89991      1.1 0.0002003604863 0.2598380081 0.760045
...
```

Finally, `--output_precision integer` will generate tabular output with the specified integer digits of precision.

2.5.4 Concatenation of Multiple Restart Files

In some instances, it is useful to combine restart files into a single master function evaluation database. For example, when constructing a data fit surrogate model, data from previous studies can be pulled in and reused to create a combined data set for the surrogate fit. An example command for concatenating multiple restart files is:

```
dakota_restart_util cat dakota.rst.1 dakota.rst.2 dakota.rst.3 dakota.rst.all
```

which results in a report similar to the following:

```
Writing new restart file dakota.rst.all
dakota.rst.1 processing completed: 10 evaluations retrieved.
dakota.rst.2 processing completed: 110 evaluations retrieved.
dakota.rst.3 processing completed: 65 evaluations retrieved.
```

The `dakota.rst.all` database now contains 185 evaluations and can be read in for use in a subsequent Dakota study using the `-read_restart` option to the `dakota` executable.

2.5.5 Removal of Corrupted Data

On occasion, a simulation or computer system failure may cause a corruption of the Dakota restart file. For example, a simulation crash may result in failure of a post-processor to retrieve meaningful data. If 0's (or other erroneous data) are returned from the user's `analysis_driver`, then this bad data will get recorded in the restart file. If there is a clear demarcation of where corruption initiated (typical in a process with feedback, such as gradient-based optimization), then use of the `-stop_restart` option for the `dakota` executable can be effective in continuing the study from the point immediately prior to the introduction of bad data. If, however, there are interspersed corruptions throughout the restart database (typical in a process without feedback, such as sampling), then the `remove` and `remove_ids` options of `dakota_restart_util` can be useful.

An example of the command syntax for the `remove` option is:

```
dakota_restart_util remove 2.e-04 dakota.rst dakota.rst.repaired
```

which results in a report similar to the following:

```
Writing new restart file dakota.rst.repaired
Restart repair completed: 65 evaluations retrieved, 2 removed, 63 saved.
```

where any evaluations in `dakota.rst` having an active response function value that matches `2.e-04` within machine precision are discarded when creating `dakota.rst.repaired`.

An example of the command syntax for the `remove_ids` option is:

```
dakota_restart_util remove_ids 12 15 23 44 57 dakota.rst dakota.rst.repaired
```

which results in a report similar to the following:

```
Writing new restart file dakota.rst.repaired
Restart repair completed: 65 evaluations retrieved, 5 removed, 60 saved.
```

where evaluation ids 12, 15, 23, 44, and 57 have been discarded when creating `dakota.rst.repaired`. An important detail is that, unlike the `-stop_restart` option which operates on restart record numbers, the `remove_ids` option operates on evaluation ids. Thus, removal is not necessarily based on the order of appearance in the restart file. This distinction is important when removing restart records for a run that contained either asynchronous or duplicate evaluations, since the restart insertion order and evaluation ids may not correspond in these cases (asynchronous evaluations have ids assigned in the order of job creation but are inserted in the restart file in the order of job completion, and duplicate evaluations are not recorded which introduces offsets between evaluation id and record number). This can also be important if removing records from a concatenated restart file, since the same evaluation id could appear more than once. In this case, all evaluation records with ids matching the `remove_ids` list will be removed.

If neither of these removal options is sufficient to handle a particular restart repair need, then the fallback position is to resort to direct editing of a neutral file to perform the necessary modifications. <!-----

Chapter 3

Dakota HDF5 Output

Beginning with release 6.9, Dakota gained the ability to write many method results such as the correlation matrices computed by [sampling](#) studies and the best parameters discovered by optimization methods to disk in **HDF5**. In Dakota 6.10 and above, evaluation data (variables and responses for each model or interface evaluation) may also be written. Many users may find this newly supported format more convenient than scraping or copying and pasting from Dakota's console output.

To enable HDF5 output, the [results_output](#) keyword with the [hdf5](#) option must be added to the Dakota input file. In addition, Dakota must have been built with HDF5 support. Beginning with Dakota 6.10, HDF5 is enabled in our publicly available downloads. HDF5 support is considered a somewhat experimental feature. The results of some Dakota methods are not yet written to HDF5, and in a few, limited situations, enabling HDF5 will cause Dakota to crash.

3.1 HDF5 Concepts

HDF5 is a format that is widely used in scientific software for efficiently storing and organizing data. The HDF5 standard and libraries are maintained by the [HDF Group](#).

In HDF5, data are stored in multidimensional arrays called *datasets*. Datasets are organized hierarchically in *groups*, which also can contain other groups. Datasets and groups are conceptually similar to files and directories in a filesystem. In fact, every HDF5 file contains at least one group, the root group, denoted `"/`, and groups and datasets are referred to using slash-delimited absolute or relative paths, which are more accurately called *link names*.

HDF5 has as one goal that data be "self-documenting" through the use of metadata. Dakota output files include two kinds of metadata.

- **Dimension Scales.** Each dimension of a dataset may have zero or more scales, which are themselves datasets. Scales are often used to provide, for example, labels analogous to column headings in a table (see the dimension scales that Dakota applies to [moments](#)) or numerical values of an independent variable (user-specified probability levels in [level mappings](#)).
- **Attributes.** key:value pairs that annotate a group or dataset. A key is always a character string, such as `dakota_version`, and (in Dakota output) the value can be a string-, integer-, or real-valued scalar. Dakota stores the number of samples that were requested in a `sampling` study in the attribute `'samples'`.

3.2 Accessing Results

Many popular programming languages have support, either natively or from a third-party library, for reading and writing HDF5 files. The HDF Group itself supports C/C++ and Java libraries. The Dakota Project suggests the `h5py` module for Python. Examples that demonstrate using `h5py` to access and use Dakota HDF5 output may be found in the Dakota installation at `share/dakota/examples/hdf5`.

3.3 Organization of Results

Currently, complete or nearly complete coverage of results from sampling, optimization and calibration methods, parameter studies, and stochastic expansions exists. Coverage will continue to expand in future releases to include not only the results of all methods, but other potentially useful information such as interface evaluations and model transformations.

Methods in Dakota have a character string `Id` and are executed by Dakota one or more times. (Methods are executed more than once in studies that include a [nested model](#), for example.) The `Id` may be provided by the user in the input file using the `id_method` keyword, or it may be automatically generated by Dakota. Dakota uses the label `NO_METHOD_ID` for methods that are specified in the input file without an `id_method`, and `NOSPEC_METHOD_ID_<N>` for methods that it generates for its own internal use. The `<N>` in the latter case is an incrementing integer that begins at 1.

The results for the `<N>`th execution of a method that has the label `<method Id>` are stored in the group

```
/methods/<method Id>/results/execution:<N>/
```

The `/methods` group is always present in Dakota HDF5 files, provided at least one method added results to the output. (In a future Dakota release, the top level groups `/interfaces` and `/models` will be added.) The group `execution:1` also is always present, even if there is only a single execution.

The groups and datasets for each type of result that Dakota is currently capable of storing are described in the following sections. Every dataset is documented in its own table. These tables include:

- A brief *description* of the dataset.
- The *location* of the dataset relative to `/methods/<method Id>/execution:<N>`. This path may include both literal text that is always present and replacement text. Replacement text is *<enclosed in angle brackets and italicized>*. Two examples of replacement text are *<response descriptor>* and *<variable descriptor>*, which indicate that the name of a Dakota response or variable makes up a portion of the path.
- Clarifying *notes*, where appropriate.
- The *type* (String, Integer, or Real) of the information in the dataset.
- The *shape* of the dataset; that is, the number of dimensions and the size of each dimension.
- A description of the dataset's *scales*, which includes
 - The *dimension* of the dataset that the scale belongs to.
 - The *type* (String, Integer, or Real) of the information in the scale.
 - The *label* or name of the scale.
 - The *contents* of the scale. Contents that appear in plaintext are literal and will always be present in a scale. Italicized text describes content that varies.
 - *notes* that provide further clarification about the scale.

- A description of the dataset's *attributes*, which are key:value pairs that provide helpful context for the dataset.

The **Expected Output** section of each [method](#)'s keyword documentation indicates the kinds of output, if any, that method currently can write to HDF5. These are typically in the form of bulleted lists with clarifying notes that refer back to the sections that follow.

3.3.1 Study Metadata

Several pieces of information about the Dakota study are stored as attributes of the top-level HDF5 root group (""). These include:

3.3.2 A Note about Variables Storage

Variables in most Dakota output (e.g. tabular data files) and input (e.g. imported data to construct surrogates) are listed in "input spec" order. (The [variables](#) keyword section is arranged by input spec order.) In this ordering, they are sorted first by function:

1. Design
2. Aleatory
3. Epistemic
4. State

And within each of these categories, they are sorted by domain:

1. Continuous
2. Discrete integer (sets and ranges)
3. Discrete string
4. Discrete real

A shortcoming of HDF5 is that datasets are homogeneous; for example, string- and real-valued data cannot readily be stored in the same dataset. As a result, Dakota has chosen to flip "input spec" order for HDF5 and sort first by domain, then by function when storing variable information. When applicable, there may be as many as four datasets to store variable information: one to store continuous variables, another to store discrete integer variables, and so on. Within each of these, variables will be ordered by function.

3.3.3 Sampling Moments

[sampling](#) produces moments (e.g. mean, standard deviation or variance) of all responses, as well as 95% lower and upper confidence intervals for the 1st and 2nd moments. These are stored as described below. When [sampling](#) is used in incremental mode by specifying [refinement.samples](#), all results, including the `moments` group, are placed within groups named `increment:<N>`, where `<N>` indicates the increment number beginning with 1.

3.3.4 Correlations

A few different methods produce information about the correlations between pairs of variables and responses (collectively: factors). The four tables in this section describe how correlation information is stored. One important note is that HDF5 has no special, native type for symmetric matrices, and so the simple correlations and simple rank correlations are stored in dense 2D datasets.

3.3.5 Probability Density

Some aleatory UQ methods estimate the probability density of responses.

3.3.6 Level Mappings

Aleatory UQ methods can calculate level mappings (from user-specified probability, reliability, or generalized reliability to response, or vice versa).

3.3.7 Variance-Based Decomposition (Sobol' Indices)

Dakota's [sampling](#) method can produce main and total effects; stochastic expansions ([polynomial_chaos](#), [stoch.-collocation](#)) additionally can produce interaction effects.

Each order (pair, 3-way, 4-way, etc) of interaction is stored in a separate dataset. The scales are unusual in that they are two-dimensional to contain the labels of the variables that participate in each interaction.

3.3.8 Integration and Expansion Moments

Stochastic expansion methods can obtain moments two ways.

3.3.9 Extreme Responses

[sampling](#) with epistemic variables produces extreme values (minimum and maximum) for each response.

3.3.10 Parameter Sets

All parameter studies ([vector_parameter_study](#), [list_parameter_study](#), [multidim_parameter_study](#), [centered_parameter_study](#)) record tables of evaluations (parameter-response pairs), similar to Dakota's tabular output file. Centered parameter studies additionally store evaluations in an order that is more natural to interpret, which is described below.

In the tabular-like listing, variables are stored according to the scheme described in a [previous section](#).

3.3.11 Variable Slices

Centered parameter studies store "slices" of the tabular data that make evaluating the effects of each variable on each response more convenient. The steps for each individual variable, including the initial or center point, and corresponding responses are stored in separate groups.

3.3.12 Best Parameters

Dakota's optimization and calibration methods report the parameters at the best point (or points, for multiple [final solutions](#)) discovered. These are stored using the scheme described in the [variables](#) section. When more than one solution is reported, the best parameters are nested in groups named `set : <N>`, where <N> is an integer numbering the set and beginning with 1.

State (and other inactive variables) are reported when using [objective functions](#) and for some [calibration](#) studies. However, when using configuration variables in a calibration, state variables are suppressed.

3.3.13 Best Objective Functions

Dakota's optimization methods report the objective functions at the best point (or points, for multiple [final solutions](#)) discovered. When more than one solution is reported, the best objective functions are nested in groups named `set : <N>`, where `<N>` is a integer numbering the set and beginning with 1.

3.3.14 Best Nonlinear Constraints

Dakota's optimization and calibration methods report the nonlinear constraints at the best point (or points, for multiple [final solutions](#)) discovered. When more than one solution is reported, the best constraints are nested in groups named `set : <N>`, where `N` is a integer numbering the set and beginning with 1.

3.3.15 Calibration

When using [calibration terms](#) with an optimization method, or when using a nonlinear least squares method such as `nl2sol`, Dakota reports residuals and residual norms for the best point (or points, for multiple [final solutions](#)) discovered.

3.3.16 Parameter Confidence Intervals

Least squares methods (`nl2sol`, `nlssol_sqp`, `optpp_g_newton`) compute confidence intervals on the calibration parameters.

3.3.17 Best Model Responses (without configuration variables)

When performing calibration with experimental data (but no configuration variables), Dakota records, in addition to the best residuals, the best original model responses.

3.3.18 Best Model Responses (with configuration variables)

When performing calibration with experimental data that includes configuration variables, Dakota reports the best model responses for each experiment. These results include the configuration variables, stored in the scheme described in the [variables](#) section, and the model responses.

3.3.19 Multistart and Pareto Set

The `multi_start` and `pareto_set` methods are meta-iterators that control multiple optimization sub-iterators. For both methods, Dakota stores the results of the sub-iterators (best parameters and best results). For `multi_start`, Dakota additionally stores the initial points, and for `pareto_set`, it stores the objective function weights.

3.4 Organization of Evaluations

An *evaluation* is a mapping from variables to responses performed by a Dakota model or interface. Beginning with release 6.10, Dakota has the ability to report evaluation history in HDF5 format. The HDF5 format offers many advantages over existing console output and [tabular output](#). Requiring no "scraping", it is more convenient for most users than the former, and being unrestricted to a two-dimensional, tabular arrangement of information, it is far richer than the latter.

This section begins by describing the Dakota components that can generate evaluation data. It then documents the high-level organization of the data from those components. Detailed documentation of the individual datasets

(the "low-level" organization) where data are stored follows. Finally, information is provided concerning input keywords that control which components report evaluations.

3.4.1 Sources of Evaluation Data

Evaluation data are produced by only two kinds of components in Dakota: **models** and **interfaces**. The purpose of this subsection is to provide a basic description of models and interfaces for the purpose of equipping users to manage and understand HDF5-format evaluation data.

Because interfaces and models must be specified in even simple Dakota studies, most novice users of Dakota will have some familiarity with these concepts. However, the exact nature of the relationship between methods, models, and interfaces may be unclear. Moreover, the models and interfaces present in a Dakota study are not always limited to those specified by the user. Some input keywords or combinations of components cause Dakota to create new models or interfaces "behind the scenes" and without the user's direct knowledge. Not only can user-specified models and interfaces write evaluation data to HDF5, but also these auto-generated components. Accordingly, it may be helpful for consumers of Dakota's evaluation data to have a basic understanding of how Dakota creates and employs models and interfaces.

Consider first the input file shown here.

```
environment
  tabular_data
  results_output
  hdf5

method
  id_method 'sampling'
  sampling
    samples 20
  model_pointer 'sim'

model
  id_model 'sim'
  single
  interface_pointer 'tb'

variables
  uniform_uncertain 2
  descriptors 'x1' 'x2'
  lower_bounds 0.0 0.0
  upper_bounds 1.0 1.0

responses
  response_functions 1
  descriptors 'f'
  no_gradients
  no_hessians

interface
  id_interface 'tb'
  fork
  analysis_drivers 'text_book'
```

This simple input file specifies a single method of type [sampling](#), which also has the Id 'sampling'. The 'sampling' method possesses a [model](#) of type [single](#) (alias simulation) named 'sim', which it uses to perform evaluations. (Dakota would have automatically generated a single model had one not been specified.) That is to say, for each variables-to-response mapping required by the method, it provides variables to the model and receives back responses from it.

Single/simulation models like 'sim' perform evaluations by means of an interface, typically an interface to an external simulation. In this case, the interface is 'tb'. The model passes the variables to 'tb', which executes the `text_book` driver, and receives back responses.

It is clear that two components produce evaluation data in this study. The first is the single model 'sim', which receives and fulfills evaluation requests from the method 'sampling', and the second is the interface 'tb', which similarly receives requests from 'sim' and fulfills them by running the `text_book` driver.

Because [tabular data](#) was requested in the environment block, a record of the model's evaluations will be reported to a tabular file. The interface's evaluations could be dumped from the restart file using `dakota-restart_util`.

If we compared these evaluation histories from 'sim' and 'tb', we would see that they are identical to one another. The model 'sim' is a mere "middle man" whose only responsibility is passing variables from the method down to the interface, executing the interface, and passing responses back up to the method. However, this is not always the case.

For example, if this study were converted to a gradient-based optimization using `optpp-q-newton`, and the user specified [numerical gradients](#) :

```
# model and interface same as above. Replace the method, variables, and responses with:

method
  id_method 'opt'
  optpp_q_newton

variables
  continuous_design 2
  descriptors 'x1' 'x2'
  lower_bounds 0.0 0.0
  upper_bounds 1.0 1.0

responses
  objective_functions 1
  descriptors 'f'
  numerical_gradients
  no_hessians
```

Then the model would have the responsibility of performing finite differencing to estimate gradients of the response 'f' requested by the method. Multiple function evaluations of 'tb' would map to a single gradient evaluation at the model level, and the evaluation histories of 'sim' and 'tb' would contain different information.

Note that because it is unwieldy to report gradients (or Hessians) in a tabular format, they are not written to the tabular file, and historically were available only in the console output. The HDF5 format provides convenient access to both the "raw" evaluations performed by the interface and higher level model evaluations that include estimated gradients.

This pair of examples hopefully provides a basic understanding of the flow of evaluation data between a method, model, and interface, and explains why models and interfaces are producers of evaluation data.

Next consider a somewhat more complex study that includes a Dakota model of type [surrogate](#). A surrogate model performs evaluations requested by a method by executing a special kind of interface called an *approximation interface*, which Dakota implicitly creates without the direct knowledge of the user. Approximation interfaces are a generic container for the various kinds of surrogates Dakota can use, such as [gaussian processes](#).

A Dakota model of type global surrogate may use a user-specified [dace method](#) to construct the actual underlying model(s) that it evaluates via its approximation interface. The dace method will have its own model (typically of type single/simulation), which will have a user-specified interface.

In this more complicated case there are at least four components that produce evaluation data: (1) the surrogate model and (2) its approximation interface, and (3) the dace method's model and (4) its interface. Although only components (1), (3), and (4) are user-specified, evaluation data produced by (2) may be written to HDF5, as well. (As [explained below](#), only evaluations performed by the surrogate model and the dace interface will be recorded

by default. This can be overridden using `hdf5` sub-keywords.) This is an example where "extra" and potentially confusing data appears in Dakota's output due to an auto-generated component.

An important family of implicitly-created models is the *recast* models, which have the responsibility of transforming variables and responses. One type of recast called a *data transform model* is responsible for computing residuals when a user provides [experimental data](#) in a calibration study. *Scaling* recast models are employed when scaling is requested by the user for variables and/or responses.

Recast models work on the principle of function composition, and "wrap" a submodel, which may itself also be a recast model. The innermost model in the recursion often will be the simulation or surrogate model specified by the user in the input file. Dakota is capable of recording evaluation data at each level of recast.

3.4.2 High-level Organization of Evaluation Data

This subsection describes how evaluation data produced by models and interfaces are organized at high level. A detailed description of the datasets and subgroups that contain evaluation data for a specific model or interface is given in the [next subsection](#).

Two top level groups contain evaluation data, `/interfaces` and `/models`.

Interfaces

Because interfaces can be executed by more than one model, interface evaluations are more precisely thought of as evaluations of an interface/model combination. Consequently, interface evaluations are grouped not only by interface Id ('tb' in the example above), but also the Id of the model that requested them ('sim').

```
/interfaces/<interface Id>/<model Id>/
```

If the user does not provide an Id for an interface that he specifies, Dakota assigns it the Id `NO_ID`. Approximation interfaces receive the Id `APPROX_INTERFACE_<N>`, where N is an incrementing integer beginning at 1. Other kinds of automatically generated interfaces are named `NOSPEC_INTERFACE_ID_<N>`.

Models

The top-level group for model evaluations is `/models`. Within this group, model evaluations are grouped by type: `simulation`, `surrogate`, `nested`, or `recast`, and then by model Id. That is:

```
/models/<type>/<model Id>/
```

Similar to interfaces, user-specified models that lack an Id are given one by Dakota. A single model is named `NO_MODEL_ID`. Some automatically generated models receive the name `NOSPEC_MODEL_ID`.

Recast models are a special case and receive the name `RECAST_<WRAPPED-MODEL>_<TYPE>_<N>`. In this string:

- `WRAPPED-MODEL` is the Id of the innermost wrapped model, typically a user-specified model
- `TYPE` is the specific kind of recast. The three most common recasts are:
 - `RECAST`: several generic responsibilities, including summing objective functions to present to a single-objective optimizer
 - `DATA_TRANSFORM`: Compute residuals in a calibration
 - `SCALING`: scale variables and responses
- N is an incrementing integer that begins with 1. It is employed to distinguish recasts of the same type that wrap the same underlying model.

The model's evaluations may be the result of combining information from multiple sources. A simulation/single model will receive all the information it requires from its interface, but more complicated model types may use information not only from interfaces, but also other models and the results of method executions. Nested models, for instance, receive information from a submethod (the mean of a response from a sampling study, for instance) and potentially also an [optional interface](#).

The sources of a model's evaluations may be roughly identified by examining the contents of that model's `sources` group. The `sources` group contains softlinks (note: softlinks are an HDF5 feature analogous to soft or symbolic links on many file systems) to groups for the interfaces, models, or methods that the model used to produce its evaluation data. (At this time, Dakota does not report the specific interface or model evaluations or method executions that were used to produce a specific model evaluation, but this is a planned feature.)

Method results likewise have a `sources` group that identifies the models or methods employed by that method. By following the softlinks contained in a method's or model's `sources` group, it is possible to "drill down" from a method to its ultimate sources of information. In the sampling example above, interface evaluations performed via the 'sim' model at the request of the 'sampling' method could be obtained at the HDF5 path: `/methods/sampling/sources/sim/sources/tb/`

3.4.3 Low-Level Organization of Evaluation Data

The evaluation data for each interface and model are stored using the same schema in a collection of groups and datasets that reside within that interface or model's high-level location in the HDF5 file. This section describes that "low-level" schema.

Data are divided first of all into `variables`, `responses`, and `metadata` groups.

Variables

The `variables` group contains datasets that store the variables information for each evaluation. Four datasets may be present, one for each "domain": `continuous`, `discrete_integer`, `discrete_string`, and `discrete_real`. These datasets are two-dimensional, with a row (0th dimension) for each evaluation and a column (1st dimension) for each variable. The 0th dimension has one dimension scale for the integer-valued evaluation Id. The 1st dimension has two scales. The 0th scale contains descriptors of the variables, and the 1st contains their variable Ids. In this context, the Ids are a 1-to-N ranking of the variables in Dakota "input spec" order.

Responses

The `responses` group contains datasets for functions and, when available, gradients and Hessians.

Functions: The `functions` dataset is two-dimensional and contains function values for all responses. Like the variables datasets, evaluations are stored along the 0th dimension, and responses are stored along the 1st. The evaluation Ids and response descriptors are attached as scales to these axes, respectively.

Gradients: The `gradients` dataset is three-dimensional. It has the shape $evaluations \times responses \times variables$. Dakota supports a specification of `mixed_gradients`, and the `gradients` dataset is sized and organized such that only those responses for which gradients are available are stored. When `mixed_gradients` are employed, a response will not necessarily have the same index in the `functions` and `gradients` datasets.

Because it is possible that the gradient could be computed with respect to any of the continuous variables, active or inactive, that belong to the associated model, the `gradients` dataset is sized to accommodate gradients taken with respect to all continuous variables. Components that were not included in a particular evaluation will be set to NaN (not a number), and the `derivative_variables_vector` (in the `metadata` group) for that evaluation can be examined as well.

Hessians: Hessians are stored in a four-dimensional dataset, $evaluations \times responses \times variables \times variables$. The `hessians` dataset shares many of the characteristics with the `gradients`: in the mixed-hessians case, it will be smaller in the response dimension than the `functions` dataset, and unrequested components are set to NaN.

Metadata

The metadata group contains up to three datasets.

Active Set Vector: The first is the `active_set_vector`. It is two dimensional, with rows corresponding to evaluations and columns corresponding to responses. Each element contains an integer in the range 0-7, which indicates the request (function, gradient, Hessian) for the corresponding response for that evaluation. The 0th dimension has the evaluations Ids scale, and the 1st dimension has two scales: the response descriptors and the "default" or "maximal" ASV, an integer 0-7 for each response that indicates the information (function, gradient, Hessian) that possibly could have been requested during the study.

Derivative Variables Vector: The second dataset in the metadata group is the `derivative_variables_vector` dataset. It is included only when gradients or Hessians are available. Like the ASV, it is two-dimensional. Each column of the DVV dataset corresponds to a continuous variable and contains a 0 or 1, indicating whether gradients and Hessians were computed with respect to that variable for the evaluation. The 0th dimension has the evaluation Ids as a scale, and the 1st dimension has two scales. The 0th is the descriptors of the continuous variables. The 1st contains the variable Ids of the continuous variables.

Analysis Components: The final dataset in the metadata group is the `analysis_components` dataset. It is a 1D dataset that is present only when the user specified analysis components, and it contains those components as strings.

3.4.4 Selecting Models and Interfaces to Store

When HDF5 output is enabled (by including the `hdf5` keyword), then by default evaluation data for the following components will be stored:

- The model that belongs to the top-level method. (Currently, if the top-level method is a metaiterator such as `method-hybrid`, no model evaluation data will be stored.)
- All simulation interfaces. (interfaces of type `fork`, `system`, `direct`, etc).

The user can override these defaults using the keywords `model_selection` and `interface_selection`.

The choices for `model_selection` are:

- `top_method` : (*default*) Store evaluation data for the top method's model only.
- `all_methods` : Store evaluation data for all models that belong directly to a method. Note that a these models may be recasts of user-specified models, not the user-specified models themselves.
- `all` : Store evaluation data for all models.
- `none` : Store evaluation data for no models.

The choices for `interface_selection` are:

- `simulation` : (*default*) Store evaluation data for simulation interfaces.
- `all` : Store evaluation data for all interfaces.
- `none` : Store evaluation data for no interfaces.

If a model or interface is excluded from storage by these selections, then they cannot appear in the `sources` group for methods or models.

3.5 Distribution Parameters

Variables are characterized by parameters such as the mean and standard deviation or lower and upper bounds. Typically, users provide these parameters as part of their input to Dakota, but Dakota itself may also compute them as it scales and transforms variables, normalizes empirical distributions (e.g. for `histogram.bin_uncertain` variables), or calculates alternative parameterizations (lambda and zeta vs mean and standard deviation for a `lognormal_uncertain`).

Beginning with release 6.11, models write their variables parameters to HDF5. The information is located in each model's `metadata/variable_parameters` subgroup. Within this group, parameters are stored by Dakota variable type (e.g. `normal_uncertain`), with one 1D dataset per type. The datasets have the same names as their variable types and have one element per variable. Parameters are stored by name.

Consider the following variable specification, which includes two normal and two uniform variables:

```
variables
normal_uncertain 2
  descriptors 'nuv_1' 'nuv_2'
  means 0.0 1.0
  std_deviations 1.0 0.5
uniform_uncertain 2
  descriptors 'uuv_1' 'uuv_2'
  lower_bounds -1.0 0.0
  upper_bounds 1.0 1.0
```

Given this specification, and assuming a model ID of `tb_model`, Dakota will write two 1D datasets, both of length 2, to the group `/models/simulation/tb_model/metadata/variable_parameters`, the first named `normal_uncertain`, and the second named `uniform_uncertain`. Using a JSON-like representation for illustration, the `normal_uncertain` dataset will appear as:

```
[
  {
    "mean": 0.0,
    "std_deviation": 1.0,
    "lower_bound": -inf,
    "upper_bound": inf
  },
  {
    "mean": 1.0,
    "std_deviation": 0.5,
    "lower_bound": -inf,
    "upper_bound": inf
  }
]
```

The `uniform_uncertain` dataset will contain:

```
[
  {
    "lower_bound": -1.0,
    "upper_bound": 1.0
  },
  {
    "lower_bound": 0.0,
    "upper_bound": 1.0
  }
]
```

In these representations of the `normal_uncertain` and `uniform_uncertain` datasets, the outer square brackets (`[]`) enclose the dataset, and each element within the datasets are enclosed in curly braces (`{}`). The curly braces are meant to indicate that the elements are dictionary-like objects that support access by string field name.

A bit more concretely, the following code snippet demonstrates reading the mean of the second normal variable, `nuv_2`.

```

1 import h5py
2
3 with h5py.File("dakota_results.h5") as h:
4     model = h["/models/simulation/tb_model/"]
5     # nu_vars is the dataset that contains distribution parameters for
6     # normal_uncertain variables
7     nu_vars = model["variable_parameters/normal_uncertain"]
8     nuv_2.mu = nu_vars[1]["mean"] # 1 is the 0-based index of nuv_2, and
9                                   # "mean" is the name of the field where
10                                  # the mean is stored; nuv_2.mu now contains
11                                  # 1.0.

```

The feature in HDF5 that underlies this name-based storage of fields is compound datatypes, which are similar to C/C++ structs or Python dictionaries. Further information about how to work with compound datatypes is available in the `h5py` documentation.

3.5.1 Naming Conventions and Layout

In most cases, datasets for storing parameters have names that match their variable types. The `normal_uncertain` and `uniform_uncertain` datasets illustrated above are examples. Exceptions include types such as `discrete_design_set`, which has string, integer, and real subtypes. For these, the dataset name is the top-level type with `_string`, `_int`, or `_real` appended: `discrete_design_set_string`, `discrete_design_set_int`, and `discrete_design_set_real`.

Most Dakota variable types have scalar parameters. For these, the names of the parameters are generally the singular form of the associated Dakota keyword. For example, `triangular_uncertain` variables are characterized in Dakota input using the plural keywords `modes`, `lower_bounds`, and `upper_bounds`. The singular field names are, respectively, "mode", "lower_bound", and "upper_bound". In this case, all three parameters are real-valued and stored as floating point numbers, but variable types/fields can also be integer-valued (e.g. `binomial_uncertain/num_trials`) or string-valued.

Some variable/parameter fields contain 1D arrays or vectors of information. Consider `histogram_bin_uncertain` variables, for which the user specifies not just one value, but an ordered collection of abscissas and corresponding ordinates or counts. Dakota stores the abscissas in the "abscissas" field, which is a 1D dataset of floating-point numbers. It similarly stores the counts in the "counts" field. (In this case, only the normalized counts are stored, regardless of whether the user provided counts or ordinates.)

When the user specifies more than one `histogram_bin_uncertain` variable, it often is also necessary to include the `pairs_per_variable` keyword to divide the abscissa/count pairs among the variables. This raises the question of how lists of parameters that vary in length across the variables ought to be stored.

Although HDF5 supports variable-length datasets, for simplicity (and due to limitations in `h5py` at the time of the 6.11 release), Dakota stores vector parameter fields in conventional fixed-length datasets. The lengths of these datasets are determined at runtime in the following way: For a particular variable type and field, the field for all variables is sized to be large enough to accommodate the variable with the longest list of parameters. Any unused space for a particular variable is filled with NaN (if the parameter is real-valued), INTMAX (integer-valued), or an empty string (string-valued). In addition, each variable has an additional field, "num_elements", that reports the number of elements in the fields that contain actual data and not fill values.

Consider this example, in which the user has specified a pair of `histogram_bin_uncertain` variables. The first has 3 pairs, and the second has 4.

```

variables
  histogram_bin_uncertain 2
    pairs_per_variable 2 3
    abscissas 0.0 0.5 1.0
              -1.0 -0.5 0.5 1.0

```

```
counts      0.25  0.75  0.0
            0.2   0.4   0.2  0.0
```

For this specification, Dakota will write a dataset named `histogram_bin_uncertain` to the `metadata/variable-parameters/` subgroup for the model. It will be of length 2, one element for each variable, and contain the following:

```
[
  {
    "num_elements": 3,
    "abscissas": [0.0, 0.5, 1.0, NaN],
    "counts": [0.25, 0.75, 0.0, NaN]
  },
  {
    "num_elements": 4,
    "abscissas": [-1.0, -0.5, 0.5, 1.0],
    "counts": [0.2, 0.4, 0.2, 0.0]
  }
]
```

3.5.2 h5py Examples

The fields available for a variable parameters dataset can be determined in `h5py` by examining the datatype of the dataset.

```
1 import h5py
2 with h5py.File("dakota_results.h5") as h:
3     model = h["models/simulation/NO_MODEL_ID/"]
4     md = model["metadata/variable_parameters"]
5     nu = md["normal_uncertain"]
6     nu_param_names = nu.dtype.names
7     # nu_param_names is a tuple of strings: ('mean', 'std_deviation',
8     # 'lower_bound', 'upper_bound')
```

3.5.3 Known Limitations

`h5py` has a known bug that prevents parameters for some types of variables from being accessed (the Python interpreter crashes with a segfault). These include:

- `histogram_point_uncertain` string
- `discrete_uncertain_set` string

3.5.4 Metadata

The variable parameter datasets have two dimension scales. The first (index 0) contains the variable descriptors, and the second (index 1) contains variable Ids. Available Parameters

3.5.5 Parameter Listing for All Types

The table below lists all Dakota variables and parameters that can be stored.

Chapter 4

Test Problems

This page contains additional information about two test problems that are used in Dakota examples throughout the Dakota manuals [Textbook](#) and [Rosenbrock](#).

Many of these examples are also used as code verification tests. The examples are run periodically and the results are checked against known solutions. This ensures that the algorithms are correctly implemented.

Additional test problems are described in the User's Manual.

4.1 Textbook

The two-variable version of the “textbook” test problem provides a nonlinearly constrained optimization test case. It is formulated as:

$$\begin{aligned} & \text{minimize } f = (x_1 - 1)^4 + (x_2 - 1)^4 \\ & \text{subject to } g_1 = x_1^2 - \frac{x_2}{2} \leq 0 \\ & \quad g_2 = x_2^2 - \frac{x_1}{2} \leq 0 \\ & \quad 0.5 \leq x_1 \leq 5.8 \\ & \quad -2.9 \leq x_2 \leq 2.9 \end{aligned} \tag{textbookform}$$

Contours of this test problem are illustrated in the next two figures.

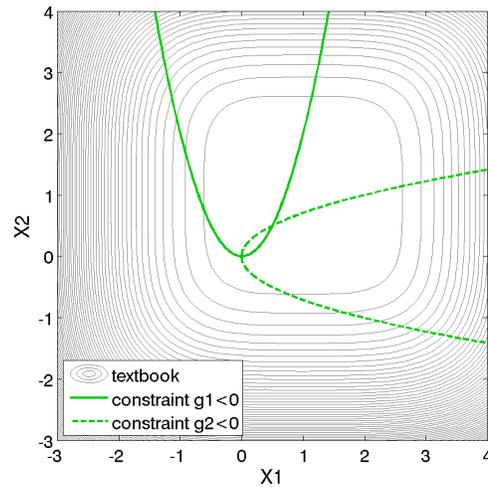

Figure 4.1: Contours of the textbook problem on the $[-3,4] \times [-3,4]$ domain. The feasible region lies at the intersection of the two constraints g_1 (solid) and g_2 (dashed).

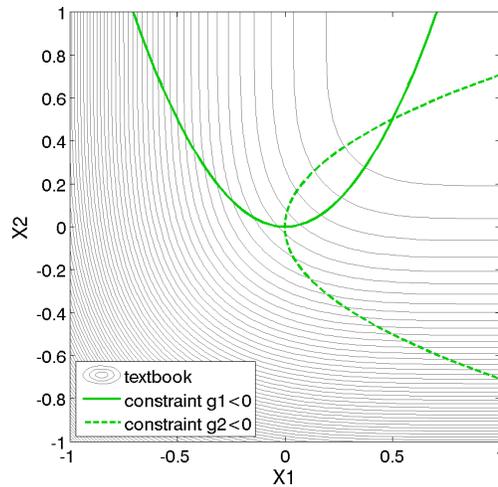

Figure 4.2: Contours of the textbook problem zoomed into an area containing the constrained optimum point $(x_1, x_2) = (0.5, 0.5)$. The feasible region lies at the intersection of the two constraints g_1 (solid) and g_2 (dashed).

For the textbook test problem, the unconstrained minimum occurs at $(x_1, x_2) = (1, 1)$. However, the inclusion of the constraints moves the minimum to $(x_1, x_2) = (0.5, 0.5)$. Equation `textbookform` presents the 2-dimensional

form of the textbook problem. An extended formulation is stated as

$$\begin{aligned}
 & \text{minimize } f = \sum_{i=1}^n (x_i - 1)^4 \\
 & \text{subject to } g_1 = x_1^2 - \frac{x_2}{2} \leq 0 \\
 & \quad \quad \quad g_2 = x_2^2 - \frac{x_1}{2} \leq 0 \\
 & \quad \quad \quad 0.5 \leq x_1 \leq 5.8 \\
 & \quad \quad \quad -2.9 \leq x_2 \leq 2.9
 \end{aligned} \tag{tbe}$$

where n is the number of design variables. The objective function is designed to accommodate an arbitrary number of design variables in order to allow flexible testing of a variety of data sets. Contour plots for the $n = 2$ case have been shown previously.

For the optimization problem given in Equation [tbe](#), the unconstrained solution (num.nonlinear.inequality.constraints set to zero) for two design variables is:

$$\begin{aligned}
 x_1 &= 1.0 \\
 x_2 &= 1.0
 \end{aligned}$$

with

$$f^* = 0.0$$

The solution for the optimization problem constrained by g_1 (num.nonlinear.inequality.constraints set to one) is:

$$\begin{aligned}
 x_1 &= 0.763 \\
 x_2 &= 1.16
 \end{aligned}$$

with

$$\begin{aligned}
 f^* &= 0.00388 \\
 g_1^* &= 0.0 \text{ (active)}
 \end{aligned}$$

The solution for the optimization problem constrained by g_1 and g_2 (num.nonlinear.inequality.constraints set to two) is:

$$\begin{aligned}
 x_1 &= 0.500 \\
 x_2 &= 0.500
 \end{aligned}$$

with

$$\begin{aligned}
 f^* &= 0.125 \\
 g_1^* &= 0.0 \text{ (active)} \\
 g_2^* &= 0.0 \text{ (active)}
 \end{aligned}$$

Note that as constraints are added, the design freedom is restricted (the additional constraints are active at the solution) and an increase in the optimal objective function is observed.

4.2 Rosenbrock

The Rosenbrock function[34] is a well-known test problem for optimization algorithms. The standard formulation includes two design variables, and computes a single objective function. This problem can also be posed as a least-squares optimization problem with two residuals to be minimized because the objective function is the sum of squared terms.

Standard Formulation

The standard two-dimensional formulation can be stated as

$$\text{minimize } f = 100(x_2 - x_1^2)^2 + (1 - x_1)^2 \quad (\text{rosenstd})$$

Surface and contour plots for this function are shown in the Dakota User's Manual.

The optimal solution is:

$$\begin{aligned} x_1 &= 1.0 \\ x_2 &= 1.0 \end{aligned}$$

with

$$f^* = 0.0$$

A Least-Squares Optimization Formulation

This test problem may also be used to exercise least-squares solution methods by recasting the standard problem formulation into:

$$\text{minimize } f = (f_1)^2 + (f_2)^2 \quad (\text{rosenls})$$

where

$$f_1 = 10(x_2 - x_1^2) \quad (\text{rosenr1})$$

and

$$f_2 = 1 - x_1 \quad (\text{rosenr2})$$

are residual terms.

The included analysis driver can handle both formulations. In the `dakota/share/dakota/test` directory, the `rosenbrock` executable (compiled from `Dakota_Source/test/rosenbrock.cpp`) checks the number of response functions passed in the parameters file and returns either an objective function (as computed from Equation [rosenstd](#)) for use with optimization methods or two least squares terms (as computed from Equations [rosenr1](#) -[rosenr2](#)) for use with least squares methods. Both cases support analytic gradients of the function set with respect to the design variables. See the User's Manual for examples of both cases (search for `Rosenbrock`).

Chapter 5

Dakota Input Specification

Dakota input is specified in a text file, e.g., `dakota_uq.in` containing blocks of keywords that control program behavior. This section describes the format and admissible elements of an input file.

5.1 Dakota Keywords

Valid Dakota input keywords are dictated by `dakota.xml`, included in source and binary distributions of Dakota. This specification file is used with the NIDR[30] parser to validate user input and is therefore the definitive source for input syntax, capability options, and optional and required capability sub-parameters for any given Dakota version. A more readable variant of the specification `dakota.input.summary` is also distributed.

While complete, users may find `dakota.input.summary` overwhelming or confusing and will likely derive more benefit from adapting example input files to a particular problem. Some examples can be found here: [Sample Input Files](#). Advanced users can master the many input specification possibilities by understanding the structure of the input specification file.

5.2 Input Spec Overview

Refer to the `dakota.input.summary` file, in [Input Spec Summary](#), for all current valid input keywords.

- The summary describes every keyword including:
 - Whether it is required or optional
 - Whether it takes ARGUMENTS (always required) Additional notes about ARGUMENTS can be found here: [Specifying Arguments](#).
 - Whether it has an ALIAS, or synonym
 - Which additional keywords can be specified to change its behavior
- Additional details and descriptions are described in [Keywords Area](#)
- For additional details on NIDR specification logic and rules, refer to[30] (Gay, 2008).

5.2.1 Common Specification Mistakes

Spelling mistakes and omission of required parameters are the most common errors. Some causes of errors are more obscure:

- Documentation of new capability sometimes lags its availability in source and executables, especially stable releases. When parsing errors occur that the documentation cannot explain, reference to the particular input specification `dakota.input.summary` used in building the executable, which is installed alongside the executable, will often resolve the errors.
- If you want to compare results with those obtained using an earlier version of Dakota (prior to 4.1), your input file for the earlier version must use backslashes to indicate continuation lines for Dakota keywords. For example, rather than

```
# Comment about the following "responses" keyword...
responses,
  objective_functions = 1
  # Comment within keyword "responses"
  analytic_gradients
# Another comment within keyword "responses"
no_hessians
```

you would need to write

```
# Comment about the following "responses" keyword...
responses,
  objective_functions = 1
  # Comment within keyword "responses"
  analytic_gradients
# Another comment within keyword "responses"
no_hessians
```

with no white space (blanks or tabs) after the `\` character.

In most cases, the Dakota parser provides error messages that help the user isolate errors in input files. Running `dakota -input dakota_study.in -check` will validate the input file without running the study.

5.2.2 Specifying Arguments

Some keywords, such as those providing bounds on variables, have an associated list of values or strings, referred to as arguments.

When the same value should be repeated several times in a row, you can use the notation `N*value` instead of repeating the value `N` times.

For example

```
lower_bounds -2.0 -2.0 -2.0
upper_bounds 2.0 2.0 2.0
```

could also be written

```
lower_bounds 3*-2.0
upper_bounds 3* 2.0
```

(with optional spaces around the `*`).

Another possible abbreviation is for sequences: `L:S:U` (with optional spaces around the `:`) is expanded to `L+S L+2*S ... U`, and `L:U` (with no second colon) is treated as `L:1:U`.

For example, in one of the test examples distributed with Dakota (test case 2 of `test/dakota_uq-textbook_sop_lhs.in`),

```
histogram_point = 2
abscissas = 50. 60. 70. 80. 90.
           30. 40. 50. 60. 70.
counts = 10 20 30 20 10
         10 20 30 20 10
```

could also be written

```

histogram_point = 2
  abscissas      = 50 : 10 : 90
                  30 : 10 : 70
  counts        = 10:10:30 20 10
                  10:10:30 20 10

```

Count and sequence abbreviations can be used together. For example

```

response_levels =
  0.0 0.1 0.2 0.3 0.4 0.5 0.6 0.7 0.8 0.9 1.0
  0.0 0.1 0.2 0.3 0.4 0.5 0.6 0.7 0.8 0.9 1.0

```

can be abbreviated

```

response_levels =
  2*0.0:0.1:1.0

```

5.3 Sample Input Files

A Dakota input file is a collection of fields from the `dakota.input.summary` file that describe the problem to be solved by Dakota. Several examples follow.

Sample 1: Optimization

The following sample input file shows single-method optimization of the Textbook Example (see [Textbook](#)) using DOT's modified method of feasible directions. A similar file is available as `dakota/share/dakota/examples/users/_opt_conmin.in`.

```

# Dakota Input File: textbook_opt_conmin.in
environment
  tabular_data
    tabular_data_file = 'textbook_opt_conmin.dat'

method
# dot_mmfd #DOT performs better but may not be available
  conmin_mfd
    max_iterations = 50
    convergence_tolerance = 1e-4

variables
  continuous_design = 2
    initial_point 0.9 1.1
    upper_bounds 5.8 2.9
    lower_bounds 0.5 -2.9
    descriptors 'x1' 'x2'

interface
  direct
    analysis_driver = 'text_book'

responses
  objective_functions = 1
  nonlinear_inequality_constraints = 2
  numerical_gradients
    method_source dakota
    interval_type central
    fd_gradient_step_size = 1.e-4
  no_hessians

```

Sample 2: Least Squares (Calibration)

The following sample input file shows a nonlinear least squares (calibration) solution of the Rosenbrock Example (see [Rosenbrock](#)) using the NL2SOL method. A similar file is available as `dakota/share/dakota/examples/users/rose_opt_nls.in`

```
# Dakota Input File: rosen_opt_nls.in
environment
  tabular_data
    tabular_data_file = 'rosen_opt_nls.dat'

method
  max_iterations = 100
  convergence_tolerance = 1e-4
  nl2sol

model
  single

variables
  continuous_design = 2
  initial_point   -1.2  1.0
  lower_bounds    -2.0  -2.0
  upper_bounds    2.0   2.0
  descriptors     'x1'  "x2"

interface
  analysis_driver = 'rosenbrock'
  direct

responses
  calibration_terms = 2
  analytic_gradients
  no_hessians
```

Sample 3: Nondeterministic Analysis

The following sample input file shows Latin Hypercube Monte Carlo sampling using the Textbook Example (see [Textbook](#)). A similar file is available as `dakota/share/dakota/test/dakota_uq_textbook_lhs.in`.

```
method,
  sampling,
  samples = 100 seed = 1
  complementary distribution
  response_levels = 3.6e+11 4.0e+11 4.4e+11
                   6.0e+04 6.5e+04 7.0e+04
                   3.5e+05 4.0e+05 4.5e+05
  sample_type lhs

variables,
  normal_uncertain = 2
  means            = 248.89, 593.33
  std_deviations  = 12.4, 29.7
  descriptors      = 'TF1n' 'TF2n'
  uniform_uncertain = 2
  lower_bounds    = 199.3, 474.63
  upper_bounds    = 298.5, 712.
  descriptors     = 'TF1u' 'TF2u'
  weibull_uncertain = 2
  alphas          = 12., 30.
  betas           = 250., 590.
  descriptors     = 'TF1w' 'TF2w'
```

```

    histogram_bin_uncertain = 2
    num_pairs = 3 4
    abscissas = 5 8 10 .1 .2 .3 .4
    counts = 17 21 0 12 24 12 0
    descriptors = 'TF1h' 'TF2h'
    histogram_point_uncertain = 1
    num_pairs = 2
    abscissas = 3 4
    counts = 1 1
    descriptors = 'TF3h'

interface,
    fork async evaluation_concurrency = 5
    analysis_driver = 'text_book'

responses,
    response_functions = 3
    no_gradients
    no_hessians

```

Sample 4: Parameter Study

The following sample input file shows a 1-D vector parameter study using the Textbook Example (see [Textbook](#)). It makes use of the default environment and model specifications, so they can be omitted. A similar file is available in the test directory as `dakota/share/dakota/examples/users/rosen_ps_vector.in`.

```

# Dakota Input File: rosen_ps_vector.in
environment
    tabular_data
    tabular_data_file = 'rosen_ps_vector.dat'

method
    vector_parameter_study
    final_point = 1.1 1.3
    num_steps = 10

variables
    continuous_design = 2
    initial_point -0.3 0.2
    descriptors 'x1' "x2"

interface
    analysis_driver = 'rosenbrock'
    direct

responses
    objective_functions = 1
    no_gradients
    no_hessians

```

Sample 5: Hybrid Strategy

The following sample input file shows a hybrid environment using three methods. It employs a genetic algorithm, pattern search, and full Newton gradient-based optimization in succession to solve the Textbook Example (see [Textbook](#)). A similar file is available as `dakota/share/dakota/examples/users/textbook_hybrid_strat.in`.

```

environment

  objective_functions = 1
  analytic_gradients
  analytic_hessians

```

Additional example input files, as well as the corresponding output, are provided in the Tutorial chapter of the Users Manual [4].

5.4 Input Spec Summary

This file is derived automatically from `dakota.xml`, which is used in the generation of parser system files that are compiled into the Dakota executable. Therefore, these files are the definitive source for input syntax, capability options, and associated data inputs. Refer to the Developers Manual information on how to modify the input specification and propagate the changes through the parsing system.

Key features of the input specification and the associated user input files include:

- In the input specification, required individual specifications simply appear, optional individual and group specifications are enclosed in `[]`, required group specifications are enclosed in `()`, and either-or relationships are denoted by the `|` symbol. These symbols only appear in `dakota.input.summary`; they must not appear in actual user input files.
- Keyword specifications (i.e., `environment`, `method`, `model`, `variables`, `interface`, and `responses`) begin with the keyword possibly preceded by white space (blanks, tabs, and newlines) both in the input specifications and in user input files. For readability, keyword specifications may be spread across several lines. Earlier versions of Dakota (prior to 4.1) required a backslash character (`\`) at the ends of intermediate lines of a keyword. While such backslashes are still accepted, they are no longer required.
- Some of the keyword components within the input specification indicate that the user must supply `INTEGER`, `REAL`, `STRING`, `INTEGERLIST`, `REALLIST`, or `STRINGLIST` data as part of the specification. In a user input file, the `"="` is optional, data in a `LIST` can be separated by commas or whitespace, and the `STRING` data are enclosed in single or double quotes (e.g., `'text_book'` or `"text_book"`).
- In user input files, input is largely order-independent (except for entries in lists of data), case insensitive, and white-space insensitive. Although the order of input shown in the [Sample Input Files](#) generally follows the order of options in the input specification, this is not required.
- In user input files, specifications may be abbreviated so long as the abbreviation is unique. For example, the `npsol_sqp` specification within the `method` keyword could be abbreviated as `npsol`, but `dot_sqp` should not be abbreviated as `dot` since this would be ambiguous with other `DOT` method specifications.
- In both the input specification and user input files, comments are preceded by `#`.
- `ALIAS` refers to synonymous keywords, which often exist for backwards compatibility. Users are encouraged to use the most current keyword.

Keywords and Concepts relating inputs to Dakota and outputs from Dakota

Related Topics

- [dakota_inputs](#)
- [dakota_output](#)
- [file_formats](#)

Related Keywords

- [error_file](#) : Base filename for error redirection
- [output_file](#) : Base filename for output redirection
- [input](#) : Base filename for post-run mode data input

- [output](#) : Base filename for post-run mode data output
- [input](#) : Base filename for pre-run mode data input
- [output](#) : Base filename for pre-run mode data output
- [read_restart](#) : Base filename for restart file read
- [stop_restart](#) : Evaluation ID number at which to stop reading restart file
- [input](#) : Base filename for run mode data input
- [output](#) : Base filename for run mode data output
- [write_restart](#) : Base filename for restart file write

6.2.1 dakota_inputs

Description

empty

Related Topics

- [block](#)
- [data_import_capabilities](#)

Related Keywords

block

Description

A block is the highest level of keyword organization in Dakota. There are currently 6 blocks in the Dakota input spec:

Related Topics

- [block_identifier](#)
- [block_pointer](#)

Related Keywords

- [environment](#) : Top-level settings for Dakota execution
- [interface](#) : Specifies how function evaluations will be performed in order to map the variables into the responses.
- [method](#) : Begins Dakota method selection and behavioral settings.
- [model](#) : Specifies how variables are mapped into a set of responses
- [responses](#) : Description of the model output data returned to Dakota upon evaluation of an interface.
- [variables](#) : Specifies the parameter set to be iterated by a particular method.

- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `method_pointer` : Pointer to sub-method to run from each starting point
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `method_pointer` : Pointer to optimization or least-squares sub-method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method

- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `method_pointer` : Pointer to sub-method to apply to a surrogate or branch-and-bound sub-problem
- `model_pointer` : Identifier for model block to be used by a method
- `method_pointer` : Pointer to sub-method to apply to a surrogate or branch-and-bound sub-problem
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `actual_model_pointer` : Pointer to specify a full-space model, from which to construct a lower dimensional surrogate
- `actual_model_pointer` : Pointer to specify a "truth" model, from which to construct a surrogate
- `optional_interface_pointer` : Pointer to interface that provides non-nested responses
- `optional_interface_responses_pointer` : Pointer to responses block that defines non-nested responses
- `sub_method_pointer` : The `sub_method_pointer` specifies the method block for the sub-iterator
- `responses_pointer` : Specify which responses block will be used by this model block
- `interface_pointer` : Interface block pointer for the single model type
- `dace_method_pointer` : Specify a method to gather training data
- `actual_model_pointer` : Pointer to specify a "truth" model, from which to construct a surrogate
- `actual_model_pointer` : Pointer to specify a "truth" model, from which to construct a surrogate
- `variables_pointer` : Specify which variables block will be included with this model block

data_import_capabilities

Description

Related Keywords

6.2.2 dakota_output

Description

empty

Related Topics

Related Keywords

- [graphics](#) : (DEPRECATED) Display plots of variables and responses
- [output_precision](#) : Control the output precision
- [results_output](#) : (Experimental) Write a summary file containing the final results
- [hdf5](#) : Write results to file in HDF5 format
- [interface_selection](#) : Select the models that write evaluation data to HDF5
- [all](#) : Write evaluation data for all interfaces to HDF5
- [none](#) : Write evaluation data for no interfaces to HDF5
- [simulation](#) : Write evaluation data only for simulation interfaces to HDF5
- [model_selection](#) : Select the models that write evaluation data to HDF5
- [all](#) : Write evaluation data to HDF5 for all models
- [all_methods](#) : Write evaluation data to HDF5 for all models that belong directly to methods
- [none](#) : Write evaluation data for no models to HDF5
- [top_method](#) : Write evaluation data only for the top-level method's model to HDF5
- [results_output_file](#) : The base file name of the results file
- [text](#) : Write results to file in text format
- [tabular_data](#) : Write a tabular results file with variable and response history
- [tabular_data_file](#) : File name for tabular data output
- [output](#) : Control how much method information is written to the screen and output file

6.2.3 file_formats

Description

See sections "Inputs to Dakota" and "Outputs from Dakota" in the Dakota User's Manual[4].

6.3 dakota_concepts

Description

Miscellaneous concepts related to Dakota operation

Related Topics

- [method_independent_controls](#)
- [block](#)
- [strategies](#)
- [command_line_options](#)
- [restarts](#)
- [pointers](#)

Related Keywords

6.3.1 `method_independent_controls`

Description

The `<method_independent_controls>` are those controls which are valid for a variety of methods. In some cases, these controls are abstractions which may have slightly different implementations from one method to the next. While each of these controls is not valid for every method, the controls are valid for enough methods that it was reasonable to consolidate the specifications.

Related Topics

Related Keywords

- [max_iterations](#) : Number of iterations allowed for optimizers and adaptive UQ methods
- [constraint_tolerance](#) : Maximum allowable constraint violation still considered feasible
- [max_function_evaluations](#) : Number of function evaluations allowed for optimizers
- [scaling](#) : Turn on scaling for variables, responses, and constraints
- [convergence_tolerance](#) : Stopping criterion based on objective function or statistics convergence
- [max_iterations](#) : Number of iterations allowed for optimizers and adaptive UQ methods
- [scaling](#) : Turn on scaling for variables, responses, and constraints
- [scaling](#) : Turn on scaling for variables, responses, and constraints
- [convergence_tolerance](#) : Stopping criterion based on objective function or statistics convergence
- [max_function_evaluations](#) : Number of function evaluations allowed for optimizers
- [max_iterations](#) : Number of iterations allowed for optimizers and adaptive UQ methods

- `convergence_tolerance` : Stopping criterion based on objective function or statistics convergence
- `max_function_evaluations` : Number of function evaluations allowed for optimizers
- `max_iterations` : Number of iterations allowed for optimizers and adaptive UQ methods
- `scaling` : Turn on scaling for variables, responses, and constraints
- `convergence_tolerance` : Stopping criterion based on objective function or statistics convergence
- `max_function_evaluations` : Number of function evaluations allowed for optimizers
- `max_iterations` : Number of iterations allowed for optimizers and adaptive UQ methods
- `scaling` : Turn on scaling for variables, responses, and constraints
- `convergence_tolerance` : Stopping criterion based on objective function or statistics convergence
- `max_function_evaluations` : Number of function evaluations allowed for optimizers
- `max_iterations` : Number of iterations allowed for optimizers and adaptive UQ methods
- `scaling` : Turn on scaling for variables, responses, and constraints
- `constraint_tolerance` : Maximum allowable constraint violation still considered feasible
- `convergence_tolerance` : Stopping criterion based on objective function or statistics convergence
- `max_function_evaluations` : Number of function evaluations allowed for optimizers
- `max_iterations` : Number of iterations allowed for optimizers and adaptive UQ methods
- `scaling` : Turn on scaling for variables, responses, and constraints
- `speculative` : Compute speculative gradients
- `constraint_tolerance` : Maximum allowable constraint violation still considered feasible
- `convergence_tolerance` : Stopping criterion based on objective function or statistics convergence
- `max_function_evaluations` : Number of function evaluations allowed for optimizers
- `max_iterations` : Number of iterations allowed for optimizers and adaptive UQ methods
- `scaling` : Turn on scaling for variables, responses, and constraints
- `speculative` : Compute speculative gradients
- `max_function_evaluations` : Number of function evaluations allowed for optimizers

- `scaling` : Turn on scaling for variables, responses, and constraints
- `constraint_tolerance` : Maximum allowable constraint violation still considered feasible
- `convergence_tolerance` : Stopping criterion based on objective function or statistics convergence
- `max_function_evaluations` : Number of function evaluations allowed for optimizers
- `max_iterations` : Number of iterations allowed for optimizers and adaptive UQ methods
- `scaling` : Turn on scaling for variables, responses, and constraints
- `speculative` : Compute speculative gradients
- `constraint_tolerance` : Maximum allowable constraint violation still considered feasible
- `convergence_tolerance` : Stopping criterion based on objective function or statistics convergence

6.3.2 block

Description

A block is the highest level of keyword organization in Dakota. There are currently 6 blocks in the Dakota input spec:

Related Topics

- [block_identifier](#)
- [block_pointer](#)

Related Keywords

- [environment](#) : Top-level settings for Dakota execution
- [interface](#) : Specifies how function evaluations will be performed in order to map the variables into the responses.
- [method](#) : Begins Dakota method selection and behavioral settings.
- [model](#) : Specifies how variables are mapped into a set of responses
- [responses](#) : Description of the model output data returned to Dakota upon evaluation of an interface.
- [variables](#) : Specifies the parameter set to be iterated by a particular method.

block_identifier

Description

empty

Related Topics

Related Keywords

- [id_interface](#) : Name the interface block; helpful when there are multiple
- [id_method](#) : Name the method block; helpful when there are multiple
- [id_model](#) : Give the model block an identifying name, in case of multiple model blocks
- [id_responses](#) : Name the responses block; helpful when there are multiple
- [id_variables](#) : Name the variables block; helpful when there are multiple

block_pointer

Description

See [block_pointer](#) for details about pointers.

Related Topics

Related Keywords

- [top_method_pointer](#) : Identify which method leads the Dakota study
- [model_pointer](#) : Identifier for model block to be used by a method
- [model_pointer](#) : Identifier for model block to be used by a method
- [model_pointer](#) : Identifier for model block to be used by a method
- [model_pointer](#) : Identifier for model block to be used by a method
- [method_pointer](#) : Pointer to sub-method to apply to a surrogate or branch-and-bound sub-problem

- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `method_pointer` : Pointer to optimization or least-squares sub-method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `method_pointer` : Pointer to sub-method to apply to a surrogate or branch-and-bound sub-problem
- `model_pointer` : Identifier for model block to be used by a method
- `method_pointer` : Pointer to sub-method to apply to a surrogate or branch-and-bound sub-problem
- `model_pointer` : Identifier for model block to be used by a method
- `model_pointer` : Identifier for model block to be used by a method
- `actual_model_pointer` : Pointer to specify a full-space model, from which to construct a lower dimensional surrogate
- `actual_model_pointer` : Pointer to specify a "truth" model, from which to construct a surrogate
- `optional_interface_pointer` : Pointer to interface that provides non-nested responses
- `optional_interface_responses_pointer` : Pointer to responses block that defines non-nested responses
- `sub_method_pointer` : The `sub_method_pointer` specifies the method block for the sub-iterator
- `responses_pointer` : Specify which responses block will be used by this model block
- `interface_pointer` : Interface block pointer for the single model type
- `dace_method_pointer` : Specify a method to gather training data
- `actual_model_pointer` : Pointer to specify a "truth" model, from which to construct a surrogate
- `actual_model_pointer` : Pointer to specify a "truth" model, from which to construct a surrogate
- `variables_pointer` : Specify which variables block will be included with this model block

Related Keywords

6.5.1 variable_domain

Description

Dakota variables can be grouped by their valid domains.

1. Mixed: continuous and discrete variables are treated separately
2. Relaxed: noncategorical discrete variables are relaxed and treated as continuous variables (categorical variables are non-relaxable and remain discrete)

Refer to [mixed](#) and [relaxed](#) for additional information.

- [loguniform_uncertain](#) : Aleatory uncertain variable - loguniform
- [normal_uncertain](#) : Aleatory uncertain variable - normal (Gaussian)
- [triangular_uncertain](#) : Aleatory uncertain variable - triangular
- [uniform_uncertain](#) : Aleatory uncertain variable - uniform
- [weibull_uncertain](#) : Aleatory uncertain variable - Weibull

6.5.3 discrete_variables

Description

This page discusses discrete design, uncertain, and state variables (which have `discrete` in their keyword name) as they have similar specifications. These include:

1. Integer ranges
2. Sets of integers
3. Sets of reals
4. Sets of strings and each is described below.

In addition, some aleatory uncertain variables, e.g., [binomial_uncertain](#), are discrete integer-valued random variables specified using parameters. These are described on their individual keyword pages.

Sets

Sets of integers, reals, and strings have similar specifications, though different value types.

The variables are specified using three keywords:

- Variable declaration keyword - specifies the number of variables being defined
- `elements_per_variable` - a list of positive integers specifying how many set members each variable admits
 - Length = # of variables
- `elements` - a list of the permissible integer values in ALL sets, concatenated together.
 - Length = sum of `elements_per_variable`, or an integer multiple of number of variables

- The order is very important here.
- The list is partitioned according to the values of `elements_per_variable`, and each partition is assigned to a variable.
- The ordering of `elements_per_variable`, and the partitions of `elements` must match the strings from `descriptors`

For string variables, each string element value must be quoted and may contain alphanumeric, dash, underscore, and colon. White space, quote characters, and backslash/metacharacters are not permitted.

Examples are given on the pages:

- discrete design set [integer](#)
- discrete design set [real](#)
- discrete design set [string](#)
- discrete uncertain set [integer](#)
- discrete uncertain set [real](#)
- discrete uncertain set [string](#)

Range

For discrete variables defined by `range(s)`, the `lower_bounds` and `upper_bounds` restrict the permissible values. For design variables, this constrains the feasible design space and is frequently used to prevent nonphysical designs. This is a discrete interval variable that may take any integer value within bounds (e.g., [1, 4], allowing values of 1, 2, 3, or 4). For some variable types, each variable is can be defined by multiple ranges.

Examples are given on the pages:

- [discrete_interval_uncertain](#)

Related Topics

Related Keywords

- [binomial_uncertain](#) : Aleatory uncertain discrete variable - binomial
- [discrete_design_range](#) : Design variable - discrete range-valued

- [discrete_state_range](#) : State variables - discrete range-valued
- [discrete_state_set](#) : State variable - discrete set-valued
- [integer](#) : Discrete state variables, each defined by a set of permissible integers
- [real](#) : Discrete state variables, each defined by a set of permissible real numbers

- [string](#) : String-valued discrete state set variables
- [discrete_uncertain_set](#) : Epistemic uncertain variable - discrete set-valued
- [integer](#) : Discrete, epistemic uncertain variable - integers within a set
- [real](#) : Discrete, epistemic uncertain variable - real numbers within a set
- [string](#) : Discrete, epistemic uncertain variable - strings within a set
- [geometric_uncertain](#) : Aleatory uncertain discrete variable - geometric
- [histogram_point_uncertain](#) : Aleatory uncertain variable - discrete histogram
- [hypergeometric_uncertain](#) : Aleatory uncertain discrete variable - hypergeometric
- [negative_binomial_uncertain](#) : Aleatory uncertain discrete variable - negative binomial
- [poisson_uncertain](#) : Aleatory uncertain discrete variable - Poisson

6.5.4 linear_constraints

Description

Many methods can make use of linear equality or inequality constraints.

As the name implies, linear constraints are constraints that are linear functions of the variables. Constraints that are nonlinear functions of variables are specified using the [nonlinear_constraints](#) family of keywords. From a Dakota usage point of view, the most important difference between linear and nonlinear constraints is that the former are specified entirely within the Dakota input file and calculated by Dakota itself, while the latter must be calculated by the user's simulation and returned as responses to Dakota.

The Optimization chapter of the User's Manual[4] states which methods support linear constraints. Of those methods, a subset strictly obey linear constraints; that is, no candidate points are generated by the optimizer that violate the constraints. These include [asynch_pattern_search](#), the `optpp_*` family of optimizers (with the exception of `optpp_fd_newton`), and [npsol_sqp](#). The other methods seek feasible solutions (i.e. solutions that satisfy the linear constraints), but may violate the constraints as they run. Linear constraints may also be violated, even when using an optimizer that itself strictly respects them, if [numerical_gradients](#) are used. In this case, Dakota may request evaluations that lie outside of the feasible region when computing a gradient near the boundary.

One final limitation that bears mentioning is that linear constraints are compatible only with continuous variables. No discrete types are permitted when using linear constraints.

6.5.5 variable_type

Description

Dakota variables can be grouped their type: [design](#), uncertain (further sub-divided into [aleatory](#) and [epistemic](#)), and [state](#). These distinctions are useful in situations where the user may want to explicitly control the subset of variables that is considered [active](#) for a certain Dakota method, overriding the default active variable type.

6.5.6 design_variables

Description

Design variables are adjusted in the course of seeking an optimal design or an optimal set of deterministic calibration parameters.

Continuous design variables, which may assume any real value within specified bounds, are the most common design variable type in engineering applications. All but a handful of the optimization algorithms in Dakota support continuous design variables exclusively.

6.5.8 epistemic_uncertain_variables

Description

Epistemic uncertainty is uncertainty due to lack of knowledge.

In Dakota, epistemic uncertainty can be characterized by interval- or set-valued variables (see relevant keywords below) that are propagated to calculate bounding intervals on simulation output using interval analysis methods. These epistemic variable types can optionally include basic probability assignments for use in Dempster-Shafer theory of evidence methods. Epistemic uncertainty can alternately be modeled with probability density functions, although results from UQ studies are then typically interpreted as possibilities or bounds, as opposed to a probability distribution of responses.

Through [nested models](#), Dakota can perform combined aleatory / epistemic analyses such as second-order probability or probability of frequency. For example, a variable can be assumed to have a lognormal distribution with specified variance, with its mean expressed as an epistemic uncertainty lying in an expert-specified interval.

6.5.9 state_variables

Description

State variables provide a convenient mechanism for managing additional model parameterizations such as mesh density, simulation convergence tolerances, and time step controls. These are typically fixed parameters for a given Dakota run.

By default, only parameter studies and design of experiments methods will vary state variables. This can be overridden for other methods by specifying `active state` or `active all`.

When a state variable is held fixed, the specified `initial_state` is used as its sole value. If the state variable is defined only by its bounds, then the `initial_state` will be inferred from the variable bounds or valid set values.

If a method iterates on a state variable, the variable is treated as a design variable with the given bounds, or as a uniform uncertain variable with the given bounds.

6.8.1 parameter_studies

Description

Parameter studies employ deterministic designs to explore the effect of parametric changes within simulation models, yielding one form of sensitivity analysis. They can help assess simulation characteristics such as smoothness, multi-modality, robustness, and nonlinearity, which affect the choice of algorithms and controls in follow-on optimization and UQ studies.

Dakota's parameter study methods compute response data sets at a selection of points in the parameter space. These points may be specified as a vector, a list, a set of centered vectors, or a multi-dimensional grid. Capability overviews and examples of the different types of parameter studies are provided in the Users Manual [4].

With the exception of output verbosity (a setting of `silent` will suppress some parameter study diagnostic output), Dakota's parameter study methods do not make use of the method independent controls. Therefore, the parameter study documentation which follows is limited to the method dependent controls for the vector, list, centered, and multidimensional parameter study methods.

6.8.4 sampling

Description

Sampling techniques are selected using the `sampling` method selection. This method generates sets of samples according to the probability distributions of the uncertain variables and maps them into corresponding sets of response functions, where the number of samples is specified by the `samples` integer specification. Means, standard deviations, coefficients of variation (COVs), and 95% confidence intervals are computed for the response functions. Probabilities and reliabilities may be computed for `response_levels` specifications, and response levels may be computed for either `probability_levels` or `reliability_levels` specifications (refer to the Method Commands chapter in the Dakota Reference Manual[5] for additional information).

Currently, traditional Monte Carlo (MC) and Latin hypercube sampling (LHS) are supported by Dakota and are chosen by specifying `sample_type` as `random` or `lhs`. In Monte Carlo sampling, the samples are selected randomly according to the user-specified probability distributions. Latin hypercube sampling is a stratified sampling technique for which the range of each uncertain variable is divided into N_s segments of equal probability, where N_s is the number of samples requested. The relative lengths of the segments are determined by the nature of the specified probability distribution (e.g., uniform has segments of equal width, normal has small segments near the mean and larger segments in the tails). For each of the uncertain variables, a sample is selected randomly from each of these equal probability segments. These N_s values for each of the individual parameters are then combined in a shuffling operation to create a set of N_s parameter vectors with a specified correlation structure. A feature of the resulting sample set is that *every row and column in the hypercube of partitions has exactly one sample*. Since the total number of samples is exactly equal to the number of partitions used for each uncertain

variable, an arbitrary number of desired samples is easily accommodated (as compared to less flexible approaches in which the total number of samples is a product or exponential function of the number of intervals for each variable, i.e., many classical design of experiments methods).

Advantages of sampling-based methods include their relatively simple implementation and their independence from the scientific disciplines involved in the analysis. The main drawback of these techniques is the large number of function evaluations needed to generate converged statistics, which can render such an analysis computationally very expensive, if not intractable, for real-world engineering applications. LHS techniques, in general, require fewer samples than traditional Monte Carlo for the same accuracy in statistics, but they still can be prohibitively expensive. For further information on the method and its relationship to other sampling techniques, one is referred to the works by McKay, et al.[60], Iman and Shortencarier[53], and Helton and Davis[46]. Note that under certain separability conditions associated with the function to be sampled, Latin hypercube sampling provides a more accurate estimate of the mean value than does random sampling. That is, given an equal number of samples, the LHS estimate of the mean will have less variance than the mean value obtained through random sampling.

6.8.5 uncertainty_quantification

Description

Dakota provides a variety of methods for propagating both aleatory and epistemic uncertainty.

At a high level, uncertainty quantification (UQ) or nondeterministic analysis is the process of characterizing input uncertainties, forward propagating these uncertainties through a computational model, and performing statistical or interval assessments on the resulting responses. This process determines the effect of uncertainties and assumptions on model outputs or results. In Dakota, uncertainty quantification methods specifically focus on the forward propagation part of the process, where probabilistic or interval information on parametric inputs are mapped through the computational model to assess statistics or intervals on outputs. For an overview of these approaches for engineering applications, consult[42].

UQ is related to sensitivity analysis in that the common goal is to gain an understanding of how variations in the parameters affect the response functions of the engineering design problem. However, for UQ, some or all of the components of the parameter vector, are considered to be uncertain as specified by particular probability distributions (e.g., normal, exponential, extreme value), or other uncertainty structures. By assigning specific distributional structure to the inputs, distributional structure for the outputs (i.e, response statistics) can be inferred. This migrates from an analysis that is more *{qualitative}* in nature, in the case of sensitivity analysis, to an analysis that is more rigorously *{quantitative}*.

UQ methods are often distinguished by their ability to propagate aleatory or epistemic input uncertainty characterizations, where aleatory uncertainties are irreducible variabilities inherent in nature and epistemic uncertainties are reducible uncertainties resulting from a lack of knowledge. Since sufficient data is generally available for aleatory uncertainties, probabilistic methods are commonly used for computing response distribution statistics based on input probability distribution specifications. Conversely, for epistemic uncertainties, any use of probability distributions is based on subjective knowledge rather than objective data, and we may alternatively explore nonprobabilistic methods based on interval specifications.

Dakota contains capabilities for performing nondeterministic analysis with both types of input uncertainty. These UQ methods have been developed by Sandia Labs, in conjunction with collaborators in academia[31],[32],[21],[81].

The aleatory UQ methods in Dakota include various sampling-based approaches (e.g., Monte Carlo and Latin Hypercube sampling), local and global reliability methods, and stochastic expansion (polynomial chaos expansions and stochastic collocation) approaches. The epistemic UQ methods include local and global interval analysis and Dempster-Shafer evidence theory. These are summarized below and then described in more depth in subsequent sections of this chapter. Dakota additionally supports mixed aleatory/epistemic UQ via interval-valued probability, second-order probability, and Dempster-Shafer theory of evidence. These involve advanced model recursions and are described in Section.

These involve advanced model recursions and are described in Section.

The choice of uncertainty quantification method depends on how the input uncertainty is characterized, the computational budget, and the desired output accuracy. The recommendations for UQ methods are summarized in Table and are discussed in the remainder of the section.

6.8.8 reliability_methods

Description

Reliability methods provide an alternative approach to uncertainty quantification which can be less computationally demanding than sampling techniques. Reliability methods for uncertainty quantification are based on probabilistic approaches that compute approximate response function distribution statistics based on specified uncertain variable distributions. These response statistics include response mean, response standard deviation, and cumulative or complementary cumulative distribution functions (CDF/CCDF). These methods are often more efficient at computing statistics in the tails of the response distributions (events with low probability) than sampling based approaches since the number of samples required to resolve a low probability can be prohibitive.

The methods all answer the fundamental question: “Given a set of uncertain input variables, \mathbf{X} , and a scalar response function, g , what is the probability that the response function is below or above a certain level, \bar{z} ?” The former can be written as $P[g(\mathbf{X}) \leq \bar{z}] = F_g(\bar{z})$ where $F_g(\bar{z})$ is the cumulative distribution function (CDF) of the uncertain response $g(\mathbf{X})$ over a set of response levels. The latter can be written as $P[g(\mathbf{X}) > \bar{z}]$ and defines the complementary cumulative distribution function (CCDF).

This probability calculation involves a multi-dimensional integral over an irregularly shaped domain of interest, \mathbf{D} , where $g(\mathbf{X}) < z$ as displayed in Figure [figUQ05](#) for the case of two variables. The reliability methods all involve the transformation of the user-specified uncertain variables, \mathbf{X} , with probability density function, $p(x_1, x_2)$, which can be non-normal and correlated, to a space of independent Gaussian random variables, \mathbf{u} , possessing a mean value of zero and unit variance (i.e., standard normal variables). The region of interest, \mathbf{D} , is also mapped to the transformed space to yield, \mathbf{D}_u , where $g(\mathbf{U}) < z$ as shown in Figure [figUQ06](#). The Nataf transformation[17], which is identical to the Rosenblatt transformation[74] in the case of independent random variables, is used in Dakota to accomplish this mapping. This transformation is performed to make the probability calculation more tractable. In the transformed space, probability contours are circular in nature as shown in Figure [figUQ06](#) unlike in the original uncertain variable space, Figure [figUQ05](#). Also, the multi-dimensional integrals can be approximated by simple functions of a single parameter, β , called the reliability index. β is the minimum Euclidean distance from the origin in the transformed space to the response surface. This point is also known as the most probable point (MPP) of failure. Note, however, the methodology is equally applicable for generic functions, not simply those corresponding to failure criteria; this nomenclature is due to the origin of these methods within the disciplines of structural safety and reliability. Note that there are local and global reliability methods. The majority of the methods available are local, meaning that a local optimization formulation is used to locate one MPP. In contrast, global methods can find multiple MPPs if they exist.

6.8.9 stochastic_expansion_methods

Description

The development of these techniques mirrors that of deterministic finite element analysis utilizing the notions of projection, orthogonality, and weak convergence[31],[32]. Rather than estimating point probabilities, they form an approximation to the functional relationship between response functions and their random inputs, which provides a more complete uncertainty representation for use in multi-code simulations. Expansion methods include polynomial chaos expansions (PCE), which employ multivariate orthogonal polynomials that are tailored to representing particular input probability distributions, and stochastic collocation (SC), which employs multivariate interpolation polynomials. For PCE, expansion coefficients may be evaluated using a spectral projection approach (based on sampling, tensor-product quadrature, Smolyak sparse grid, or cubature methods for numerical integration) or a regression approach (least squares or compressive sensing). For SC, interpolants are formed over tensor-product or sparse grids and may be local or global, value-based or gradient-enhanced, and nodal or hierarchical. In global value-based cases (Lagrange polynomials), the barycentric formulation is used[10],[56],[49] to improve numerical efficiency and stability. Both sets of methods provide analytic response moments and variance-based metrics; however, CDF/CCDF probabilities are evaluated numerically by sampling on the expansion.

6.8.10 epistemic_uncertainty_quantification_methods

Description

Epistemic uncertainty is uncertainty due to lack of knowledge.

In Dakota, epistemic uncertainty analysis is performed using interval analysis or Dempster-Shafer theory of evidence.

Note that epistemic uncertainty can also be modeled probabilistically. It would be more accurate to call this class of method, non-probabilistic uncertainty quantification, but the name persists for historical reasons.

6.8.11 interval_estimation

Description

In interval analysis, one assumes that nothing is known about an epistemic uncertain variable except that its value lies somewhere within an interval. In this situation, it is NOT assumed that the value has a uniform probability of occurring within the interval. Instead, the interpretation is that any value within the interval is a possible value or a potential realization of that variable. In interval analysis, the uncertainty quantification problem is one of determining the resulting bounds on the output (defining the output interval) given interval bounds on the inputs. Again, any output response that falls within the output interval is a possible output with no frequency information assigned to it.

We have the capability to perform interval analysis using either `global_interval_est` or `local_interval_est`. In the global approach, one uses either a global optimization method or a sampling method to assess the bounds. `global_interval_est` allows the user to specify either `lhs`, which performs Latin Hypercube Sampling and takes the minimum and maximum of the samples as the bounds (no optimization is performed) or `ego`. In the case of `ego`, the efficient global optimization method is used to calculate bounds. The `ego` method is described in Section . If the problem is amenable to local optimization methods (e.g. can provide derivatives or use finite difference method to calculate derivatives), then one can use local methods to calculate these bounds. `local_interval_est` allows the user to specify either `sqp` which is sequential quadratic programming, or `nip` which is a nonlinear interior point method.

Note that when performing interval analysis, it is necessary to define interval uncertain variables as described in Section . For interval analysis, one must define only one interval per input variable, in contrast with Dempster-Shafer evidence theory, where an input can have several possible intervals. Interval analysis can be considered a special case of Dempster-Shafer evidence theory where each input is defined by one input interval with a basic probability assignment of one. In Dakota, however, the methods are separate and semantic differences exist in the output presentation. If you are performing a pure interval analysis, we recommend using either `global_interval_est` or `local_interval_est` instead of `global_evidence` or `local_evidence`, for reasons of simplicity. An example of interval estimation is found in the `dakota/share/dakota/examples/users/cantilever_uq_global_interval.in`, and also in Section .

Note that we have kept separate implementations of interval analysis and Dempster-Shafer evidence theory because our users often want to couple interval analysis on an outer loop'' with an aleatory, probabilistic analysis on an inner loop'' for nested, second-order probability calculations. See Section for additional details on these nested approaches. These interval methods can also be used as the outer loop within an interval-valued probability analysis for propagating mixed aleatory and epistemic uncertainty – refer to Section for additional details.

Interval analysis is often used to model epistemic uncertainty. In interval analysis, the uncertainty quantification problem is one of determining the resulting bounds on the output (defining the output interval) given interval bounds on the inputs.

We can do interval analysis using either `%global_interval_est` or `local_interval_est`. In the global approach, one uses either a global optimization method or a sampling method to assess the bounds, whereas the local method uses gradient information in a derivative-based optimization approach.

An example of interval estimation is shown in Figure , with example results in Figure . This example is a demonstration of calculating interval bounds for three outputs of the cantilever beam problem. The cantilever beam problem is described in detail in Section . Given input intervals of [1,10] on beam width and beam thickness, we can see that the interval estimate of beam weight is approximately [1,100].

```

6.8.12 evidence_theory

Description

This section discusses Dempster-Shafer evidence theory. In this approach, one does not assign a probability distribution to each uncertain input variable. Rather, one divides each uncertain input variable into one or more intervals. The input parameters are only known to occur within intervals: nothing more is assumed.

Each interval is defined by its upper and lower bounds, and a Basic Probability Assignment (BPA) associated with that interval. The BPA represents a probability of that uncertain variable being located within that interval.

The intervals and BPAs are used to construct uncertainty measures on the outputs called "belief" and "plausibility." Belief represents the smallest possible probability that is consistent with the evidence, while plausibility represents the largest possible probability that is consistent with the evidence. For more information about the Dempster-Shafer theory of evidence, see [68] and [47].

Similar to the interval approaches, one may use global or local methods to determine plausibility and belief measures for the outputs.

Usage Notes

Note that to calculate the plausibility and belief cumulative distribution functions, one has to look at all combinations of intervals for the uncertain variables. Within each interval cell combination, the minimum and maximum value of the objective function determine the belief and plausibility, respectively. In terms of implementation, global methods use LHS sampling or global optimization to calculate the minimum and maximum values of the objective function within each interval cell, while local methods use gradient-based optimization methods to calculate these minima and maxima.

Finally, note that many non-deterministic keywords apply to the evidence methods, but one needs to be careful about the interpretation and translate probabilistic measures to epistemic ones. For example, if the user specifies distribution of type complementary, a complementary plausibility and belief function will be generated for the evidence methods (as opposed to a complementary distribution function in the `sampling` case). If the user specifies a set of responses levels, both the belief and plausibility will be calculated for each response level. Likewise, if the user specifies a probability level, the probability level will be interpreted both as a belief and plausibility, and response levels corresponding to the belief and plausibility levels will be calculated. Finally, if generalized reliability levels are specified, either as inputs (`gen_reliability_levels`) or outputs (`response_levels` with `compute_gen_reliabilities`), then these are directly converted to/from probability levels and the same probability-based mappings described above are performed.

6.8.13 `variable_support`

Description

Different nondeterministic methods have differing support for uncertain variable distributions. Tables 5.37, 5.38, and 5.39 summarize the uncertain variables that are available for use by the different methods, where a "-" indicates that the distribution is not supported by the method, a "U" means the uncertain input variables of this type must be uncorrelated, a "C" denotes that correlations are supported involving uncertain input variables of this type, and an "A" means the appropriate variables must be specified as active in the variables specification block. For example, if one wants to support sampling or a stochastic expansion method over both continuous uncertain and continuous state variables, the specification `active all` must be listed in the variables specification block. Additional notes include:

- we have four variants for stochastic expansions (SE), listed as Wiener, Askey, Extended, and Piecewise which draw from different sets of basis polynomials. The term stochastic expansion indicates polynomial chaos and stochastic collocation collectively, although the Piecewise option is only currently supported for stochastic collocation. Refer to [polynomial_chaos](#) and [stoch_collocation](#) for additional information on these three options.
- methods supporting the epistemic interval distributions have differing approaches: `sampling` and the `lhs` option of `global_interval_est` model the interval basic probability assignments (BPAs) as continuous histogram bin distributions for purposes of generating samples; `local_interval_est` and the `ego` option of `global_interval_est` ignore the BPA details and models these variables as simple bounded regions defined by the cell extremes; and `local_evidence` and `global_evidence` model the interval specifications as true BPAs.

6.8.14 `optimization_and_calibration`

Description

Optimization algorithms work to minimize (or maximize) an objective function, typically calculated by the user simulation code, subject to constraints on design variables and responses. Available approaches in Dakota include well-tested, proven gradient-based, derivative-free local, and global methods for use in science and engineering design applications. Dakota also offers more advanced algorithms, e.g., to manage multi-objective optimization or perform surrogate-based minimization. This chapter summarizes optimization problem formulation, standard algorithms available in Dakota (mostly through included third-party libraries, see Section 6.5 of [4]), some advanced capabilities, and offers usage guidelines.

Optimization Formulations

This section provides a basic introduction to the mathematical formulation of optimization, problems. The primary goal of this section is to introduce terms relating to these topics, and is not intended to be a description of theory or numerical algorithms. For further details, consult [8], [34], [41], [66], and [86].

A general optimization problem is formulated as follows:

$$\begin{aligned}
&\text{minimize:} && f(\mathbf{x}) \\
&&& \mathbf{x} \in \mathfrak{R}^n \\
&\text{subject to:} && \mathbf{g}_L \leq \mathbf{g}(\mathbf{x}) \leq \mathbf{g}_U \\
&&& \mathbf{h}(\mathbf{x}) = \mathbf{h}_t \\
&&& \mathbf{a}_L \leq \mathbf{A}_i \mathbf{x} \leq \mathbf{a}_U \\
&&& \mathbf{A}_e \mathbf{x} = \mathbf{a}_t \\
&&& \mathbf{x}_L \leq \mathbf{x} \leq \mathbf{x}_U
\end{aligned} \tag{6.1}$$

where vector and matrix terms are marked in bold typeface. In this formulation, $\mathbf{x} = [x_1, x_2, \dots, x_n]$ is an n -dimensional vector of real-valued *design variables* or *design parameters*. The n -dimensional vectors, \mathbf{x}_L and \mathbf{x}_U , are the lower and upper bounds, respectively, on the design parameters. These bounds define the allowable values for the elements of \mathbf{x} , and the set of all allowable values is termed the *design space* or the *parameter space*. A *design point* or a *sample point* is a particular set of values within the parameter space.

The optimization goal is to minimize the *objective function*, $f(\mathbf{x})$, while satisfying the constraints. Constraints can be categorized as either linear or nonlinear and as either inequality or equality. The *nonlinear inequality constraints*, $\mathbf{g}(\mathbf{x})$, are “2-sided,” in that they have both lower and upper bounds, \mathbf{g}_L and \mathbf{g}_U , respectively. The *nonlinear equality constraints*, $\mathbf{h}(\mathbf{x})$, have target values specified by \mathbf{h}_t . The linear inequality constraints create a linear system $\mathbf{A}_i \mathbf{x}$, where \mathbf{A}_i is the coefficient matrix for the linear system. These constraints are also 2-sided as they have lower and upper bounds, \mathbf{a}_L and \mathbf{a}_U , respectively. The linear equality constraints create a linear system $\mathbf{A}_e \mathbf{x}$, where \mathbf{A}_e is the coefficient matrix for the linear system and \mathbf{a}_t are the target values. The constraints partition the parameter space into feasible and infeasible regions. A design point is said to be *feasible* if and only if it satisfies all of the constraints. Correspondingly, a design point is said to be *infeasible* if it violates one or more of the constraints.

Many different methods exist to solve the optimization problem given in Section 6.1 of [4], all of which iterate on \mathbf{x} in some manner. That is, an initial value for each parameter in \mathbf{x} is chosen, the *response quantities*, $f(\mathbf{x})$, $\mathbf{g}(\mathbf{x})$, $\mathbf{h}(\mathbf{x})$, are computed, often by running a simulation, and some algorithm is applied to generate a new \mathbf{x} that will either reduce the objective function, reduce the amount of infeasibility, or both. To facilitate a general presentation of these methods, three criteria will be used in the following discussion to differentiate them: optimization problem type, search goal, and search method.

The **optimization problem type** can be characterized both by the types of constraints present in the problem and by the linearity or nonlinearity of the objective and constraint functions. For constraint categorization, a hierarchy of complexity exists for optimization algorithms, ranging from simple bound constraints, through linear constraints, to full nonlinear constraints. By the nature of this increasing complexity, optimization problem categorizations are inclusive of all constraint types up to a particular level of complexity. That is, an *unconstrained problem* has no constraints, a *bound-constrained problem* has only lower and upper bounds on the design parameters, a *linearly-constrained problem* has both linear and bound constraints, and a *nonlinearly-constrained problem* may contain the full range of nonlinear, linear, and bound constraints. If all of the linear and nonlinear constraints are equality constraints, then this is referred to as an *equality-constrained problem*, and if all of the linear and nonlinear constraints are inequality constraints, then this is referred to as an *inequality-constrained problem*. Further categorizations can be made based on the linearity of the objective and constraint functions. A problem where the objective function and all constraints are linear is called a *linear programming (LP) problem*. These types of problems commonly arise in scheduling, logistics, and resource allocation applications. Likewise, a problem where at least some of the objective and constraint functions are nonlinear is called a *nonlinear programming (NLP) problem*. These NLP problems predominate in engineering applications and are the primary focus of Dakota.

The **search goal** refers to the ultimate objective of the optimization algorithm, i.e., either global or local optimization. In *global optimization*, the goal is to find the design point that gives the lowest feasible objective

function value over the entire parameter space. In contrast, in *local optimization*, the goal is to find a design point that is lowest relative to a “nearby” region of the parameter space. In almost all cases, global optimization will be more computationally expensive than local optimization. Thus, the user must choose an optimization algorithm with an appropriate search scope that best fits the problem goals and the computational budget.

The **search method** refers to the approach taken in the optimization algorithm to locate a new design point that has a lower objective function or is more feasible than the current design point. The search method can be classified as either *gradient-based* or *nongradient-based*. In a gradient-based algorithm, gradients of the response functions are computed to find the direction of improvement. Gradient-based optimization is the search method that underlies many efficient local optimization methods. However, a drawback to this approach is that gradients can be computationally expensive, inaccurate, or even nonexistent. In such situations, nongradient-based search methods may be useful. There are numerous approaches to nongradient-based optimization. Some of the more well known of these include pattern search methods (nongradient-based local techniques) and genetic algorithms (nongradient-based global techniques).

Because of the computational cost of running simulation models, surrogate-based optimization (SBO) methods are often used to reduce the number of actual simulation runs. In SBO, a surrogate or approximate model is constructed based on a limited number of simulation runs. The optimization is then performed on the surrogate model. Dakota has an extensive framework for managing a variety of local, multipoint, global, and hierarchical surrogates for use in optimization. Finally, sometimes there are multiple objectives that one may want to optimize simultaneously instead of a single scalar objective. In this case, one may employ multi-objective methods that are described in Section 6.3.1 of [4].

This overview of optimization approaches underscores that no single optimization method or algorithm works best for all types of optimization problems. Section 6.4 of [4] offers guidelines for choosing a Dakota optimization algorithm best matched to your specific optimization problem.

Constraint Considerations Dakota’s input commands permit the user to specify two-sided nonlinear inequality constraints of the form $g_{L_i} \leq g_i(\mathbf{x}) \leq g_{U_i}$, as well as nonlinear equality constraints of the form $h_j(\mathbf{x}) = h_{t_j}$. Some optimizers (e.g., `npsol_`, `optpp_`, `soga`, and `moga` methods) can handle these constraint forms directly, whereas other optimizers (e.g., `asynch_pattern_search`, `dot_`, and `conmin_`, `mesh_adaptive_search`) require Dakota to perform an internal conversion of all constraints to one-sided inequality constraints of the form $g_i(\mathbf{x}) \leq 0$. In the latter case, the two-sided inequality constraints are treated as $g_i(\mathbf{x}) - g_{U_i} \leq 0$ and $g_{L_i} - g_i(\mathbf{x}) \leq 0$ and the equality constraints are treated as $h_j(\mathbf{x}) - h_{t_j} \leq 0$ and $h_{t_j} - h_j(\mathbf{x}) \leq 0$. The situation is similar for linear constraints: `asynch_pattern_search`, `npsol_`, `optpp_`, `soga`, and `moga` methods support them directly, whereas `dot_` and `conmin_` methods do not. For linear inequalities of the form $a_{L_i} \leq \mathbf{a}_i^T \mathbf{x} \leq a_{U_i}$ and linear equalities of the form $\mathbf{a}_i^T \mathbf{x} = a_{t_j}$, the nonlinear constraint arrays in `dot_` and `conmin_` methods are further augmented to include $\mathbf{a}_i^T \mathbf{x} - a_{U_i} \leq 0$ and $a_{L_i} - \mathbf{a}_i^T \mathbf{x} \leq 0$ in the inequality case and $\mathbf{a}_i^T \mathbf{x} - a_{t_j} \leq 0$ and $a_{t_j} - \mathbf{a}_i^T \mathbf{x} \leq 0$ in the equality case. Awareness of these constraint augmentation procedures can be important for understanding the diagnostic data returned from the `dot_` and `conmin_` methods. Other optimizers fall somewhere in between. `nlpql_` methods support nonlinear equality constraints $h_j(\mathbf{x}) = 0$ and nonlinear one-sided inequalities $g_i(\mathbf{x}) \geq 0$, but does not natively support linear constraints. Constraint mappings are used with NLPQL for both linear and nonlinear cases. Most `coliny_` methods now support two-sided nonlinear inequality constraints and nonlinear constraints with targets, but do not natively support linear constraints.

When gradient and Hessian information is used in the optimization, derivative components are most commonly computed with respect to the active continuous variables, which in this case are the *continuous design variables*. This differs from parameter study methods (for which all continuous variables are active) and from nondeterministic analysis methods (for which the uncertain variables are active). Refer to Chapter 11 of [4] for additional information on derivative components and active continuous variables.

Optimizing with Dakota: Choosing a Method

This section summarizes the optimization methods available in Dakota. We group them according to search method and search goal and establish their relevance to types of problems. For a summary of this discussion, see Section 6.4 of[4].

Gradient-Based Local Methods Gradient-based optimizers are best suited for efficient navigation to a local minimum in the vicinity of the initial point. They are not intended to find global optima in nonconvex design spaces. For global optimization methods, see Section 6.2.3 of[4]. Gradient-based optimization methods are highly efficient, with the best convergence rates of all of the local optimization methods, and are the methods of choice when the problem is smooth, unimodal, and well-behaved. However, these methods can be among the least robust when a problem exhibits nonsmooth, discontinuous, or multimodal behavior. The derivative-free methods described in Section 6.2.2 of[4] are more appropriate for problems with these characteristics.

Gradient accuracy is a critical factor for gradient-based optimizers, as inaccurate derivatives will often lead to failures in the search or pre-mature termination of the method. Analytic gradients and Hessians are ideal but often unavailable. If analytic gradient and Hessian information can be provided by an application code, a full Newton method will achieve quadratic convergence rates near the solution. If only gradient information is available and the Hessian information is approximated from an accumulation of gradient data, the superlinear convergence rates can be obtained. It is most often the case for engineering applications, however, that a finite difference method will be used by the optimization algorithm to estimate gradient values. Dakota allows the user to select the step size for these calculations, as well as choose between forward-difference and central-difference algorithms. The finite difference step size should be selected as small as possible, to allow for local accuracy and convergence, but not so small that the steps are “in the noise.” This requires an assessment of the local smoothness of the response functions using, for example, a parameter study method. Central differencing will generally produce more reliable gradients than forward differencing but at roughly twice the expense.

Gradient-based methods for nonlinear optimization problems can be described as iterative processes in which a sequence of subproblems, usually which involve an approximation to the full nonlinear problem, are solved until the solution converges to a local optimum of the full problem. The optimization methods available in Dakota fall into several categories, each of which is characterized by the nature of the subproblems solved at each iteration.

sequential_quadratic_programming**Description**

Sequential Quadratic Programming (SQP) algorithms are a class of mathematical programming problems used to solve nonlinear optimization problems with nonlinear constraints. These methods are a generalization of Newton's method: each iteration involves minimizing a quadratic model of the problem. These subproblems are formulated as minimizing a quadratic approximation of the Lagrangian subject to linearized constraints. Only gradient information is required; Hessians are approximated by low-rank updates defined by the step taken at each iteration. It is important to note that while the solution found by an SQP method will respect the constraints, the intermediate iterates may not. SQP methods available in Dakota are `dot_sqp`, `nlpql_sqp`, `nlssol_sqp`, and `npsol_sqp`. The particular implementation in `nlpql_sqp` uses a variant with distributed and non-monotone line search. Thus, this variant is designed to be more robust in the presence of inaccurate or noisy gradients common in many engineering applications.

6.8.18 nonlinear_least_squares

Description

Dakota's least squares branch currently contains three methods for solving nonlinear least squares problems:

- NL2SOL, a trust-region method that adaptively chooses between two Hessian approximations (Gauss-Newton and Gauss-Newton plus a quasi-Newton approximation to the rest of the Hessian)
- NLSSOL, a sequential quadratic programming (SQP) approach that is from the same algorithm family as NPSOL
- Gauss-Newton, which supplies the Gauss-Newton Hessian approximation to the full-Newton optimizers from OPT++.

The important difference of these algorithms from general-purpose optimization methods is that the response set is defined by calibration terms (e.g. separate terms for each residual), rather than an objective function. Thus, a finer granularity of data is used by least squares solvers as compared to that used by optimizers. This allows the exploitation of the special structure provided by a sum of squares objective function.

6.10.1 package_coliny

Description

SCOLIB (formerly known as COLINY) is a collection of nongradient-based optimizers that support the Common Optimization Library INterface (COLIN). SCOLIB optimizers currently include `coliny_cobylya`, `coliny_direct`, `coliny_ea`, `coliny_pattern_search` and `coliny_solis_wets`. (Yes, the input spec still has “coliny” prepended to the method name.) Additional SCOLIB information is available from <https://software.sandia.gov/trac/acro>.

SCOLIB solvers now support bound constraints and general nonlinear constraints. Supported nonlinear constraints include both equality and two-sided inequality constraints. SCOLIB solvers do not yet support linear constraints. Most SCOLIB optimizers treat constraints with a simple penalty scheme that adds `constraint_penalty` times the sum of squares of the constraint violations to the objective function. Specific exceptions to this method for handling constraint violations are noted below. (The default value of `constraint_penalty` is 1000.0, except for methods that dynamically adapt their constraint penalty, for which the default value is 1.0.)

The method independent controls for `max_iterations` and `max_function_evaluations` limit the number of major iterations and the number of function evaluations that can be performed during a SCOLIB optimization, respectively. The `convergence_tolerance` control defines the threshold value on relative change in the objective function that indicates convergence. The `output_verbosity` specification controls the amount of information generated by SCOLIB: the `silent`, `quiet`, and `normal` settings correspond to minimal reporting from SCOLIB, whereas the `verbose` setting corresponds to a higher level of information, and `debug` outputs method initialization and a variety of internal SCOLIB diagnostics. The majority of SCOLIB’s methods perform independent function evaluations that can directly take advantage of Dakota’s parallel capabilities. Only `coliny_solis_wets`, `coliny_cobylya`, and certain configurations of `coliny_pattern_search` are inherently serial. The parallel methods automatically utilize parallel logic when the Dakota configuration supports parallelism. Lastly, neither `speculative_gradients` nor linear constraints are currently supported with SCOLIB.

Some SCOLIB methods exploit parallelism through the use of Dakota’s concurrent function evaluations. The nature of the algorithms, however, limits the amount of concurrency that can be exploited. The maximum amount of evaluation concurrency that can be leveraged by the various methods is as follows:

- COBYLA: one
- DIRECT: twice the number of variables
- Evolutionary Algorithms: size of the population
- Pattern Search: size of the search pattern
- Solis-Wets: one

All SCOLIB methods support the `show_misc_options` optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The `misc_options` optional specification provides a means for inputting additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

Each of the SCOLIB methods supports the `solution_target` control, which defines a convergence criterion in which the optimizer will terminate if it finds an objective function value lower than the specified target.

6.10.2 package_conmin

Description

The CONMIN library[85] is a public domain library of nonlinear programming optimizers, specifically the Fletcher-Reeves conjugate gradient ([conmin_frcg](#)) method for unconstrained optimization, and the method of feasible directions ([conmin_mfd](#)) for constrained optimization. As CONMIN was a predecessor to the DOT commercial library, the algorithm controls are very similar.

Related Topics

Related Keywords

- [conmin_mfd](#) : CONMIN method of feasible directions

6.10.3 package_ddace

Description

The Distributed Design and Analysis of Computer Experiments (DDACE) library provides the following DACE techniques: grid sampling (`grid`), pure random sampling (`random`), orthogonal array sampling (`oas`), latin hypercube sampling (`lhs`), orthogonal array latin hypercube sampling (`oa_lhs`), Box-Behnken (`box-behnen`), and central composite design (`central_composite`).

It is worth noting that there is some overlap in sampling techniques with those available from the non-deterministic branch. The current distinction is that the nondeterministic branch methods are designed to sample within a variety of probability distributions for uncertain variables, whereas the design of experiments methods

treat all variables as having uniform distributions. As such, the design of experiments methods are well-suited for performing parametric studies and for generating data sets used in building global approximations, but are not currently suited for assessing the effect of uncertainties characterized with probability distribution. If a design of experiments over both design/state variables (treated as uniform) and uncertain variables (with probability distributions) is desired, then `sampling` can support this with `active all` specified in the Variables specification block.

6.10.4 `package_dot`

Description

The DOT library[87] contains nonlinear programming optimizers, specifically the Broyden-Fletcher-Goldfarb--Shanno (`dot_bfgs`) and Fletcher-Reeves conjugate gradient (`dot_frcg`) methods for unconstrained optimization, and the modified method of feasible directions (`dot_mmf`), sequential linear programming (`dot_slp`), and sequential quadratic programming (`dot_sqp`) methods for constrained optimization. To use DOT, one of these methods must be specified.

Specialized handling of linear constraints is supported with DOT; linear constraint coefficients, bounds, and targets can be provided to DOT at start-up and tracked internally.

Method Independent Controls - Stopping Criteria

Stopping criteria are set by: `max_iterations`, `max_function_evaluations`, `convergence_tolerance`, and `constraint_tolerance`

Note: The `convergence_tolerance` criterion must be satisfied for two consecutive iterations before DOT will terminate.

Method Independent Controls - Output

The output verbosity specification controls the amount of information generated by DOT: the `silent` and `quiet` settings result in header information, final results, and objective function, constraint, and parameter information on each iteration; whereas the `verbose` and `debug` settings add additional information on gradients, search direction, one-dimensional search results, and parameter scaling factors.

Concurrency

DOT contains no parallel algorithms which can directly take advantage of concurrent evaluations. However, if `numerical_gradients` with `method_source dakota` is specified, then the finite difference function evaluations can be performed concurrently (using any of the parallel modes described in the Users Manual[4]). In addition, if `speculative` is specified, then gradients (`dakota numerical` or `analytic` gradients) will be computed on each line search evaluation in order to balance the load and lower the total run time in parallel optimization studies.

6.10.5 package `fsudace`

Description

The Florida State University Design and Analysis of Computer Experiments (FSUDace) library provides the following DACE techniques: quasi-Monte Carlo sampling (`fsu_quasi_mc`) based on the Halton sequence (`halton`) or the Hammersley sequence (`hammersley`), and Centroidal Voronoi Tessellation (`fsu_cvt`).

6.10.6 package `hopspack`

Description

The HOPSPACK software [71] contains the asynchronous parallel pattern search (APPS) algorithm [37]. It can handle unconstrained problems as well as those with bound constraints, linear constraints, and general nonlinear constraints.

HOPSPACK is available to the public under the GNU LGPL and the source code is included with Dakota. HOPSPACK-specific software documentation is available from <https://software.sandia.gov/trac/hopspack>.

Related Keywords

- `asynch_pattern_search` : Pattern search, derivative free optimization method

6.10.7 package `jega`

Description

The JEGA library[19] contains two global optimization methods. The first is a Multi-objective Genetic Algorithm (MOGA) which performs Pareto optimization. The second is a Single-objective Genetic Algorithm (SOGA) which performs optimization on a single objective function. Both methods support general constraints and a mixture of real and discrete variables. The JEGA library was written by John Eddy, currently a member of the technical staff in the System Readiness and Sustainment Technologies department at Sandia National Laboratories in Albuquerque. These algorithms are accessed as `moga` and `soga` within Dakota.

6.10.8 package `nlpql`

Description

The NLPQL library includes a sequential quadratic programming (SQP) optimizer, specified as Dakota's `nlpql_sqp` method, for constrained optimization. The particular implementation used is NLPQLP[76], a variant with distributed and non-monotone line search. NLPQL is commercially licensed (available from the author) and not distributed with public versions of Dakota.

Related Topics

Related Keywords

- [nlpql_sqp](#) : NLPQL Sequential Quadratic Program

6.10.9 package `npsol`

Description

The NPSOL library[33] contains a sequential quadratic programming (SQP) implementation (the `npsol_sqp` method). SQP is a nonlinear programming optimizer for constrained minimization.

Related Topics

Related Keywords

- [npsol_sqp](#) : NPSOL Sequential Quadratic Program

6.10.10 package `optpp`

Description

The OPT++ library[61] contains primarily gradient-based nonlinear programming optimizers for unconstrained, bound-constrained, and nonlinearly constrained minimization: Polak-Ribiere conjugate gradient (Dakota's `optpp_cg` method), quasi-Newton (Dakota's `optpp_q_newton` method), finite difference Newton (Dakota's `optpp_fd_newton` method), and full Newton (Dakota's `optpp_newton` method).

The conjugate gradient method is strictly unconstrained, and each of the Newton-based methods are automatically bound to the appropriate OPT++ algorithm based on the user constraint specification (unconstrained, bound-constrained, or generally-constrained). In the generally-constrained case, the Newton methods use a nonlinear interior-point approach to manage the constraints. The library also contains a direct search algorithm, PDS (parallel direct search, Dakota's `optpp_pds` method), which supports bound constraints.

Controls

1. `max_iterations`

2. `max_function_evaluations`
3. `convergence_tolerance`
4. `output`
5. `speculative`

Concurrency

OPT++'s gradient-based methods are not parallel algorithms and cannot directly take advantage of concurrent function evaluations. However, if `numerical_gradients` with `method_source dakota` is specified, a parallel Dakota configuration can utilize concurrent evaluations for the finite difference gradient computations.

Constraints

Linear constraint specifications are supported by each of the Newton methods (`optpp_newton`, `optpp_q_newton`, `optpp_fd_newton`, and `optpp_g_newton`)

- `optpp_cg` must be unconstrained
- `optpp_pds` can be, at most, bound-constrained.

6.10.11 package_psuade

Description

The Problem Solving Environment for Uncertainty Analysis and Design Exploration (PSUADE) is a Lawrence Livermore National Laboratory tool for metamodeling, sensitivity analysis, uncertainty quantification, and optimization. Its features include non-intrusive and parallel function evaluations, sampling and analysis methods, an integrated design and analysis framework, global optimization, numerical integration, response surfaces (MARS and higher order regressions), graphical output with Pgplot or Matlab, and fault tolerance [83].

6.10.13 package_scolib

Description

SCOLIB (formerly known as COLINY) is a collection of nongradient-based optimizers that support the Common Optimization Library INterface (COLIN). SCOLIB optimizers currently include `coliny_cobylya`, `coliny_direct`, `coliny_ea`, `coliny_pattern_search` and `coliny_solis_wets`. (Yes, the input spec still has "coliny" prepended to the method name.) Additional SCOLIB information is available from <https://software.sandia.gov/trac/acro>.

SCOLIB solvers now support bound constraints and general nonlinear constraints. Supported nonlinear constraints include both equality and two-sided inequality constraints. SCOLIB solvers do not yet support linear constraints. Most SCOLIB optimizers treat constraints with a simple penalty scheme that adds `constraint_penalty` times the sum of squares of the constraint violations to the objective function. Specific exceptions to this method for handling constraint violations are noted below. (The default value of `constraint_penalty` is 1000.0, except for methods that dynamically adapt their constraint penalty, for which the default value is 1.0.)

The method independent controls for `max_iterations` and `max_function_evaluations` limit the number of major iterations and the number of function evaluations that can be performed during a SCOLIB optimization, respectively. The `convergence_tolerance` control defines the threshold value on relative change in the objective function that indicates convergence. The `output_verbosity` specification controls the amount of information generated by SCOLIB: the `silent`, `quiet`, and `normal` settings correspond to minimal reporting from SCOLIB, whereas the `verbose` setting corresponds to a higher level of information, and `debug` outputs method initialization and a variety of internal SCOLIB diagnostics. The majority of SCOLIB's methods perform independent function evaluations that can directly take advantage of Dakota's parallel capabilities. Only `coliny_solis_wets`, `coliny_cobylya`, and certain configurations of `coliny_pattern_search` are inherently serial. The parallel methods automatically utilize parallel logic when the Dakota configuration supports parallelism. Lastly, neither `speculative` gradients nor linear constraints are currently supported with SCOLIB.

Some SCOLIB methods exploit parallelism through the use of Dakota's concurrent function evaluations. The nature of the algorithms, however, limits the amount of concurrency that can be exploited. The maximum amount of evaluation concurrency that can be leveraged by the various methods is as follows:

- COBYLA: one
- DIRECT: twice the number of variables
- Evolutionary Algorithms: size of the population

- Pattern Search: size of the search pattern
- Solis-Wets: one

All SCOLIB methods support the `show_misc_options` optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The `misc_options` optional specification provides a means for inputting additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

Each of the SCOLIB methods supports the `solution_target` control, which defines a convergence criterion in which the optimizer will terminate if it finds an objective function value lower than the specified target.

Chapter 7

Keywords Area

This page summarizes the overall input file structure, syntax, and the six types of blocks that may appear in Dakota input. Some are optional and some may appear multiple times:

- [environment](#) (optional; 0 or 1 may appear)
- [method](#) (required; 1 or more may appear)
- [model](#) (optional; 0 or more may appear)
- [variables](#) (required; 1 or more may appear)
- [interface](#) (required; 1 or more may appear)
- [responses](#) (required; 1 or more may appear)

Introduction to Dakota Keywords

In Dakota, the *environment* manages execution modes and I/O streams and defines the top-level iterator. Generally speaking, an iterator contains a model and a model contains a set of *variables*, an *interface*, and a set of *responses*. An iterator repeatedly operates on the model to map the variables into responses using the interface. Each of these six components (environment, method, model, variables, interface, and responses) are separate specifications in the user's input file, and as a whole, determine the study to be performed during an execution of the Dakota software.

A Dakota execution is limited to a single environment, but may involve multiple methods and multiple models. In particular, advanced iterators (i.e., meta- and component-based iterators) and advanced models (i.e., nested and surrogate models) may specialize to include recursions with additional sub-iterators and sub-models. Since each model may contain its own variables, interface, and responses, there may be multiple specifications of the method, model, variables, interface, and responses sections.

Keyword Pages

Every Dakota keyword has its own page in this manual. The page describes:

- Whether the keyword takes ARGUMENTS, and the data type Additional notes about ARGUMENTS can be found here: [Specifying Arguments](#).
- Whether it has an ALIAS
- Which additional keywords can be specified to change its behavior
- Which of these additional keywords are required or optional
- Additional information about how to use the keyword in an input file

7.1 environment

- [Keywords Area](#)
- [environment](#)

Top-level settings for Dakota execution

Topics

This keyword is related to the topics:

- [block](#)

Specification

Alias: none

Argument(s): none

Default: no environment

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			tabular_data	Write a tabular results file with variable and response history
	Optional		output_file	Base filename for output redirection
	Optional		error_file	Base filename for error redirection
	Optional		read_restart	Base filename for restart file read
	Optional		write_restart	Base filename for restart file write
	Optional		output_precision	Control the output precision
	Optional		results_output	(Experimental) Write a summary file containing the final results

	Optional	graphics	(DEPRECATED) Display plots of variables and responses
	Optional	check	Invoke Dakota in input check mode
	Optional	pre_run	Invoke Dakota with pre-run mode active
	Optional	run	Invoke Dakota with run mode active
	Optional	post_run	Invoke Dakota with post-run mode active
	Optional	top_method_pointer	Identify which method leads the Dakota study

Description

The environment section in a Dakota input file is optional. It specifies the top-level solution environment, optionally including run modes, output controls, and identification of the primary iterative method (`top_method_pointer`). The output-related keywords address generation of tabular and results data, and precision of numerical output.

Run Mode Defaults

Dakota run phases include `check`, `pre_run`, `run`, and `post_run`. The default behavior is to `pre_run`, `run`, and `post_run`, though any or all of these may be specified to select specific run phases. Specifying `check` will cause Dakota to exit before any selected run modes.

7.1.1 tabular_data

- [Keywords Area](#)
- [environment](#)
- [tabular_data](#)

Write a tabular results file with variable and response history

Topics

This keyword is related to the topics:

- [dakota_output](#)

Specification

Alias: `tabular_graphics_data`

Argument(s): none

Default: no tabular data output

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		tabular_data_file	File name for tabular data output
	Optional(<i>Choose One</i>)	Tabular Data Format (Group 1)	custom_annotated	Selects custom-annotated tabular file format
			annotated	Selects annotated tabular file format
			freeform	Selects freeform file format

Description

Specifying the `tabular_data` flag writes to a data file the same variable and response function history data plotted when using the (deprecated) `graphics` flag. Within the generated data file, the variables and response functions appear as columns and each function evaluation provides a new table row. This capability is most useful for post-processing of Dakota results with third-party graphics tools such as MatLab, Excel, Tecplot, etc.

There is no dependence between the `graphics` flag and the `tabular_data` flag; they may be used independently or concurrently.

Dakota exports tabular data in one of three formats:

- `annotated` (default)
- `custom_annotated`
- `freeform`

See Also

These keywords may also be of interest:

- [graphics](#)

`tabular_data_file`

- [Keywords Area](#)
- [environment](#)
- [tabular_data](#)
- [tabular_data_file](#)

File name for tabular data output

Topics

This keyword is related to the topics:

- [dakota_output](#)

Specification

Alias: tabular_graphics_file

Argument(s): STRING

Default: dakota_tabular.dat

Description

Specifies a name to use for the tabular data file, overriding the default `dakota_tabular.dat`.

custom_annotated

- [Keywords Area](#)
- [environment](#)
- [tabular_data](#)
- [custom_annotated](#)

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			header	Enable header row in custom-annotated tabular file

	Optional	eval_id	Enable evaluation ID column in custom-annotated tabular file
	Optional	interface_id	Enable interface ID column in custom-annotated tabular file

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, `eval_id` column, and `interface_id` column appear in the tabular file, thus bridging `freeform` and (fully) annotated.

Default Behavior

The `annotated` format is the default for tabular export/import. To control which header row and columns are in the input/output, specify `custom_annotated`, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and `eval_id` (no `interface_id`), and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id      x1          x2          obj_fn  nln_ineq_con_1  nln_ineq_con_2
1              0.9          1.1          0.0002         0.26           0.76
2              0.90009      1.1 0.0001996404857  0.2601620081   0.759955

annotated

- [Keywords Area](#)
- [environment](#)
- [tabular_data](#)
- [annotated](#)

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The `annotated` keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include `interface_id`, specify `custom_annotated` header `eval_id`
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export an annotated top-level tabular data file containing a header row, leading `eval_id` and `interface_id` columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated
```

Resulting tabular file:

```
%eval_id interface          x1          x2          obj_fn nln_ineq_con_1 nln_ineq_con_2
1          NO_ID            0.9         1.1         0.0002      0.26          0.76
2          NO_ID            0.90009    1.1 0.0001996404857 0.2601620081 0.759955
3          NO_ID            0.89991    1.1 0.0002003604863 0.2598380081 0.760045
...
```

freeform

- [Keywords Area](#)
- [environment](#)
- [tabular_data](#)
- [freeform](#)

Selects freeform file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The `annotated` format is the default for tabular export/import. To change this behavior, specify `freeform` in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In `freeform`, the `num_rows` x `num_cols` total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

```

      0.9          1.1          0.0002          0.26          0.76
0.90009         1.1 0.0001996404857  0.2601620081  0.759955
0.89991         1.1 0.0002003604863  0.2598380081  0.760045
...

```

7.1.2 output_file

- [Keywords Area](#)
- [environment](#)
- [output_file](#)

Base filename for output redirection

Topics

This keyword is related to the topics:

- [dakota.IO](#)
- [command_line_options](#)

Specification

Alias: none

Argument(s): STRING

Default: output to console, not file

Description

Specify a base filename to which Dakota output will be directed. Output will (necessarily) be redirected after the input file is parsed. This option is overridden by any command-line `-output` option.

Default Behavior

Output to console (screen).

7.1.3 error_file

- [Keywords Area](#)
- [environment](#)
- [error_file](#)

Base filename for error redirection

Topics

This keyword is related to the topics:

- [dakota_IO](#)
- [command_line_options](#)

Specification

Alias: none

Argument(s): STRING

Default: errors to console, not file

Description

Specify a base filename to which Dakota errors will be directed. Errors will (necessarily) be redirected after the input file is parsed. This option is overridden by any command-line `-error` option.

Default Behavior

Errors to console (screen).

7.1.4 read_restart

- [Keywords Area](#)
- [environment](#)
- [read_restart](#)

Base filename for restart file read

Topics

This keyword is related to the topics:

- [dakota_IO](#)
- [command_line_options](#)

Specification

Alias: none

Argument(s): STRING

Default: no restart read

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			stop_restart	Evaluation ID number at which to stop reading restart file

Description

Specify a base filename for the restart file Dakota should read. This option is overridden by any command-line `-read_restart` option.

Default Behavior

No restart file is read.

`stop_restart`

- [Keywords Area](#)
- [environment](#)
- [read_restart](#)
- [stop_restart](#)

Evaluation ID number at which to stop reading restart file

Topics

This keyword is related to the topics:

- [dakota_IO](#)

Specification

Alias: none

Argument(s): INTEGER

Default: read all records

Description

This option is overridden by any command-line `-stop_restart` option.

7.1.5 `write_restart`

- [Keywords Area](#)
- [environment](#)
- [write_restart](#)

Base filename for restart file write

Topics

This keyword is related to the topics:

- [dakota_IO](#)
- [command_line_options](#)

Specification

Alias: none

Argument(s): STRING

Default: dakota.rst

Description

Specify a base filename for the restart file Dakota should write. This option is overridden by any command-line `-write_restart` option.

7.1.6 output_precision

- [Keywords Area](#)
- [environment](#)
- [output_precision](#)

Control the output precision

Topics

This keyword is related to the topics:

- [dakota_output](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 10

Description

The precision of numeric output precision can be set with `output_precision`, with an upper limit of 16. When not specified, most Dakota output will default to a precision of 10, though filesystem interfaces and pre-run output use higher precision for accuracy and better results reproducibility.

7.1.7 results_output

- [Keywords Area](#)
- [environment](#)
- [results_output](#)

(Experimental) Write a summary file containing the final results

Topics

This keyword is related to the topics:

- [dakota_output](#)

Specification

Alias: none

Argument(s): none

Default: no results output

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			results_output_file	The base file name of the results file
	Optional		text	Write results to file in text format
	Optional		hdf5	Write results to file in HDF5 format

Description

(Experimental)

Dakota writes final results for most methods to the screen (console). This keyword enables experimental support for writing them to disk, as well. By default, they are written in a structured text format to a file named `dakota_results.txt`. Text format can be explicitly selected using the `text` sub-keyword. If Dakota was built with HDF5 enabled, the sub-keyword `hdf5` causes results to be written in HDF5 format, as well.

The name of the results file can be changed using the `results_output_file` keyword.

Text output eventually will be deprecated, and HDF5 will be enabled in all distributed builds of Dakota. The layout of the HDF5 file is described in the [Dakota HDF5 Output](#) section of this manual. The contents, organization, and format of results files are all under active development and are subject to change.

results_output_file

- [Keywords Area](#)
- [environment](#)
- [results_output](#)
- [results_output_file](#)

The base file name of the results file

Topics

This keyword is related to the topics:

- [dakota_output](#)

Specification

Alias: none

Argument(s): STRING

Default: dakota_results

Description

The default filename is `dakota_results.txt` for text output and `dakota_results.h5` for HDF5. The `dakota_results` stem can be changed using this keyword. Do not include the extension; these will be added by Dakota.

text

- [Keywords Area](#)
- [environment](#)
- [results_output](#)
- [text](#)

Write results to file in text format

Topics

This keyword is related to the topics:

- [dakota_output](#)

Specification

Alias: none

Argument(s): none

Default: text output

Description

When this keyword is present, Dakota will right (some) final method results to disk in a custom structured text format instead of just to the console. Support for text format results output will be deprecated in a future release, and the contents and organization of the output file is subject to change.

The default name of the file is `dakota_results.txt`. This can be changed using the `results_output_file` keyword.

Examples

```
environment
  results_output
    text
      results_output_file 'my_results' # The .txt extension will be added
```

hdf5

- [Keywords Area](#)
- [environment](#)
- [results_output](#)
- [hdf5](#)

Write results to file in HDF5 format

Topics

This keyword is related to the topics:

- [dakota_output](#)

Specification

Alias: none

Argument(s): none

Default: no HDF5 output

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		model_selection	Select the models that write evaluation data to HDF5
	Optional		interface_selection	Select the models that write evaluation data to HDF5

Description

When this keyword is present, Dakota will write (some) final method results to disk in HDF5 format instead of just to the console. This is an experimental feature, and the contents and organization of the output file is subject to change. The current organization and a brief explanation of HDF5 is provided in the [Dakota HDF5 Output](#) section of this manual.

With `hdf5` selected, the default name of the output file is `dakota_results.h5`. This can be changed using the `results_output_file` keyword.

Examples

```
environment
  results_output
    hdf5
      results_output_file 'my_results' # The .h5 extension will be added
```

model_selection

- [Keywords Area](#)
- [environment](#)
- [results_output](#)
- [hdf5](#)
- [model_selection](#)

Select the models that write evaluation data to HDF5

Topics

This keyword is related to the topics:

- [dakota_output](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/- Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Model Evaluation Storage Selection (Group 1)	top_method	Write evaluation data only for the top-level method's model to HDF5
			none	Write evaluation data for no models to HDF5
			all_methods	Write evaluation data to HDF5 for all models that belong directly to methods

			all	Write evaluation data to HDF5 for all models
--	--	--	---------------------	--

Description

By default, when HDF5 output is enabled, Dakota writes evaluation data only for the model that belongs to the top-level method. This keyword group is used to override the default.

HDF5 output is an experimental feature, and the contents and organization of the output file is subject to change. The current organization and a brief explanation of HDF5 is provided in the [Dakota HDF5 Output](#) section of this manual.

The example below will be used to explain the effect of each keyword.

Examples

```
environment
  results_output
    hdf5
      # model_selection
      # top_method
      # all_methods
      # all
      # none
      results_output_file 'my_results' # The .h5 extension will be added

top_method

- [Keywords Area](#)
- [environment](#)
- [results_output](#)
- [hdf5](#)
- [model_selection](#)
- [top_method](#)

Write evaluation data only for the top-level method's model to HDF5

Topics

This keyword is related to the topics:

- [dakota_output](#)

Specification

Alias: none

Argument(s): none

Default: top_method

Description

When this option is selected, evaluation data only for the model that belongs to the top-level method will be written to HDF5.

HDF5 output is an experimental feature, and the contents and organization of the output file is subject to change. The current organization and a brief explanation of HDF5 is provided in the [Dakota HDF5 Output](#) section of this manual.

Examples

For the example input in the parent keyword, the following model groups would be written:

- /models/recast/RECAST_surr.RECAST_1/

The recast model, in this case, is automatically generated by Dakota to handle summing the pair of objective functions. It is the model that belongs directly to the method 'opt', which is the top-level method. See [Sources of Evaluation Data](#) for further explanation.

The following links would be added to methods and models `sources` groups:

- /methods/opt/sources/RECAST_surr.RECAST_1 → /models/recast/RECAST_surr_RECAST_1/

none

- [Keywords Area](#)
- [environment](#)
- [results_output](#)
- [hdf5](#)
- [model_selection](#)
- [none](#)

Write evaluation data for no models to HDF5

Topics

This keyword is related to the topics:

- [dakota_output](#)

Specification

Alias: none

Argument(s): none

Default: top_method

Description

When this option is selected, no model evaluation data is written to HDF5, and the `/models` group itself is not created.

HDF5 output is an experimental feature, and the contents and organization of the output file is subject to change. The current organization and a brief explanation of HDF5 is provided in the [Dakota HDF5 Output](#) section of this manual.

all_methods

- [Keywords Area](#)
- [environment](#)
- [results_output](#)
- [hdf5](#)
- [model_selection](#)
- [all_methods](#)

Write evaluation data to HDF5 for all models that belong directly to methods

Topics

This keyword is related to the topics:

- [dakota_output](#)

Specification

Alias: none

Argument(s): none

Default: top_method

Description

When this option is selection, evaluation data for all models that belong directly to methods will be written to HDF5. Models that belong to other models (e.g. wrapped models in a recast relationship) are not stored.

By default, when HDF5 output is enabled, Dakota writes evaluation data only for the model that belongs to the top-level method. This keyword group is used to override the default.

HDF5 output is an experimental feature, and the contents and organization of the output file is subject to change. The current organization and a brief explanation of HDF5 is provided in the [Dakota HDF5 Output](#) section of this manual.

Examples

For the example input in the parent keyword, the following model groups would be written:

- /models/recast/RECAST_surr_RECAST_1/
- /models/simulation/truth_m/

The recast model, in this case, is automatically generated by Dakota to handle summing the pair of objective functions. It is the model that belongs directly to the method 'opt'. See [Sources of Evaluation Data](#) for further explanation.

The following links would be added to methods and models sources groups:

- /methods/opt/sources/RECAST_surr_RECAST_1 → /models/recast/RECAST_surr_RECAST_1/
- /methods/training/sources/truth_m → /models/simulation/truth_m/

Depending on [interface_selection](#), the following links may also be added to model sources groups:

- /models/simulation/truth_m/sources/truth → /interfaces/truth/truth_m/

- [hdf5](#)
- [model_selection](#)
- [all](#)

Write evaluation data to HDF5 for all models

Topics

This keyword is related to the topics:

- [dakota_output](#)

Specification

Alias: none

Argument(s): none

Default: top_method

Description

When this option is selected, evaluation for all models will be written to HDF5.

HDF5 output is an experimental feature, and the contents and organization of the output file is subject to change. The current organization and a brief explanation of HDF5 is provided in the [Dakota HDF5 Output](#) section of this manual.

Examples

For the example input in the parent keyword, the following model groups would be written:

- /models/recast/RECAST_surr_RECAST_1/
- /models/simulation/truth_m/
- /models/surrogate/surr/

The recast model, in this case, is automatically generated by Dakota to handle summing the pair of objective functions. See [Sources of Evaluation Data](#) for further explanation.

The following links would be added to methods and models sources groups:

- /methods/opt/sources/RECAST_surr_RECAST_1 → /models/recast/RECAST_surr_RECAST_1/
- /methods/training/sources/truth_m → /models/simulation/truth_m/
- /models/recast/RECAST_surr_RECAST_1/sources/surr → /models/surrogate/surr/

Depending on [interface_selection](#), the following links may also be added to model sources groups:

- /models/surrogate/surr/sources/APPROX_INTERFACE_1 → /interfaces/APPROX_INTERFACE_1/surr/
- /models/simulation/truth_m/sources/truth → /interfaces/truth/truth_m/

interface_selection

- [all](#)

Write evaluation data for all interfaces to HDF5

Topics

This keyword is related to the topics:

- [dakota_output](#)

Specification

Alias: none

Argument(s): none

Default: top_simulation

Description

When this option is selected, evaluation data for all interfaces, including both simulations and approximations, will be written to HDF5.

HDF5 output is an experimental feature, and the contents and organization of the output file is subject to change. The current organization and a brief explanation of HDF5 is provided in the [Dakota HDF5 Output](#) section of this manual.

Examples

For the example input in the parent keyword, the following interface groups would be written:

- `/interfaces/truth/truth.m/`
- `/interfaces/APPROX_INTERFACE_1/surr/`

Depending on the [model_selection](#), the following links may be added to model sources groups.

- `/models/simulation/truth.m/sources/truth → /interfaces/truth/truth.m/`
- `/models/surrogate/surr/sources/APPROX_INTERFACE_1 → /interfaces/APPROX_INTERFACE_1/surr/`

7.1.8 graphics

- [Keywords Area](#)
- [environment](#)
- [graphics](#)

(DEPRECATED) Display plots of variables and responses

Topics

This keyword is related to the topics:

- [dakota_output](#)

Specification

Alias: none

Argument(s): none

Default: graphics off

Description

Activate Dakota's legacy X Windows-based graphics feature. Dakota plotting and visualization capabilities are increasingly available in the Dakota graphical user interface (GUI); see the Dakota GUI User Manual in the documentation section of the Dakota website for additional details.

The `graphics` flag activates a 2D graphics window containing history plots for the variables and response functions in the study. This window is updated approximately every two seconds. Some study types such as surrogate-based optimization or local reliability specialize the use of the graphics window.

There is no dependence between the `graphics` flag and the `tabular_data` flag; they may be used independently or concurrently.

Base filename for pre-run mode data output

Topics

This keyword is related to the topics:

- [dakota_IO](#)

Specification

Alias: none

Argument(s): STRING

Default: no pre-run specific output written

Child Keywords:

	Required/- Optional <i>Optional(Choose One)</i>	Description of Group Tabular Format (Group 1)	Dakota Keyword custom_annotated	Dakota Keyword Description Selects custom-annotated tabular file format
			annotated	Selects annotated tabular file format
			freeform	Selects freeform file format

Description

Specify a base filename to which Dakota will write any pre-run output data (typically parameter sets to be evaluated). This option is overridden by any command-line `-pre_run` arguments.

Usage Tips

Dakota exports tabular data in one of three formats:

- `annotated` (default)
- `custom_annotated`
- `freeform`

`custom_annotated`

- [Keywords Area](#)
- [environment](#)
- [pre_run](#)
- [output](#)
- [custom_annotated](#)

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		<code>header</code>	Enable header row in custom-annotated tabular file
	Optional		<code>eval_id</code>	Enable evaluation ID column in custom-annotated tabular file
	Optional		<code>interface_id</code>	Enable interface ID column in custom-annotated tabular file

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether `header` row, `eval_id` column, and `interface_id` column appear in the tabular file, thus bridging `freeform` and (fully) `annotated`.

Default Behavior

The `annotated` format is the default for tabular export/import. To control which header row and columns are in the input/output, specify `custom_annotated`, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to `annotated` format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only `header` and `eval_id` (no `interface_id`), and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id      x1          x2          obj_fn  nln_ineq_con_1  nln_ineq_con_2
1              0.9          1.1          0.0002          0.26           0.76

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The `annotated` keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include `interface_id`, specify `custom_annotated` header `eval_id`
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export an annotated top-level tabular data file containing a header row, leading `eval_id` and `interface_id` columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
  annotated
```

Resulting tabular file:

```
%eval_id interface          x1          x2          obj_fn nln_ineq_con_1 nln_ineq_con_2
1          NO_ID            0.9          1.1          0.0002          0.26          0.76

```

freeform

- [Keywords Area](#)
- [environment](#)
- [pre_run](#)
- [output](#)
- [freeform](#)

Selects freeform file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The `annotated` format is the default for tabular export/import. To change this behavior, specify `freeform` in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to `annotated` format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- In `freeform`, the `num_rows` x `num_cols` total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    freeform
```

Resulting tabular file:

```
      0.9      1.1      0.0002      0.26      0.76
0.90009      1.1 0.0001996404857 0.2601620081 0.759955

- [dakota.IO](#)

Specification

Alias: none

Argument(s): STRING

Default: no post-run specific output written

Description

(For future expansion; not currently used by any methods.) Specify a base filename to which Dakota will write any post-run output data. This option is overridden by any command-line `-post_run` arguments.

7.1.13 `top_method_pointer`

- [Keywords Area](#)
- [environment](#)
- [top_method_pointer](#)

Identify which method leads the Dakota study

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: `method_pointer`

Argument(s): STRING

Default: see discussion

Description

An optional `top_method_pointer` specification may be used to point to a particular method specification that will lead the Dakota analysis. The associated string must be a method identifier specified via `id.method`. If `top_method_pointer` is not used, then it will be inferred as described below (no `top_method_pointer` within an environment specification is treated the same as no environment specification).

Default Behavior

The `top_method_pointer` keyword is typically used in Dakota studies consisting of more than one `method` block to clearly indicate which is the leading method. This method provides the starting point for the iteration. The corresponding method specification may recurse with additional sub-method pointers in the case of "meta-iteration" (see `method`) or may specify a single method without recursion. Either case will ultimately result in identification of one or more model specifications using `model_pointer`, which again may or may not involve further recursion (see `nested` and `surrogate` for recursion cases). Each of the model specifications identify the

variables and responses specifications (using [variables_pointer](#) and [responses_pointer](#)) that are used to build the model, and depending on the type of model, may also identify an interface specification (for example, using [interface_pointer](#)). If one of these specifications does not provide an optional pointer, then that component will be constructed using the last specification parsed.

When the environment block is omitted, the top level method will be inferred as follows: When a single method is specified, there is no ambiguity and the sole method will be the top method. When multiple methods are specified, the top level method will be deduced from the hierarchical relationships implied by method pointers. If this inference is not well defined (e.g., there are multiple method specifications without any pointer relationship), then the default behavior is to employ the last method specification parsed.

Examples

Specify that the optimization method is the outermost method in an optimization under uncertainty study

```
environment
  top_method_pointer 'OPTIMIZATION_METHOD'
method
  id_method 'UQ_METHOD'
...
method
  id_method 'OPTIMIZATION_METHOD'
...
```

Description

The `method` keyword signifies the start of a block in the Dakota input file. A method block contains the various keywords necessary to select a method and to control its behavior.

Method Block Requirements

At least one `method` block must appear in the Dakota input file. Multiple `method` blocks may be needed to fully define advanced analysis approaches.

Each `method` block must specify one method and, optionally, any associated keywords that govern the behavior of the method.

The Methods

Each `method` block must select one method.

Starting with Dakota v6.0, the methods are grouped into two types: standard methods and multi-component methods.

The standard methods are stand-alone and self-contained in the sense that they only require a model to perform a study. They do not call other methods. While methods such as `polynomial_chaos` and `efficient_global` internally utilize multiple iterator and surrogate model components, these components are generally hidden from user control due to restrictions on modularity; thus, these methods are stand-alone.

The multi-component group of methods provides a higher level "meta-algorithm" that points to other methods and models that support sub-iteration. For example, in a sequential hybrid method, the `hybrid` method specification must identify a list of subordinate methods, and the "meta-algorithm" executes these methods in sequence and transfers information between them. Surrogate-based minimizers provide another example in that they point both to other methods (e.g. what optimization method is used to solve the approximate subproblem) as well as to models (e.g. what type of surrogate model is employed). Multi-component methods generally provide some level of "plug and play" modularity, through their flexible support of a variety of method and model selections.

Component-Based Iterator Commands

Component-based iterator specifications include `hybrid`, `multi-start`, `pareto set`, `surrogate-based local`, `surrogate-based global`, and `branch and bound` methods. Whereas a standard iterator specification only needs an optional model pointer string (specified with `model_pointer`), component-based iterator specifications can include

method pointer, method name, and model pointer specifications in order to define the components employed in the "meta-iteration." In particular, these specifications identify one or more methods (by pointer or by name) to specify the subordinate iterators that will be used in the top-level algorithm. Identifying a sub-iterator by name instead of by pointer is a lightweight option that relaxes the need for a separate method specification for the sub-iterator; however, a model pointer may be required in this case to provide the specification connectivity normally supported by the method pointer. Refer to these individual method descriptions for specific requirements for these advanced methods.

Method Independent Controls

In addition to the method, there are 10 optional keywords, which are referred to as method independent controls. These controls are valid for enough methods that it was reasonable to pull them out of the method dependent blocks and consolidate the specifications, however, they are NOT universally respected by all methods.

Examples

Several examples follow. The first example shows a minimal specification for an optimization method.

```
method
  dot_sqp
```

This example uses all of the defaults for this method.

A more sophisticated example would be

```
method,
  id_method = 'NLP1'
  dot_sqp
  max_iterations = 50
  convergence_tolerance = 1e-4
  output verbose
  model_pointer = 'M1'
```

This example demonstrates the use of identifiers and pointers as well as some method independent and method dependent controls for the sequential quadratic programming (SQP) algorithm from the DOT library. The `max_iterations`, `convergence_tolerance`, and `output` settings are method independent controls, in that they are defined for a variety of methods.

The next example shows a specification for a least squares method.

```
method
  optpp_g_newton
  max_iterations = 10
  convergence_tolerance = 1.e-8
  search_method trust_region
  gradient_tolerance = 1.e-6
```

Some of the same method independent controls are present along with several method dependent controls (`search_method` and `gradient_tolerance`) which are only meaningful for OPT++ methods (see [package.optpp](#)).

The next example shows a specification for a nondeterministic method with several method dependent controls (refer to [sampling](#)).

```
method
  sampling
  samples = 100
  seed = 12345
  sample_type lhs
  response_levels = 1000. 500.
```

The last example shows a specification for a parameter study method where, again, each of the controls are method dependent (refer to [vector_parameter.study](#)).

```
method
  vector_parameter_study
  step_vector = 1. 1. 1.
  num_steps = 10
```

7.2.1 id_method

- [Keywords Area](#)
- [method](#)
- [id_method](#)

Name the method block; helpful when there are multiple

Topics

This keyword is related to the topics:

- [block_identifier](#)
- [method_independent_controls](#)

Specification

Alias: none

Argument(s): STRING

Default: strategy use of last method parsed

Description

The method identifier string is supplied with `id_method` and is used to provide a unique identifier string for use with environment or meta-iterator specifications (refer to [environment](#)). It is appropriate to omit a method identifier string if only one method is included in the input file, since the single method to use is unambiguous in this case.

7.2.2 output

- [Keywords Area](#)
- [method](#)
- [output](#)

Control how much method information is written to the screen and output file

Topics

This keyword is related to the topics:

- [dakota_output](#)
- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: normal

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Output Level (Group 1)	debug	Level 5 of 5 - maximum
			verbose	Level 4 of 5 - more than normal
			normal	Level 3 of 5 - default
			quiet	Level 2 of 5 - less than normal
			silent	Level 1 of 5 - minimum

Description

Choose from a total of five output levels during the course of a Dakota study. If there is no user specification for output verbosity, then the default setting is `normal`.

Specific mappings are as follows:

- `silent` (i.e., really quiet): silent iterators, silent model, silent interface, quiet approximation, quiet file operations
- `quiet`: quiet iterators, quiet model, quiet interface, quiet approximation, quiet file operations
- `normal`: normal iterators, normal model, normal interface, quiet approximation, quiet file operations
- `verbose`: verbose iterators, normal model, verbose interface, verbose approximation, verbose file operations
- `debug` (i.e., really verbose): debug iterators, normal model, debug interface, verbose approximation, verbose file operations

Note that iterators and interfaces utilize the full granularity in verbosity, whereas models, approximations, and file operations do not. With respect to iterator verbosity, different iterators implement this control in slightly different ways (as described below in the method independent controls descriptions for each iterator), however the meaning is consistent.

For models, interfaces, approximations, and file operations, `quiet` suppresses parameter and response set reporting and `silent` further suppresses function evaluation headers and scheduling output. Similarly, `verbose` adds file management, approximation evaluation, and global approximation coefficient details, and `debug` further adds diagnostics from nonblocking schedulers.

debug

- [Keywords Area](#)
- [method](#)
- [output](#)
- [debug](#)

Level 5 of 5 - maximum

Specification

7.2.3 final_solutions

- [Keywords Area](#)
- [method](#)
- [final_solutions](#)

Number of designs returned as the best solutions

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 1

Description

The `final_solutions` controls the number of final solutions returned by the iterator as the best solutions.

For most optimizers, this is one, but some optimizers can produce multiple solutions (e.g. genetic algorithms).

When using a `hybrid` strategy, the number of final solutions dictates how many solutions are passed from one method to another.

Examples

In the case of sampling methods, if one specifies 100 samples (for example) but also specifies `final_solutions = 5`, the five best solutions (in order of lowest response function value) are returned.

7.2.4 hybrid

- [Keywords Area](#)
- [method](#)
- [hybrid](#)

Strategy in which a set of methods synergistically seek an optimal design

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required(<i>Choose One</i>)	Hybrid Method Type (Group 1)	sequential	Methods are run one at a time, in sequence
			embedded	A subordinate local method provides periodic refinements to a top-level global method
			collaborative	Multiple methods run concurrently and share information

Description

In a hybrid minimization method (*hybrid*), a set of methods synergistically seek an optimal design. The relationships among the methods are categorized as:

- collaborative
- embedded
- sequential

The goal in each case is to exploit the strengths of different optimization and nonlinear least squares algorithms at different stages of the minimization process. Global + local hybrids (e.g., genetic algorithms combined with nonlinear programming) are a common example in which the desire for identification of a global optimum is balanced with the need for efficient navigation to a local optimum.

sequential

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [sequential](#)

Methods are run one at a time, in sequence

Specification

Alias: uncoupled

Argument(s): none

Child Keywords:

	Required/ Optional Required (<i>Choose One</i>)	Description of Group Sub-method Selection (Group 1)	Dakota Keyword method_name_list	Dakota Keyword Description List of Dakota methods to sequentially or collaboratively run
			method_pointer_list	Pointers to methods to execute sequentially or collaboratively
	Optional		iterator_servers	Specify the number of iterator servers when Dakota is run in parallel
	Optional		iterator_scheduling	Specify the scheduling of concurrent iterators when Dakota is run in parallel
	Optional		processors_per_iterator	Specify the number of processors per iterator server when Dakota is run in parallel

Description

In the `sequential` approach, methods are run one at a time, in sequence. The best solutions from one method are used to initialize the next method.

The sequence of methods (i.e. iterators) to run are specified using either a `method_pointer_list` or a `method_name_list` (with optional `model_pointer_list`). Any number of iterators may be specified.

Method switching is managed through the separate convergence controls of each method. The number of solutions transferred between methods is specified by the particular method through its `final_solutions` method control.

For example, if one sets up a two-level study with a first method that generates multiple solutions such as a genetic algorithm, followed by a second method that is initialized only at a single point such as a gradient-based algorithm, it is possible to take the multiple solutions generated by the first method and create several instances of the second method, each one with a different initial starting point.

The logic governing the transfer of multiple solutions between methods is as follows:

- if one solution is returned from method A, then one solution is transferred to method B.
- If multiple solutions are returned from method A, and method B can accept multiple solutions as input (for example, as a genetic algorithm population), then one instance of method B is initialized with multiple solutions.
- If multiple solutions are returned from method A but method B only can accept one initial starting point, then method B is run several times, each one with a separate starting point from the results of method A.

method_name_list

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [sequential](#)
- [method_name_list](#)

List of Dakota methods to sequentially or collaboratively run

Specification

Alias: none

Argument(s): STRINGLIST

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		model_pointer_list	Associate models with method names

Description

`method_name_list` specifies a list of Dakota methods (e.g. [soga](#), [conmin_freq](#)) that will be run by a hybrid sequential or hybrid collaborative method. The methods are executed with default options. The optional `model_pointer_list` may be used to associate a model with each method.

model_pointer_list

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [sequential](#)
- [method_name_list](#)
- [model_pointer_list](#)

Associate models with method names

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Description

Using the optional keyword `method_pointer_list`, models can be assigned to methods specified in the `method_name_list`. Models are referred to by name (i.e. by their `id_model` labels). The length of the `method_pointer_list` must be either 1 or match the length of the `method_name_list`. If the former, the same model will be used for all methods, and if the latter, methods and models will be paired in the order that they appear in the two lists.

`method_pointer_list`

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [sequential](#)
- [method_pointer_list](#)

Pointers to methods to execute sequentially or collaboratively

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRINGLIST

Description

`method_pointer_list` specifies by name the methods that are to be executed by a `hybrid sequential` or `hybrid collaborative` method. Its argument is a list of strings that refer to method blocks by name (i.e. to their `id_method` labels).

`iterator_servers`

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [sequential](#)
- [iterator_servers](#)

Specify the number of iterator servers when Dakota is run in parallel

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): INTEGER

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional `iterator_servers` specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, `hybrid`, `multi_start`, and `pareto_set` component-based iterators support concurrency in their sub-iterators. Refer to `ParallelLibrary` and the Parallel Computing chapter of the Users Manual [4] for additional information.

`iterator_scheduling`

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [sequential](#)
- [iterator_scheduling](#)

Specify the scheduling of concurrent iterators when Dakota is run in parallel

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Required (<i>Choose One</i>)	Description of Group Scheduling Mode (Group 1)	Dakota Keyword	Dakota Keyword Description
			master	Specify a dedicated master partition for parallel iterator scheduling
			peer	Specify a peer partition for parallel iterator scheduling

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional `iterator_scheduling` specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, `hybrid`, `multi_start`, and `pareto_set` component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [4] for additional information.

master

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [sequential](#)
- [iterator_scheduling](#)
- [master](#)

Specify a dedicated master partition for parallel iterator scheduling

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): none

Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a dedicated master partition. In a dedicated master partition, one processor (the "master") dynamically schedules work on the iterator servers. This reduces the number of processors available to create servers by 1.

peer

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [sequential](#)
- [iterator_scheduling](#)
- [peer](#)

Specify a peer partition for parallel iterator scheduling

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): none

Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a peer partition. In a peer partition, all processors are available to be assigned to iterator servers. Note that unlike the case of `evaluation_scheduling`, it is not possible to specify `static` or `dynamic`.

processors_per_iterator

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [sequential](#)
- [processors_per_iterator](#)

Specify the number of processors per iterator server when Dakota is run in parallel

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): INTEGER

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional `processors_per_iterator` specification supports user override of the automatic parallel configuration for the number of processors in each iterator server. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired server size at the iterator parallelism level. Currently, `hybrid`, `multi_start`, and `pareto_set` component-based iterators support concurrency in their sub-iterators. Refer to `ParallelLibrary` and the `Parallel Computing` chapter of the `Users Manual`[4] for additional information.

embedded

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [embedded](#)

A subordinate local method provides periodic refinements to a top-level global method

Specification

Alias: coupled

Argument(s): none

Child Keywords:

	Required/ Optional Required (<i>Choose One</i>)	Description of Group Global Sub-method Selection (Group	Dakota Keyword	Dakota Keyword Description
		1)	global_method_- name	Specify the global method by Dakota name
			global_method_- pointer	Pointer to global method
	Required (<i>Choose One</i>)	Local Sub-method Selection (Group 2)	local_method_- name	Specify the local method by Dakota name
			local_method_- pointer	Pointer to local method
	Optional		local_search_- probability	Probability of executing local searches

	Optional	iterator_servers	Specify the number of iterator servers when Dakota is run in parallel
	Optional	iterator_scheduling	Specify the scheduling of concurrent iterators when Dakota is run in parallel
	Optional	processors_per_iterator	Specify the number of processors per iterator server when Dakota is run in parallel

Description

In the `embedded` approach, a tightly-coupled hybrid is employed in which a subordinate local method provides periodic refinements to a top-level global method.

Global and local method strings supplied with the `global_method_pointer` and `local_method_pointer` specifications identify the two methods to be used. Alternatively, Dakota method names (e.g. `'soga'`) can be supplied using the `global_method_name` and `local_method_name` keywords, which each have optional model pointer specifications. The `local_search_probability` setting is an optional specification for supplying the probability (between 0.0 and 1.0) of employing local search to improve estimates within the global search.

`global_method_name`

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [embedded](#)
- [global_method_name](#)

Specify the global method by Dakota name

Specification

Alias: none

Argument(s): STRING

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
--	-----------------------	-------------------------	----------------	-------------------------------

	Optional	global_model_pointer	Pointer to model used by global method
--	-----------------	--------------------------------------	--

Description

`global_method_name` is used to specify the global method in a `hybrid` embedded optimization by Dakota name (e.g. 'soga'). The name of the method is provided as a string. The method is executed with default options.

global_model_pointer

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [embedded](#)
- [global_method_name](#)
- [global_model_pointer](#)

Pointer to model used by global method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Description

`global_model_pointer` can be used to specify a model for use with the Dakota method named by the `global_method_name` specification. The argument is a string that refers to the [id_model](#) label of the desired model.

global_method_pointer

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [embedded](#)
- [global_method_pointer](#)

Pointer to global method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Description

The `global_method_pointer` identifies the method block to use as the global method in a hybrid embedded optimization using its `id_method` label.

local_method_name

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [embedded](#)
- [local_method_name](#)

Specify the local method by Dakota name

Specification

Alias: none

Argument(s): STRING

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			local_model_ pointer	Pointer to model used by local method

Description

`local_method_name` is used to specify the local method in a hybrid embedded optimization by Dakota name (e.g. `'conmin_mfd'`). The name of the method is provided as a string. The method is executed with default options.

local_model_pointer

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [embedded](#)
- [local_method_name](#)
- [local_model_pointer](#)

Pointer to model used by local method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Description

`local_model_pointer` can be used to specify a model for use with the Dakota method named by the `local_method_name` specification. The argument is a string that refers to the `id_model` label of the desired model.

local_method_pointer

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [embedded](#)
- [local_method_pointer](#)

Pointer to local method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Description

The `local_method_pointer` identifies the method block to use as the local method in a `hybrid` embedded optimization using its `id_method`

`local_search_probability`

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [embedded](#)
- [local_search_probability](#)

Probability of executing local searches

Specification

Alias: none

Argument(s): REAL

Description

The `local_search_probability` setting is an optional specification for supplying the probability (between 0.0 and 1.0) of employing local search to improve estimates within the global search. Its default value is 0.1.

`iterator_servers`

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [embedded](#)
- [iterator_servers](#)

Specify the number of iterator servers when Dakota is run in parallel

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): INTEGER

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional `iterator_servers` specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, `hybrid`, `multi_start`, and `pareto_set` component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [4] for additional information.

iterator_scheduling

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [embedded](#)
- [iterator_scheduling](#)

Specify the scheduling of concurrent iterators when Dakota is run in parallel

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required(<i>Choose One</i>)	Scheduling Mode (Group 1)	master	Specify a dedicated master partition for parallel iterator scheduling
			peer	Specify a peer partition for parallel iterator scheduling

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional `iterator_scheduling` specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, `hybrid`, `multi_start`, and `pareto_set` component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [4] for additional information.

master

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [embedded](#)
- [iterator_scheduling](#)
- [master](#)

Specify a dedicated master partition for parallel iterator scheduling

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): none

Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a dedicated master partition. In a dedicated master partition, one processor (the "master") dynamically schedules work on the iterator servers. This reduces the number of processors available to create servers by 1.

peer

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [embedded](#)
- [iterator_scheduling](#)
- [peer](#)

Specify a peer partition for parallel iterator scheduling

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): none

Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a peer partition. In a peer partition, all processors are available to be assigned to iterator servers. Note that unlike the case of `evaluation--scheduling`, it is not possible to specify `static` or `dynamic`.

processors_per_iterator

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [embedded](#)
- [processors_per_iterator](#)

Specify the number of processors per iterator server when Dakota is run in parallel

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): INTEGER

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional `processors_per_iterator` specification supports user override of the automatic parallel configuration for the number of processors in each iterator server. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired server size at the iterator parallelism level. Currently, `hybrid`, `multi_start`, and `pareto_set` component-based iterators support concurrency in their sub-iterators. Refer to `ParallelLibrary` and the `Parallel Computing` chapter of the `Users Manual`[4] for additional information.

collaborative

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [collaborative](#)

Multiple methods run concurrently and share information

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Sub-method Selection (Group 1)	method_name_list	List of Dakota methods to sequentially or collaboratively run
			method_pointer_list	Pointers to methods to execute sequentially or collaboratively
	Optional		iterator_servers	Specify the number of iterator servers when Dakota is run in parallel
	Optional		iterator_scheduling	Specify the scheduling of concurrent iterators when Dakota is run in parallel
	Optional		processors_per_iterator	Specify the number of processors per iterator server when Dakota is run in parallel

Description

In the collaborative approach, multiple methods work together and share solutions while executing concurrently. A list of method strings specifies the pool of iterators to be used. Any number of iterators may be specified. The method collaboration logic follows that of either the Agent-Based Optimization or HOPSPACK codes and is currently under development and not available at this time.

method_name_list

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [collaborative](#)
- [method_name_list](#)

List of Dakota methods to sequentially or collaboratively run

Specification

Alias: none

Argument(s): STRINGLIST

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		model_pointer_list	Associate models with method names

Description

`method_name_list` specifies a list of Dakota methods (e.g. [soga](#), [conmin.frcg](#)) that will be run by a hybrid sequential or hybrid collaborative method. The methods are executed with default options. The optional `model_pointer_list` may be used to associate a model with each method.

`model_pointer_list`

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [collaborative](#)
- [method_name_list](#)
- [model_pointer_list](#)

Associate models with method names

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Description

Using the optional keyword `model_pointer_list`, models can be assigned to methods specified in the `method_name_list`. Models are referred to by name (i.e. by their `id_model` labels). The length of the `model_pointer_list` must be either 1 or match the length of the `method_name_list`. If the former, the same model will be used for all methods, and if the latter, methods and models will be paired in the order that they appear in the two lists.

method_pointer_list

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [collaborative](#)
- [method_pointer_list](#)

Pointers to methods to execute sequentially or collaboratively

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRINGLIST

Description

`method_pointer_list` specifies by name the methods that are to be executed by a `hybrid sequential` or `hybrid collaborative` method. Its argument is a list of strings that refer to method blocks by name (i.e. to their `id_method` labels).

iterator_servers

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [collaborative](#)
- [iterator_servers](#)

Specify the number of iterator servers when Dakota is run in parallel

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): INTEGER

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional `iterator_servers` specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, `hybrid`, `multi_start`, and `pareto_set` component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [4] for additional information.

iterator_scheduling

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [collaborative](#)
- [iterator_scheduling](#)

Specify the scheduling of concurrent iterators when Dakota is run in parallel

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required(<i>Choose One</i>)	Scheduling Mode (Group 1)	master	Specify a dedicated master partition for parallel iterator scheduling
			peer	Specify a peer partition for parallel iterator scheduling

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional `iterator_scheduling` specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, `hybrid`, `multi_start`, and `pareto_set` component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [4] for additional information.

master

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [collaborative](#)
- [iterator_scheduling](#)
- [master](#)

Specify a dedicated master partition for parallel iterator scheduling

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): none

Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a dedicated master partition. In a dedicated master partition, one processor (the "master") dynamically schedules work on the iterator servers. This reduces the number of processors available to create servers by 1.

peer

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [collaborative](#)
- [iterator_scheduling](#)
- [peer](#)

Specify a peer partition for parallel iterator scheduling

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): none

Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a peer partition. In a peer partition, all processors are available to be assigned to iterator servers. Note that unlike the case of `evaluation_scheduling`, it is not possible to specify `static` or `dynamic`.

processors_per_iterator

- [Keywords Area](#)
- [method](#)
- [hybrid](#)
- [collaborative](#)
- [processors_per_iterator](#)

Specify the number of processors per iterator server when Dakota is run in parallel

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): INTEGER

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional `processors_per_iterator` specification supports user override of the automatic parallel configuration for the number of processors in each iterator server. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired server size at the iterator parallelism level. Currently, `hybrid`, `multi_start`, and `pareto_set` component-based iterators support concurrency in their sub-iterators. Refer to `ParallelLibrary` and the `Parallel Computing` chapter of the `Users Manual`[4] for additional information.

7.2.5 multi_start

- [Keywords Area](#)
- [method](#)
- [multi_start](#)

Multi-Start Optimization Method

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Required(<i>Choose One</i>)	Description of Group Sub-method Selection (Group 1)	Dakota Keyword <i>method_name</i>	Dakota Keyword Description Specify sub-method by name
			<i>method_pointer</i>	Pointer to sub-method to run from each starting point
	Optional		<i>random_starts</i>	Number of random starting points
	Optional		<i>starting_points</i>	List of user-specified starting points
	Optional		<i>iterator_servers</i>	Specify the number of iterator servers when Dakota is run in parallel
	Optional		<i>iterator_scheduling</i>	Specify the scheduling of concurrent iterators when Dakota is run in parallel
	Optional		<i>processors_per_ iterator</i>	Specify the number of processors per iterator server when Dakota is run in parallel

Description

In the multi-start iteration method (*multi_start*), a series of iterator runs are performed for different values of parameters in the model. A common use is for multi-start optimization (i.e., different local optimization runs from different starting points for the design variables), but the concept and the code are more general. Multi-start iteration is implemented within the *MetaIterator* branch of the *Iterator* hierarchy within the *ConcurrentMetaIterator* class. Additional information on the multi-start algorithm is available in the Users Manual[4].

The *multi_start* meta-iterator must specify a sub-iterator using either a *method_pointer* or a *method_name* plus optional *model_pointer*. This iterator is responsible for completing a series of iterative analyses from a set of different starting points. These starting points can be specified as follows: (1) using *random_starts*, for which the specified number of starting points are selected randomly within the variable bounds, (2) using *starting_points*, in which the starting values are provided in a list, or (3) using both *random_starts* and *starting_points*, for which the combined set of points will be used. In aggregate, at least one starting point must be specified. The most common example of a multi-start algorithm is multi-start optimization,

in which a series of optimizations are performed from different starting values for the design variables. This can be an effective approach for problems with multiple minima.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the [hdf5](#) keyword, this method writes the starting points for each sub-iterator it runs, as well as the best parameters and responses returned by each sub-iterator. See the [Multistart and Pareto Set](#) documentation for details.

method_name

- [Keywords Area](#)
- [method](#)
- [multi_start](#)
- [method_name](#)

Specify sub-method by name

Specification

Alias: none

Argument(s): STRING

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		model_pointer	Identifier for model block to be used by a method

Description

The `method_name` keyword is used to specify a sub-method by Dakota method name (e.g. 'npsol_sqp') rather than block pointer. The method will be executed using its default settings. The optional `model_pointer` specification can be used to associate a model block with the method.

model_pointer

- [Keywords Area](#)
- [method](#)
- [multi_start](#)
- [method_name](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which [model](#) block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a [model](#) block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2

variables
  uniform_uncertain = 2
  lower_bounds = 0.  0.
  upper_bounds = 1.  1.
  descriptors = 'x1' 'x2'

interface
  id_interface = 'I1'
  system_async_evaluation_concurrency = 5
  analysis_driver = 'text_book'

responses
  response_functions = 3
  no_gradients
  no_hessians

```

method_pointer

- [Keywords Area](#)
- [method](#)
- [multi_start](#)
- [method_pointer](#)

Pointer to sub-method to run from each starting point

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Description

The `method_pointer` keyword is used to specify a pointer to the sub-method block that will be run from each starting point.

random_starts

- [Keywords Area](#)
- [method](#)
- [multi_start](#)
- [random_starts](#)

Number of random starting points

Specification

Alias: none

Argument(s): INTEGER

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		<code>seed</code>	Seed of the random number generator

Description

The `multi_start` meta-iterator must specify a sub-iterator using either a `method_pointer` or a `method_name` plus optional `model_pointer`. This iterator is responsible for completing a series of iterative analyses from a set of different starting points. These starting points can be specified as follows: (1) using `random_starts`, for which the specified number of starting points are selected randomly within the variable bounds, (2) using `starting_points`, in which the starting values are provided in a list, or (3) using both `random_starts` and `starting_points`, for which the combined set of points will be used.

seed

- [Keywords Area](#)
- [method](#)
- [multi_start](#)
- [random_starts](#)
- [seed](#)

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)

Description

The random `seed` control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

starting_points

- [Keywords Area](#)
- [method](#)
- [multi_start](#)
- [starting_points](#)

List of user-specified starting points

Specification

Alias: none

Argument(s): REALLIST

Description

The `multi_start` meta-iterator must specify a sub-iterator using either a `method_pointer` or a `method_name` plus optional `model_pointer`. This iterator is responsible for completing a series of iterative analyses from a set of different starting points. These starting points can be specified as follows: (1) using `random_starts`, for which the specified number of starting points are selected randomly within the variable bounds, (2) using `starting_points`, in which the starting values are provided in a list, or (3) using both `random_starts` and `starting_points`, for which the combined set of points will be used.

iterator_servers

- [Keywords Area](#)
- [method](#)
- [multi_start](#)
- [iterator_servers](#)

Specify the number of iterator servers when Dakota is run in parallel

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): INTEGER

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional `iterator_servers` specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, `hybrid`, `multi_start`, and `pareto_set` component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [4] for additional information.

iterator_scheduling

- [Keywords Area](#)
- [method](#)
- [multi_start](#)
- [iterator_scheduling](#)

Specify the scheduling of concurrent iterators when Dakota is run in parallel

Topics

This keyword is related to the topics:

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Required (<i>Choose One</i>)	Description of Group Scheduling Mode (Group 1)	Dakota Keyword	Dakota Keyword Description
			master	Specify a dedicated master partition for parallel iterator scheduling
			peer	Specify a peer partition for parallel iterator scheduling

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional `iterator_scheduling` specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, `hybrid`, `multi_start`, and `pareto_set` component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [4] for additional information.

master

- [Keywords Area](#)
- [method](#)
- [multi_start](#)
- [iterator_scheduling](#)
- [master](#)

Specify a dedicated master partition for parallel iterator scheduling

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): none

Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a dedicated master partition. In a dedicated master partition, one processor (the "master") dynamically schedules work on the iterator servers. This reduces the number of processors available to create servers by 1.

peer

- [Keywords Area](#)
- [method](#)
- [multi_start](#)
- [iterator_scheduling](#)
- [peer](#)

Specify a peer partition for parallel iterator scheduling

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): none

Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a peer partition. In a peer partition, all processors are available to be assigned to iterator servers. Note that unlike the case of `evaluation_scheduling`, it is not possible to specify `static` or `dynamic`.

`processors_per_iterator`

- [Keywords Area](#)
- [method](#)
- [multi_start](#)
- [processors_per_iterator](#)

Specify the number of processors per iterator server when Dakota is run in parallel

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): INTEGER

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional `processors_per_iterator` specification supports user override of the automatic parallel configuration for the number of processors in each iterator server. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired server size at the iterator parallelism level. Currently, `hybrid`, `multi_start`, and `pareto_set` component-based iterators support concurrency in their sub-iterators. Refer to `ParallelLibrary` and the `Parallel Computing` chapter of the `Users Manual`[4] for additional information.

7.2.6 `pareto_set`

- [Keywords Area](#)
- [method](#)
- [pareto_set](#)

Pareto set optimization

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Sub-method Selection (Group 1)	method_name	Specify sub-method by name
			method_pointer	Pointer to optimization or least-squares sub-method
	Optional		random_weight_ sets	Number of random weighting sets
	Optional		weight_sets	List of user-specified weighting sets
	Optional		iterator_servers	Specify the number of iterator servers when Dakota is run in parallel
	Optional		iterator_scheduling	Specify the scheduling of concurrent iterators when Dakota is run in parallel
	Optional		processors_per_ iterator	Specify the number of processors per iterator server when Dakota is run in parallel

Description

In the `pareto_set` minimization method (`pareto_set`), a series of optimization or least squares calibration runs are performed for different weightings applied to multiple objective functions. This set of optimal solutions defines a "Pareto set," which is useful for investigating design trade-offs between competing objectives. The code is similar enough to the `multi_start` technique that both algorithms are implemented in the same `Concurrent-MetaIterator` class.

The `pareto_set` specification must identify an optimization or least squares calibration method using either a `method_pointer` or a `method_name` plus optional `model_pointer`. This minimizer is responsible for computing a set of optimal solutions from a set of response weightings (multi-objective weights or least squares term weights). These weightings can be specified as follows: (1) using `random_weight_sets`, in which case weightings are selected randomly within [0,1] bounds, (2) using `weight_sets`, in which the weighting sets are specified in a list, or (3) using both `random_weight_sets` and `weight_sets`, for which the combined set of weights will be used. In aggregate, at least one set of weights must be specified. The set of optimal solutions is called the "pareto set," which can provide valuable design trade-off information when there are competing objectives.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the `hdf5` keyword, this method writes the best parameters and responses returned by each sub-iterator. The weights are provided as metadata. See the [Multistart and Pareto](#)

[Set](#) documentation for details.

method_name

- [Keywords Area](#)
- [method](#)
- [pareto_set](#)
- [method_name](#)

Specify sub-method by name

Specification

Alias: opt_method_name

Argument(s): STRING

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			model_pointer	Identifier for model block to be used by a method

Description

The `method_name` keyword is used to specify a sub-method by Dakota method name (e.g. 'npsol_sqp') rather than block pointer. The method will be executed using its default settings. The optional `model_pointer` specification can be used to associate a model block with the method.

model_pointer

- [Keywords Area](#)
- [method](#)
- [pareto_set](#)
- [method_name](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: `opt_model_pointer`

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                    0.1 0.2 0.6
                    0.1 0.2 0.6

  sample_type lhs
  distribution cumulative

model
  id_model = 'SURR'
  surrogate global,
  dace_method_pointer = 'DACE'
  polynomial quadratic

method
  id_method = 'DACE'
  model_pointer = 'DACE_M'
  sampling sample_type lhs
  samples = 121 seed = 5034 rng rnum2

model
  id_model = 'DACE_M'
  single
  interface_pointer = 'I1'

variables
  uniform_uncertain = 2
  lower_bounds = 0. 0.
  upper_bounds = 1. 1.
  descriptors = 'x1' 'x2'
```

```
interface
  id_interface = 'I1'
  system async evaluation_concurrency = 5
  analysis_driver = 'text_book'

responses
  response_functions = 3
  no_gradients
  no_hessians
```

method_pointer

- [Keywords Area](#)
- [method](#)
- [pareto_set](#)
- [method_pointer](#)

Pointer to optimization or least-squares sub-method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: `opt_method_pointer`

Argument(s): STRING

Description

The `method_pointer` keyword is used to specify a pointer to an optimization or least-squares sub-method that is responsible for computing a set of optimal solutions for a set of response weightings.

random_weight_sets

- [Keywords Area](#)
- [method](#)
- [pareto_set](#)
- [random_weight_sets](#)

Number of random weighting sets

Specification

Alias: none

Argument(s): INTEGER

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		seed	Seed of the random number generator

Description

The `pareto_set` specification must identify an optimization or least squares calibration method using either a `method_pointer` or a `method_name` plus optional `model_pointer`. This minimizer is responsible for computing a set of optimal solutions from a set of response weightings (multi-objective weights or least squares term weights). These weightings can be specified as follows: (1) using `random_weight_sets`, in which case weightings are selected randomly within [0,1] bounds, (2) using `weight_sets`, in which the weighting sets are specified in a list, or (3) using both `random_weight_sets` and `weight_sets`, for which the combined set of weights will be used. In aggregate, at least one set of weights must be specified. The set of optimal solutions is called the "pareto set," which can provide valuable design trade-off information when there are competing objectives.

seed

- [Keywords Area](#)
- [method](#)
- [pareto_set](#)
- [random_weight_sets](#)
- [seed](#)

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)

Description

The random `seed` control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

--	--	--	----------------------	---

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional `iterator_scheduling` specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, `hybrid`, `multi_start`, and `pareto_set` component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [4] for additional information.

master

- [Keywords Area](#)
- [method](#)
- [pareto_set](#)
- [iterator_scheduling](#)
- [master](#)

Specify a dedicated master partition for parallel iterator scheduling

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): none

Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a dedicated master partition. In a dedicated master partition, one processor (the "master") dynamically schedules work on the iterator servers. This reduces the number of processors available to create servers by 1.

peer

- [Keywords Area](#)
- [method](#)
- [pareto_set](#)
- [iterator_scheduling](#)

- [peer](#)

Specify a peer partition for parallel iterator scheduling

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): none

Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a peer partition. In a peer partition, all processors are available to be assigned to iterator servers. Note that unlike the case of `evaluation_scheduling`, it is not possible to specify `static` or `dynamic`.

processors_per_iterator

- [Keywords Area](#)
- [method](#)
- [pareto_set](#)
- [processors_per_iterator](#)

Specify the number of processors per iterator server when Dakota is run in parallel

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): INTEGER

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional `processors_per_iterator` specification supports user override of the automatic parallel configuration for the number of processors in each iterator server. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired server size at the iterator parallelism level. Currently, `hybrid`, `multi_start`, and `pareto_set` component-based iterators support concurrency in their sub-iterators. Refer to `ParallelLibrary` and the `Parallel Computing` chapter of the `Users Manual`[4] for additional information.

7.2.7 branch_and_bound

- [Keywords Area](#)
- [method](#)
- [branch_and_bound](#)

(Experimental Capability) Solves a mixed integer nonlinear optimization problem

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Required(<i>Choose One</i>)	Description of Group Local Optimizer Selection (Group 1)	Dakota Keyword	Dakota Keyword Description
			method_pointer	Pointer to sub-method to apply to a surrogate or branch-and-bound sub-problem
			method_name	Specify sub-method by name
	Optional		scaling	Turn on scaling for variables, responses, and constraints

Description

The branch-and-bound optimization methods solves mixed integer nonlinear optimization problems. It does so by partitioning the parameter space according to some criteria along the integer or discrete variables. It then relaxes (i.e., treats all variables as continuous) the sub-problems created by the partitions and solves each sub-problem with a continuous nonlinear optimization method. Results of the sub-problems are combined in such a way that yields the solution to the original optimization problem.

Default Behavior

Branch-and-bound expects all discrete variables to be relaxable. If your problem has categorical or otherwise non-relaxable discrete variables, then this is not the optimization method you are looking for.

Expected Output

The optimal solution and associated parameters will be printed to the screen output.

Usage Tips

The user must choose a nonlinear optimization method to solve the sub- problems. We recommend choosing a method that would be chosen to solve a continuous problem that has similar form to the mixed integer problem.

Examples

```

environment
  method_pointer = 'BandB'

method
  id_method = 'BandB'
  branch_and_bound
  output verbose
  method_pointer = 'SubNLP'

method
  id_method = 'SubNLP'
  coliny_ea
  seed = 12345
  max_iterations = 100
  max_function_evaluations = 100

variables,
  continuous_design = 3
  initial_point   -1.0   1.5   2.0
  upper_bounds    10.0   10.0  10.0
  lower_bounds   -10.0  -10.0 -10.0
  descriptors      'x1'  'x2'  'x3'
  discrete_design_range = 2
  initial_point    2     2
  lower_bounds     1     1
  upper_bounds     4     9
  descriptors      'y1'  'y2'

interface,
  fork
  analysis_driver = 'text_book'

responses,
  objective_functions = 1
  nonlinear_inequality_constraints = 2
  numerical_gradients
  no_hessians

```

method_pointer

- [Keywords Area](#)
- [method](#)
- [branch_and_bound](#)
- [method_pointer](#)

Pointer to sub-method to apply to a surrogate or branch-and-bound sub-problem

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Description

The `method_pointer` keyword is used to specify a pointer to an optimization or least-squares sub-method to apply in the context of what could be described as hierarchical methods. In surrogate-based methods, the sub-method is applied to the surrogate model. In the branch-and-bound method, the sub-method is applied to the relaxed sub-problems.

Any `model_pointer` identified in the sub-method specification is ignored. Instead, the parent method is responsible for selecting the appropriate model to use as specified by its `model_pointer`. In surrogate-based methods, it is a surrogate model defined using its `model_pointer`. In branch-and-bound methods, it is the relaxed model that is constructed internally from the original model.

method_name

- [Keywords Area](#)
- [method](#)
- [branch_and_bound](#)
- [method_name](#)

Specify sub-method by name

Specification

Alias: none

Argument(s): STRING

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		model_pointer	Identifier for model block to be used by a method

Description

The `method_name` keyword is used to specify a sub-method by Dakota method name (e.g. 'npsol_sqp') rather than block pointer. The method will be executed using its default settings. The optional `model_pointer` specification can be used to associate a model block with the method.

model_pointer

- [Keywords Area](#)
- [method](#)
- [branch_and_bound](#)

- [method_name](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which [model](#) block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a [model](#) block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                    0.1 0.2 0.6
                    0.1 0.2 0.6

  sample_type lhs
  distribution cumulative

model
  id_model = 'SURR'
  surrogate global,
  dace_method_pointer = 'DACE'
  polynomial quadratic

method
  id_method = 'DACE'
```

```

model_pointer = 'DACE_M'
sampling sample_type lhs
samples = 121 seed = 5034 rng rnum2

model
  id_model = 'DACE_M'
  single
  interface_pointer = 'I1'

variables
  uniform_uncertain = 2
  lower_bounds = 0. 0.
  upper_bounds = 1. 1.
  descriptors = 'x1' 'x2'

interface
  id_interface = 'I1'
  system async evaluation_concurrency = 5
  analysis_driver = 'text_book'

responses
  response_functions = 3
  no_gradients
  no_hessians

```

scaling

- [Keywords Area](#)
- [method](#)
- [branch_and_bound](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are

performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*_scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling
3. `auto` - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. `log` - logarithmic scaling

First, any characteristic values from the optional `*_scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*_scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- `none`, `auto`, `log` - optional
- `value` - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100

responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

7.2.8 surrogate_based_local

- [Keywords Area](#)
- [method](#)
- [surrogate_based_local](#)

Local Surrogate Based Optimization

Topics

This keyword is related to the topics:

	Optional	convergence_tolerance	Stopping criterion based on objective function or statistics convergence

	Optional	constraint_tolerance	Maximum allowable constraint violation still considered feasible
--	-----------------	--------------------------------------	--

Description

In surrogate-based optimization (SBO) and surrogate-based nonlinear least squares (SBNLS), minimization occurs using a set of one or more approximations, defined from a surrogate model, that are built and periodically updated using data from a "truth" model. The surrogate model can be a global data fit (e.g., regression or interpolation of data generated from a design of computer experiments), a multipoint approximation, a local Taylor Series expansion, or a model hierarchy approximation (e.g., a low-fidelity simulation model), whereas the truth model involves a high-fidelity simulation model. The goals of surrogate-based methods are to reduce the total number of truth model simulations and, in the case of global data fit surrogates, to smooth noisy data with an easily navigated analytic function.

In the surrogate-based local method, a trust region approach is used to manage the minimization process to maintain acceptable accuracy between the surrogate model and the truth model (by limiting the range over which the surrogate model is trusted). The process involves a sequence of minimizations performed on the surrogate model and bounded by the trust region. At the end of each approximate minimization, the candidate optimum point is validated using the truth model. If sufficient decrease has been obtained in the truth model, the trust region is re-centered around the candidate optimum point and the trust region will either shrink, expand, or remain the same size depending on the accuracy with which the surrogate model predicted the truth model decrease. If sufficient decrease has not been attained, the trust region center is not updated and the entire trust region shrinks by a user-specified factor. The cycle then repeats with the construction of a new surrogate model, a minimization, and another test for sufficient decrease in the truth model. This cycle continues until convergence is attained.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the [hdf5](#) keyword, this method writes the following results to HDF5:

- [Best Parameters](#)
- [Best Objective Functions](#) (when [objective_functions](#) are specified)
- [Best Nonlinear Constraints](#)
- [Calibration](#) (when [calibration_terms](#) are specified)

Theory

For [surrogate_based_local](#) problems with nonlinear constraints, a number of algorithm formulations exist as described in[23] and as summarized in the Advanced Examples section of the Models chapter of the Users Manual[4].

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required(<i>Choose One</i>)	Merit Function (Group 1)	penalty_merit	Use penalty merit function
			adaptive_penalty_ merit	Use adaptive penalty merit function
			lagrangian_merit	Use first-order Lagrangian merit function
			augmented_ lagrangian_merit	Use combined penalty and zeroth-order Lagrangian merit function

Description

Following optimization of the approximate subproblem, the candidate iterate is evaluated using a merit function, which can be selected to be a simple penalty function with penalty ramped by `surrogate_based_local` iteration number (`penalty_merit`), an adaptive penalty function where the penalty ramping may be accelerated in order to avoid rejecting good iterates which decrease the constraint violation (`adaptive_penalty_merit`), a Lagrangian merit function which employs first-order Lagrange multiplier updates (`lagrangian_merit`), or an augmented Lagrangian merit function which employs both a penalty parameter and zeroth-order Lagrange multiplier updates (`augmented_lagrangian_merit`). When an augmented Lagrangian is selected for either the subproblem objective or the merit function (or both), updating of penalties and multipliers follows the approach described in[16].

penalty_merit

- [merit_function](#)
- [penalty_merit](#)

Use penalty merit function

Specification

Alias: none

Argument(s): none

Description

Second, the surrogate constraints in the approximate subproblem can be selected to be surrogates of the original constraints (`original_constraints`) or linearized approximations to the surrogate constraints (`linearized_constraints`), or constraints can be omitted from the subproblem (`no_constraints`). Following optimization of the approximate subproblem, the candidate iterate is evaluated using a merit function, which can be

selected to be a simple penalty function with penalty ramped by SBL iteration number (`penalty_merit`), an adaptive penalty function where the penalty ramping may be accelerated in order to avoid rejecting good iterates which decrease the constraint violation (`adaptive_penalty_merit`), a Lagrangian merit function which employs first-order Lagrange multiplier updates (`lagrangian_merit`), or an augmented Lagrangian merit function which employs both a penalty parameter and zeroth-order Lagrange multiplier updates (`augmented_lagrangian_merit`). When an augmented Lagrangian is selected for either the subproblem objective or the merit function (or both), updating of penalties and multipliers follows the approach described in[16].

Set criteria for trusted surrogate

Specification

Alias: none

Argument(s): none

Default: filter

Child Keywords:

	Required/- Optional Required (<i>Choose One</i>)	Description of Group Acceptance Logic (Group 1)	Dakota Keyword	Dakota Keyword Description
			tr_ratio	Surrogate-Based Local iterate acceptance logic
			filter	Surrogate-Based Local iterate acceptance logic

Description

Following calculation of the merit function for the new iterate, the iterate is accepted or rejected and the trust region size is adjusted for the next `surrogate_based_local` iteration. Iterate acceptance is governed either by a trust region ratio (`tr_ratio`) formed from the merit function values or by a filter method (`filter`); however, trust region resizing logic is currently based only on the trust region ratio. For infeasible iterates, constraint relaxation can be used for balancing constraint satisfaction and progress made toward an optimum.

trust_region

- [Keywords Area](#)
- [method](#)
- [surrogate_based_local](#)
- [trust_region](#)

Specification group for trust region model management

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		initial_size	Trust region initial size (relative to bounds)
	Optional		minimum_size	Trust region minimum size
	Optional		contract_threshold	Shrink trust region if trust region ratio is below this value
	Optional		expand_threshold	Expand trust region if trust region ratio is above this value
	Optional		contraction_factor	Amount by which step length is rescaled
	Optional		expansion_factor	Trust region expansion factor

Description

The `trust_region` optional group specification can be used to specify the initial size of the trust region (using `initial_size`) relative to the total variable bounds, the minimum size of the trust region (using `minimum_size`), the contraction factor for the trust region size (using `contraction_factor`) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using `expansion_factor`) used when the the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using `contract_threshold`) and the trust region size expansion threshold (using `expand_threshold`). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command `contract_threshold` sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next `surrogate_based_local` iteration. The command `expand_threshold` determines the trust region value above which the trust region will expand for the next `surrogate_based_local` iteration.

Each of these specifications are REAL scalars, with the exception of `initial_size`, which is a REALLIST.

`initial_size`

- [Keywords Area](#)
- [method](#)
- [surrogate_based_local](#)
- [trust_region](#)
- [initial_size](#)

Trust region initial size (relative to bounds)

Specification

Alias: none

Argument(s): REALLIST

Description

The `trust_region` optional group specification can be used to specify the initial size of the trust region (using `initial_size`) relative to the total variable bounds, the minimum size of the trust region (using `minimum_size`), the contraction factor for the trust region size (using `contraction_factor`) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using `expansion_factor`) used when the the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using `contract_threshold`) and the trust region size expansion threshold (using `expand_threshold`). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command `contract_threshold` sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command `expand_threshold` determines the trust region value above which the trust region will expand for the next SBL iteration.

All of these specifications are REAL scalars, with the exception of the specification of `initial_size`, which is a REALLIST. This array corresponds to the case when there are more than 2 model forms or discretizations within a model hierarchy. The default `initial_size` involves a recursive halving of the global bounds for each trust region in the hierarchy: e.g., a scalar value of .5 for a single trust region managing two model forms/discretizations, or an array of (.125, .25, .5) for four model forms/discretizations (three trust regions ordered from the lowest to highest fidelity surrogate, with model four as truth).

minimum_size

- [Keywords Area](#)
- [method](#)

- [expand_threshold](#)

Expand trust region if trust region ratio is above this value

Specification

Alias: none

Argument(s): REAL

Default: 0.75

Description

The `trust_region` optional group specification can be used to specify the initial size of the trust region (using `initial_size`) relative to the total variable bounds, the minimum size of the trust region (using `minimum_size`), the contraction factor for the trust region size (using `contraction_factor`) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using `expansion_factor`) used when the the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using `contract_threshold`) and the trust region size expansion threshold (using `expand_threshold`). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command `contract_threshold` sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command `expand_threshold` determines the trust region value above which the trust region will expand for the next SBL iteration.

contraction_factor

- [Keywords Area](#)
- [method](#)
- [surrogate_based_local](#)
- [trust_region](#)
- [contraction_factor](#)

Amount by which step length is rescaled

Specification

Alias: none

Argument(s): REAL

Default: 0.25

Description

For pattern search methods, `contraction_factor` specifies the amount by which step length is rescaled after unsuccessful iterates, must be strictly between 0 and 1.

For methods that can expand the step length, the expansion is $1/\text{contraction_factor}$

expansion_factor

- [Keywords Area](#)
- [method](#)
- [surrogate_based_local](#)
- [trust_region](#)
- [expansion_factor](#)

Trust region expansion factor

Specification

Alias: none

Argument(s): REAL

Default: 2.0

Description

The `trust_region` optional group specification can be used to specify the initial size of the trust region (using `initial_size`) relative to the total variable bounds, the minimum size of the trust region (using `minimum_size`), the contraction factor for the trust region size (using `contraction_factor`) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using `expansion_factor`) used when the the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using `contract_threshold`) and the trust region size expansion threshold (using `expand_threshold`). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command `contract_threshold` sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command `expand_threshold` determines the trust region value above which the trust region will expand for the next SBL iteration.

max_iterations

- [Keywords Area](#)
- [method](#)
- [surrogate_based_local](#)
- [max_iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: fsu_cvt , local_reliability: 25; global_{reliability , interval_est , evidence} / efficient-global: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

convergence_tolerance

- [Keywords Area](#)
- [method](#)
- [surrogate_based_local](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

constraint_tolerance

- [Keywords Area](#)
- [method](#)
- [surrogate_based_local](#)
- [constraint_tolerance](#)

Maximum allowable constraint violation still considered feasible

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: Library default

Description

Sets the maximum allowable value of infeasibility that any constraint in an optimization problem may possess and still be considered to be satisfied.

If a constraint's violation is greater than this value then it is considered to be violated by the optimization algorithm. This specification gives some control over how tightly the constraints will be satisfied at convergence of the algorithm. However, if the value is set too small the algorithm may terminate with one or more constraints being violated.

Defaults

Defaults vary depending on the method.

- CONMIN optimizers: 1.0e-3

- DOT constrained optimizers: 3.0e-3
- [surrogate_based_local](#) : 1.0e-4

7.2.9 surrogate_based_global

- [Keywords Area](#)
- [method](#)
- [surrogate_based_global](#)

Global Surrogate Based Optimization

Topics

This keyword is related to the topics:

- [surrogate_based_optimization_methods](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Required(<i>Choose One</i>)	Description of Group Sub-method Selection (Group 1)	Dakota Keyword	Dakota Keyword Description
			method_pointer	Pointer to sub-method to apply to a surrogate or branch-and-bound sub-problem
			method_name	Specify sub-method by name
	Required		model_pointer	Identifier for model block to be used by a method
	Optional		replace_points	(Recommended) Replace points in the surrogate training set, instead of appending

	Optional	<code>max_iterations</code>	Number of iterations allowed for optimizers and adaptive UQ methods
--	-----------------	-----------------------------	---

Description

The `surrogate_based_global` specification must identify:

- a sub-method, using either `method_pointer` or `method_name`
- `model_pointer` must be used to identify a surrogate model

`surrogate_based_global` works in an iterative scheme where optimization is performed on a global surrogate using the same bounds during each iteration.

- In one iteration, the optimal solutions of the surrogate model are found, and then a selected set of these optimal surrogate solutions are passed to the next iteration.
- At the next iteration, these surrogate points are evaluated with the "truth" model, and then these points are added back to the set of points upon which the next surrogate is constructed.

In this way, the optimization acts on a more accurate surrogate during each iteration, presumably driving to optimality quickly.

Known Issue: When using discrete variables, there have been sometimes significant differences in surrogate behavior observed across computing platforms in some cases. The cause has not yet been fully diagnosed and is currently under investigation. In addition, guidance on appropriate construction and use of surrogates with discrete variables is under development. In the meantime, users should therefore be aware that there is a risk of inaccurate results when using surrogates with discrete variables.

Method Independent Controls

- `max_iterations` is used as a stopping criterion (see note below)

Notes

We have some cautionary notes before using the surrogate-based global method:

- **This approach has no guarantee of convergence.**
- One might first try a single minimization method coupled with a surrogate model prior to using the surrogate-based global method. This is essentially equivalent to setting `max_iterations` to 1 and will allow one to get a sense of what surrogate types are the most accurate to use for the problem.
- Also note that one can specify that surrogates be built for all primary functions and constraints or for only a subset of these functions and constraints. This allows one to use a "truth" model directly for some of the response functions, perhaps due to them being much less expensive than other functions.
- We initially recommend a small number of maximum iterations, such as 3-5, to get a sense of how the optimization is evolving as the surrogate gets updated. If it appears to be changing significantly, then a larger number (used in combination with restart) may be needed.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the `hdf5` keyword, this method writes the following results to HDF5:

- [Best Parameters](#)
- [Best Objective Functions](#) (when `objective_functions` are specified)
- [Best Nonlinear Constraints](#)
- [Calibration](#) (when `calibration_terms` are specified)

Theory

In surrogate-based optimization (SBO) and surrogate-based nonlinear least squares (SBNLS), minimization occurs using a set of one or more approximations, defined from a surrogate model, that are built and periodically updated using data from a "truth" model. The surrogate model can be a global data fit (e.g., regression or interpolation of data generated from a design of computer experiments), a multipoint approximation, a local Taylor Series expansion, or a model hierarchy approximation (e.g., a low-fidelity simulation model), whereas the truth model involves a high-fidelity simulation model. The goals of surrogate-based methods are to reduce the total number of truth model simulations and, in the case of global data fit surrogates, to smooth noisy data with an easily navigated analytic function.

It was originally designed for MOGA (a multi-objective genetic algorithm). Since genetic algorithms often need thousands or tens of thousands of points to produce optimal or near-optimal solutions, the use of surrogates can be helpful for reducing the truth model evaluations. Instead of creating one set of surrogates for the individual objectives and running the optimization algorithm on the surrogate once, the idea is to select points along the (surrogate) Pareto frontier, which can be used to supplement the existing points.

In this way, one does not need to use many points initially to get a very accurate surrogate. The surrogate becomes more accurate as the iterations progress.

See Also

These keywords may also be of interest:

- [efficient_global](#)
- [surrogate_based_local](#)

method_pointer

- [Keywords Area](#)
- [method](#)
- [surrogate_based_global](#)
- [method_pointer](#)

Pointer to sub-method to apply to a surrogate or branch-and-bound sub-problem

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: `approx_method_pointer`
Argument(s): STRING

Description

The `method_pointer` keyword is used to specify a pointer to an optimization or least-squares sub-method to apply in the context of what could be described as hierarchical methods. In surrogate-based methods, the sub-method is applied to the surrogate model. In the branch-and-bound method, the sub-method is applied to the relaxed sub-problems.

Any `model_pointer` identified in the sub-method specification is ignored. Instead, the parent method is responsible for selecting the appropriate model to use as specified by its `model_pointer`. In surrogate-based methods, it is a surrogate model defined using its `model_pointer`. In branch-and-bound methods, it is the relaxed model that is constructed internally from the original model.

method_name

- [Keywords Area](#)
- [method](#)
- [surrogate_based_global](#)
- [method_name](#)

Specify sub-method by name

Specification

Alias: `approx_method_name`
Argument(s): STRING

Description

The `method_name` keyword is used to specify a sub-method by Dakota method name (e.g. 'npsol_sqp') rather than block pointer. The method will be executed using its default settings. The optional `model_pointer` specification can be used to associate a model block with the method.

model_pointer

- [Keywords Area](#)
- [method](#)
- [surrogate_based_global](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: `approx_model_pointer`

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which [model](#) block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a [model](#) block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                    0.1 0.2 0.6

  id_interface = 'I1'
  system async evaluation_concurrency = 5
  analysis_driver = 'text_book'

responses
  response_functions = 3
  no_gradients
  no_hessians
```

replace_points

- [Keywords Area](#)
- [method](#)
- [surrogate_based_global](#)
- [replace_points](#)

(Recommended) Replace points in the surrogate training set, instead of appending

Specification

Alias: none

Argument(s): none

Default: Points appended, not replaced

Description

The user has the option of appending the optimal points from the surrogate model to the current set of truth points or using the optimal points from the surrogate model to replace the optimal set of points from the previous iteration. Although appending to the set is the default behavior, at this time we strongly recommend using the option `replace_points` because it appears to be more accurate and robust.

max.iterations

- [Keywords Area](#)
- [method](#)
- [surrogate_based_global](#)
- [max.iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: fsu_cvt, local_reliability: 25; global_{reliability, interval_est, evidence} / efficient-global: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

7.2.10 dot_frcg

- [Keywords Area](#)
- [method](#)
- [dot_frcg](#)

DOT conjugate gradient optimization method

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			max_iterations	Number of iterations allowed for optimizers and adaptive UQ methods

	Optional	convergence_-tolerance	Stopping criterion based on objective function or statistics convergence
	Optional	constraint_-tolerance	Maximum allowable constraint violation still considered feasible
	Optional	speculative	Compute speculative gradients
	Optional	max_function_-evaluations	Number of function evaluations allowed for optimizers
	Optional	scaling	Turn on scaling for variables, responses, and constraints
	Optional	model_pointer	Identifier for model block to be used by a method

Description

DOT library[87] implementation of Fletcher-Reeves conjugate gradient method for unconstrained optimization.

See [package.dot](#) for information common to all DOT methods.

DOT requires a separate software license and therefore may not be available in all versions of Dakota. COMIN or OPT++ methods may be suitable alternatives.

Caution regarding dot_frcg. In DOT Version 4.20, we have noticed inconsistent behavior of this algorithm across different versions of Linux. Our best assessment is that it is due to different treatments of uninitialized variables. As we do not know the intention of the code authors and maintaining DOT source code is outside of the Dakota project scope, we have not made nor are we recommending any code changes to address this. However, all users who use `dot_frcg` in DOT Version 4.20 should be aware that results may not be reliable.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the [hdf5](#) keyword, this method writes the following results to HDF5:

- [Best Parameters](#)
- [Best Objective Functions](#) (when [objective_functions](#) are specified)
- [Calibration](#) (when [calibration_terms](#) are specified)

max_iterations

- [Keywords Area](#)
- [method](#)
- [dot_frcg](#)
- [max_iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: fsu_cvt, local_reliability: 25; global_{reliability, interval_est, evidence} / efficient-global: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

convergence_tolerance

- [Keywords Area](#)
- [method](#)
- [dot_frcg](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

`constraint_tolerance`

- [Keywords Area](#)
- [method](#)
- [dot_frcg](#)
- [constraint_tolerance](#)

Maximum allowable constraint violation still considered feasible

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: Library default

Description

Sets the maximum allowable value of infeasibility that any constraint in an optimization problem may possess and still be considered to be satisfied.

If a constraint's violation is greater than this value then it is considered to be violated by the optimization algorithm. This specification gives some control over how tightly the constraints will be satisfied at convergence of the algorithm. However, if the value is set too small the algorithm may terminate with one or more constraints being violated.

Defaults

Defaults vary depending on the method.

- CONMIN optimizers: 1.0e-3
- DOT constrained optimizers: 3.0e-3
- [surrogate_based_local](#) : 1.0e-4

speculative

- [Keywords Area](#)
- [method](#)
- [dot_frcg](#)
- [speculative](#)

Compute speculative gradients

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no speculation

Description

When performing gradient-based optimization in parallel, `speculative` gradients can be selected to address the load imbalance that can occur between gradient evaluation and line search phases. In a typical gradient-based optimization, the line search phase consists primarily of evaluating the objective function and any constraints at a trial point, and then testing the trial point for a sufficient decrease in the objective function value and/or constraint violation. If a sufficient decrease is not observed, then one or more additional trial points may be attempted sequentially. However, if the trial point is accepted then the line search phase is complete and the gradient evaluation phase begins. By speculating that the gradient information associated with a given line search trial point will be used later, additional coarse grained parallelism can be introduced by computing the gradient information (either by finite difference or analytically) in parallel, at the same time as the line search phase trial-point function values. This balances the total amount of computation to be performed at each design point and allows for

efficient utilization of multiple processors. While the total amount of work performed will generally increase (since some speculative gradients will not be used when a trial point is rejected in the line search phase), the run time will usually decrease (since gradient evaluations needed at the start of each new optimization cycle were already performed in parallel during the line search phase). Refer to [14] for additional details. The speculative specification is implemented for the gradient-based optimizers in the DOT, CONMIN, and OPT++ libraries, and it can be used with dakota numerical or analytic gradient selections in the responses specification (refer to [responses](#) gradient section for information on these specifications). It should not be selected with vendor numerical gradients since vendor internal finite difference algorithms have not been modified for this purpose. In full-Newton approaches, the Hessian is also computed speculatively. NPSOL and NLSSOL do not support speculative gradients, as their gradient-based line search in user-supplied gradient mode (dakota numerical or analytic gradients) is a superior approach for load-balanced parallel execution.

The `speculative` specification enables speculative computation of gradient and/or Hessian information, where applicable, for parallel optimization studies. By speculating that the derivative information at the current point will be used later, the complete data set (all available gradient/Hessian information) can be computed on every function evaluation. While some of these computations will be wasted, the positive effects are a consistent parallel load balance and usually shorter wall clock time. The `speculative` specification is applicable only when parallelism in the gradient calculations can be exploited by Dakota (it will be ignored for vendor numerical gradients).

max_function_evaluations

- [Keywords Area](#)
- [method](#)
- [dot_frcg](#)
- [max_function_evaluations](#)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

Default Behavior

Default value is 1000.

scaling

- [Keywords Area](#)
- [method](#)
- [dot_frcg](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*_scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling

3. `auto` - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. `log` - logarithmic scaling

First, any characteristic values from the optional `*scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- `none`, `auto`, `log` - optional
- `value` - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100
```

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value" "value" "value"
primary_scales = 1 1 100
```

model_pointer

- [Keywords Area](#)
- [method](#)
- [dot_frcg](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                      0.1 0.2 0.6
                      0.1 0.2 0.6

  sample_type lhs
  distribution cumulative

model
  id_model = 'SURR'
```

- [method](#)
- [dot_mmf](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling

3. auto - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. log - logarithmic scaling

First, any characteristic values from the optional `*scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- none, auto, log - optional
- value - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

`constraint_tolerance`

- [Keywords Area](#)
- [method](#)
- [dot_bfgs](#)
- [constraint_tolerance](#)

Maximum allowable constraint violation still considered feasible

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: Library default

Description

Sets the maximum allowable value of infeasibility that any constraint in an optimization problem may possess and still be considered to be satisfied.

If a constraint's violation is greater than this value then it is considered to be violated by the optimization algorithm. This specification gives some control over how tightly the constraints will be satisfied at convergence of the algorithm. However, if the value is set too small the algorithm may terminate with one or more constraints being violated.

Defaults

Defaults vary depending on the method.

- [speculative](#)

Compute speculative gradients

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no speculation

Description

When performing gradient-based optimization in parallel, `speculative` gradients can be selected to address the load imbalance that can occur between gradient evaluation and line search phases. In a typical gradient-based optimization, the line search phase consists primarily of evaluating the objective function and any constraints at a trial point, and then testing the trial point for a sufficient decrease in the objective function value and/or constraint violation. If a sufficient decrease is not observed, then one or more additional trial points may be attempted sequentially. However, if the trial point is accepted then the line search phase is complete and the gradient evaluation phase begins. By speculating that the gradient information associated with a given line search trial point will be used later, additional coarse grained parallelism can be introduced by computing the gradient information (either by finite difference or analytically) in parallel, at the same time as the line search phase trial-point function values. This balances the total amount of computation to be performed at each design point and allows for

efficient utilization of multiple processors. While the total amount of work performed will generally increase (since some speculative gradients will not be used when a trial point is rejected in the line search phase), the run time will usually decrease (since gradient evaluations needed at the start of each new optimization cycle were already performed in parallel during the line search phase). Refer to [14] for additional details. The speculative specification is implemented for the gradient-based optimizers in the DOT, CONMIN, and OPT++ libraries, and it can be used with dakota numerical or analytic gradient selections in the responses specification (refer to [responses](#) gradient section for information on these specifications). It should not be selected with vendor numerical gradients since vendor internal finite difference algorithms have not been modified for this purpose. In full-Newton approaches, the Hessian is also computed speculatively. NPSOL and NLSSOL do not support speculative gradients, as their gradient-based line search in user-supplied gradient mode (dakota numerical or analytic gradients) is a superior approach for load-balanced parallel execution.

The `speculative` specification enables speculative computation of gradient and/or Hessian information, where applicable, for parallel optimization studies. By speculating that the derivative information at the current point will be used later, the complete data set (all available gradient/Hessian information) can be computed on every function evaluation. While some of these computations will be wasted, the positive effects are a consistent parallel load balance and usually shorter wall clock time. The `speculative` specification is applicable only when parallelism in the gradient calculations can be exploited by Dakota (it will be ignored for vendor numerical gradients).

max_function_evaluations

- [Keywords Area](#)
- [method](#)
- [dot_bfgs](#)
- [max_function_evaluations](#)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

Default Behavior

Default value is 1000.

scaling

- [Keywords Area](#)
- [method](#)
- [dot_bfgs](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling

3. `auto` - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. `log` - logarithmic scaling

First, any characteristic values from the optional `*scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- `none`, `auto`, `log` - optional
- `value` - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100
```

```
responses

```

model_pointer

- [Keywords Area](#)
- [method](#)
- [dot_bfgs](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```

When performing gradient-based optimization in parallel, `speculative` gradients can be selected to address the load imbalance that can occur between gradient evaluation and line search phases. In a typical gradient-based optimization, the line search phase consists primarily of evaluating the objective function and any constraints at a trial point, and then testing the trial point for a sufficient decrease in the objective function value and/or constraint violation. If a sufficient decrease is not observed, then one or more additional trial points may be attempted sequentially. However, if the trial point is accepted then the line search phase is complete and the gradient evaluation phase begins. By speculating that the gradient information associated with a given line search trial point will be used later, additional coarse grained parallelism can be introduced by computing the gradient information (either by finite difference or analytically) in parallel, at the same time as the line search phase trial-point function values. This balances the total amount of computation to be performed at each design point and allows for

efficient utilization of multiple processors. While the total amount of work performed will generally increase (since some speculative gradients will not be used when a trial point is rejected in the line search phase), the run time will usually decrease (since gradient evaluations needed at the start of each new optimization cycle were already performed in parallel during the line search phase). Refer to [14] for additional details. The speculative specification is implemented for the gradient-based optimizers in the DOT, CONMIN, and OPT++ libraries, and it can be used with dakota numerical or analytic gradient selections in the responses specification (refer to [responses](#) gradient section for information on these specifications). It should not be selected with vendor numerical gradients since vendor internal finite difference algorithms have not been modified for this purpose. In full-Newton approaches, the Hessian is also computed speculatively. NPSOL and NLSSOL do not support speculative gradients, as their gradient-based line search in user-supplied gradient mode (dakota numerical or analytic gradients) is a superior approach for load-balanced parallel execution.

The `speculative` specification enables speculative computation of gradient and/or Hessian information, where applicable, for parallel optimization studies. By speculating that the derivative information at the current point will be used later, the complete data set (all available gradient/Hessian information) can be computed on every function evaluation. While some of these computations will be wasted, the positive effects are a consistent parallel load balance and usually shorter wall clock time. The `speculative` specification is applicable only when parallelism in the gradient calculations can be exploited by Dakota (it will be ignored for vendor numerical gradients).

max_function_evaluations

- [Keywords Area](#)
- [method](#)
- [dot_sqp](#)
- [max_function_evaluations](#)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

Default Behavior

Default value is 1000.

scaling

- [Keywords Area](#)
- [method](#)
- [dot_sqp](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling

3. `auto` - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. `log` - logarithmic scaling

First, any characteristic values from the optional `*scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- `none`, `auto`, `log` - optional
- `value` - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100
```

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value" "value" "value"
primary_scales = 1 1 100
```

model_pointer

- [Keywords Area](#)
- [method](#)
- [dot_sqp](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                    0.1 0.2 0.6
                    0.1 0.2 0.6

  sample_type lhs
  distribution cumulative

model
  id_model = 'SURR'
```

```

surrogate global,

7.2.15 conmin_frcg

- [Keywords Area](#)
- [method](#)
- [conmin_frcg](#)

CONMIN conjugate gradient optimization method

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			max_iterations	Number of iterations allowed for optimizers and adaptive UQ methods

	Optional	convergence_-tolerance	Stopping criterion based on objective function or statistics convergence
	Optional	constraint_-tolerance	Maximum allowable constraint violation still considered feasible
	Optional	speculative	Compute speculative gradients
	Optional	max_function_-evaluations	Number of function evaluations allowed for optimizers
	Optional	scaling	Turn on scaling for variables, responses, and constraints
	Optional	model_pointer	Identifier for model block to be used by a method

Description

The interpretations of the method independent controls for CONMIN are essentially identical to those for DOT.

See [package.dot](#) for information related to CONMIN methods, specifically [dot.frcg](#).

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the [hdf5](#) keyword, this method writes the following results to HDF5:

- [Best Parameters](#)
- [Best Objective Functions](#) (when [objective_functions](#) are specified)
- [Calibration](#) (when [calibration_terms](#) are specified)

See Also

These keywords may also be of interest:

- [dot.frcg](#)

max_iterations

- [Keywords Area](#)
- [method](#)
- [conmin_frcg](#)
- [max_iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: fsu_cvt, local_reliability: 25; global_{reliability, interval_est, evidence} / efficient_global: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

convergence_tolerance

- [Keywords Area](#)
- [method](#)
- [conmin_frcg](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

`constraint_tolerance`

- [Keywords Area](#)
- [method](#)
- [conmin_frcg](#)
- [constraint_tolerance](#)

Maximum allowable constraint violation still considered feasible

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: Library default

Description

Sets the maximum allowable value of infeasibility that any constraint in an optimization problem may possess and still be considered to be satisfied.

If a constraint's violation is greater than this value then it is considered to be violated by the optimization algorithm. This specification gives some control over how tightly the constraints will be satisfied at convergence of the algorithm. However, if the value is set too small the algorithm may terminate with one or more constraints being violated.

Defaults

Defaults vary depending on the method.

- CONMIN optimizers: 1.0e-3

speculative

- [Keywords Area](#)
- [method](#)
- [conmin_frcg](#)
- [speculative](#)

Compute speculative gradients

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no speculation

Description

When performing gradient-based optimization in parallel, `speculative` gradients can be selected to address the load imbalance that can occur between gradient evaluation and line search phases. In a typical gradient-based optimization, the line search phase consists primarily of evaluating the objective function and any constraints at a trial point, and then testing the trial point for a sufficient decrease in the objective function value and/or constraint violation. If a sufficient decrease is not observed, then one or more additional trial points may be attempted sequentially. However, if the trial point is accepted then the line search phase is complete and the gradient evaluation phase begins. By speculating that the gradient information associated with a given line search trial point will be used later, additional coarse grained parallelism can be introduced by computing the gradient information (either by finite difference or analytically) in parallel, at the same time as the line search phase trial-point function values. This balances the total amount of computation to be performed at each design point and allows for

efficient utilization of multiple processors. While the total amount of work performed will generally increase (since some speculative gradients will not be used when a trial point is rejected in the line search phase), the run time will usually decrease (since gradient evaluations needed at the start of each new optimization cycle were already performed in parallel during the line search phase). Refer to [14] for additional details. The speculative specification is implemented for the gradient-based optimizers in the DOT, CONMIN, and OPT++ libraries, and it can be used with dakota numerical or analytic gradient selections in the responses specification (refer to [responses](#) gradient section for information on these specifications). It should not be selected with vendor numerical gradients since vendor internal finite difference algorithms have not been modified for this purpose. In full-Newton approaches, the Hessian is also computed speculatively. NPSOL and NLSSOL do not support speculative gradients, as their gradient-based line search in user-supplied gradient mode (dakota numerical or analytic gradients) is a superior approach for load-balanced parallel execution.

The `speculative` specification enables speculative computation of gradient and/or Hessian information, where applicable, for parallel optimization studies. By speculating that the derivative information at the current point will be used later, the complete data set (all available gradient/Hessian information) can be computed on every function evaluation. While some of these computations will be wasted, the positive effects are a consistent parallel load balance and usually shorter wall clock time. The `speculative` specification is applicable only when parallelism in the gradient calculations can be exploited by Dakota (it will be ignored for vendor numerical gradients).

- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling

3. auto - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. log - logarithmic scaling

First, any characteristic values from the optional `*scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- none, auto, log - optional
- value - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling

3. `auto` - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. `log` - logarithmic scaling

First, any characteristic values from the optional `*scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- `none`, `auto`, `log` - optional
- `value` - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100
```

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value" "value" "value"
primary_scales = 1 1 100
```

model_pointer

- [Keywords Area](#)
- [method](#)
- [conmin_mfd](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'

Specification

Alias: none

Argument(s): STRING

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description

	Optional	max_function_- evaluations	Number of function evaluations allowed for optimizers
	Optional	scaling	Turn on scaling for variables, responses, and constraints
	Optional	model_pointer	Identifier for model block to be used by a method

Description

This keyword specifies a dynamically-loaded optimization solver library, an experimental Dakota feature that is not enabled by default.

max_function_evaluations

- [Keywords Area](#)
- [method](#)
- [dl_solver](#)
- [max_function_evaluations](#)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

Default Behavior

Default value is 1000.

scaling

- [Keywords Area](#)

NPSOL Sequential Quadratic Program

Topics

This keyword is related to the topics:

- [package_npsol](#)
- [sequential_quadratic_programming](#)
- [local_optimization_methods](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			verify_level	Verify the quality of analytic gradients
	Optional		function_precision	Specify the maximum precision of the analysis code responses
	Optional		linesearch_tolerance	Choose how accurately the algorithm will compute the minimum in a line search
	Optional		convergence_tolerance	Stopping criterion based on objective function convergence
	Optional		max_iterations	Number of iterations allowed for optimizers and adaptive UQ methods
	Optional		constraint_tolerance	Maximum allowable constraint violation still considered feasible
	Optional		speculative	Compute speculative gradients
	Optional		max_function_evaluations	Number of function evaluations allowed for optimizers
	Optional		scaling	Turn on scaling for variables, responses, and constraints

	Optional	<code>model_pointer</code>	Identifier for model block to be used by a method
--	-----------------	----------------------------	---

Description

Sequential quadratic programming optimizer.

NPSOL requires a separate software license and therefore may not be available in all versions of Dakota. CONMIN or OPT++ methods may be suitable alternatives.

Stopping Criteria

The method independent controls for `max_iterations` and `max_function_evaluations` limit the number of major SQP iterations and the number of function evaluations that can be performed during an NPSOL optimization. The `convergence_tolerance` control defines NPSOL's internal optimality tolerance which is used in evaluating if an iterate satisfies the first-order Kuhn-Tucker conditions for a minimum. The magnitude of `convergence_tolerance` approximately specifies the number of significant digits of accuracy desired in the final objective function (e.g., `convergence_tolerance = 1.e-6` will result in approximately six digits of accuracy in the final objective function). The `constraint_tolerance` control defines how tightly the constraint functions are satisfied at convergence. The default value is dependent upon the machine precision of the platform in use, but is typically on the order of `1.e-8` for double precision computations. Extremely small values for `constraint_tolerance` may not be attainable. The output verbosity setting controls the amount of information generated at each major SQP iteration: the `silent` and `quiet` settings result in only one line of diagnostic output for each major iteration and print the final optimization solution, whereas the `verbose` and `debug` settings add additional information on the objective function, constraints, and variables at each major iteration.

Concurrency

NPSOL is not a parallel algorithm and cannot directly take advantage of concurrent evaluations. However, if `numerical_gradients` with `method_source dakota` is specified, then the finite difference function evaluations can be performed concurrently (using any of the parallel modes described in the Users Manual [4]).

An important related observation is the fact that NPSOL uses two different line searches depending on how gradients are computed. For either `analytic_gradients` or `numerical_gradients` with `method_source dakota`, NPSOL is placed in user-supplied gradient mode (NPSOL's "Derivative Level" is set to 3) and it uses a gradient-based line search (the assumption is that user-supplied gradients are inexpensive). On the other hand, if `numerical_gradients` are selected with `method_source vendor`, then NPSOL is computing finite differences internally and it will use a value-based line search (the assumption is that finite differencing on each line search evaluation is too expensive). The ramifications of this are: (1) performance will vary between `method_source dakota` and `method_source vendor` for `numerical_gradients`, and (2) gradient speculation is unnecessary when performing optimization in parallel since the gradient-based line search in user-supplied gradient mode is already load balanced for parallel execution. Therefore, a `speculative` specification will be ignored by NPSOL, and optimization with numerical gradients should select `method_source dakota` for load balanced parallel operation and `method_source vendor` for efficient serial operation.

Linear constraints

Lastly, NPSOL supports specialized handling of linear inequality and equality constraints. By specifying the coefficients and bounds of the linear inequality constraints and the coefficients and targets of the linear equality constraints, this information can be provided to NPSOL at initialization and tracked internally, removing the need for the user to provide the values of the linear constraints on every function evaluation.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the `hdf5` keyword, this method writes the following results to HDF5:

- [Best Parameters](#)
- [Best Objective Functions](#) (when `objective_functions` are specified)
- [Best Nonlinear Constraints](#)
- [Calibration](#) (when `calibration_terms` are specified)

verify_level

- [Keywords Area](#)
- [method](#)
- [npsol_sqp](#)
- [verify_level](#)

Verify the quality of analytic gradients

Specification

Alias: none

Argument(s): INTEGER

Default: -1 (no gradient verification)

Description

`verify_level` instructs the NPSOL and NLSSOL algorithms to perform their own finite difference verification of the gradients provided by Dakota. Typically these are used to verify `analytic_gradients` produced by a simulation code, though the option can be used with other Dakota-supplied gradient types including numerical or mixed.

Level 1 will verify the objective gradients, level 2, the nonlinear constraint gradients, and level 3, both. See the Optional Input Parameters section of the NPSOL manual[33] for additional information, including options to verify at the user-supplied initial point vs. first feasible point.

function_precision

- [Keywords Area](#)
- [method](#)
- [npsol_sqp](#)
- [function_precision](#)

Specify the maximum precision of the analysis code responses

Specification

Alias: none

Argument(s): REAL

Default: 1.0e-10

Description

The `function_precision` control provides the algorithm with an estimate of the accuracy to which the problem functions can be computed. This is used to prevent the algorithm from trying to distinguish between function values that differ by less than the inherent error in the calculation.

linesearch_tolerance

- [Keywords Area](#)
- [method](#)
- [npsol_sqp](#)
- [linesearch_tolerance](#)

Choose how accurately the algorithm will compute the minimum in a line search

Specification

Alias: none

Argument(s): REAL

Default: 0.9 (inaccurate line search)

Description

The `linesearch_tolerance` setting controls the accuracy of the line search. The smaller the value (between 0 and 1), the more accurately the algorithm will attempt to compute a precise minimum along the search direction.

convergence_tolerance

- [Keywords Area](#)
- [method](#)
- [npsol_sqp](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function convergence

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

NPSOL defines an internal optimality tolerance which is used in evaluating if an iterate satisfies the first-order Kuhn-Tucker conditions for a minimum. The magnitude of `convergence_tolerance` approximately specifies the number of significant digits of accuracy desired in the final objective function (e.g., `convergence_tolerance = 1.0e-6` will result in approximately six digits of accuracy in the final objective function).

max.iterations

- [Keywords Area](#)
- [method](#)
- [npsol.sqp](#)
- [max.iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: `fsu_cvt`, `local_reliability`: 25; `global_{reliability, interval_est, evidence}` / `efficient_global`: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

constraint_tolerance

- [Keywords Area](#)
- [method](#)
- [npsol.sqp](#)

- [constraint_tolerance](#)

Maximum allowable constraint violation still considered feasible

Specification

Alias: none

Argument(s): REAL

Default: Library default

Description

Sets the maximum allowable value of infeasibility that any constraint in an optimization problem may possess and still be considered to be satisfied.

If a constraint's violation is greater than this value then it is considered to be violated by the optimization algorithm. This specification gives some control over how tightly the constraints will be satisfied at convergence of the algorithm. However, if the value is set too small the algorithm may terminate with one or more constraints being violated.

Dakota's `convergence_tolerance` settings maps to NPSOL's feasibility tolerance which is an absolute tolerance on the constraints.

speculative

- [Keywords Area](#)
- [method](#)
- [npsol_sqp](#)
- [speculative](#)

Compute speculative gradients

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no speculation

Description

When performing gradient-based optimization in parallel, `speculative` gradients can be selected to address the load imbalance that can occur between gradient evaluation and line search phases. In a typical gradient-based optimization, the line search phase consists primarily of evaluating the objective function and any constraints at a trial point, and then testing the trial point for a sufficient decrease in the objective function value and/or constraint violation. If a sufficient decrease is not observed, then one or more additional trial points may be attempted

sequentially. However, if the trial point is accepted then the line search phase is complete and the gradient evaluation phase begins. By speculating that the gradient information associated with a given line search trial point will be used later, additional coarse grained parallelism can be introduced by computing the gradient information (either by finite difference or analytically) in parallel, at the same time as the line search phase trial-point function values. This balances the total amount of computation to be performed at each design point and allows for efficient utilization of multiple processors. While the total amount of work performed will generally increase (since some speculative gradients will not be used when a trial point is rejected in the line search phase), the run time will usually decrease (since gradient evaluations needed at the start of each new optimization cycle were already performed in parallel during the line search phase). Refer to [14] for additional details. The speculative specification is implemented for the gradient-based optimizers in the DOT, CONMIN, and OPT++ libraries, and it can be used with dakota numerical or analytic gradient selections in the responses specification (refer to [responses](#) gradient section for information on these specifications). It should not be selected with vendor numerical gradients since vendor internal finite difference algorithms have not been modified for this purpose. In full-Newton approaches, the Hessian is also computed speculatively. NPSOL and NLSSOL do not support speculative gradients, as their gradient-based line search in user-supplied gradient mode (dakota numerical or analytic gradients) is a superior approach for load-balanced parallel execution.

The `speculative` specification enables speculative computation of gradient and/or Hessian information, where applicable, for parallel optimization studies. By speculating that the derivative information at the current point will be used later, the complete data set (all available gradient/Hessian information) can be computed on every function evaluation. While some of these computations will be wasted, the positive effects are a consistent parallel load balance and usually shorter wall clock time. The `speculative` specification is applicable only when parallelism in the gradient calculations can be exploited by Dakota (it will be ignored for vendor numerical gradients).

max_function_evaluations

- [Keywords Area](#)
- [method](#)
- [npsol_sqp](#)
- [max_function_evaluations](#)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

Default Behavior

Default value is 1000.

scaling

- [Keywords Area](#)
- [method](#)
- [npsol_sqp](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*_scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling
3. `auto` - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. `log` - logarithmic scaling

First, any characteristic values from the optional `*_scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*_scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- `none`, `auto`, `log` - optional
- `value` - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100

responses
objective_functions 3
sense "maximize"
primary_scale_types = "value" "value" "value"
primary_scales = 1 1 100
```

model_pointer

- [Keywords Area](#)
- [method](#)
- [npsol_sqp](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

	Optional		<code>scaling</code>	Turn on scaling for variables, responses, and constraints

	Optional	model_pointer	Identifier for model block to be used by a method
--	-----------------	-------------------------------	---

Description

NLSSOL supports unconstrained, bound-constrained, and generally-constrained least-squares calibration problems. It exploits the structure of a least squares objective function through the periodic use of Gauss-Newton Hessian approximations to accelerate the SQP algorithm.

NLSSOL requires a separate software license and therefore may not be available in all versions of Dakota. [nl2sol](#) or [optpp_g_newton](#) may be suitable alternatives.

Stopping Criteria

The method independent controls for `max.iterations` and `max.function_evaluations` limit the number of major SQP iterations and the number of function evaluations that can be performed during an NPSOL optimization. The `convergence_tolerance` control defines NPSOL's internal optimality tolerance which is used in evaluating if an iterate satisfies the first-order Kuhn-Tucker conditions for a minimum. The magnitude of `convergence_tolerance` approximately specifies the number of significant digits of accuracy desired in the final objective function (e.g., `convergence_tolerance = 1.e-6` will result in approximately six digits of accuracy in the final objective function). The `constraint_tolerance` control defines how tightly the constraint functions are satisfied at convergence. The default value is dependent upon the machine precision of the platform in use, but is typically on the order of `1.e-8` for double precision computations. Extremely small values for `constraint_tolerance` may not be attainable.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the [hdf5](#) keyword, this method writes the following results to HDF5:

- [Best Parameters](#)
- [Best Nonlinear Constraints](#)
- [Calibration](#) (when `calibration_terms` are specified)
- [Parameter Confidence Intervals](#) (when `num.experiments` equals 1)

See Also

These keywords may also be of interest:

- [npsol_sqp](#)
- [nl2sol](#)
- [optpp_g_newton](#)
- [field_calibration_terms](#)

verify_level

- [Keywords Area](#)
- [method](#)
- [nlssol_sqp](#)

- [verify_level](#)

Verify the quality of analytic gradients

Specification

Alias: none

Argument(s): INTEGER

Default: -1 (no gradient verification)

Description

`verify_level` instructs the NPSOL and NLSSOL algorithms to perform their own finite difference verification of the gradients provided by Dakota. Typically these are used to verify `analytic_gradients` produced by a simulation code, though the option can be used with other Dakota-supplied gradient types including numerical or mixed.

Level 1 will verify the objective gradients, level 2, the nonlinear constraint gradients, and level 3, both. See the Optional Input Parameters section of the NPSOL manual[33] for additional information, including options to verify at the user-supplied initial point vs. first feasible point.

function_precision

- [Keywords Area](#)
- [method](#)
- [nlssol_sqp](#)
- [function_precision](#)

Specify the maximum precision of the analysis code responses

Specification

Alias: none

Argument(s): REAL

Default: 1.0e-10

Description

The `function_precision` control provides the algorithm with an estimate of the accuracy to which the problem functions can be computed. This is used to prevent the algorithm from trying to distinguish between function values that differ by less than the inherent error in the calculation.

linesearch_tolerance

- [Keywords Area](#)
- [method](#)
- [nlssol_sqp](#)
- [linesearch_tolerance](#)

Choose how accurately the algorithm will compute the minimum in a line search

Specification

Alias: none

Argument(s): REAL

Default: 0.9 (inaccurate line search)

Description

The `linesearch_tolerance` setting controls the accuracy of the line search. The smaller the value (between 0 and 1), the more accurately the algorithm will attempt to compute a precise minimum along the search direction.

convergence_tolerance

- [Keywords Area](#)
- [method](#)
- [nlssol_sqp](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function convergence

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

NPSOL defines an internal optimality tolerance which is used in evaluating if an iterate satisfies the first-order Kuhn-Tucker conditions for a minimum. The magnitude of `convergence_tolerance` approximately specifies the number of significant digits of accuracy desired in the final objective function (e.g., `convergence_tolerance = 1.0e-6` will result in approximately six digits of accuracy in the final objective function).

max_iterations

- [Keywords Area](#)
- [method](#)
- [nlssol_sqp](#)
- [max_iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: fsu_cvt , local_reliability: 25; global_{reliability , interval_est , evidence} / efficient-global: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_--iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

constraint_tolerance

- [Keywords Area](#)
- [method](#)
- [nlssol_sqp](#)
- [constraint_tolerance](#)

Maximum allowable constraint violation still considered feasible

Specification

Alias: none

Argument(s): REAL

Default: Library default

Description

Sets the maximum allowable value of infeasibility that any constraint in an optimization problem may possess and still be considered to be satisfied.

If a constraint's violation is greater than this value then it is considered to be violated by the optimization algorithm. This specification gives some control over how tightly the constraints will be satisfied at convergence of the algorithm. However, if the value is set too small the algorithm may terminate with one or more constraints being violated.

Dakota's `convergence_tolerance` settings maps to NPSOL's feasibility tolerance which is an absolute tolerance on the constraints.

speculative

- [Keywords Area](#)
- [method](#)
- [nlssol_sqp](#)
- [speculative](#)

Compute speculative gradients

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no speculation

Description

When performing gradient-based optimization in parallel, `speculative` gradients can be selected to address the load imbalance that can occur between gradient evaluation and line search phases. In a typical gradient-based optimization, the line search phase consists primarily of evaluating the objective function and any constraints at a trial point, and then testing the trial point for a sufficient decrease in the objective function value and/or constraint violation. If a sufficient decrease is not observed, then one or more additional trial points may be attempted sequentially. However, if the trial point is accepted then the line search phase is complete and the gradient evaluation phase begins. By speculating that the gradient information associated with a given line search trial point will be used later, additional coarse grained parallelism can be introduced by computing the gradient information (either by finite difference or analytically) in parallel, at the same time as the line search phase trial-point function values. This balances the total amount of computation to be performed at each design point and allows for efficient utilization of multiple processors. While the total amount of work performed will generally increase (since some speculative gradients will not be used when a trial point is rejected in the line search phase), the run time will usually decrease (since gradient evaluations needed at the start of each new optimization cycle were already performed in parallel during the line search phase). Refer to [14] for additional details. The speculative specification is implemented for the gradient-based optimizers in the DOT, CONMIN, and OPT++ libraries, and it can be used with dakota numerical or analytic gradient selections in the responses specification (refer to [responses](#) gradient section for information on these specifications). It should not be selected with vendor numerical gradients since vendor internal finite difference algorithms have not been modified for this purpose. In full-Newton approaches, the Hessian is also computed speculatively. NPSOL and NLSSOL do not support speculative gradients, as their gradient-based line search in user-supplied gradient mode (dakota numerical or analytic gradients) is a superior approach for load-balanced parallel execution.

The `speculative` specification enables speculative computation of gradient and/or Hessian information, where applicable, for parallel optimization studies. By speculating that the derivative information at the current point will be used later, the complete data set (all available gradient/Hessian information) can be computed on every function evaluation. While some of these computations will be wasted, the positive effects are a consistent parallel load balance and usually shorter wall clock time. The `speculative` specification is applicable

only when parallelism in the gradient calculations can be exploited by Dakota (it will be ignored for vendor numerical gradients).

max_function_evaluations

- [Keywords Area](#)
- [method](#)
- [nlssol_sqp](#)
- [max_function_evaluations](#)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

Default Behavior

Default value is 1000.

scaling

- [Keywords Area](#)
- [method](#)
- [nlssol_sqp](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*_scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling
3. `auto` - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. `log` - logarithmic scaling

First, any characteristic values from the optional `*_scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*_scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- none, auto, log - optional
- value - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100

responses
objective_functions 3
sense "maximize"
primary_scale_types = "value" "value" "value"
primary_scales = 1 1 100
```

model_pointer

- [Keywords Area](#)
- [method](#)
- [nlssol_sqp](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last `model` block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                    0.1 0.2 0.6
                    0.1 0.2 0.6
  sample_type lhs
  distribution cumulative

model
  id_model = 'SURR'

  lower_bounds = 0. 0.
  upper_bounds = 1. 1.
  descriptors = 'x1' 'x2'

interface
  id_interface = 'I1'
  system async evaluation_concurrency = 5
  analysis_driver = 'text_book'

responses
```

```
response_functions = 3
no_gradients
no_hessians
```

7.2.20 nlpql_sqp

- [Keywords Area](#)
- [method](#)
- [nlpql_sqp](#)

NLPQL Sequential Quadratic Program

Topics

This keyword is related to the topics:

- [package_nlpql](#)
- [sequential_quadratic_programming](#)
- [local_optimization_methods](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			max_iterations	Number of iterations allowed for optimizers and adaptive UQ methods
	Optional		convergence_tolerance	Stopping criterion based on objective function or statistics convergence

	Optional	max_function_- evaluations	Number of function evaluations allowed for optimizers
	Optional	scaling	Turn on scaling for variables, responses, and constraints
	Optional	model_pointer	Identifier for model block to be used by a method

Description

NLPQL implementation of sequential quadratic programming. The particular SQP implementation in `nlpql_`
`sqp` uses a variant with distributed and non-monotone line search. Thus, this variant is designed to be more robust in the presence of inaccurate or noisy gradients common in many engineering applications.

NLPQL requires a separate software license and therefore may not be available in all versions of Dakota. CONMIN or OPT++ methods may be suitable alternatives.

The method independent controls for maximum iterations and output verbosity are mapped to NLPQL controls MAXIT and IPRINT, respectively. The maximum number of function evaluations is enforced within the NLPQLOptimizer class.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the [hdf5](#) keyword, this method writes the following results to HDF5:

- [Best Parameters](#)
- [Best Objective Functions](#) (when [objective_functions](#) are specified)
- [Best Nonlinear Constraints](#)
- [Calibration](#) (when [calibration_terms](#) are specified)

max_iterations

- [Keywords Area](#)
- [method](#)
- [nlpql_sqp](#)
- [max_iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: `fsu_cvt`, `local_reliability`: 25; `global_{reliability, interval_est, evidence}` / `efficient_global`: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_--iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

`convergence_tolerance`

- [Keywords Area](#)
- [method](#)
- [nlpql_sq](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

max_function_evaluations

- [Keywords Area](#)
- [method](#)
- [nlpql_sqp](#)
- [max_function_evaluations](#)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- [method](#)
- [optpp_cg](#)

A conjugate gradient optimization method

Topics

This keyword is related to the topics:

- [package_optpp](#)
- [local_optimization_methods](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		max_step	Max change in design point
	Optional		gradient_tolerance	Stopping criteria based on L2 norm of gradient
	Optional		max_iterations	Number of iterations allowed for optimizers and adaptive UQ methods
	Optional		convergence_-tolerance	Stopping criterion based on objective function or statistics convergence
	Optional		speculative	Compute speculative gradients
	Optional		max_function_-evaluations	Number of function evaluations allowed for optimizers
	Optional		scaling	Turn on scaling for variables, responses, and constraints
	Optional		model_pointer	Identifier for model block to be used by a method

Description

The conjugate gradient method is an implementation of the Polak-Ribiere approach and handles only unconstrained problems.

See [package_optpp](#) for info related to all `optpp` methods.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the `hdf5` keyword, this method writes the following results to HDF5:

- [Best Parameters](#)
- [Best Objective Functions](#) (when `objective_functions` are specified)
- [Calibration](#) (when `calibration_terms` are specified)

See Also

These keywords may also be of interest:

max_step

- [Keywords Area](#)
- [method](#)
- [optpp_cg](#)
- [max_step](#)

Max change in design point

Specification

Alias: none

Argument(s): REAL

Default: 1000.

Description

The `max_step` control specifies the maximum step that can be taken when computing a change in the current design point (e.g., limiting the Newton step computed from current gradient and Hessian information). It is equivalent to a move limit or a maximum trust region size. The `gradient_tolerance` control defines the threshold value on the L2 norm of the objective function gradient that indicates convergence to an unconstrained minimum (no active constraints). The `gradient_tolerance` control is defined for all gradient-based optimizers.

gradient_tolerance

- [Keywords Area](#)
- [method](#)
- [optpp_cg](#)
- [gradient_tolerance](#)

Stopping criteria based on L2 norm of gradient

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `gradient_tolerance` control defines the threshold value on the L2 norm of the objective function gradient (for unconstrained minimum or no active constraints) or the Lagrangian gradient (for constrained minimum) that indicates convergence to a stationary point. The `gradient_tolerance` control is currently defined only for the OPT++ and ROL libraries.

max_iterations

- [Keywords Area](#)
- [method](#)
- [optpp_cg](#)
- [max_iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: `fsu_cvt`, `local_reliability`: 25; `global_{reliability, interval_est, evidence}` / `efficient-global`: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

convergence_tolerance

- [Keywords Area](#)
- [method](#)
- [optpp_cg](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

speculative

- [Keywords Area](#)
- [method](#)
- [optpp_cg](#)
- [speculative](#)

Compute speculative gradients

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no speculation

Description

When performing gradient-based optimization in parallel, `speculative` gradients can be selected to address the load imbalance that can occur between gradient evaluation and line search phases. In a typical gradient-based optimization, the line search phase consists primarily of evaluating the objective function and any constraints at a trial point, and then testing the trial point for a sufficient decrease in the objective function value and/or constraint violation. If a sufficient decrease is not observed, then one or more additional trial points may be attempted sequentially. However, if the trial point is accepted then the line search phase is complete and the gradient evaluation phase begins. By speculating that the gradient information associated with a given line search trial point will be used later, additional coarse grained parallelism can be introduced by computing the gradient information (either by finite difference or analytically) in parallel, at the same time as the line search phase trial-point function values. This balances the total amount of computation to be performed at each design point and allows for efficient utilization of multiple processors. While the total amount of work performed will generally increase (since some speculative gradients will not be used when a trial point is rejected in the line search phase), the run time will usually decrease (since gradient evaluations needed at the start of each new optimization cycle were already performed in parallel during the line search phase). Refer to [14] for additional details. The speculative specification is implemented for the gradient-based optimizers in the DOT, CONMIN, and OPT++ libraries, and it can be used with dakota numerical or analytic gradient selections in the responses specification (refer to [responses](#) gradient section for information on these specifications). It should not be selected with vendor numerical gradients since vendor internal finite difference algorithms have not been modified for this purpose. In full-Newton approaches, the Hessian is also computed speculatively. NPSOL and NLSSOL do not support speculative gradients, as their gradient-based line search in user-supplied gradient mode (dakota numerical or analytic gradients) is a superior approach for load-balanced parallel execution.

The `speculative` specification enables speculative computation of gradient and/or Hessian information, where applicable, for parallel optimization studies. By speculating that the derivative information at the current point will be used later, the complete data set (all available gradient/Hessian information) can be computed on every function evaluation. While some of these computations will be wasted, the positive effects are a consistent parallel load balance and usually shorter wall clock time. The `speculative` specification is applicable

only when parallelism in the gradient calculations can be exploited by Dakota (it will be ignored for vendor numerical gradients).

max_function_evaluations

- [Keywords Area](#)
- [method](#)
- [optpp_cg](#)
- [max_function_evaluations](#)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

Default Behavior

Default value is 1000.

scaling

- [Keywords Area](#)
- [method](#)
- [optpp_cg](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*_scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling
3. `auto` - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval $[0,1]$;
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into $[0,1]$.

4. `log` - logarithmic scaling

First, any characteristic values from the optional `*_scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- none, auto, log - optional
- value - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100
```

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value" "value" "value"
primary_scales = 1 1 100
```

model_pointer

- [Keywords Area](#)
- [method](#)
- [optpp_cg](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last `model` block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                    0.1 0.2 0.6
                    0.1 0.2 0.6
  sample_type lhs
  distribution cumulative

model
  id_model = 'SURR'
  surrogate global,
  dace_method_pointer = 'DACE'
  polynomial quadratic

method
  id_method = 'DACE'
  model_pointer = 'DACE_M'
  sampling sample_type lhs
  samples = 121 seed = 5034 rng rnum2

model
  id_model = 'DACE_M'
  single
  interface_pointer = 'I1'

variables
  uniform_uncertain = 2
  lower_bounds = 0. 0.
  upper_bounds = 1. 1.
  descriptors = 'x1' 'x2'

interface
  id_interface = 'I1'
  system asynch evaluation_concurrency = 5
  analysis_driver = 'text_book'

responses
```

```
response_functions = 3
no_gradients
no_hessians
```

7.2.22 optpp_q_newton

- [Keywords Area](#)
- [method](#)
- [optpp_q_newton](#)

Quasi-Newton optimization method

Topics

This keyword is related to the topics:

- [package_optpp](#)
- [local_optimization_methods](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			search_method	Select a search method for Newton-based optimizers
	Optional		merit_function	Balance goals of reducing objective function and satisfying constraints
	Optional		steplength_to_- boundary	Controls how close to the boundary of the feasible region the algorithm is allowed to move

	Optional	centering_-parameter	Controls how closely the algorithm should follow the "central path"
	Optional	max_step	Max change in design point
	Optional	gradient_tolerance	Stopping criteria based on L2 norm of gradient
	Optional	max_iterations	Number of iterations allowed for optimizers and adaptive UQ methods
	Optional	convergence_-tolerance	Stopping criterion based on objective function or statistics convergence
	Optional	speculative	Compute speculative gradients
	Optional	max_function_-evaluations	Number of function evaluations allowed for optimizers
	Optional	scaling	Turn on scaling for variables, responses, and constraints
	Optional	model_pointer	Identifier for model block to be used by a method

Description

This is a Newton method that expects a gradient and computes a low-rank approximation to the Hessian. Each of the Newton-based methods are automatically bound to the appropriate OPT++ algorithm based on the user constraint specification (unconstrained, bound-constrained, or generally-constrained). In the generally-constrained case, the Newton methods use a nonlinear interior-point approach to manage the constraints.

See [package_optpp](#) for info related to all `optpp` methods.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the `hdf5` keyword, this method writes the following results to HDF5:

- [Best Parameters](#)
- [Best Objective Functions](#) (when `objective_functions` are specified)
- [Best Nonlinear Constraints](#)
- [Calibration](#) (when `calibration_terms` are specified)

search_method

- [Keywords Area](#)
- [method](#)
- [optpp_q_newton](#)
- [search_method](#)

Select a search method for Newton-based optimizers

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Line Search Method (Group 1)	value_based_line_search	Use only function values for line search
			gradient_based_line_search	Set the search method to use the gradient
			trust_region	Use trust region as the globalization strategy.
			tr_pds	Use direct search as the local search in a trust region method

Description

The `search_method` control is defined for all Newton-based optimizers and is used to select between `trust_region`, `gradient_based_line_search`, and `value_based_line_search` methods. The `gradient_based_line_search` option uses the line search method proposed by [62]. This option satisfies sufficient decrease and curvature conditions; whereas, `value_based_line_search` only satisfies the sufficient decrease condition. At each line search iteration, the `gradient_based_line_search` method computes the function and gradient at the trial point. Consequently, given expensive function evaluations, the `value_based_line_search` method is preferred to the `gradient_based_line_search` method. Each of these Newton methods additionally supports the `tr_pds` selection for unconstrained problems. This option performs a robust trust region search using pattern search techniques. Use of a line search is the default for bound-constrained and generally-constrained problems, and use of a `trust_region` search method is the default for unconstrained problems.

value_based_line_search

trust_region

- [Keywords Area](#)
- [method](#)
- [optpp-q-newton](#)
- [search_method](#)
- [trust_region](#)

Use trust region as the globalization strategy.

Specification

Alias: none

Argument(s): none

Description

The `trust_region` optional group specification can be used to specify the initial size of the trust region (using `initial_size`) relative to the total variable bounds, the minimum size of the trust region (using `minimum_size`), the contraction factor for the trust region size (using `contraction_factor`) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using `expansion_factor`) used when the the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using `contract_threshold`) and the trust region size expansion threshold (using `expand_threshold`). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command `contract_threshold` sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command `expand_threshold` determines the trust region value above which the trust region will expand for the next SBL iteration.

tr_pds

- [Keywords Area](#)

merit_function

- [Keywords Area](#)
- [method](#)
- [optpp-q-newton](#)
- [merit_function](#)

Balance goals of reducing objective function and satisfying constraints

Specification

Alias: none

Argument(s): none

Default: `argaez_tapia`

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Merit Function (Group 1)	el_bakry	El-Bakry merit function

			argaez_tapia	The merit function by Tapia and Argaez
			van_shanno	The merit function by Vanderbei and Shanno

Description

A `merit_function` is a function in constrained optimization that attempts to provide joint progress toward reducing the objective function and satisfying the constraints.

`el_bakry`

- [Keywords Area](#)
- [method](#)
- [optpp_q_newton](#)
- [merit_function](#)
- [el_bakry](#)

El-Bakry merit function

Specification

Alias: none

Argument(s): none

Description

The "el_bakry" merit function is the L2-norm of the first order optimality conditions for the nonlinear programming problem. The cost per linesearch iteration is $n+1$ function evaluations. For more information, see[20].

`argaez_tapia`

- [Keywords Area](#)
- [method](#)
- [optpp_q_newton](#)
- [merit_function](#)
- [argaez_tapia](#)

The merit function by Tapia and Argaez

Specification

Alias: none

Argument(s): none

Description

The "argaez_tapia" merit function can be classified as a modified augmented Lagrangian function. The augmented Lagrangian is modified by adding to its penalty term a potential reduction function to handle the perturbed complementarity condition. The cost per linesearch iteration is one function evaluation. For more information, see [82].

If the function evaluation is expensive or noisy, set the `merit_function` to "argaez_tapia" or "van_shanno".

van_shanno

- [Keywords Area](#)
- [method](#)
- [optpp_q_newton](#)
- [merit_function](#)
- [van_shanno](#)

The merit function by Vanderbei and Shanno

Specification

Alias: none

Argument(s): none

Description

The "van_shanno" merit function can be classified as a penalty function for the logarithmic barrier formulation of the nonlinear programming problem. The cost per linesearch iteration is one function evaluation. For more information see [84].

If the function evaluation is expensive or noisy, set the `merit_function` to "argaez_tapia" or "van_shanno".

steplength_to_boundary

- [Keywords Area](#)
- [method](#)
- [optpp_q_newton](#)
- [steplength_to_boundary](#)

Controls how close to the boundary of the feasible region the algorithm is allowed to move

Specification

Alias: none

Argument(s): REAL

Default: Merit function dependent: 0.8 (el_bakry), 0.99995 (argaez_tapia), 0.95 (van_shanno)

Description

The `steplength_to_boundary` specification is a parameter (between 0 and 1) that controls how close to the boundary of the feasible region the algorithm is allowed to move. A value of 1 means that the algorithm is allowed to take steps that may reach the boundary of the feasible region. If the user wishes to maintain strict feasibility of the design parameters this value should be less than 1. Default values are .8, .99995, and .95 for the `el_bakry`, `argaez_tapia`, and `van_shanno` merit functions, respectively.

centering_parameter

- [Keywords Area](#)
- [method](#)
- [optpp_q_newton](#)
- [centering_parameter](#)

Controls how closely the algorithm should follow the "central path"

Specification

Alias: none

Argument(s): REAL

Default: Merit function dependent: 0.2 (`el_bakry`), 0.2 (`argaez_tapia`), 0.1 (`van_shanno`)

Description

The `centering_parameter` specification is a parameter (between 0 and 1) that controls how closely the algorithm should follow the "central path". See[91] for the definition of central path. The larger the value, the more closely the algorithm follows the central path, which results in small steps. A value of 0 indicates that the algorithm will take a pure Newton step. Default values are .2, .2, and .1 for the `el_bakry`, `argaez_tapia`, and `van_shanno` merit functions, respectively.

max_step

- [Keywords Area](#)
- [method](#)
- [optpp_q_newton](#)
- [max_step](#)

Max change in design point

Specification

Alias: none

Argument(s): REAL

Default: 1000.

Description

The `max_step` control specifies the maximum step that can be taken when computing a change in the current design point (e.g., limiting the Newton step computed from current gradient and Hessian information). It is equivalent to a move limit or a maximum trust region size. The `gradient_tolerance` control defines the threshold value on the L2 norm of the objective function gradient that indicates convergence to an unconstrained minimum (no active constraints). The `gradient_tolerance` control is defined for all gradient-based optimizers.

gradient_tolerance

- [Keywords Area](#)
- [method](#)
- [optpp_q_newton](#)
- [gradient_tolerance](#)

Stopping criteria based on L2 norm of gradient

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `gradient_tolerance` control defines the threshold value on the L2 norm of the objective function gradient (for unconstrained minimum or no active constraints) or the Lagrangian gradient (for constrained minimum) that indicates convergence to a stationary point. The `gradient_tolerance` control is currently defined only for the OPT++ and ROL libraries.

max_iterations

- [Keywords Area](#)
- [method](#)
- [optpp_q_newton](#)
- [max_iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: `fsu_cvt`, `local_reliability`: 25; `global_{reliability, interval_est, evidence}` / `efficient_global`: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_``iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

`convergence_tolerance`

- [Keywords Area](#)
- [method](#)
- [optpp_q_newton](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

speculative

- [Keywords Area](#)
- [method](#)
- [optpp_q_newton](#)
- [speculative](#)

Compute speculative gradients

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no speculation

Description

When performing gradient-based optimization in parallel, `speculative` gradients can be selected to address the load imbalance that can occur between gradient evaluation and line search phases. In a typical gradient-based optimization, the line search phase consists primarily of evaluating the objective function and any constraints at a trial point, and then testing the trial point for a sufficient decrease in the objective function value and/or constraint violation. If a sufficient decrease is not observed, then one or more additional trial points may be attempted sequentially. However, if the trial point is accepted then the line search phase is complete and the gradient evaluation phase begins. By speculating that the gradient information associated with a given line search trial point will be used later, additional coarse grained parallelism can be introduced by computing the gradient information (either by finite difference or analytically) in parallel, at the same time as the line search phase trial-point function values. This balances the total amount of computation to be performed at each design point and allows for efficient utilization of multiple processors. While the total amount of work performed will generally increase (since some speculative gradients will not be used when a trial point is rejected in the line search phase), the run time will usually decrease (since gradient evaluations needed at the start of each new optimization cycle were already performed in parallel during the line search phase). Refer to [14] for additional details. The speculative

specification is implemented for the gradient-based optimizers in the DOT, CONMIN, and OPT++ libraries, and it can be used with dakota numerical or analytic gradient selections in the responses specification (refer to [responses](#) gradient section for information on these specifications). It should not be selected with vendor numerical gradients since vendor internal finite difference algorithms have not been modified for this purpose. In full-Newton approaches, the Hessian is also computed speculatively. NPSOL and NLSSOL do not support speculative gradients, as their gradient-based line search in user-supplied gradient mode (dakota numerical or analytic gradients) is a superior approach for load-balanced parallel execution.

The `speculative` specification enables speculative computation of gradient and/or Hessian information, where applicable, for parallel optimization studies. By speculating that the derivative information at the current point will be used later, the complete data set (all available gradient/Hessian information) can be computed on every function evaluation. While some of these computations will be wasted, the positive effects are a consistent parallel load balance and usually shorter wall clock time. The `speculative` specification is applicable only when parallelism in the gradient calculations can be exploited by Dakota (it will be ignored for vendor numerical gradients).

max_function_evaluations

- [Keywords Area](#)
- [method](#)
- [optpp-q-newton](#)
- [max_function_evaluations](#)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

Default Behavior

Default value is 1000.

scaling

- [Keywords Area](#)
- [method](#)
- [optpp_q_newton](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling

3. `auto` - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. `log` - logarithmic scaling

First, any characteristic values from the optional `*scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- `none`, `auto`, `log` - optional
- `value` - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100
```

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value" "value" "value"
primary_scales = 1 1 100
```

model_pointer

- [Keywords Area](#)
- [method](#)
- [optpp_q_newton](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                    0.1 0.2 0.6
                    0.1 0.2 0.6

  sample_type lhs
  distribution cumulative

model
  id_model = 'SURR'
```

```

surrogate global,
dace_method_pointer = 'DACE'
polynomial quadratic

method
id_method = 'DACE'
model_pointer = 'DACE_M'
sampling sample_type lhs
samples = 121 seed = 5034 rng rnum2

model
id_model = 'DACE_M'
single
interface_pointer = 'I1'

variables
uniform_uncertain = 2
lower_bounds = 0. 0.
upper_bounds = 1. 1.
descriptors = 'x1' 'x2'

interface
id_interface = 'I1'
system async evaluation_concurrency = 5
analysis_driver = 'text_book'

responses
response_functions = 3
no_gradients
no_hessians

```

7.2.23 optpp_fd_newton

- [Keywords Area](#)
- [method](#)

Finite Difference Newton optimization method

Topics

This keyword is related to the topics:

- [package_optpp](#)
- [local_optimization_methods](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			search_method	Select a search method for Newton-based optimizers
	Optional		merit_function	Balance goals of reducing objective function and satisfying constraints
	Optional		steplength_to_- boundary	Controls how close to the boundary of the feasible region the algorithm is allowed to move
	Optional		centering_- parameter	Controls how closely the algorithm should follow the "central path"
	Optional		max_step	Max change in design point
	Optional		gradient_tolerance	Stopping criteria based on L2 norm of gradient
	Optional		max_iterations	Number of iterations allowed for optimizers and adaptive UQ methods
	Optional		convergence_- tolerance	Stopping criterion based on objective function or statistics convergence

	Optional	speculative	Compute speculative gradients
	Optional	max_function_- evaluations	Number of function evaluations allowed for optimizers
	Optional	scaling	Turn on scaling for variables, responses, and constraints
	Optional	model_pointer	Identifier for model block to be used by a method

Description

This is a Newton method that expects a gradient and computes a finite-difference approximation to the Hessian. Each of the Newton-based methods are automatically bound to the appropriate OPT++ algorithm based on the user constraint specification (unconstrained, bound-constrained, or generally-constrained). In the generally-constrained case, the Newton methods use a nonlinear interior-point approach to manage the constraints.

See [package_optpp](#) for info related to all `optpp` methods.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the [hdf5](#) keyword, this method writes the following results to HDF5:

- [Best Parameters](#)
- [Best Objective Functions](#) (when [objective_functions](#) are specified)
- [Best Nonlinear Constraints](#)
- [Calibration](#) (when [calibration_terms](#) are specified)

search_method

- [Keywords Area](#)
- [method](#)
- [optpp_fd_newton](#)
- [search_method](#)

Select a search method for Newton-based optimizers

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Line Search Method (Group 1)	value_based_line_search	Use only function values for line search
			gradient_based_line_search	Set the search method to use the gradient
			trust_region	Use trust region as the globalization strategy.
			tr_pds	Use direct search as the local search in a trust region method

Description

The `search_method` control is defined for all Newton-based optimizers and is used to select between `trust_region`, `gradient_based_line_search`, and `value_based_line_search` methods. The `gradient_based_line_search` option uses the line search method proposed by [62]. This option satisfies sufficient decrease and curvature conditions; whereas, `value_based_line_search` only satisfies the sufficient decrease condition. At each line search iteration, the `gradient_based_line_search` method computes the function and gradient at the trial point. Consequently, given expensive function evaluations, the `value_based_line_search` method is preferred to the `gradient_based_line_search` method. Each of these Newton methods additionally supports the `tr_pds` selection for unconstrained problems. This option performs a robust trust region search using pattern search techniques. Use of a line search is the default for bound-constrained and generally-constrained problems, and use of a `trust_region` search method is the default for unconstrained problems.

`trust_region`

- [Keywords Area](#)
- [method](#)
- [optpp_fd_newton](#)
- [search_method](#)
- [trust_region](#)

Use trust region as the globalization strategy.

Specification

Alias: none

Argument(s): none

Description

The `trust_region` optional group specification can be used to specify the initial size of the trust region (using `initial_size`) relative to the total variable bounds, the minimum size of the trust region (using `minimum_size`), the contraction factor for the trust region size (using `contraction_factor`) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using `expansion_factor`) used when the the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using `contract_threshold`) and the trust region size expansion threshold (using `expand_threshold`). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command `contract_threshold` sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command `expand_threshold` determines the trust region value above which the trust region will expand for the next SBL iteration.

`tr_pds`

- [Keywords Area](#)

merit_function

- [Keywords Area](#)
- [method](#)
- [optpp_fd_newton](#)
- [merit_function](#)

Balance goals of reducing objective function and satisfying constraints

Specification

Alias: none

Argument(s): none

Default: `argaez_tapia`

Child Keywords:

	Required/- Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Merit Function (Group 1)	el_bakry	El-Bakry merit function

		argaez_tapia	The merit function by Tapia and Argaez
		van_shanno	The merit function by Vanderbei and Shanno

Description

A `merit_function` is a function in constrained optimization that attempts to provide joint progress toward reducing the objective function and satisfying the constraints.

`el_bakry`

- [Keywords Area](#)
- [method](#)
- [optpp_fd_newton](#)
- [merit_function](#)
- [el_bakry](#)

El-Bakry merit function

Specification

Alias: none

Argument(s): none

Description

The "el_bakry" merit function is the L2-norm of the first order optimality conditions for the nonlinear programming problem. The cost per linesearch iteration is $n+1$ function evaluations. For more information, see[20].

`argaez_tapia`

- [Keywords Area](#)
- [method](#)
- [optpp_fd_newton](#)
- [merit_function](#)
- [argaez_tapia](#)

The merit function by Tapia and Argaez

Specification

Alias: none

Argument(s): none

Description

The "argaez_tapia" merit function can be classified as a modified augmented Lagrangian function. The augmented Lagrangian is modified by adding to its penalty term a potential reduction function to handle the perturbed complementarity condition. The cost per linesearch iteration is one function evaluation. For more information, see [82].

If the function evaluation is expensive or noisy, set the `merit_function` to "argaez_tapia" or "van_shanno".

van_shanno

- [Keywords Area](#)
- [method](#)
- [optpp_fd_newton](#)
- [merit_function](#)
- [van_shanno](#)

The merit function by Vanderbei and Shanno

Specification

Alias: none

Argument(s): none

Description

The "van_shanno" merit function can be classified as a penalty function for the logarithmic barrier formulation of the nonlinear programming problem. The cost per linesearch iteration is one function evaluation. For more information see [84].

If the function evaluation is expensive or noisy, set the `merit_function` to "argaez_tapia" or "van_shanno".

stlength_to_boundary

- [Keywords Area](#)
- [method](#)
- [optpp_fd_newton](#)
- [stlength_to_boundary](#)

Controls how close to the boundary of the feasible region the algorithm is allowed to move

Specification

Alias: none

Argument(s): REAL

Default: Merit function dependent: 0.8 (el_bakry), 0.99995 (argaez_tapia), 0.95 (van_shanno)

Description

The `stplength_to_boundary` specification is a parameter (between 0 and 1) that controls how close to the boundary of the feasible region the algorithm is allowed to move. A value of 1 means that the algorithm is allowed to take steps that may reach the boundary of the feasible region. If the user wishes to maintain strict feasibility of the design parameters this value should be less than 1. Default values are .8, .99995, and .95 for the `el_bakry`, `argaez_tapia`, and `van_shanno` merit functions, respectively.

centering_parameter

- [Keywords Area](#)
- [method](#)
- [optpp_fd_newton](#)
- [centering_parameter](#)

Controls how closely the algorithm should follow the "central path"

Specification

Alias: none

Argument(s): REAL

Default: Merit function dependent: 0.2 (`el_bakry`), 0.2 (`argaez_tapia`), 0.1 (`van_shanno`)

Description

The `centering_parameter` specification is a parameter (between 0 and 1) that controls how closely the algorithm should follow the "central path". See[91] for the definition of central path. The larger the value, the more closely the algorithm follows the central path, which results in small steps. A value of 0 indicates that the algorithm will take a pure Newton step. Default values are .2, .2, and .1 for the `el_bakry`, `argaez_tapia`, and `van_shanno` merit functions, respectively.

max_step

- [Keywords Area](#)
- [method](#)
- [optpp_fd_newton](#)
- [max_step](#)

Max change in design point

Specification

Alias: none

Argument(s): REAL

Default: 1000.

Description

The `max_step` control specifies the maximum step that can be taken when computing a change in the current design point (e.g., limiting the Newton step computed from current gradient and Hessian information). It is equivalent to a move limit or a maximum trust region size. The `gradient_tolerance` control defines the threshold value on the L2 norm of the objective function gradient that indicates convergence to an unconstrained minimum (no active constraints). The `gradient_tolerance` control is defined for all gradient-based optimizers.

gradient_tolerance

- [Keywords Area](#)
- [method](#)
- [optpp_fd_newton](#)
- [gradient_tolerance](#)

Stopping criteria based on L2 norm of gradient

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `gradient_tolerance` control defines the threshold value on the L2 norm of the objective function gradient (for unconstrained minimum or no active constraints) or the Lagrangian gradient (for constrained minimum) that indicates convergence to a stationary point. The `gradient_tolerance` control is currently defined only for the OPT++ and ROL libraries.

max_iterations

- [Keywords Area](#)
- [method](#)
- [optpp_fd_newton](#)
- [max_iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: `fsu_cvt`, `local_reliability`: 25; `global_{reliability, interval_est, evidence}` / `efficient_global`: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_--iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

`convergence_tolerance`

- [Keywords Area](#)
- [method](#)
- [optpp_fd_newton](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

speculative

- [Keywords Area](#)
- [method](#)
- [optpp_fd_newton](#)
- [speculative](#)

Compute speculative gradients

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no speculation

Description

When performing gradient-based optimization in parallel, `speculative` gradients can be selected to address the load imbalance that can occur between gradient evaluation and line search phases. In a typical gradient-based optimization, the line search phase consists primarily of evaluating the objective function and any constraints at a trial point, and then testing the trial point for a sufficient decrease in the objective function value and/or constraint violation. If a sufficient decrease is not observed, then one or more additional trial points may be attempted sequentially. However, if the trial point is accepted then the line search phase is complete and the gradient evaluation phase begins. By speculating that the gradient information associated with a given line search trial point will be used later, additional coarse grained parallelism can be introduced by computing the gradient information (either by finite difference or analytically) in parallel, at the same time as the line search phase trial-point function values. This balances the total amount of computation to be performed at each design point and allows for efficient utilization of multiple processors. While the total amount of work performed will generally increase (since some speculative gradients will not be used when a trial point is rejected in the line search phase), the run time will usually decrease (since gradient evaluations needed at the start of each new optimization cycle were already performed in parallel during the line search phase). Refer to [14] for additional details. The speculative

specification is implemented for the gradient-based optimizers in the DOT, CONMIN, and OPT++ libraries, and it can be used with dakota numerical or analytic gradient selections in the responses specification (refer to [responses](#) gradient section for information on these specifications). It should not be selected with vendor numerical gradients since vendor internal finite difference algorithms have not been modified for this purpose. In full-Newton approaches, the Hessian is also computed speculatively. NPSOL and NLSSOL do not support speculative gradients, as their gradient-based line search in user-supplied gradient mode (dakota numerical or analytic gradients) is a superior approach for load-balanced parallel execution.

The `speculative` specification enables speculative computation of gradient and/or Hessian information, where applicable, for parallel optimization studies. By speculating that the derivative information at the current point will be used later, the complete data set (all available gradient/Hessian information) can be computed on every function evaluation. While some of these computations will be wasted, the positive effects are a consistent parallel load balance and usually shorter wall clock time. The `speculative` specification is applicable only when parallelism in the gradient calculations can be exploited by Dakota (it will be ignored for vendor numerical gradients).

max_function_evaluations

- [Keywords Area](#)
- [method](#)
- [optpp_fd_newton](#)
- [max_function_evaluations](#)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

Default Behavior

Default value is 1000.

scaling

- [Keywords Area](#)
- [method](#)
- [optpp_fd_newton](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling

3. auto - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. log - logarithmic scaling

First, any characteristic values from the optional `*scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- none, auto, log - optional
- value - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100
```

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value" "value" "value"
primary_scales = 1 1 100
```

model_pointer

- [Keywords Area](#)
- [method](#)
- [optpp_fd_newton](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                    0.1 0.2 0.6
                    0.1 0.2 0.6

  sample_type lhs
  distribution cumulative

model
  id_model = 'SURR'
```

```

surrogate global,
dace_method_pointer = 'DACE'
polynomial quadratic

method
id_method = 'DACE'
model_pointer = 'DACE_M'
sampling sample_type lhs
samples = 121 seed = 5034 rng rnum2

model
id_model = 'DACE_M'
single
interface_pointer = 'I1'

variables

	Optional	model_pointer	Identifier for model block to be used by a method

Description

The Gauss-Newton algorithm is available as `optpp_g_newton` and supports unconstrained, bound-constrained, and generally-constrained problems. When interfaced with the unconstrained, bound-constrained, and nonlinear interior point full-Newton optimizers from the OPT++ library, it provides a Gauss-Newton least squares capability which – on zero-residual test problems – can exhibit quadratic convergence rates near the solution. (Real problems almost never have zero residuals, i.e., perfect fits.)

See [package.optpp](#) for info related to all `optpp` methods.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the [hdf5](#) keyword, this method writes the following results to HDF5:

- [Best Parameters](#)
- [Best Nonlinear Constraints](#)
- [Calibration](#) (when [calibration_terms](#) are specified)
- [Parameter Confidence Intervals](#) (when [num_experiments](#) equals 1)

See Also

These keywords may also be of interest:

- [search_method](#)

Select a search method for Newton-based optimizers

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/- Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Line Search Method (Group 1)	value_based_line_search	Use only function values for line search
			gradient_based_line_search	Set the search method to use the gradient
			trust_region	Use trust region as the globalization strategy.
			tr_pds	Use direct search as the local search in a trust region method

Description

The `search_method` control is defined for all Newton-based optimizers and is used to select between `trust_region`, `gradient_based_line_search`, and `value_based_line_search` methods. The `gradient_based_line_search` option uses the line search method proposed by [62]. This option satisfies sufficient decrease and curvature conditions; whereas, `value_based_line_search` only satisfies the sufficient decrease condition. At each line search iteration, the `gradient_based_line_search` method computes the function and gradient at the trial point. Consequently, given expensive function evaluations, the `value_based_line_search` method is preferred to the `gradient_based_line_search` method. Each of these Newton methods additionally supports the `tr_pds` selection for unconstrained problems. This option performs a robust trust region search using pattern search techniques. Use of a line search is the default for bound-constrained and generally-constrained problems, and use of a `trust_region` search method is the default for unconstrained problems.

trust_region

- [Keywords Area](#)
- [method](#)
- [optpp_g_newton](#)
- [search_method](#)
- [trust_region](#)

Use trust region as the globalization strategy.

Specification

Alias: none

Argument(s): none

Description

The `trust_region` optional group specification can be used to specify the initial size of the trust region (using `initial_size`) relative to the total variable bounds, the minimum size of the trust region (using `minimum_size`), the contraction factor for the trust region size (using `contraction_factor`) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using `expansion_factor`) used when the the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using `contract_threshold`) and the trust region size expansion threshold (using `expand_threshold`). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command `contract_threshold` sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command `expand_threshold` determines the trust region value above which the trust region will expand for the next SBL iteration.

tr_pds

merit_function

- [Keywords Area](#)
- [method](#)
- [optpp_g_newton](#)
- [merit_function](#)

Balance goals of reducing objective function and satisfying constraints

Specification

Alias: none

Argument(s): none

Default: `argaez_tapia`

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Merit Function (Group 1)	el_bakry	El-Bakry merit function

			argaez_tapia	The merit function by Tapia and Argaez
			van_shanno	The merit function by Vanderbei and Shanno

Description

A `merit_function` is a function in constrained optimization that attempts to provide joint progress toward reducing the objective function and satisfying the constraints.

`el_bakry`

- [Keywords Area](#)
- [method](#)
- [optpp_g_newton](#)
- [merit_function](#)
- [el_bakry](#)

El-Bakry merit function

Specification

Alias: none

Argument(s): none

Description

The "el_bakry" merit function is the L2-norm of the first order optimality conditions for the nonlinear programming problem. The cost per linesearch iteration is $n+1$ function evaluations. For more information, see[20].

`argaez_tapia`

- [Keywords Area](#)
- [method](#)
- [optpp_g_newton](#)
- [merit_function](#)
- [argaez_tapia](#)

The merit function by Tapia and Argaez

Specification

Alias: none

Argument(s): none

Description

The "argaez_tapia" merit function can be classified as a modified augmented Lagrangian function. The augmented Lagrangian is modified by adding to its penalty term a potential reduction function to handle the perturbed complementarity condition. The cost per linesearch iteration is one function evaluation. For more information, see [82].

If the function evaluation is expensive or noisy, set the `merit_function` to "argaez_tapia" or "van_shanno".

van_shanno

- [Keywords Area](#)
- [method](#)
- [optpp_g_newton](#)
- [merit_function](#)
- [van_shanno](#)

The merit function by Vanderbei and Shanno

Specification

Alias: none

Argument(s): none

Description

The "van_shanno" merit function can be classified as a penalty function for the logarithmic barrier formulation of the nonlinear programming problem. The cost per linesearch iteration is one function evaluation. For more information see [84].

If the function evaluation is expensive or noisy, set the `merit_function` to "argaez_tapia" or "van_shanno".

steplength_to_boundary

- [Keywords Area](#)
- [method](#)
- [optpp_g_newton](#)
- [steplength_to_boundary](#)

Controls how close to the boundary of the feasible region the algorithm is allowed to move

Specification

Alias: none

Argument(s): REAL

Default: Merit function dependent: 0.8 (el_bakry), 0.99995 (argaez_tapia), 0.95 (van_shanno)

Description

The `steplength_to_boundary` specification is a parameter (between 0 and 1) that controls how close to the boundary of the feasible region the algorithm is allowed to move. A value of 1 means that the algorithm is allowed to take steps that may reach the boundary of the feasible region. If the user wishes to maintain strict feasibility of the design parameters this value should be less than 1. Default values are .8, .99995, and .95 for the `el_bakry`, `argaez_tapia`, and `van_shanno` merit functions, respectively.

centering_parameter

- [Keywords Area](#)
- [method](#)
- [optpp_g_newton](#)
- [centering_parameter](#)

Controls how closely the algorithm should follow the "central path"

Specification

Alias: none

Argument(s): REAL

Default: Merit function dependent: 0.2 (`el_bakry`), 0.2 (`argaez_tapia`), 0.1 (`van_shanno`)

Description

The `centering_parameter` specification is a parameter (between 0 and 1) that controls how closely the algorithm should follow the "central path". See[91] for the definition of central path. The larger the value, the more closely the algorithm follows the central path, which results in small steps. A value of 0 indicates that the algorithm will take a pure Newton step. Default values are .2, .2, and .1 for the `el_bakry`, `argaez_tapia`, and `van_shanno` merit functions, respectively.

max_step

- [Keywords Area](#)
- [method](#)
- [optpp_g_newton](#)
- [max_step](#)

Max change in design point

Specification

Alias: none

Argument(s): REAL

Default: 1000.

Description

The `max_step` control specifies the maximum step that can be taken when computing a change in the current design point (e.g., limiting the Newton step computed from current gradient and Hessian information). It is equivalent to a move limit or a maximum trust region size. The `gradient_tolerance` control defines the threshold value on the L2 norm of the objective function gradient that indicates convergence to an unconstrained minimum (no active constraints). The `gradient_tolerance` control is defined for all gradient-based optimizers.

gradient_tolerance

- [Keywords Area](#)
- [method](#)
- [optpp_g_newton](#)
- [gradient_tolerance](#)

Stopping criteria based on L2 norm of gradient

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `gradient_tolerance` control defines the threshold value on the L2 norm of the objective function gradient (for unconstrained minimum or no active constraints) or the Lagrangian gradient (for constrained minimum) that indicates convergence to a stationary point. The `gradient_tolerance` control is currently defined only for the OPT++ and ROL libraries.

max_iterations

- [Keywords Area](#)
- [method](#)
- [optpp_g_newton](#)
- [max_iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: `fsu_cvt`, `local_reliability`: 25; `global_{reliability, interval_est, evidence}` / `efficient_global`: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_``iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

`convergence_tolerance`

- [Keywords Area](#)
- [method](#)
- [optpp_g_newton](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

speculative

- [Keywords Area](#)
- [method](#)
- [optpp_g_newton](#)
- [speculative](#)

Compute speculative gradients

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no speculation

Description

When performing gradient-based optimization in parallel, `speculative` gradients can be selected to address the load imbalance that can occur between gradient evaluation and line search phases. In a typical gradient-based optimization, the line search phase consists primarily of evaluating the objective function and any constraints at a trial point, and then testing the trial point for a sufficient decrease in the objective function value and/or constraint violation. If a sufficient decrease is not observed, then one or more additional trial points may be attempted sequentially. However, if the trial point is accepted then the line search phase is complete and the gradient evaluation phase begins. By speculating that the gradient information associated with a given line search trial point will be used later, additional coarse grained parallelism can be introduced by computing the gradient information (either by finite difference or analytically) in parallel, at the same time as the line search phase trial-point function values. This balances the total amount of computation to be performed at each design point and allows for efficient utilization of multiple processors. While the total amount of work performed will generally increase (since some speculative gradients will not be used when a trial point is rejected in the line search phase), the run time will usually decrease (since gradient evaluations needed at the start of each new optimization cycle were already performed in parallel during the line search phase). Refer to [14] for additional details. The speculative

specification is implemented for the gradient-based optimizers in the DOT, CONMIN, and OPT++ libraries, and it can be used with dakota numerical or analytic gradient selections in the responses specification (refer to [responses](#) gradient section for information on these specifications). It should not be selected with vendor numerical gradients since vendor internal finite difference algorithms have not been modified for this purpose. In full-Newton approaches, the Hessian is also computed speculatively. NPSOL and NLSSOL do not support speculative gradients, as their gradient-based line search in user-supplied gradient mode (dakota numerical or analytic gradients) is a superior approach for load-balanced parallel execution.

The `speculative` specification enables speculative computation of gradient and/or Hessian information, where applicable, for parallel optimization studies. By speculating that the derivative information at the current point will be used later, the complete data set (all available gradient/Hessian information) can be computed on every function evaluation. While some of these computations will be wasted, the positive effects are a consistent parallel load balance and usually shorter wall clock time. The `speculative` specification is applicable only when parallelism in the gradient calculations can be exploited by Dakota (it will be ignored for vendor numerical gradients).

max_function_evaluations

- [Keywords Area](#)
- [method](#)
- [optpp_g_newton](#)
- [max_function_evaluations](#)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

Default Behavior

Default value is 1000.

scaling

- [Keywords Area](#)
- [method](#)
- [optpp_g_newton](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling

3. auto - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. log - logarithmic scaling

First, any characteristic values from the optional `*scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- none, auto, log - optional
- value - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100
```

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value" "value" "value"
primary_scales = 1 1 100
```

model_pointer

- [Keywords Area](#)
- [method](#)
- [optpp_g_newton](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                    0.1 0.2 0.6
                    0.1 0.2 0.6

  sample_type lhs

	Optional	max_function_- evaluations	Number of function evaluations allowed for optimizers
	Optional	scaling	Turn on scaling for variables, responses, and constraints
	Optional	model_pointer	Identifier for model block to be used by a method

Description

This is a full Newton method that expects a gradient and a Hessian. Each of the Newton-based methods are automatically bound to the appropriate OPT++ algorithm based on the user constraint specification (unconstrained, bound-constrained, or generally-constrained). In the generally-constrained case, the Newton methods use a non-linear interior-point approach to manage the constraints.

See [package_optpp](#) for info related to all `optpp` methods.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the [hdf5](#) keyword, this method writes the following results to HDF5:

- [Best Parameters](#)
- [Best Objective Functions](#) (when [objective_functions](#) are specified)
- [Best Nonlinear Constraints](#)
- [Calibration](#) (when [calibration_terms](#) are specified)

Select a search method for Newton-based optimizers

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Line Search Method (Group 1)	value_based_line_search	Use only function values for line search
			gradient_based_line_search	Set the search method to use the gradient
			trust_region	Use trust region as the globalization strategy.
			tr_pds	Use direct search as the local search in a trust region method

Description

The `search_method` control is defined for all Newton-based optimizers and is used to select between `trust_region`, `gradient_based_line_search`, and `value_based_line_search` methods. The `gradient_based_line_search` option uses the line search method proposed by [62]. This option satisfies sufficient decrease and curvature conditions; whereas, `value_based_line_search` only satisfies the sufficient decrease condition. At each line search iteration, the `gradient_based_line_search` method computes the function and gradient at the trial point. Consequently, given expensive function evaluations, the `value_based_line_search` method is preferred to the `gradient_based_line_search` method. Each of these Newton methods additionally supports the `tr_pds` selection for unconstrained problems. This option performs a robust trust region search using pattern search techniques. Use of a line search is the default for bound-constrained and generally-constrained problems, and use of a `trust_region` search method is the default for unconstrained problems.

value_based_line_search

- [Keywords Area](#)
- [method](#)

- [optpp_newton](#)
- [search_method](#)
- [value_based_line_search](#)

Use only function values for line search

Specification

Alias: none

Argument(s): none

Default: `trust_region` (unconstrained), `value_based_line_search` (bound/general constraints)

Description

The `search_method` control is defined for all Newton-based optimizers and is used to select between `trust_region`, `gradient_based_line_search`, and `value_based_line_search` methods. The `gradient_based_line_search` option uses the line search method proposed by [62]. This option satisfies sufficient decrease and curvature conditions; whereas, `value_based_line_search` only satisfies the sufficient decrease condition. At each line search iteration, the `gradient_based_line_search` method computes the function and gradient at the trial point. Use of a line search is the default for bound-constrained and generally-constrained problems, and use of a `trust_region` search method is the default for unconstrained problems.

`trust_region`

- [Keywords Area](#)
- [method](#)
- [optpp_newton](#)
- [search_method](#)
- [trust_region](#)

Use trust region as the globalization strategy.

Specification

Alias: none

Argument(s): none

Description

The `trust_region` optional group specification can be used to specify the initial size of the trust region (using `initial_size`) relative to the total variable bounds, the minimum size of the trust region (using `minimum_size`), the contraction factor for the trust region size (using `contraction_factor`) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using `expansion_factor`) used when the the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using `contract_threshold`) and the trust region size expansion threshold (using `expand_threshold`). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command `contract_threshold` sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command `expand_threshold` determines the trust region value above which the trust region will expand for the next SBL iteration.

`tr_pds`

- [Keywords Area](#)
- [method](#)

- [optpp_newton](#)
- [search_method](#)
- [tr_pds](#)

Use direct search as the local search in a trust region method

Specification

Alias: none

Argument(s): none

Description

The `search_method` control is defined for all Newton-based optimizers and is used to select between `trust_region`, `gradient_based_line_search`, and `value_based_line_search` methods. The `gradient_based_line_search` option uses the line search method proposed by [62]. This option satisfies sufficient decrease and curvature conditions; whereas, `value_based_line_search` only satisfies the sufficient decrease condition. At each line search iteration, the `gradient_based_line_search` method computes the function and gradient at the trial point. Consequently, given expensive function evaluations, the `value_based_line_search` method is preferred to the `gradient_based_line_search` method. Each of these Newton methods additionally supports the `tr_pds` selection for unconstrained problems. This option performs a robust trust region search using pattern search techniques. Use of a line search is the default for bound-constrained and generally-constrained problems, and use of a `trust_region` search method is the default for unconstrained problems.

merit_function

- [Keywords Area](#)
- [method](#)
- [optpp_newton](#)
- [merit_function](#)

Balance goals of reducing objective function and satisfying constraints

Specification

Alias: none

Argument(s): none

Default: `argaez_tapia`

Child Keywords:

	Required/- Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Merit Function (Group 1)	el_bakry	El-Bakry merit function

		argaez_tapia	The merit function by Tapia and Argaez
		van_shanno	The merit function by Vanderbei and Shanno

Description

A `merit_function` is a function in constrained optimization that attempts to provide joint progress toward reducing the objective function and satisfying the constraints.

`el_bakry`

- [Keywords Area](#)
- [method](#)
- [optpp_newton](#)
- [merit_function](#)
- [el_bakry](#)

El-Bakry merit function

Specification

Alias: none

Argument(s): none

Description

The "el_bakry" merit function is the L2-norm of the first order optimality conditions for the nonlinear programming problem. The cost per linesearch iteration is $n+1$ function evaluations. For more information, see[20].

`argaez_tapia`

- [Keywords Area](#)
- [method](#)
- [optpp_newton](#)
- [merit_function](#)
- [argaez_tapia](#)

The merit function by Tapia and Argaez

Specification

Alias: none

Argument(s): none

Description

The "argaez_tapia" merit function can be classified as a modified augmented Lagrangian function. The augmented Lagrangian is modified by adding to its penalty term a potential reduction function to handle the perturbed complementarity condition. The cost per linesearch iteration is one function evaluation. For more information, see [82].

If the function evaluation is expensive or noisy, set the `merit_function` to "argaez_tapia" or "van_shanno".

van_shanno

- [Keywords Area](#)
- [method](#)
- [optpp_newton](#)
- [merit_function](#)
- [van_shanno](#)

The merit function by Vanderbei and Shanno

Specification

Alias: none

Argument(s): none

Description

The "van_shanno" merit function can be classified as a penalty function for the logarithmic barrier formulation of the nonlinear programming problem. The cost per linesearch iteration is one function evaluation. For more information see [84].

If the function evaluation is expensive or noisy, set the `merit_function` to "argaez_tapia" or "van_shanno".

stlength_to_boundary

- [Keywords Area](#)
- [method](#)
- [optpp_newton](#)
- [stlength_to_boundary](#)

Controls how close to the boundary of the feasible region the algorithm is allowed to move

Specification

Alias: none

Argument(s): REAL

Default: Merit function dependent: 0.8 (el_bakry), 0.99995 (argaez_tapia), 0.95 (van_shanno)

Description

The `stplength_to_boundary` specification is a parameter (between 0 and 1) that controls how close to the boundary of the feasible region the algorithm is allowed to move. A value of 1 means that the algorithm is allowed to take steps that may reach the boundary of the feasible region. If the user wishes to maintain strict feasibility of the design parameters this value should be less than 1. Default values are .8, .99995, and .95 for the `el_bakry`, `argaez_tapia`, and `van_shanno` merit functions, respectively.

centering_parameter

- [Keywords Area](#)
- [method](#)
- [optpp_newton](#)
- [centering_parameter](#)

Controls how closely the algorithm should follow the "central path"

Specification

Alias: none

Argument(s): REAL

Default: Merit function dependent: 0.2 (`el_bakry`), 0.2 (`argaez_tapia`), 0.1 (`van_shanno`)

Description

The `centering_parameter` specification is a parameter (between 0 and 1) that controls how closely the algorithm should follow the "central path". See[91] for the definition of central path. The larger the value, the more closely the algorithm follows the central path, which results in small steps. A value of 0 indicates that the algorithm will take a pure Newton step. Default values are .2, .2, and .1 for the `el_bakry`, `argaez_tapia`, and `van_shanno` merit functions, respectively.

max_step

- [Keywords Area](#)
- [method](#)
- [optpp_newton](#)
- [max_step](#)

Max change in design point

Specification

Alias: none

Argument(s): REAL

Default: 1000.

Description

The `max_step` control specifies the maximum step that can be taken when computing a change in the current design point (e.g., limiting the Newton step computed from current gradient and Hessian information). It is equivalent to a move limit or a maximum trust region size. The `gradient_tolerance` control defines the threshold value on the L2 norm of the objective function gradient that indicates convergence to an unconstrained minimum (no active constraints). The `gradient_tolerance` control is defined for all gradient-based optimizers.

gradient_tolerance

- [Keywords Area](#)
- [method](#)
- [optpp_newton](#)
- [gradient_tolerance](#)

Stopping criteria based on L2 norm of gradient

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `gradient_tolerance` control defines the threshold value on the L2 norm of the objective function gradient (for unconstrained minimum or no active constraints) or the Lagrangian gradient (for constrained minimum) that indicates convergence to a stationary point. The `gradient_tolerance` control is currently defined only for the OPT++ and ROL libraries.

max_iterations

- [Keywords Area](#)
- [method](#)
- [optpp_newton](#)
- [max_iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: `fsu_cvt`, `local_reliability`: 25; `global_{reliability, interval_est, evidence}` / `efficient_global`: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_--iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

`convergence_tolerance`

- [Keywords Area](#)
- [method](#)
- [optpp_newton](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

speculative

- [Keywords Area](#)
- [method](#)
- [optpp_newton](#)
- [speculative](#)

Compute speculative gradients

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no speculation

Description

When performing gradient-based optimization in parallel, `speculative` gradients can be selected to address the load imbalance that can occur between gradient evaluation and line search phases. In a typical gradient-based optimization, the line search phase consists primarily of evaluating the objective function and any constraints at a trial point, and then testing the trial point for a sufficient decrease in the objective function value and/or constraint violation. If a sufficient decrease is not observed, then one or more additional trial points may be attempted sequentially. However, if the trial point is accepted then the line search phase is complete and the gradient evaluation phase begins. By speculating that the gradient information associated with a given line search trial point will be used later, additional coarse grained parallelism can be introduced by computing the gradient information (either by finite difference or analytically) in parallel, at the same time as the line search phase trial-point function values. This balances the total amount of computation to be performed at each design point and allows for efficient utilization of multiple processors. While the total amount of work performed will generally increase (since some speculative gradients will not be used when a trial point is rejected in the line search phase), the run time will usually decrease (since gradient evaluations needed at the start of each new optimization cycle were already performed in parallel during the line search phase). Refer to [14] for additional details. The speculative

specification is implemented for the gradient-based optimizers in the DOT, CONMIN, and OPT++ libraries, and it can be used with dakota numerical or analytic gradient selections in the responses specification (refer to [responses](#) gradient section for information on these specifications). It should not be selected with vendor numerical gradients since vendor internal finite difference algorithms have not been modified for this purpose. In full-Newton approaches, the Hessian is also computed speculatively. NPSOL and NLSSOL do not support speculative gradients, as their gradient-based line search in user-supplied gradient mode (dakota numerical or analytic gradients) is a superior approach for load-balanced parallel execution.

The `speculative` specification enables speculative computation of gradient and/or Hessian information, where applicable, for parallel optimization studies. By speculating that the derivative information at the current point will be used later, the complete data set (all available gradient/Hessian information) can be computed on every function evaluation. While some of these computations will be wasted, the positive effects are a consistent parallel load balance and usually shorter wall clock time. The `speculative` specification is applicable only when parallelism in the gradient calculations can be exploited by Dakota (it will be ignored for vendor numerical gradients).

max_function_evaluations

- [Keywords Area](#)
- [method](#)
- [optpp_newton](#)
- [max_function_evaluations](#)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

Default Behavior

Default value is 1000.

scaling

- [Keywords Area](#)
- [method](#)
- [optpp_newton](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling

3. auto - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. log - logarithmic scaling

First, any characteristic values from the optional `*scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- none, auto, log - optional
- value - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100
```

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value" "value" "value"
primary_scales = 1 1 100
```

model_pointer

- [Keywords Area](#)
- [method](#)
- [optpp_newton](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                    0.1 0.2 0.6
                    0.1 0.2 0.6

  sample_type lhs
  distribution cumulative

model
  id_model = 'SURR'
```

```

surrogate global,
dace_method_pointer = 'DACE'
polynomial quadratic

method
id_method = 'DACE'
model_pointer = 'DACE_M'
sampling sample_type lhs
samples = 121 seed = 5034 rng rnum2

model
id_model = 'DACE_M'
single
interface_pointer = 'I1'

variables
uniform_uncertain = 2
lower_bounds = 0. 0.
upper_bounds = 1. 1.
descriptors = 'x1' 'x2'

interface
id_interface = 'I1'
system asynch evaluation_concurrency = 5
analysis_driver = 'text_book'

responses
response_functions = 3
no_gradients
no_hessians

```

7.2.26 optpp_pds

- [Keywords Area](#)
- [method](#)
- [optpp_pds](#)

Simplex-based derivative free optimization method

Topics

This keyword is related to the topics:

- [package_optpp](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description

	Optional	search_scheme_-size	Number of points to be used in the direct search template
	Optional	max_iterations	Number of iterations allowed for optimizers and adaptive UQ methods
	Optional	convergence_-tolerance	Stopping criterion based on objective function or statistics convergence
	Optional	max_function_-evaluations	Number of function evaluations allowed for optimizers
	Optional	scaling	Turn on scaling for variables, responses, and constraints
	Optional	model_pointer	Identifier for model block to be used by a method

Description

The direct search algorithm, PDS (parallel direct search method), supports bound constraints.

The PDS method can directly exploit asynchronous evaluations; however, this capability has not yet been implemented in Dakota.

See [package_optpp](#) for info related to all `optpp` methods.

See Also

These keywords may also be of interest:

- [optpp_cg](#)
- [optpp_g_newton](#)
- [optpp_fd_newton](#)
- [optpp_newton](#)
- [optpp_g_newton](#)

search_scheme_size

- [Keywords Area](#)
- [method](#)
- [optpp_pds](#)
- [search_scheme_size](#)

Number of points to be used in the direct search template

Specification

Alias: none

Argument(s): INTEGER

Default: 32

Description

The `search_scheme_size` is defined for the PDS method to specify the number of points to be used in the direct search template.

max_iterations

- [Keywords Area](#)
- [method](#)
- [optpp_pds](#)
- [max_iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: `fsu_cvt`, `local_reliability: 25`; `global_{reliability, interval_est, evidence} / efficient-global: 25*n`)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

convergence_tolerance

- [Keywords Area](#)
- [method](#)
- [optpp_pds](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

max_function_evaluations

- [Keywords Area](#)
- [method](#)
- [optpp_pds](#)
- [max_function_evaluations](#)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

Default Behavior

Default value is 1000.

scaling

- [Keywords Area](#)

- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*_scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling
3. `auto` - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. `log` - logarithmic scaling

First, any characteristic values from the optional `*_scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*_scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- none, auto, log - optional
- value - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100

responses
objective_functions 3
sense "maximize"
primary_scale_types = "value" "value" "value"
primary_scales = 1 1 100
```

model_pointer

- [Keywords Area](#)
- [method](#)
- [optpp_pds](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last `model` block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                    0.1 0.2 0.6
                    0.1 0.2 0.6
  sample_type lhs
  distribution cumulative

model
  id_model = 'SURR'
  surrogate global,
  dace_method_pointer = 'DACE'
  polynomial quadratic

method
  id_method = 'DACE'
  model_pointer = 'DACE_M'
  sampling sample_type lhs
  samples = 121 seed = 5034 rng rnum2

model
  id_model = 'DACE_M'
  single
  interface_pointer = 'I1'

variables
  uniform_uncertain = 2
  lower_bounds = 0. 0.
  upper_bounds = 1. 1.
  descriptors = 'x1' 'x2'

interface
  id_interface = 'I1'
  system async evaluation_concurrency = 5
  analysis_driver = 'text_book'

responses
```

```
response_functions = 3
no_gradients
no_hessians
```

7.2.27 demo_tpl

- [Keywords Area](#)
- [method](#)
- [demo_tpl](#)

(Keep it short, say 3-10 words. Some keywords require arguments (real number, string, list of reals or strings, etc). For these, blurb should begin with a noun and define the information that the user should provide to Dakota. Example–method-sampling-samples: Number of samples for sampling-based methods. Example–method-sampling-model_pointer: Identifier for model block to be used by a method. For keywords that do not require arguments, blurb should be in a verb form that answers the question What does Dakota do if I specify this keyword? Example–method: Begins Dakota method selection and behavioral settings. Example–method-sampling-sample_type-random: Uses Monte-Carlo sampling. Try to provide a hint of contextnot always easy to do concisely. Example–method-sampling-variance_based_decomp: Activates global sensitivity analysis based on decomposition of response variance into contributions from variables. Anti example–max_step: Max change in design point (note lack of optimization context). To the extent possible, avoid using the keyword to define itself. Note that there are some cases where this doesnt make sense. Anti example–importance_sampling: Importance sampling.)

--	-----------------	------------------------------	---

Description

(Insert brief description. Treat this as an extended blurb. It should still be relatively short, say 2-3 sentences that expand on what was hinted at in the blurb. Example–lhs: The lhs keyword invokes Latin Hypercube Sampling as the means of drawing samples of uncertain variables according to their probability distributions. This is a stratified, space-filling approach that selects variable values from a set of equi-probable bins.)

Default Behavior

(For keywords with arguments, include the default value. For keywords without arguments, include whether it defaults to on or off. Include other keywords that must be used simultaneously. Include variable types operated on by default. Include valid response types. Etc Example–sampling: By default, sampling methods operate on aleatory and epistemic uncertain variables. The types of variables can be restricted or expanded (to include design or state variables) through use of the active keyword in the variables block in the Dakota input file. If continuous design and/or state variables are designated as active, the sampling algorithm will treat them as parameters with uniform probability distributions between their upper and lower bounds.)

Expected Output

(This should describe what information Dakota will provide as a result of using this keyword and where to find it (e.g., screen, what file). This is not valid for all keywords, so omit when appropriate. Example–variance_based_decomp: When variance_based_decomp is specified, sensitivity indices for main effects and total effects will be reported. Main effects (roughly) represent the percent contribution of each individual variable to the variance in the model response. Total effects represent the percent contribution of each individual variable in combination with all other variables to the variance in the model response.)

Usage Tips

(Include any rules of thumb for when to use the keyword and how to set it. We dont necessarily have this for all keywords at this point, so omit as needed. Example–variance_based_decomp: To obtain sensitivity indices that are reasonably accurate, we recommend that N, the number of samples, be at least one hundred and preferably several hundred or thousands.)

Additional Discussion

(Optional. Put it here or in the Theory block. If not here, remove header.)

Examples

(Include at least one example, preferably a full Dakota input file. Partial file, e.g., a single input block, is OK if syntax is really simple and theres nothing more to illustrate. If this is the case, pointers to related examples may be helpful. If syntax is complicated, add some explanatory text. If expected output needs explanation, show it and include explanation pointing out things to look for.)

Default Behavior

(For keywords with arguments, include the default value. For keywords without arguments, include whether it defaults to on or off. Include other keywords that must be used simultaneously. Include variable types operated on by default. Include valid response types. Etc Example–sampling: By default, sampling methods operate on aleatory and epistemic uncertain variables. The types of variables can be restricted or expanded (to include design or state variables) through use of the active keyword in the variables block in the Dakota input file. If continuous design and/or state variables are designated as active, the sampling algorithm will treat them as parameters with uniform probability distributions between their upper and lower bounds.)

Expected Output

(This should describe what information Dakota will provide as a result of using this keyword and where to find it (e.g., screen, what file). This is not valid for all keywords, so omit when appropriate. Example—variance_based_decomp: When variance_based_decomp is specified, sensitivity indices for main effects and total effects will be reported. Main effects (roughly) represent the percent contribution of each individual variable to the variance in the model response. Total effects represent the percent contribution of each individual variable in combination with all other variables to the variance in the model response.)

Usage Tips

(Include any rules of thumb for when to use the keyword and how to set it. We don't necessarily have this for all keywords at this point, so omit as needed. Example—variance_based_decomp: To obtain sensitivity indices that are reasonably accurate, we recommend that N, the number of samples, be at least one hundred and preferably several hundred or thousands.)

Additional Discussion

(Optional. Put it here or in the Theory block. If not here, remove header.)

Examples

(Include at least one example, preferably a full Dakota input file. Partial file, e.g., a single input block, is OK if syntax is really simple and there's nothing more to illustrate. If this is the case, pointers to related examples may be helpful. If syntax is complicated, add some explanatory text. If expected output needs explanation, show it and include explanation pointing out things to look for.)

7.2.28 rol

- [Keywords Area](#)
- [method](#)
- [rol](#)

Rapid Optimization Library (ROL) is a large-scale optimization package within Trilinos.

Topics

This keyword is related to the topics:

- [local_optimization_methods](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			max_iterations	Number of iterations allowed for optimizers and adaptive UQ methods
	Optional		variable_tolerance	Step length-based stopping criteria for derivative-free optimizers
	Optional		gradient_tolerance	Stopping criteria based on L2 norm of gradient
	Optional		constraint_-tolerance	Maximum allowable constraint violation still considered feasible
	Optional		options_file	File containing advanced ROL options
	Optional		scaling	Turn on scaling for variables, responses, and constraints
	Optional		model_pointer	Identifier for model block to be used by a method

Description

ROL is used for the solution of optimal design, optimal control and inverse problems in large-scale engineering applications.

Usage Tips

ROL is a general gradient-based library designed to scale well to very large problem sizes. For large problem sizes (i.e. number of variables), ROLs trust region method and conjugate gradient methods exhibit good scalability for unconstrained problems. ROL handles equality constraints natively but converts inequality constraints into equality constraints with bounded slack variables. This has might degrade convergence for problems involving large number of inequality constraints. ROL has traditionally been applied to problems with analytic gradients (and Hessians)but can can be used with Dakota-provided finite-differencing approximations to the gradient of both objective and constraints. However, a user employing these is advised to use alternative optimizers such as DOT until performance of ROL improves in future releases.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the [hdf5](#) keyword, this method writes the following

results to HDF5:

- [Best Parameters](#)
- [Best Objective Functions](#) (when [objective_functions](#) are specified)
- [Calibration](#) (when [calibration_terms](#) are specified)

max_iterations

- [Keywords Area](#)
- [method](#)
- [rol](#)
- [max_iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: `fsu_cvt`, `local_reliability`: 25; `global_{reliability, interval_est, evidence}` / `efficient-global`: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

variable_tolerance

- [Keywords Area](#)
- [method](#)
- [rol](#)
- [variable_tolerance](#)

Step length-based stopping criteria for derivative-free optimizers

Specification

Alias: none

Argument(s): REAL

Default: 0.01

Description

The `variable_tolerance` keyword defines the minimum step length allowed by the optimizer and is used to determine convergence. It is applicable to `asynch_pattern_search`, `coliny_cobyla`, `coliny_pattern_search`, `coliny_solis_wets`, and `mesh_adaptive_search`.

Default Behavior

The default value varies according to method as follows:

- `asynch_pattern_search`: 1.0e-2
- `coliny_cobyla`: 1.0e-4
- `coliny_pattern_search`: 1.0e-5
- `coliny_solis_wets`: 1.0e-6
- `mesh_adaptive_search`: 1.0e-6

Usage Tips

It is recommended that `variable_tolerance` be set to a value for which changes of that scale in parameter values cause negligible changes in the objective function.

Examples

Three example method input blocks appear below.

For `asynch_pattern_search`:

```
method
  asynch_pattern_search
    contraction_factor = 0.25
    variable_tolerance = 1.e-4
    solution_target = 1.e-6
    max_function_evaluations 500
    constraint_tolerance 1.e-6
```

For `coliny_pattern_search`:

```
method
  coliny_pattern_search
    initial_delta = .2
    variable_tolerance = 1.e-4
    max_iterations 100
    solution_accuracy = 1.e-6
    seed = 1234
    max_function_evaluations = 1000
```

For `mesh_adaptive_search`

```
method
  mesh_adaptive_search
    variable_tolerance = 0.01
    seed = 1234
```

gradient_tolerance

- [Keywords Area](#)
- [method](#)
- [rol](#)
- [gradient_tolerance](#)

Stopping criteria based on L2 norm of gradient

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `gradient_tolerance` control defines the threshold value on the L2 norm of the objective function gradient (for unconstrained minimum or no active constraints) or the Lagrangian gradient (for constrained minimum) that indicates convergence to a stationary point. The `gradient_tolerance` control is currently defined only for the OPT++ and ROL libraries.

constraint_tolerance

- [Keywords Area](#)
- [method](#)
- [rol](#)
- [constraint_tolerance](#)

Maximum allowable constraint violation still considered feasible

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: Library default

Description

Sets the maximum allowable value of infeasibility that any constraint in an optimization problem may possess and still be considered to be satisfied.

If a constraint's violation is greater than this value then it is considered to be violated by the optimization algorithm. This specification gives some control over how tightly the constraints will be satisfied at convergence of the algorithm. However, if the value is set too small the algorithm may terminate with one or more constraints being violated.

Defaults

Defaults vary depending on the method.

- CONMIN optimizers: 1.0e-3
- DOT constrained optimizers: 3.0e-3
- `surrogate_based_local` : 1.0e-4

options_file

- [Keywords Area](#)
- `method`
- `rol`
- `options_file`

File containing advanced ROL options

Specification

Alias: none

Argument(s): STRING

Default: no advanced options file

Description

Allow power users to override default ROL options

Default Behavior No advanced options used.

Usage Tips The `options_file` offers a final override over other options settings, which are applied with the following precedence:

1. ROL library defaults
2. Dakota hard-coded defaults
3. Settings from Dakota input file
4. Settings from the advanced `options_file`

scaling

- [Keywords Area](#)
- [method](#)
- [rol](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*_scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling

3. `auto` - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. `log` - logarithmic scaling

First, any characteristic values from the optional `*scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- `none`, `auto`, `log` - optional
- `value` - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100
```

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value" "value" "value"
primary_scales = 1 1 100
```

model_pointer

- [Keywords Area](#)
- [method](#)
- [rol](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                    0.1 0.2 0.6
                    0.1 0.2 0.6

  sample_type lhs
  distribution cumulative

model
  id_model = 'SURR'
```

```

surrogate global,
dace_method_pointer = 'DACE'
polynomial quadratic

method
id_method = 'DACE'
model_pointer = 'DACE_M'
sampling sample_type lhs
samples = 121 seed = 5034 rng rnum2

model
id_model = 'DACE_M'
single
interface_pointer = 'I1'

variables
uniform_uncertain = 2
lower_bounds = 0. 0.
upper_bounds = 1. 1.
descriptors = 'x1' 'x2'

interface
id_interface = 'I1'
system asynch evaluation_concurrency = 5
analysis_driver = 'text_book'

responses
response_functions = 3
no_gradients
no_hessians

```

7.2.29 `asynch_pattern_search`

- [Keywords Area](#)
- [method](#)
- [asynch_pattern_search](#)

Pattern search, derivative free optimization method

Topics

This keyword is related to the topics:

- [package_hopspack](#)
- [global_optimization_methods](#)

Specification

Alias: coliny_apps

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			initial_delta	Initial step size for derivative-free optimizers
	Optional		contraction_factor	Amount by which step length is rescaled
	Optional		variable_tolerance	Step length-based stopping criteria for derivative-free optimizers
	Optional		solution_target	Stopping criteria based on objective function value
	Optional		synchronization	Select how Dakota schedules function evaluations in a pattern search
	Optional		merit_function	Balance goals of reducing objective function and satisfying constraints
	Optional		constraint_penalty	Multiplier for the penalty function
	Optional		smoothing_factor	Smoothing value for smoothed penalty functions
	Optional		constraint-tolerance	Maximum allowable constraint violation still considered feasible

	Optional	<code>max_function_-</code> <code>evaluations</code>	Number of function evaluations allowed for optimizers
	Optional	<code>scaling</code>	Turn on scaling for variables, responses, and constraints
	Optional	<code>model_pointer</code>	Identifier for model block to be used by a method

Description

The asynchronous parallel pattern search (APPS) algorithm [37] is a fully asynchronous pattern search technique in that the search along each offset direction continues without waiting for searches along other directions to finish.

Currently, APPS only supports coordinate bases with a total of $2n$ function evaluations in the pattern, and these patterns may only contract.

Concurrency

APPS exploits parallelism through the use of Dakota's concurrent function evaluations. The variant of the algorithm that is currently exposed, however, limits the amount of concurrency that can be exploited. In particular, APPS can leverage an evaluation concurrency level of at most twice the number of variables. More options that allow for greater evaluation concurrency may be exposed in future releases.

Algorithm Behavior

- `initial_delta`: the initial step length, must be positive
- `variable_tolerance`: step length used to determine convergence, must be greater than or equal to $4.4\text{e-}16$
- `contraction_factor`: amount by which step length is rescaled after unsuccessful iterates, must be strictly between 0 and 1

Merit Functions

APPS solves nonlinearly constrained problems by solving a sequence of linearly constrained merit function-base subproblems. There are several exact and smoothed exact penalty functions that can be specified with the `merit_function` control. The options are as follows:

- `merit_max`: based on ℓ_∞ norm
- `merit_max_smooth`: based on smoothed ℓ_∞ norm
- `merit1`: based on ℓ_1 norm
- `merit1_smooth`: based on smoothed ℓ_1 norm
- `merit2`: based on ℓ_2 norm
- `merit2_smooth`: based on smoothed ℓ_2 norm

- `merit2_squared`: based on ℓ_2^2 norm

The user can also specify the following to affect the merit functions:

- `constraint_penalty`
- `smoothing_parameter`

Method Independent Controls

The only method independent controls that are currently mapped to APPS are:

- [max_function_evaluations](#)
- [constraint_tolerance](#)
- [output](#)

Note that while APPS treats the constraint tolerance separately for linear and nonlinear constraints, we apply the same value to both if the user specifies `constraint_tolerance`.

The APPS internal display level is mapped to the Dakota `output` settings as follows:

- `debug`: display final solution, all input parameters, variable and constraint info, trial points, search directions, and execution details
- `verbose`: display final solution, all input parameters, variable and constraint info, and trial points
- `normal`: display final solution, all input parameters, variable and constraint summaries, and new best points
- `quiet`: display final solution and all input parameters
- `silent`: display final solution

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the `hdf5` keyword, this method writes the following results to HDF5:

- [Best Parameters](#)
- [Best Objective Functions](#) (when `objective_functions` are specified)
- [Best Nonlinear Constraints](#)
- [Calibration](#) (when `calibration_terms` are specified)

`initial_delta`

- [Keywords Area](#)
- [method](#)
- [asynch_pattern_search](#)
- [initial_delta](#)

Initial step size for derivative-free optimizers

Specification

Alias: none

Argument(s): REAL

Default: 1.0

Description

The `initial_delta` keyword defines the size of the first search step in derivative-free optimization methods, specifically `asynch_pattern_search`, `coliny_cobyla`, `coliny_pattern_search`, `coliny_solis_wets`, and `mesh_adaptive_search`. It is applied in an absolute sense to all search directions.

Default Behavior

The default value is 1.0.

Usage Tips

It is recommended that `initial_delta` be the approximate distance from the initial point to the solution. If this distance is unknown, it is advisable to err on the side of choosing an `initial_delta` that is too large or to not specify it. Relative application of `initial_delta` is not available unless the user scales the problem accordingly.

Examples

Three example method input blocks appear below.

For `asynch_pattern_search`:

```
method
  asynch_pattern_search
    initial_delta = .5
    contraction_factor = 0.25
    merit_function merit1_smooth
    smoothing_factor = 1.0
    constraint_tolerance = 1.e-6
```

For `coliny_pattern_search`:

```
method
  coliny_pattern_search
    initial_delta = .2
    variable_tolerance = 1.e-4
    max_iterations 100
    solution_accuracy = 1.e-6
    seed = 1234
    max_function_evaluations = 1000
```

For `mesh_adaptive_search`

```
method
  mesh_adaptive_search
    initial_delta = 2.0
    seed = 1234
```

contraction_factor

- [Keywords Area](#)
- [method](#)
- [asynch_pattern_search](#)

- [contraction_factor](#)

Amount by which step length is rescaled

Specification

Alias: none

Argument(s): REAL

Default: 0.5

Description

For pattern search methods, `contraction_factor` specifies the amount by which step length is rescaled after unsuccessful iterates, must be strictly between 0 and 1.

For methods that can expand the step length, the expansion is $1/\text{contraction_factor}$

variable_tolerance

- [Keywords Area](#)
- [method](#)
- [asynch_pattern_search](#)
- [variable_tolerance](#)

Step length-based stopping criteria for derivative-free optimizers

Specification

Alias: none

Argument(s): REAL

Default: 0.01

Description

The `variable_tolerance` keyword defines the minimum step length allowed by the optimizer and is used to determine convergence. It is applicable to `asynch_pattern_search`, `coliny_cobyala`, `coliny_pattern_search`, `coliny_solis_wets`, and `mesh_adaptive_search`.

Default Behavior

The default value varies according to method as follows:

- `asynch_pattern_search`: 1.0e-2
- `coliny_cobyala`: 1.0e-4
- `coliny_pattern_search`: 1.0e-5
- `coliny_solis_wets`: 1.0e-6
- `mesh_adaptive_search`: 1.0e-6

Usage Tips

It is recommended that `variable_tolerance` be set to a value for which changes of that scale in parameter values cause negligible changes in the objective function.

Examples

Three example method input blocks appear below.

For `asynch_pattern_search`:

```
method
  asynch_pattern_search
    contraction_factor = 0.25
    variable_tolerance = 1.e-4
    solution_target = 1.e-6
    max_function_evaluations 500
    constraint_tolerance 1.e-6
```

For `coliny_pattern_search`:

```
method
  coliny_pattern_search
    initial_delta = .2
    variable_tolerance = 1.e-4
    max_iterations 100
    solution_accuracy = 1.e-6
    seed = 1234
    max_function_evaluations = 1000
```

For `mesh_adaptive_search`

```
method
  mesh_adaptive_search
    variable_tolerance = 0.01
    seed = 1234
```

solution_target

- [Keywords Area](#)
- [method](#)
- [asynch_pattern_search](#)
- [solution_target](#)

Stopping criteria based on objective function value

Specification

Alias: `solution_accuracy`

Argument(s): REAL

Default: no target

Description

`solution_target` is a termination criterion. The algorithm will terminate when the function value falls below `solution_target`.

synchronization

- [Keywords Area](#)
- [method](#)
- [asynch_pattern_search](#)
- [synchronization](#)

Select how Dakota schedules function evaluations in a pattern search

Specification

Alias: none

Argument(s): none

Default: nonblocking

Child Keywords:

	Required/ Optional Required (<i>Choose One</i>)	Description of Group Synchronization (Group 1)	Dakota Keyword blocking	Dakota Keyword Description Evaluate all points in a pattern
			nonblocking	Evaluate points in the pattern until an improving point is found

Description

The `synchronization` specification can be used to specify the use of either `blocking` or `nonblocking` schedulers.

blocking

- [Keywords Area](#)
- [method](#)
- [asynch_pattern_search](#)
- [synchronization](#)
- [blocking](#)

Evaluate all points in a pattern

Specification

Alias: none

Argument(s): none

Description

In the `blocking` case, all points in the pattern are evaluated (in parallel), and if the best of these trial points is an improving point, then it becomes the next iterate. These runs are reproducible, assuming use of the same seed in the stochastic case.

nonblocking

- [Keywords Area](#)
- [method](#)
- [asynch_pattern_search](#)
- [synchronization](#)
- [nonblocking](#)

Evaluate points in the pattern until an improving point is found

Specification

Alias: none

Argument(s): none

Description

In the `nonblocking` case, all points in the pattern may not be evaluated. The first improving point found becomes the next iterate. Since the algorithm steps will be subject to parallel timing variabilities, these runs will not generally be repeatable.

merit_function

- [Keywords Area](#)
- [method](#)
- [asynch_pattern_search](#)
- [merit_function](#)

Balance goals of reducing objective function and satisfying constraints

Specification

Alias: none

Argument(s): none

Default: `merit2_squared`

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description

			merit_max	Nonsmoothed merit function
	Required (<i>Choose One</i>)	Merit Function (Group 1)	merit_max_smooth	Smoothed merit function
			merit1	Nonsmoothed merit function
			merit1_smooth	Smoothed merit function
			merit2	Nonsmoothed merit function
			merit2_smooth	Smoothed merit function
			merit2_squared	Nonsmoothed merit function

Description

A `merit_function` is a function in constrained optimization that attempts to provide joint progress toward reducing the objective function and satisfying the constraints.

`merit_max`

- [Keywords Area](#)
- [method](#)
- [asynch_pattern_search](#)

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: Library default

Description

Sets the maximum allowable value of infeasibility that any constraint in an optimization problem may possess and still be considered to be satisfied.

If a constraint's violation is greater than this value then it is considered to be violated by the optimization algorithm. This specification gives some control over how tightly the constraints will be satisfied at convergence of the algorithm. However, if the value is set too small the algorithm may terminate with one or more constraints being violated.

Defaults

Defaults vary depending on the method.

- CONMIN optimizers: 1.0e-3
- DOT constrained optimizers: 3.0e-3

max_function_evaluations

- [Keywords Area](#)
- [method](#)
- [asynch_pattern_search](#)
- [max_function_evaluations](#)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

Default Behavior

Default value is 1000.

scaling

- [Keywords Area](#)
- [method](#)
- [asynch_pattern_search](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling

3. `auto` - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. `log` - logarithmic scaling

First, any characteristic values from the optional `*scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- `none`, `auto`, `log` - optional
- `value` - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100
```

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value" "value" "value"
primary_scales = 1 1 100
```

model_pointer

- [Keywords Area](#)
- [method](#)
- [asynch_pattern_search](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                    0.1 0.2 0.6
                    0.1 0.2 0.6

  sample_type lhs
  distribution cumulative

```

7.2.30 mesh_adaptive_search

- [Keywords Area](#)
- [method](#)
- [mesh_adaptive_search](#)

Finds optimal variable values using adaptive mesh-based search

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			initial_delta	Initial step size for derivative-free optimizers

	Optional	<code>variable_tolerance</code>	Step length-based stopping criteria for derivative-free optimizers
	Optional	<code>function_precision</code>	Specify the maximum precision of the analysis code responses
	Optional	<code>seed</code>	Seed of the random number generator
	Optional	<code>history_file</code>	Name of file where mesh adaptive search records all evaluation points.
	Optional	<code>display_format</code>	Information to be reported from mesh adaptive search's internal records.
	Optional	<code>variable_-neighborhood_-search</code>	Percentage of evaluations to do to escape local minima.
	Optional	<code>neighbor_order</code>	Number of dimensions in which to perturb categorical variables.
	Optional	<code>display_all_-evaluations</code>	Shows mesh adaptive search's internally held list of all evaluations

	Optional	use_surrogate	Surrogate model usage mode for mesh adaptive search
	Optional	max_iterations	Number of iterations allowed for optimizers and adaptive UQ methods
	Optional	max_function_ evaluations	Number of function evaluations allowed for optimizers
	Optional	scaling	Turn on scaling for variables, responses, and constraints
	Optional	model_pointer	Identifier for model block to be used by a method

Description

The mesh adaptive direct search algorithm[9] is a derivative-free generalized pattern search in which the set of points evaluated becomes increasingly dense, leading to good convergence properties. It can handle unconstrained problems as well as those with bound constraints and general nonlinear constraints. Furthermore, it can handle continuous, discrete, and categorical variables.

Default Behavior

By default, `mesh_adaptive_search` operates on design variables. The types of variables can be expanded through the use of the `active` keyword in the `variables` block in the Dakota input file. Categorical variables, however, must be limited to design variables.

Expected Outputs

The best objective function value achieved and associated parameter and constraint values can be found at the end of the Dakota output. The method's internally summarized iteration history will appear in the screen output by default, with the option to control the method's output through Dakota's output level. It also generates a history file containing a list of all function evaluations done.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the `hdf5` keyword, this method writes the following results to HDF5:

- [Best Parameters](#)
- [Best Objective Functions](#) (when `objective_functions` are specified)
- [Best Nonlinear Constraints](#)

- **Calibration** (when `calibration_terms` are specified)

Additional Discussion

The mesh adaptive direct search method is made available in Dakota through the NOMAD software[2], available to the public under the GNU LGPL from <http://www.gerad.ca/nomad>.

Examples

The following is an example of a Dakota input file that makes use of `mesh_adaptive_search` to optimize the textbook function.

```
method,
  mesh_adaptive_search
  seed = 1234

variables,
  continuous_design = 3
  initial_point    -1.0   1.5   2.0
  upper_bounds     10.0  10.0  10.0
  lower_bounds     -10.0 -10.0 -10.0
  descriptors      'x1'  'x2'  'x3'

interface,
  direct
  analysis_driver = 'text_book'

responses,
  objective_functions = 1
  no_gradients
  no_hessians
```

The best function value and associated parameters are found at the end of the Dakota output.

```
<<<<< Function evaluation summary: 674 total (674 new, 0 duplicate)
<<<<< Best parameters =
          1.0000000000e+00 x1
          1.0000000000e+00 x2
          1.0000000000e+00 x3
<<<<< Best objective function =
          1.0735377280e-52
<<<<< Best data captured at function evaluation 658
```

A NOMAD-generated iteration summary is also printed to the screen.

```

initial_delta

- [Keywords Area](#)
- [method](#)
- [mesh_adaptive_search](#)
- [initial_delta](#)

Initial step size for derivative-free optimizers

Specification

Alias: none

Argument(s): REAL

Default: 1.0

Description

The `initial_delta` keyword defines the size of the first search step in derivative-free optimization methods, specifically `asynch_pattern_search`, `coliny_cobyala`, `coliny_pattern_search`, `coliny_solis_wets`, and `mesh_adaptive_search`. It is applied in an absolute sense to all search directions.

Default Behavior

The default value is 1.0.

Usage Tips

It is recommended that `initial_delta` be the approximate distance from the initial point to the solution. If this distance is unknown, it is advisable to err on the side of choosing an `initial_delta` that is too large or to not specify it. Relative application of `initial_delta` is not available unless the user scales the problem accordingly.

Examples

Three example method input blocks appear below.

For `asynch_pattern_search`:

```
method
  asynch_pattern_search
    initial_delta = .5
    contraction_factor = 0.25
    merit_function merit1_smooth
    smoothing_factor = 1.0
    constraint_tolerance = 1.e-6
```

For `coliny_pattern_search`:

```
method
  coliny_pattern_search
    initial_delta = .2
    variable_tolerance = 1.e-4
    max_iterations 100
    solution_accuracy = 1.e-6
    seed = 1234
    max_function_evaluations = 1000
```

For `mesh_adaptive_search`

```
method
  mesh_adaptive_search
    initial_delta = 2.0
    seed = 1234
```

variable_tolerance

- [Keywords Area](#)
- [method](#)
- [mesh_adaptive_search](#)

- [variable_tolerance](#)

Step length-based stopping criteria for derivative-free optimizers

Specification

Alias: none

Argument(s): REAL

Default: 1.0e-6

Description

The `variable_tolerance` keyword defines the minimum step length allowed by the optimizer and is used to determine convergence. It is applicable to `asynch_pattern_search`, `coliny_cobyla`, `coliny_pattern_search`, `coliny_solis_wets`, and `mesh_adaptive_search`.

Default Behavior

The default value varies according to method as follows:

- `asynch_pattern_search`: 1.0e-2
- `coliny_cobyla`: 1.0e-4
- `coliny_pattern_search`: 1.0e-5
- `coliny_solis_wets`: 1.0e-6
- `mesh_adaptive_search`: 1.0e-6

Usage Tips

It is recommended that `variable_tolerance` be set to a value for which changes of that scale in parameter values cause negligible changes in the objective function.

Examples

Three example method input blocks appear below.

For `asynch_pattern_search`:

```
method
  asynch_pattern_search
    contraction_factor = 0.25
    variable_tolerance = 1.e-4
    solution_target = 1.e-6
    max_function_evaluations 500
    constraint_tolerance 1.e-6
```

For `coliny_pattern_search`:

```
method
  coliny_pattern_search
    initial_delta = .2
    variable_tolerance = 1.e-4
    max_iterations 100
    solution_accuracy = 1.e-6
    seed = 1234
    max_function_evaluations = 1000
```

For `mesh_adaptive_search`

```
method
  mesh_adaptive_search
    variable_tolerance = 0.01
    seed = 1234
```

function_precision

- [Keywords Area](#)
- [method](#)
- [mesh_adaptive_search](#)
- [function_precision](#)

Specify the maximum precision of the analysis code responses

Specification

Alias: none

Argument(s): REAL

Default: 1.0e-10

Description

The `function_precision` control provides the algorithm with an estimate of the accuracy to which the problem functions can be computed. This is used to prevent the algorithm from trying to distinguish between function values that differ by less than the inherent error in the calculation.

seed

- [Keywords Area](#)
- [method](#)
- [mesh_adaptive_search](#)
- [seed](#)

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)

Description

The random `seed` control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

history_file

- [Keywords Area](#)
- [method](#)
- [mesh_adaptive_search](#)
- [history_file](#)

Name of file where mesh adaptive search records all evaluation points.

Specification

Alias: none

Argument(s): STRING

Default: mads_history

Description

The `history_file` is used to specify the name of a file to which mesh adaptive direct search will write its own list of evaluated points.

Default Behavior

By default, mesh adaptive direct search will write the list of evaluation points in a file named `mads_history-xxxx`, where `xxxx` corresponds to a randomly generated number. Dakota's output level controls the method's level of output to file.

Examples

The example below shows the syntax for specifying the name of the history file.

```
method
  mesh_adaptive_search
    history_file = 'output.log'
    seed = 1234
```

display_format

- [Keywords Area](#)
- [method](#)
- [mesh_adaptive_search](#)
- [display_format](#)

Information to be reported from mesh adaptive search's internal records.

Specification

Alias: none

Argument(s): STRING

Description

The `display_format` keyword is used to specify the set of information to be reported by the mesh adaptive direct search method. This is information mostly internal to the method and not reported via Dakota output.

Default Behavior

By default, only the number of function evaluations (bbe) and the objective function value (obj) are reported. The full list of options is as follows. Note that case does not matter.

- BBE: Blackbox evaluations.
- BBO: Blackbox outputs.
- EVAL: Evaluations (includes cache hits).
- MESH_INDEX: Mesh index.
- MESH_SIZE: Mesh size parameter.
- OBJ: Objective function value.
- POLL_SIZE: Poll size parameter.
- SOL: Solution, with format iSOLj where i and j are two (optional) strings: i will be displayed before each coordinate, and j after each coordinate (except the last).
- STAT_AVG: The AVG statistic.
- STAT_SUM: The SUM statistic defined by argument.
- TIME: Wall-clock time.

- VAR*i*: Value of variable *i*. The index 0 corresponds to the first variable.

Expected Outputs

A list of the requested information will be printed to the screen.

Usage Tips

This will most likely only be useful for power users who want to understand and/or report more detailed information on method behavior.

Examples

The following example shows the syntax for specifying `display_format`. Note that all desired information options should be listed within a single string.

```
method
  mesh_adaptive_search
  display_format 'bbe obj poll_size'
  seed = 1234
```

Below is the output reported for the above example.

```
MADS run {
  BBE OBJ POLL_SIZE

variable_neighborhood_search

- [Keywords Area](#)
- [method](#)
- [mesh_adaptive_search](#)
- [variable_neighborhood_search](#)

Percentage of evaluations to do to escape local minima.

Specification

Alias: none

Argument(s): REAL

Default: 0.0

Description

The `variable_neighborhood_search` keyword is used to set the percentage (in decimal form) of function evaluations used to escape local minima. The mesh adaptive direct search method will try to perform a maximum of that percentage of the function evaluations within this more extensive search.

Default Behavior

By default, `variable_neighborhood_search` is not used.

Usage Tips

Using `variable_neighborhood_search` results in an increased number of function evaluations. If the desired result is a local minimum, the added cost is of little or no value, so the recommendation is not to use it. If the desired result is the best local minimum possible within a computational budget, then there is value in setting this parameter. Note that the higher the value, the greater the computational cost. The value should be no greater than 1.0.

Examples

The following example shows the syntax used to set `variable_neighborhood_search`.

```
method
  mesh_adaptive_search
  seed = 1234
  variable_neighborhood_search = 0.1
```

neighbor_order

- [Keywords Area](#)
- [method](#)
- [mesh_adaptive_search](#)
- [neighbor_order](#)

Number of dimensions in which to perturb categorical variables.

Specification

Alias: none

Argument(s): INTEGER

Description

The `neighbor_order` keyword allows the user to specify the number of categorical dimensions to perturb when determining neighboring points that will be used by the mesh adaptive direct search method to augment its search. When greater than 1, the neighbors are defined from the tensor product of the admissible 1-dimensional perturbations.

Default Behavior

By default, the categorical neighbors will be defined by perturbing only one categorical variable at a time (according to the corresponding `adjacency_matrix`; see [adjacency_matrix](#)) while leaving the others fixed at their current values.

Usage Tips

The maximum meaningful value `neighbor_order` can take on is the number of categorical variables.

Examples

In this example, suppose we have the following categorical variables and associated adjacency matrices.

```
variables
  discrete_design_set
    real = 2
    categorical yes yes
    num_set_values = 3 5
    set_values = 1.2 2.3 3.4
                1.2 3.3 4.4 5.5 7.7
    adjacency_matrix = 1 1 0
                      1 1 1
                      0 1 1
                      1 0 1 0 1
                      0 1 0 1 0
                      1 0 1 0 1
                      0 1 0 1 0
                      1 0 1 0 1
```

Also suppose that we have the following method specification.

```
method
  mesh_adaptive_search
    seed = 1234
```

If the mesh adaptive direct search is at the point (1.2, 1.2), then the neighbors will be defined by the default 1-dimensional perturbations and would be the following:

```
(2.3, 1.2)
(1.2, 4.4)
(1.2, 7.7)
```

If, instead, the method specification is the following:

```
method
  mesh_adaptive_search
    seed = 1234
    neighbor_order = 2
```

The neighbors will be defined by 2-dimensional perturbations defined from the tensor product of the 1-dimensional perturbation and would be the following:

```
(2.3, 1.2)
(2.3, 4.4)
(2.3, 7.7)
(1.2, 4.4)
(1.2, 7.7)
```

- [method](#)
- [mesh_adaptive_search](#)
- [display_all_evaluations](#)

Shows mesh adaptive search's internally held list of all evaluations

Specification

Alias: none

Argument(s): none

Default: false

Description

If set, `display_all_evaluations` will instruct the mesh adaptive direct search method to print out its own record of all evaluations. The information reported may be controlled using [display_format](#).

Default Behavior

By default, mesh adaptive direct search does not report information on all evaluations, only on those for which an improvement in the objective function is found.

Expected Outputs

The information specified by `display_format` will be reported to the screen for every function evaluation.

Usage Tips

This will most likely only be useful for power users who want to understand and/or report more detailed information on method behavior.

Examples

The following example shows the syntax for specifying `display_all_evaluations`.

```
method
  mesh_adaptive_search
  display_all_evaluations
  max_function_evaluations=20
  seed = 1234
```

Note that the output below reports information (default for `display_format`) for all function evaluations.

```
MADS run {

  BBE OBJ

  1  17.0625000000
  2  1.0625000000
  3  1297.0625000000
  4  257.0625000000
  5  81.0625000000
  6  151.0625000000
  7  1051.0625000000
  8  40.0625000000
  9  17.0625000000
```

```

10 40.0625000000
11 1.0625000000
12 102.0625000000
13 0.0625000000
14 231.0625000000
15 16.0625000000
16 5.0625000000
17 16.0625000000
18 71.0625000000
19 0.0625000000
20 1.0625000000

} end of run (max number of blackbox evaluations)

blackbox evaluations          : 20
best feasible solution      : ( 1 0.5 1 ) h=0 f=0.0625

```

That is in contrast with what would be reported by default.

```

MADS run {

  BBE OBJ

  1 17.0625000000
  2 1.0625000000
 13 0.0625000000
 20 0.0625000000

} end of run (max number of blackbox evaluations)

blackbox evaluations          : 20
best feasible solution      : ( 1 0.5 1 ) h=0 f=0.0625

```

- [use_surrogate](#)

Surrogate model usage mode for mesh adaptive search

Specification

Alias: none

Argument(s): none

Default: optimize

Child Keywords:

	Required/ Optional Required(Choose One)	Description of Group Surrogate Purpose (Group 1)	Dakota Keyword <code>inform_search</code>	Dakota Keyword Description Surrogate informs evaluation order in mesh adaptive search
			<code>optimize</code>	Surrogate is used in lieu of true model for mesh adaptive search

Description

The `use_surrogate` keyword is used to define how a surrogate model (if one is provided) is to be used by `mesh_adaptive_search`. There are two approaches available: `inform_search` uses the surrogate to sort list of trial points and subsequently the true function is evaluated on the most promising points first. Both true function and surrogate are used interchangeably within the method. `optimize` forces the use of a surrogate in lieu of the true model and thus the true function is never invoked except to construct the surrogate.

Known Issue: When using discrete variables, there have been sometimes significant differences in surrogate behavior observed across computing platforms in some cases. The cause has not yet been fully diagnosed and is currently under investigation. In addition, guidance on appropriate construction and use of surrogates with discrete variables is under development. In the meantime, users should therefore be aware that there is a risk of inaccurate results when using surrogates with discrete variables.

Default Behavior

By default, `mesh_adaptive_search` follows behaviour provided by `optimize` option.

Examples

The following example shows the syntax used to set `use_surrogate`.

```
method,
  mesh_adaptive_search
  model_pointer = 'SURROGATE'
  use_surrogate inform_search

model,
  id_model = 'SURROGATE'
  surrogate global
  polynomial quadratic
  dace_method_pointer = 'SAMPLING'

variables,
  continuous_design = 3
  initial_point      -1.0    1.5    2.0
  upper_bounds       10.0   10.0   10.0
  lower_bounds       -10.0  -10.0 -10.0
  descriptors         'x1'   'x2'   'x3'

    no_hessians

```

inform_search

- [Keywords Area](#)
- [method](#)
- [mesh_adaptive_search](#)
- [use_surrogate](#)
- [inform_search](#)

Surrogate informs evaluation order in mesh adaptive search

Specification

Alias: none

Argument(s): none

Description

When `inform_search` is specified with `use_surrogate`, `mesh_adaptive_search` uses the surrogate to sort list of trial points and subsequently the true function is evaluated on the most promising points first. Both true function and surrogate are used interchangeably within the method.

Default Behavior

`inform_search` is not the default surrogate usage mode.

Expected Output

The user can expect to see both the number of true model evaluations and the number of approximation (i.e., surrogate) evaluations reported in the Dakota screen output. The former captures the sum of truth evaluations done for the surrogate construction and for the optimization.

Usage Tips

When `inform_search` is specified, the `maximum_function_evaluations` keyword applies to only the optimization method and does not account for evaluations needed to construct the surrogate. If the user has a strict evaluation budget, they should set `maximum_function_evaluations` such that `evaluation budget = number of evaluations to construct surrogate + maximum_function_evaluations`.

Examples

The following example shows the syntax used to set `use_surrogate` to optimize.

```
method,
  mesh_adaptive_search
  model_pointer = 'SURROGATE'
  use_surrogate inform_search

model,
  id_model = 'SURROGATE'
  surrogate global
  polynomial quadratic
  dace_method_pointer = 'SAMPLING'

variables,
  continuous_design = 3
    initial_point   -1.0   1.5   2.0
    upper_bounds    10.0  10.0  10.0
    lower_bounds    -10.0 -10.0 -10.0
    descriptors     'x1'  'x2'  'x3'
  discrete_design_range = 2
    initial_point   2     2
    lower_bounds    1     1
    upper_bounds    4     9
    descriptors     'y1'  'y2'
  discrete_design_set
    real = 2
      elements_per_variable = 4 5
      elements = 1.2 2.3 3.4 4.5 1.2 3.3 4.4 5.5 7.7
      descriptors     'y3'  'y4'
    integer = 2
      elements_per_variable = 2 2
      elements = 4 7 8 9
      descriptors     'z1'  'z2'

method,
  id_method = 'SAMPLING'
  model_pointer = 'TRUTH'
  sampling
  samples = 55

model,
  id_model = 'TRUTH'
  single
  interface_pointer = 'TRUE_FN'

interface,
  id_interface = 'TRUE_FN'
  direct
  analysis_driver = 'text_book'
```

```
responses,
  objective_functions = 1
  no_gradients
  no_hessians
```

The following will appear toward the end of the screen output when Dakota is run on this example. The number of true function evaluations includes the 55 evaluations that were done to construct the surrogate (as specified in the SAMPLING method block) plus the number of truth evaluations done by `mesh_adaptive_search`.

```
<<<<< Function evaluation summary (APPROX_INTERFACE): 1660 total (1660 new, 0 duplicate)
<<<<< Function evaluation summary (TRUE_FN): 795 total (795 new, 0 duplicate)
```

optimize

- [Keywords Area](#)
- [method](#)
- [mesh_adaptive_search](#)
- [use_surrogate](#)
- [optimize](#)

Surrogate is used in lieu of true model for mesh adaptive search

Specification

Alias: none

Argument(s): none

Description

When `optimize` is specified with `use_surrogate`, `mesh_adaptive_search` will use the surrogate in lieu of the true model and thus the true function is never invoked except to construct the surrogate.

Default Behavior

`optimize` is the default surrogate usage mode.

Expected Output

The user can expect to see both the number of true model evaluations and the number of approximation (i.e., surrogate) evaluations reported in the Dakota screen output. The former should equal the number of truth evaluations done for the surrogate construction.

Examples

The following example shows the syntax used to set `use_surrogate` to `optimize`.

```
method,
  mesh_adaptive_search
  model_pointer = 'SURROGATE'
  use_surrogate optimize

model,
  id_model = 'SURROGATE'
  surrogate global
```

```

- [max.iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: fsu_cvt, local_reliability: 25; global_{reliability, interval_est, evidence} / efficient-global: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_`
`iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

`max_function_evaluations`

- [Keywords Area](#)
- [method](#)
- [mesh_adaptive_search](#)
- [max_function_evaluations](#)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

Default Behavior

Default value is 1000.

scaling

- [Keywords Area](#)
- [method](#)
- [mesh_adaptive_search](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*_scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling
3. `auto` - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. `log` - logarithmic scaling

First, any characteristic values from the optional `*_scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*_scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- `none`, `auto`, `log` - optional
- `value` - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100

responses
objective_functions 3
sense "maximize"
primary_scale_types = "value" "value" "value"
primary_scales = 1 1 100
```

model_pointer

- [Keywords Area](#)
- [method](#)
- [mesh_adaptive_search](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'

7.2.31 nowpac

- [Keywords Area](#)
- [method](#)
- [nowpac](#)

Gradient-free inequality-constrained optimization using Nonlinear Optimization With Path Augmented Constraints (NOWPAC).

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			trust_region	Use trust region as the globalization strategy.

	Optional	max_iterations	Number of iterations allowed for optimizers and adaptive UQ methods
	Optional	max_function_ evaluations	Number of function evaluations allowed for optimizers
	Optional	scaling	Turn on scaling for variables, responses, and constraints
	Optional	model_pointer	Identifier for model block to be used by a method

Description

NOWPAC is a provably-convergent gradient-free optimization method from MIT that solves a series of trust region surrogate-based subproblems to generate improving steps. Due to its use of an interior penalty scheme and enforcement of strict feasibility, it does not support linear or nonlinear *equality* constraints. As opposed to the stochastic version (SNOWPAC), NOWPAC does not currently support a feasibility restoration mode, so it is necessary to start from a feasible design.

Note: (S)NOWPAC is not configured with Dakota by default and requires a separate installation of the NOWPAC distribution from MIT, combined with its TPLs of Eigen and NLOPT.

Examples

```
method
  nowpac
    max_function_evaluations = 1000
    convergence_tolerance = 1e-4
    trust_region
      initial_size = 0.10
      minimum_size = 1.0e-6
      contract_threshold = 0.25
      expand_threshold   = 0.75
      contraction_factor = 0.50
      expansion_factor   = 1.50
```

trust_region

- [Keywords Area](#)
- [method](#)
- [nowpac](#)
- [trust_region](#)

Use trust region as the globalization strategy.

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			initial_size	Trust region initial size (relative to bounds)
	Optional		minimum_size	Trust region minimum size
	Optional		contract_threshold	Shrink trust region if trust region ratio is below this value
	Optional		expand_threshold	Expand trust region if trust region ratio is above this value
	Optional		contraction_factor	Amount by which step length is rescaled
	Optional		expansion_factor	Trust region expansion factor

Description

The `trust_region` optional group specification can be used to specify the initial size of the trust region (using `initial_size`) relative to the total variable bounds, the minimum size of the trust region (using `minimum_size`), the contraction factor for the trust region size (using `contraction_factor`) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using `expansion_factor`) used when the the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using `contract_threshold`) and the trust region size expansion threshold (using `expand_threshold`). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command `contract_threshold` sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command `expand_threshold` determines the trust region value above which the trust region will expand for the next SBL iteration.

`initial_size`

- [Keywords Area](#)
- [method](#)
- [nowpac](#)
- [trust_region](#)

- [initial_size](#)

Trust region initial size (relative to bounds)

Specification

Alias: none

Argument(s): REALLIST

Description

The `trust_region` optional group specification can be used to specify the initial size of the trust region (using `initial_size`) relative to the total variable bounds, the minimum size of the trust region (using `minimum_size`), the contraction factor for the trust region size (using `contraction_factor`) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using `expansion_factor`) used when the the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using `contract_threshold`) and the trust region size expansion threshold (using `expand_threshold`). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command `contract_threshold` sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command `expand_threshold` determines the trust region value above which the trust region will expand for the next SBL iteration.

All of these specifications are REAL scalars, with the exception of the specification of `initial_size`, which is a REALLIST. This array corresponds to the case when there are more than 2 model forms or discretizations within a model hierarchy. The default `initial_size` involves a recursive halving of the global bounds for each trust region in the hierarchy: e.g., a scalar value of .5 for a single trust region managing two model forms/discretizations, or an array of (.125, .25, .5) for four model forms/discretizations (three trust regions ordered from the lowest to highest fidelity surrogate, with model four as truth).

minimum_size

- [Keywords Area](#)
- [method](#)
- [nowpac](#)

- [minimum_size](#)

Trust region minimum size

Specification

Alias: none

Argument(s): REAL

Default: 1.e-6

Description

The `trust_region` optional group specification can be used to specify the initial size of the trust region (using `initial_size`) relative to the total variable bounds, the minimum size of the trust region (using `minimum_size`), the contraction factor for the trust region size (using `contraction_factor`) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using `expansion_factor`) used when the the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using `contract_threshold`) and the trust region size expansion threshold (using `expand_threshold`). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command `contract_threshold` sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command `expand_threshold` determines the trust region value above which the trust region will expand for the next SBL iteration.

`contract_threshold`

- [Keywords Area](#)
- [method](#)
- [nowpac](#)
- [trust_region](#)
- [contract_threshold](#)

Shrink trust region if trust region ratio is below this value

Specification

Alias: none

Argument(s): REAL

Default: 0.25

Description

The `trust_region` optional group specification can be used to specify the initial size of the trust region (using `initial_size`) relative to the total variable bounds, the minimum size of the trust region (using `minimum_size`), the contraction factor for the trust region size (using `contraction_factor`) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using `expansion_factor`) used when the the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using `contract_threshold`) and the trust region size expansion threshold (using `expand_threshold`). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command `contract_threshold` sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command `expand_threshold` determines the trust region value above which the trust region will expand for the next SBL iteration.

expand_threshold

- [Keywords Area](#)
- [method](#)
- [nowpac](#)
- [trust_region](#)
- [expand_threshold](#)

Expand trust region if trust region ratio is above this value

Specification

Alias: none

Argument(s): REAL

Default: 0.75

Description

The `trust_region` optional group specification can be used to specify the initial size of the trust region (using `initial_size`) relative to the total variable bounds, the minimum size of the trust region (using `minimum_size`), the contraction factor for the trust region size (using `contraction_factor`) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using `expansion_factor`) used when the the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using `contract_threshold`) and the trust region size expansion threshold (using `expand_threshold`). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command `contract_threshold` sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command `expand_threshold` determines the trust region value above which the trust region will expand for the next SBL iteration.

contraction_factor

- [Keywords Area](#)
- [method](#)
- [nowpac](#)
- [trust_region](#)
- [contraction_factor](#)

Amount by which step length is rescaled

Specification

Alias: none

Argument(s): REAL

Default: 0.25

Description

For pattern search methods, `contraction_factor` specifies the amount by which step length is rescaled after unsuccessful iterates, must be strictly between 0 and 1.

For methods that can expand the step length, the expansion is $1/\text{contraction_factor}$

expansion_factor

- [Keywords Area](#)
- [method](#)
- [nowpac](#)
- [trust_region](#)
- [expansion_factor](#)

Trust region expansion factor

Specification

Alias: none

Argument(s): REAL

Default: 2.0

Description

The `trust_region` optional group specification can be used to specify the initial size of the trust region (using `initial_size`) relative to the total variable bounds, the minimum size of the trust region (using `minimum_size`), the contraction factor for the trust region size (using `contraction_factor`) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using `expansion_factor`) used when the the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using `contract_threshold`) and the trust region size expansion threshold (using `expand_threshold`). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command `contract_threshold` sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command `expand_threshold` determines the trust region value above which the trust region will expand for the next SBL iteration.

max_iterations

- [Keywords Area](#)
- [method](#)
- [nowpac](#)
- [max_iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: fsu_cvt, local_reliability: 25; global_{reliability, interval_est, evidence} / efficient-global: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_``iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

max_function_evaluations

- [Keywords Area](#)
- [method](#)
- [nowpac](#)
- [max_function_evaluations](#)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

Default Behavior

Default value is 1000.

scaling

- [Keywords Area](#)
- [method](#)
- [nowpac](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling

3. `auto` - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. `log` - logarithmic scaling

First, any characteristic values from the optional `*scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- `none`, `auto`, `log` - optional
- `value` - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100
```

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value" "value" "value"
primary_scales = 1 1 100
```

7.2.32 snowpac

- [Keywords Area](#)
- [method](#)
- [snowpac](#)

Stochastic version of NOWPAC that incorporates error estimates and noise mitigation.

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			seed	Seed of the random number generator

	Optional	trust_region	Use trust region as the globalization strategy.
	Optional	max_iterations	Number of iterations allowed for optimizers and adaptive UQ methods
	Optional	max_function_ - evaluations	Number of function evaluations allowed for optimizers
	Optional	scaling	Turn on scaling for variables, responses, and constraints
	Optional	model_pointer	Identifier for model block to be used by a method

Description

NOWPAC is a provably-convergent gradient-free optimization method from MIT that solves a series of trust region surrogate-based subproblems to generate improving steps. The stochastic version is SNOWPAC, which incorporates noise estimates in its objective and inequality constraints. SNOWPAC modifies its trust region controls and adds smoothing from a Gaussian process surrogate in order to mitigate noise. SNOWPAC also supports a feasibility restoration mode, so it is not necessary to start from a feasible design.

Note: (S)NOWPAC is not configured with Dakota by default and requires a separate installation of the NOWPAC distribution from MIT, combined with its TPLs of Eigen and NLOPT.

Examples

Relative to the NOWPAC specification, SNOWPAC supports a seed control for repeatability of runs and also requires the return of error estimates from the underlying evaluator (e.g., UQ method such as Monte Carlo sampling).

```
method,
  snowpac
    seed = 2504
    max_function_evaluations = 1000
    convergence_tolerance = 1e-4
    trust_region
      initial_size = 0.10
      minimum_size = 1.0e-6
      contract_threshold = 0.25
      expand_threshold = 0.75
      contraction_factor = 0.50
      expansion_factor = 1.50
```

seed

- [Keywords Area](#)
- [method](#)
- [snowpac](#)
- [seed](#)

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)

Description

The random `seed` control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

trust_region

- [Keywords Area](#)
- [method](#)
- [snowpac](#)
- [trust_region](#)

Use trust region as the globalization strategy.

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		initial_size	Trust region initial size (relative to bounds)
	Optional		minimum_size	Trust region minimum size
	Optional		contract_threshold	Shrink trust region if trust region ratio is below this value
	Optional		expand_threshold	Expand trust region if trust region ratio is above this value
	Optional		contraction_factor	Amount by which step length is rescaled
	Optional		expansion_factor	Trust region expansion factor

Description

The `trust_region` optional group specification can be used to specify the initial size of the trust region (using `initial_size`) relative to the total variable bounds, the minimum size of the trust region (using `minimum_size`), the contraction factor for the trust region size (using `contraction_factor`) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using `expansion_factor`) used when the the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using `contract_threshold`) and the trust region size expansion threshold (using `expand_threshold`). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command `contract_threshold` sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command `expand_threshold` determines the trust region value above which the trust region will expand for the next SBL iteration.

Default: 0.25

Description

The `trust_region` optional group specification can be used to specify the initial size of the trust region (using `initial_size`) relative to the total variable bounds, the minimum size of the trust region (using `minimum_size`), the contraction factor for the trust region size (using `contraction_factor`) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using `expansion_factor`) used when the the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using `contract_threshold`) and the trust region size expansion threshold (using `expand_threshold`). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command `contract_threshold` sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command `expand_threshold` determines the trust region value above which the trust region will expand for the next SBL iteration.

expand_threshold

- [Keywords Area](#)
- [method](#)
- [snowpac](#)
- [trust_region](#)
- [expand_threshold](#)

Expand trust region if trust region ratio is above this value

Specification

Alias: none

Argument(s): REAL

Default: 0.75

Description

The `trust_region` optional group specification can be used to specify the initial size of the trust region (using `initial_size`) relative to the total variable bounds, the minimum size of the trust region (using `minimum_size`), the contraction factor for the trust region size (using `contraction_factor`) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using `expansion_factor`) used when the the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using `contract_threshold`) and the trust region size expansion threshold (using `expand_threshold`). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command `contract_threshold` sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command `expand_threshold` determines the trust region value above which the trust region will expand for the next SBL iteration.

`contraction_factor`

- [Keywords Area](#)
- [method](#)
- [snowpac](#)
- [trust_region](#)
- [contraction_factor](#)

Amount by which step length is rescaled

Specification

Alias: none

Argument(s): REAL

Default: 0.25

Description

For pattern search methods, `contraction_factor` specifies the amount by which step length is rescaled after unsuccessful iterates, must be strictly between 0 and 1.

For methods that can expand the step length, the expansion is $1/\text{contraction_factor}$

`expansion_factor`

- [Keywords Area](#)
- [method](#)
- [snowpac](#)
- [trust_region](#)
- [expansion_factor](#)

Trust region expansion factor

Specification

Alias: none

Argument(s): REAL

Default: 2.0

Description

The `trust_region` optional group specification can be used to specify the initial size of the trust region (using `initial_size`) relative to the total variable bounds, the minimum size of the trust region (using `minimum_size`), the contraction factor for the trust region size (using `contraction_factor`) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using `expansion_factor`) used when the the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using `contract_threshold`) and the trust region size expansion threshold (using `expand_threshold`). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command `contract_threshold` sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command `expand_threshold` determines the trust region value above which the trust region will expand for the next SBL iteration.

max.iterations

- [Keywords Area](#)
- [method](#)
- [snowpac](#)
- [max.iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method.independent.controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: `fsu_cvt`, `local_reliability`: 25; `global_{reliability, interval_est, evidence}` / `efficient-global`: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

max_function_evaluations

- [Keywords Area](#)
- [method](#)
- [snowpac](#)
- [max_function_evaluations](#)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

Default Behavior

Default value is 1000.

scaling

- [Keywords Area](#)
- [method](#)
- [snowpac](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*_scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling
3. `auto` - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. `log` - logarithmic scaling

First, any characteristic values from the optional `*_scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*_scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- none, auto, log - optional
- value - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100

responses
objective_functions 3
sense "maximize"
primary_scale_types = "value" "value" "value"
primary_scales = 1 1 100
```

model_pointer

- [Keywords Area](#)
- [method](#)
- [snowpac](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last `model` block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                    0.1 0.2 0.6
                    0.1 0.2 0.6
    sample_type lhs
    distribution cumulative

model
  id_model = 'SURR'
  surrogate global,
  dace_method_pointer = 'DACE'
  polynomial quadratic

method
  id_method = 'DACE'
  model_pointer = 'DACE_M'
  sampling sample_type lhs
  samples = 121 seed = 5034 rng rnum2

model
  id_model = 'DACE_M'
  single
  interface_pointer = 'I1'

variables
  uniform_uncertain = 2
  lower_bounds = 0. 0.
  upper_bounds = 1. 1.
  descriptors = 'x1' 'x2'

interface
  id_interface = 'I1'
  system async evaluation_concurrency = 5
  analysis_driver = 'text_book'

responses
```

```

response_functions = 3
no_gradients
no_hessians

```

	Optional	<code>model_pointer</code>	Identifier for model block to be used by a method

Description

`moga` stands for Multi-objective Genetic Algorithm, which is a global optimization method that does Pareto optimization for multiple objectives. It supports general constraints and a mixture of real and discrete variables.

Constraints

`moga` can utilize linear constraints using the keywords: `-* linear_inequality_constraint_matrix` `-* linear_inequality_lower_bounds` `-* linear_inequality_upper_bounds` `-* linear_inequality_scale_types` `-* linear_inequality_scales` `-* linear_equality_constraint_matrix` `-* linear_equality_targets` `-* linear_equality_scale_types` `-* linear_equality_scales`

Configuration

The genetic algorithm configurations are:

1. fitness
2. replacement
3. niching
4. convergence
5. postprocessor
6. initialization
7. crossover
8. mutation
9. population size

The steps followed by the algorithm are listed below. The configurations will effect how the algorithm completes each step.

Stopping Criteria

The `moga` method respects the `max_iterations` and `max_function_evaluations` method independent controls to provide integer limits for the maximum number of generations and function evaluations, respectively.

The algorithm also stops when convergence is reached. This involves repeated assessment of the algorithm's progress in solving the problem, until some criterion is met.

The specification for convergence in a `moga` can either be `metric_tracker` or can be omitted all together. If omitted, no convergence algorithm will be used and the algorithm will rely on stopping criteria only.

Expected Outputs

The `moga` method respects the `output` method independent control to vary the amount of information presented to the user during execution.

The final results are written to the Dakota tabular output. Additional information is also available - see the `log_file` and `print_each_pop` keywords.

Note that `moga` and `SOGA` create additional output files during execution. "finaldata.dat" is a file that holds the final set of Pareto optimal solutions after any post-processing is complete. "discards.dat" holds solutions that were discarded from the population during the course of evolution.

It can often be useful to plot objective function values from these files to visually see the Pareto front and ensure that finaldata.dat solutions dominate discards.dat solutions. The solutions are written to these output files in the format "Input1...InputN..Output1...OutputM".

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the `hdf5` keyword, this method writes the following results to HDF5:

- [Best Parameters](#)
- [Best Objective Functions](#) (when `objective_functions` are specified)
- [Best Nonlinear Constraints](#)
- [Calibration](#) (when `calibration_terms` are specified)

Important Notes

The pool of potential members is the current population and the current set of offspring.

Choice of fitness assessors is strongly related to the type of replacement algorithm being used and can have a profound effect on the solutions selected for the next generation.

If using the fitness types `layer_rank` or `domination_count`, it is strongly recommended that you use the `replacement_type` `below_limit` (although the roulette wheel selectors can also be used).

The functionality of the `domination_count` selector of JEGA v1.0 can now be achieved using the `domination_count` fitness type and `below_limit` replacement type.

Theory

The basic steps of the `moga` algorithm are as follows:

1. Initialize the population
2. Evaluate the population (calculate the values of the objective function and constraints for each population member)
3. Loop until converged, or stopping criteria reached
 - (a) Perform crossover
 - (b) Perform mutation
 - (c) Evaluate the new population
 - (d) Assess the fitness of each member in the population
 - (e) Replace the population with members selected to continue in the next generation
 - (f) Apply niche pressure to the population
 - (g) Test for convergence
4. Perform post processing

If `moga` is used in a hybrid optimization method (which requires one optimal solution from each individual optimization method to be passed to the subsequent optimization method as its starting point), the solution in the Pareto set closest to the "utopia" point is given as the best solution. This solution is also reported in the Dakota output.

This "best" solution in the Pareto set has minimum distance from the utopia point. The utopia point is defined as the point of extreme (best) values for each objective function. For example, if the Pareto front is bounded by (1,100) and (90,2), then (1,2) is the utopia point. There will be a point in the Pareto set that has minimum L2-norm distance to this point, for example (10,10) may be such a point.

If `moga` is used in a method which may require passing multiple solutions to the next level (such as the `surrogate_based_global` method or `hybrid` methods), the `orthogonal_distance` postprocessor type may be used to specify the distances between each solution value to winnow down the solutions in the full Pareto front to a subset which will be passed to the next iteration.

Argument(s): none

Default: domination_count

Child Keywords:

	Required/- Optional Required (<i>Choose One</i>)	Description of Group Fitness Type (Group 1)	Dakota Keyword	Dakota Keyword Description
			layer_rank	Assign each member to a layer, based on domination the rank based on layers
			domination_count	Rank each member by the number of members that dominate it

Description

The two JEGA methods use different fitness types, which are described on their respective pages.

layer_rank

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [fitness_type](#)
- [layer_rank](#)

Assign each member to a layer, based on domination the rank based on layers

Specification

Alias: none

Argument(s): none

Description

The `fitness_type: layer_rank` has been specifically designed to avoid problems with aggregating and scaling objective function values and transforming them into a single objective.

The `layer_rank` fitness assessor works by assigning all non-dominated designs a layer of 0, then from what remains, assigning all the non-dominated a layer of 1, and so on until all designs have been assigned a layer. The values are negated to follow the higher-is-better fitness convention.

Use of the `below_limit` selector with the `layer_rank` fitness assessor has the effect of keeping all those designs whose layer is below a certain threshold again subject to the shrinkage limit.

domination_count

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [fitness_type](#)
- [domination_count](#)

Rank each member by the number of members that dominate it

Specification

Alias: none

Argument(s): none

Description

The `fitness_type: domination_count` has been specifically designed to avoid problems with aggregating and scaling objective function values and transforming them into a single objective.

Instead, the `domination_count` fitness assessor works by ordering population members by the negative of the number of designs that dominate them. The values are negated in keeping with the convention that higher fitness is better.

The `layer_rank` fitness assessor works by assigning all non-dominated designs a layer of 0, then from what remains, assigning all the non-dominated a layer of 1, and so on until all designs have been assigned a layer. Again, the values are negated for the higher-is-better fitness convention.

Use of the `below_limit` selector with the `domination_count` fitness assessor has the effect of keeping all designs that are dominated by fewer than a limiting number of other designs subject to the shrinkage limit.

Using it with the `layer_rank` fitness assessor has the effect of keeping all those designs whose layer is below a certain threshold again subject to the shrinkage limit.

replacement_type

Select a replacement type for JEGA methods

Specification

Alias: none

Argument(s): none

Default: `below_limit`

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required(<i>Choose One</i>)	Replacement Type (Group 1)	<code>elitist</code>	Use the best designs to form a new population
			<code>roulette_wheel</code>	Replace population
			<code>unique_roulette_wheel</code>	Replace population
			<code>below_limit</code>	Limit number of designs dominating those kept

Description

Replace the population with members selected to continue in the next generation. The pool of potential members is the current population and the current set of offspring. The `replacement_type` of `roulette_wheel` or `unique_roulette_wheel` may be used either with MOGA or SOGA problems however they are not recommended for use with MOGA. Given that the only two fitness assessors for MOGA are the `layer_rank` and `domination_count`, the recommended selector is the `below_limit` selector. The `below_limit` replacement will only keep designs that are dominated by fewer than a limiting number of other designs.

In `roulette_wheel` replacement, each design is conceptually allotted a portion of a wheel proportional to its fitness relative to the fitnesses of the other Designs. Then, portions of the wheel are chosen at random and the design occupying those portions are duplicated into the next population. Those Designs allotted larger portions of the wheel are more likely to be selected (potentially many times). `unique_roulette_wheel` replacement is the same as `roulette_wheel` replacement, with the exception that a design may only be selected once. The `below_limit` selector attempts to keep all designs for which the negated fitness is below a certain limit. The values are negated to keep with the convention that higher fitness is better. The inputs to the `below_limit` selector are the limit as a real value, and a `shrinkage_percentage` as a real value. The `shrinkage_percentage` defines the minimum amount of selections that will take place if enough designs are available. It is interpreted as a percentage of the population size that must go on to the subsequent generation. To enforce this, `below_limit` makes all the selections it would make anyway and if that is not enough, it takes the remaining that it needs from the best of what is left (effectively raising its limit as far as it must to get the minimum number of selections). It continues until it has made enough selections. The `shrinkage_percentage` is designed to prevent extreme decreases in the population size at any given generation, and thus prevent a big loss of genetic diversity in a very short time. Without a shrinkage limit, a small group of "super" designs may appear and quickly cull the population down to a size on the order of the limiting value. In this case, all the diversity of the population is lost and it is expensive to re-diversify and spread the population. The

The `replacement_type` for a SOGA may be `roulette_wheel`, `unique_roulette_wheel`, `elitist`, or `favor_feasible`. The `elitist` selector simply chooses the required number of designs taking the most fit. For example, if 100 selections are requested, then the top 100 designs as ranked by fitness will be selected and the remaining will be discarded. The `favor_feasible` replacement type first considers feasibility as a selection criteria. If that does not produce a "winner" then it moves on to considering fitness value. Because of this, any fitness assessor used with the `favor_feasible` selector must only account objectives in the creation of fitness. Therefore, there is such a fitness assessor and it's use is enforced when the `favor_feasible` selector

is chosen. In that case, and if the output level is set high enough, a message will be presented indicating that the `weighted_sum_only` fitness assessor will be used.

elitist

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [replacement_type](#)
- [elitist](#)

Use the best designs to form a new population

Specification

Alias: none

Argument(s): none

Description

The `elitist` (default) setting creates a new population using (a) the `replacement_size` best individuals from the current population, (b) and `population_size - replacement_size` individuals randomly selected from the newly generated individuals. It is possible in this case to lose a good solution from the newly generated individuals if it is not randomly selected for replacement; however, the default `new_solutions_generated` value is set such that the entire set of newly generated individuals will be selected for replacement.

roulette_wheel

- [Keywords Area](#)

Decrease the population size by a percentage

Specification

Alias: `shrinkage_percentage`

Argument(s): REAL

Default: 0.9

Description

As of JEGA v2.0, all replacement types are common to both MOGA and SOGA. They include the `roulette_wheel`, `unique_roulette_wheel`, `elitist`, and `below_limit` selectors. In `roulette_wheel` replacement, each design is conceptually allotted a portion of a wheel proportional to its fitness relative to the fitnesses of the other Designs. Then, portions of the wheel are chosen at random and the design occupying those portions are duplicated into the next population. Those Designs allotted larger portions of the wheel are more likely to be selected (potentially many times). `unique_roulette_wheel` replacement is the same as `roulette_wheel` replacement, with the exception that a design may only be selected once. The `below_limit` selector attempts to keep all designs for which the negated fitness is below a certain limit. The values are negated to keep with the convention that higher fitness is better. The inputs to the `below_limit` selector are the limit as a real value, and a `shrinkage_percentage` as a real value. The `shrinkage_percentage` defines the minimum amount of selections that will take place if enough designs are available. It is interpreted as a percentage of the population

size that must go on to the subsequent generation. To enforce this, `below_limit` makes all the selections it would make anyway and if that is not enough, it takes the remaining that it needs from the best of what is left (effectively raising its limit as far as it must to get the minimum number of selections). It continues until it has made enough selections. The `shrinkage_percentage` is designed to prevent extreme decreases in the population size at any given generation, and thus prevent a big loss of genetic diversity in a very short time. Without a shrinkage limit, a small group of "super" designs may appear and quickly cull the population down to a size on the order of the limiting value. In this case, all the diversity of the population is lost and it is expensive to re-diversify and spread the population. The `elitist` selector simply chooses the required number of designs taking the most fit. For example, if 100 selections are requested, then the top 100 designs as ranked by fitness will be selected and the remaining will be discarded.

niching_type

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [niching_type](#)

Specify the type of niching pressure

Specification

Alias: none

Argument(s): none

Default: No niche pressure

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Niching Type (Group 1)	radial	Set niching distance to percentage of non-dominated range
			distance	Enforce minimum Euclidean distance between designs
			max_designs	Limit number of solutions to remain in the population

Description

The purpose of niching is to encourage differentiation along the Pareto frontier and thus a more even and uniform sampling.

This is typically accomplished by discouraging clustering of design points in the performance space. In JE-GA, the application of niche pressure occurs as a secondary selection operation. The nicher is given a chance to perform a pre-selection operation prior to the operation of the selection (replacement) operator, and is then called to perform niching on the set of designs that were selected by the selection operator.

The radial nicher takes information input from the user to compute a minimum allowable distance between designs in the performance space and acts as a secondary selection operator whereby it enforces this minimum distance. The distance nicher requires that solutions must be separated from other solutions by a minimum distance in each dimension (vs. Euclidean distance for the radial niching). After niching is complete, all designs in the population will be at least the minimum distance from one another in all directions.

The `radial` niche pressure applicator works by enforcing a minimum Euclidean distance between designs in the performance space at each generation. The algorithm proceeds by starting at the (or one of the) extreme designs along objective dimension 0 and marching through the population removing all designs that are too close to the current design. One exception to the rule is that the algorithm will never remove an extreme design which is defined as a design that is maximal or minimal in all but 1 objective dimension (for a classical 2 objective problem, the extreme designs are those at the tips of the non-dominated frontier). The `distance` nicher enforces a minimum distance in each dimension.

The designs that are removed by the nicher are not discarded. They are buffered and re-inserted into the population during the next pre-selection operation. This way, the selector is still the only operator that discards designs and the algorithm will not waste time "re-filling" gaps created by the nicher.

The `radial` nicher requires as input a vector of fractions with length equal to the number of objectives. The elements of the vector are interpreted as percentages of the non-dominated range for each objective defining a minimum distance to all other designs. All values should be in the range (0, 1). The minimum allowable distance between any two designs in the performance space is the Euclidian (simple square-root-sum-of-squares calculation) distance defined by these percentages. The `distance` nicher has a similar input vector requirement, only the distance is the minimum distance in each dimension.

The `max_designs` niche pressure applicator is designed to choose a limited number of solutions to remain in the population. That number is specified by `num_designs`. It does so in order to balance the tendency for populations to grow very large and thus consuming too many computer resources. It operates by ranking designs according to their fitness standing and a computed count of how many other designs are too close to them. Too close is a function of the supplied `niche_vector`, which specifies the minimum distance between any two points in the performance space along each dimension individually. Once the designs are all ranked, the top `c \ num_` designs designs are kept in the population and the remaining ones are buffered or discarded. Note that like other niching operators, this one will not discard an extreme design.

radial

	Optional		num_generations	Define the convergence criterion for JEGA methods

Description

The two JEGA methods use different convergence types, which are described on their respective pages.

All the convergence types are modified by the optional keywords `percent_change` and `num_generations`.

metric_tracker

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [convergence_type](#)
- [metric_tracker](#)

Track changes in the non-dominated frontier

Specification

Alias: none

Argument(s): none

Default: metric_tracker

Description

The moga converger (`metric_tracker`) operates by tracking various changes in the non-dominated frontier from generation to generation. When the changes occurring over a user specified number of generations fall below a user specified threshold, the algorithm stops.

If `metric_tracker` is specified, then a `percent_change` and `num_generations` must be supplied as well. These are listed as optional keywords in the input spec.

Theory

The `metric_tracker` converger tracks 3 metrics specific to the non-dominated frontier from generation to generation. All 3 of these metrics are computed as percent changes between the generations. In order to compute these metrics, the converger stores a duplicate of the non-dominated frontier at each generation for comparison to the non-dominated frontier of the next generation.

The first metric is one that indicates how the expanse of the frontier is changing. The expanse along a given objective is defined by the range of values existing within the non-dominated set. The expansion metric is computed by tracking the extremes of the non-dominated frontier from one generation to the next. Any movement of the extreme values is noticed and the maximum percentage movement is computed as:

$$Em = \max \text{ over } j \text{ of } \frac{\text{abs}(\text{range}(j, i) - \text{range}(j, i-1))}{\text{range}(j, i-1)} \quad j=1, \text{nof}$$

where Em is the max expansion metric, j is the objective function index, i is the current generation number, and `nof` is the total number of objectives. The range is the difference between the largest value along an objective and the smallest when considering only non-dominated designs.

The second metric monitors changes in the density of the non-dominated set. The density metric is computed as the number of non-dominated points divided by the hypervolume of the non-dominated region of space. Therefore, changes in the density can be caused by changes in the number of non-dominated points or by changes in size of the non-dominated space or both. The size of the non-dominated space is computed as:

$$Vps(i) = \text{product over } j \text{ of } \text{range}(j, i) \quad j=1, \text{nof}$$

where $Vps(i)$ is the hypervolume of the non-dominated space at generation i and all other terms have the same meanings as above.

The density of the a given non-dominated space is then:

$$Dps(i) = Pct(i) / Vps(i)$$

where $Pct(i)$ is the number of points on the non-dominated frontier at generation i .

The percentage increase in density of the frontier is then calculated as

$$Cd = \frac{\text{abs}(Dps(i) - Dps(i-1))}{Dps(i-1)}$$

where Cd is the change in density metric.

The final metric is one that monitors the "goodness" of the non-dominated frontier. This metric is computed by considering each design in the previous population and determining if it is dominated by any designs in the current population. All that are determined to be dominated are counted. The metric is the ratio of the number that are dominated to the total number that exist in the previous population.

As mentioned above, each of these metrics is a percentage. The tracker records the largest of these three at each generation. Once the recorded percentage is below the supplied percent change for the supplied number of generations consecutively, the algorithm is converged.

percent_change

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [convergence_type](#)
- [percent_change](#)

Define the convergence criterion for JEGA methods

Specification

Alias: none

Argument(s): REAL

Default: 0.1

Description

The `percent_change` is the threshold beneath which convergence is attained whereby it is compared to the metric value computed.

num_generations

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [convergence_type](#)
- [num_generations](#)

Define the convergence criterion for JEGA methods

Specification

Alias: none

Argument(s): INTEGER

Default: 10

Description

The `num_generations` is the number of generations over which the metric value should be tracked. Convergence will be attained if the recorded metric is below `percent_change` for `num_generations` consecutive generations.

postprocessor_type

- [Keywords Area](#)
- [method](#)

Post process the final solution from moga

Specification

Alias: none

Argument(s): none

Default: No post-processing of solutions

Child Keywords:

	Required/ Optional Required	Description of Group	Dakota Keyword	Dakota Keyword Description
			orthogonal_ distance	Get subset of Pareto front based on distance

Description

The purpose of this operation is to perform any needed data manipulations on the final solution deemed necessary. Currently the `orthogonal_distance` is the only one. It reduces the final solution set size such that a minimum distance in each direction exists between any two designs.

orthogonal_distance

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [postprocessor_type](#)
- [orthogonal_distance](#)

Get subset of Pareto front based on distance

Specification

Alias: none

Argument(s): REALLIST

Default: 0.01 for all objectives

Description

Note that MOGA and SOGA create additional output files during execution. "finaldata.dat" is a file that holds the final set of Pareto optimal solutions after any post-processing is complete. "discards.dat" holds solutions that were discarded from the population during the course of evolution. It can often be useful to plot objective function values from these files to visually see the Pareto front and ensure that finaldata.dat solutions dominate discards.dat solutions. The solutions are written to these output files in the format "Input1...InputN..Output1...OutputM". If MOGA is used in a hybrid optimization meta-iteration (which requires one optimal solution from each individual optimization method to be passed to the subsequent optimization method as its starting point), the solution in the Pareto set closest to the "utopia" point is given as the best solution. This solution is also reported in the Dakota output. This "best" solution in the Pareto set has minimum distance from the utopia point. The utopia point is defined as the point of extreme (best) values for each objective function. For example, if the Pareto front is bounded by (1,100) and (90,2), then (1,2) is the utopia point. There will be a point in the Pareto set that has minimum L2-norm distance to this point, for example (10,10) may be such a point. In SOGA, the solution that minimizes the single objective function is returned as the best solution. If moga is used in meta-iteration which may require passing multiple solutions to the next level (such as the `surrogate_based_global` or `hybrid` methods), the `orthogonal_distance` postprocessor type may be used to specify the distances between each solution value to winnow down the solutions in the full Pareto front to a subset which will be passed to the next iteration.

max.iterations

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [max.iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: `fsu_cvt`, `local_reliability`: 25; `global_{reliability, interval_est, evidence}` / `efficient-global`: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_--iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

max_function_evaluations

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [max_function_evaluations](#)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

Default Behavior

Default value is 1000.

scaling

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*_scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling
3. `auto` - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. `log` - logarithmic scaling

First, any characteristic values from the optional `*_scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*_scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- none, auto, log - optional
- value - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100
```

```
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

population_size

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [population_size](#)

Set the initial population size in JEGA methods

Specification

Alias: none

Argument(s): INTEGER

Default: 50

Description

The number of designs in the initial population is specified by the `population_size`. Note that the `population_size` only sets the size of the initial population. The population size may vary in the JEGA methods according to the type of operators chosen for a particular optimization run.

Also note that some initializers may not strictly respect the initial population size. See the SOGA [flat_file](#) or MOGA [flat_file](#) initializer for an example.

log_file

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [log_file](#)

Specify the name of a log file

Specification

Alias: none

Argument(s): STRING

Default: JEGAGlobal.log

Description

New as of JEGA v2.0 is the introduction of the `log_file` specification. JEGA now uses a logging library to output messages and status to the user. JEGA can be configured at build time to log to both the console window and a text file, one or the other, or neither. The `log_file` input is a string name of a file into which to log. If the build was configured without file logging in JEGA, this input is ignored. If file logging is enabled and no `log_file` is specified, the default file name of JEGAGlobal.log is used.

print_each_pop

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [print_each_pop](#)

Print every population to a population file

Specification

Alias: none

Argument(s): none

Default: No printing

Description

New to JEGA v2.0 is the introduction of the `print_each_pop` specification. It serves as a flag and if supplied, the population at each generation will be printed to a file named "population<GEN#>.dat" where <GEN#> is the number of the current generation.

initialization_type

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [initialization_type](#)

Specify how to initialize the population

Specification

Alias: none

Argument(s): none

Default: `unique_random`

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Initialization Type (Group 1)	simple_random	Create random initial solutions
			unique_random	Create random initial solutions, but enforce uniqueness (default)
			flat_file	Read initial solutions from file

Description

The `initialization_type` defines how the initial population is created for the GA. There are three types:

1. `simple_random`
2. `unique_random` (default)
3. `flat_file`

Setting the size for the `flat_file` initializer has the effect of requiring a minimum number of designs to create. If this minimum number has not been created once the files are all read, the rest are created using the `unique_random` initializer and then the `simple_random` initializer if necessary.

simple_random

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [initialization_type](#)
- [simple_random](#)

Create random initial solutions

Specification

Alias: none

Argument(s): none

Description

`simple_random` creates initial solutions with random variable values according to a uniform random number distribution. It gives no consideration to any previously generated designs.

`unique_random`

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [initialization_type](#)
- [unique_random](#)

Create random initial solutions, but enforce uniqueness (default)

Specification

Alias: none

Argument(s): none

Description

`unique_random` is the same as `simple_random`, except that when a new solution is generated, it is checked against the rest of the solutions. If it duplicates any of them, it is rejected.

`flat_file`

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [initialization_type](#)
- [flat_file](#)

Read initial solutions from file

Specification

Alias: none

Argument(s): STRING

Description

`flat_file` allows the initial population to be read from a flat file. If `flat_file` is specified, a file name must be given.

Variables can be delimited in the flat file in any way you see fit with a few exceptions. The delimiter must be the same on any given line of input with the exception of leading and trailing whitespace. So a line could look like: 1.1, 2.2,3.3 for example but could not look like: 1.1, 2.2 3.3. The delimiter can vary from line to line within the file which can be useful if data from multiple sources is pasted into the same input file. The delimiter can be any string that does not contain any of the characters `.-dDeE` or any of the digits 0-9. The input will be read until the end of the file. The algorithm will discard any configurations for which it was unable to retrieve at least the number of design variables. The objective and constraint entries are not required but if ALL are present, they will be recorded and the design will be tagged as evaluated so that evaluators may choose not to re-evaluate them.

Setting the size for this initializer has the effect of requiring a minimum number of designs to create. If this minimum number has not been created once the files are all read, the rest are created using the `unique_random` initializer and then the `simple_random` initializer if necessary. If more designs are found in the initialization files than specified by the initial size, then the initial size is ignored and all designs read out of the files are kept in the initial population.

crossover_type

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [crossover_type](#)

Select a crossover type for JEGA methods

Specification

Alias: none

Argument(s): none

Default: `shuffle_random`

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Crossover Type (Group 1)	multi_point_binary	Use bit switching for crossover events
			multi_point_-parameterized_-binary	Use bit switching to crossover each design variable
			multi_point_real	Perform crossover in real valued genome

		shuffle_random	Perform crossover by choosing design variable(s)
	Optional	crossover_rate	Specify the probability of a crossover event

Description

There are many crossover types available. `multi_point_binary` crossover requires an integer number, N, of crossover points. This crossover type performs a bit switching crossover at N crossover points in the binary encoded genome of two designs. Thus, crossover may occur at any point along a solution chromosome (in the middle of a gene representing a design variable, for example). `multi_point_parameterized_binary` crossover is similar in that it performs a bit switching crossover routine at N crossover points. However, this crossover type performs crossover on each design variable individually. So the individual chromosomes are crossed at N locations. `multi_point_real` crossover performs a variable switching crossover routing at N crossover points in the real valued genome of two designs. In this scheme, crossover only occurs between design variables (chromosomes). Note that the standard solution chromosome representation in the JEGA algorithm is real encoded and can handle integer or real design variables. For any crossover types that use a binary representation, real variables are converted to long integers by multiplying the real number by 10^6 and then truncating. Note that this assumes a precision of only six decimal places. Discrete variables are represented as integers (indices within a list of possible values) within the algorithm and thus require no special treatment by the binary operators.

The final crossover type is `shuffle_random`. This crossover type performs crossover by choosing design variables at random from a specified number of parents enough times that the requested number of children are produced. For example, consider the case of 3 parents producing 2 children. This operator would go through and for each design variable, select one of the parents as the donor for the child. So it creates a random shuffle of the parent design variable values. The relative numbers of children and parents are controllable to allow for as much mixing as desired. The more parents involved, the less likely that the children will wind up exact duplicates of the parents.

All crossover types take a `crossover_rate`. The crossover rate is used to calculate the number of crossover operations that take place. The number of crossovers is equal to the rate * population_size.

`multi_point_binary`

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [crossover_type](#)
- [multi_point_binary](#)

Use bit switching for crossover events

Specification

Alias: none

Argument(s): INTEGER

Description

There are many crossover types available. `multi_point_binary` crossover requires an integer number, N , of crossover points. This crossover type performs a bit switching crossover at N crossover points in the binary encoded genome of two designs. Thus, crossover may occur at any point along a solution chromosome (in the middle of a gene representing a design variable, for example). `multi_point_parameterized_binary` crossover is similar in that it performs a bit switching crossover routine at N crossover points. However, this crossover type performs crossover on each design variable individually. So the individual chromosomes are crossed at N locations. `multi_point_real` crossover performs a variable switching crossover routing at N crossover points in the real valued genome of two designs. In this scheme, crossover only occurs between design variables (chromosomes). Note that the standard solution chromosome representation in the JEGA algorithm is real encoded and can handle integer or real design variables. For any crossover types that use a binary representation, real variables are converted to long integers by multiplying the real number by 10^6 and then truncating. Note that this assumes a precision of only six decimal places. Discrete variables are represented as integers (indices within a list of possible values) within the algorithm and thus require no special treatment by the binary operators.

`multi_point_parameterized_binary`

- [Keywords Area](#)

Thus, crossover may occur at any point along a solution chromosome (in the middle of a gene representing a design variable, for example). `multi_point_parameterized_binary` crossover is similar in that it performs a bit switching crossover routine at N crossover points. However, this crossover type performs crossover on each design variable individually. So the individual chromosomes are crossed at N locations. `multi_point_real` crossover performs a variable switching crossover routing at N crossover points in the real real valued genome of two designs. In this scheme, crossover only occurs between design variables (chromosomes). Note that the standard solution chromosome representation in the JEGA algorithm is real encoded and can handle integer or real design variables. For any crossover types that use a binary representation, real variables are converted to long integers by multiplying the real number by 10^6 and then truncating. Note that this assumes a precision of only six decimal places. Discrete variables are represented as integers (indices within a list of possible values) within the algorithm and thus require no special treatment by the binary operators.

shuffle_random

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [crossover_type](#)
- [shuffle_random](#)

Perform crossover by choosing design variable(s)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		num_parents	Number of parents in random shuffle crossover
	Optional		num_offspring	Number of offspring in random shuffle crossover

Description

The final crossover type is `shuffle_random`. This crossover type performs crossover by choosing design variables at random from a specified number of parents enough times that the requested number of children are produced. For example, consider the case of 3 parents producing 2 children. This operator would go through and for each design variable, select one of the parents as the donor for the child. So it creates a random shuffle of the parent design variable values. The relative numbers of children and parents are controllable to allow for as much mixing as desired. The more parents involved, the less likely that the children will wind up exact duplicates of the parents.

num_parents

Description

Number of offspring in random shuffle crossover

crossover_rate

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [crossover_type](#)
- [crossover_rate](#)

Specify the probability of a crossover event

Specification

Alias: none

Argument(s): REAL

Default: 0.8

Description

The `crossover_type` controls what approach is employed for combining parent genetic information to create offspring, and the `crossover_rate` specifies the probability of a crossover operation being performed to generate a new offspring. The SCOLIB EA method supports three forms of crossover, `two_point`, `blend`, and `uniform`, which generate a new individual through combinations of two parent individuals. Two-point crossover divides each parent into three regions, where offspring are created from the combination of the middle region from one parent and the end regions from the other parent. Since the SCOLIB EA does not utilize bit representations of variable values, the crossover points only occur on coordinate boundaries, never within the bits of a particular coordinate. Uniform crossover creates offspring through random combination of coordinates from the two parents. Blend crossover generates a new individual randomly along the multidimensional vector connecting the two parents.

mutation_type

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [mutation_type](#)

Select a mutation type for JEGA methods

Specification

Alias: none

Argument(s): none

Default: `replace_uniform`

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Mutation Type (Group 1)	bit_random	Mutate by flipping a random bit
			replace_uniform	Use uniformly distributed value over range of parameter
			offset_normal	Set mutation offset to use a normal distribution
			offset_cauchy	Use a Cauchy distribution for the mutation offset
			offset_uniform	Set mutation offset to use a uniform distribution
	Optional		mutation_rate	Set probability of a mutation

Description

Five mutation types are available for selection by keyword: `replace_uniform`, `bit_random`, `offset_cauchy`, `offset_normal`, and `offset_uniform`. They are described in greater detail on their respective keyword pages.

The `offset_*` mutators all act by adding a random "offset" to a variable value. The random amount has a mean of zero in all cases. The size of the offset is controlled using the `mutation_scale` keyword, which is interpreted differently for each `offset_*` type.

The rate of mutations for all types is controlled using the `mutation_rate`. The rate is applied differently in each `mutation_type`.

bit_random

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [mutation_type](#)
- [bit_random](#)

Mutate by flipping a random bit

Specification

Alias: none

Argument(s): none

Description

The `bit_random` mutator introduces random variation by first converting a randomly chosen variable of a randomly chosen design into a binary string. It then flips a randomly chosen bit in the string from a 1 to a 0 or visa versa. In this mutation scheme, the resulting value has more probability of being similar to the original value.

replace_uniform

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [mutation_type](#)
- [replace_uniform](#)

Use uniformly distributed value over range of parameter

Specification

Alias: none

Argument(s): none

Description

`replace_uniform` introduces random variation by first randomly choosing a design variable of a randomly selected design and reassigning it to a random valid value for that variable. No consideration of the current value is given when determining the new value.

offset_normal

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [mutation_type](#)
- [offset_normal](#)

Set mutation offset to use a normal distribution

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			mutation_scale	Scales mutation across range of parameter

Description

The `offset_normal` mutator introduces random variation by adding a Gaussian random amount to a variable value. The random amount has a standard deviation dependent on the `mutation_scale`.

mutation_scale

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [mutation_type](#)
- [offset_normal](#)
- [mutation_scale](#)

Scales mutation across range of parameter

Specification

Alias: none

Argument(s): REAL

Default: 0.15

Description

The `mutation_scale` is a fraction in the range [0, 1] and is meant to help control the amount of variation that takes place when a variable is mutated. Its behavior depends on the selected `mutation_type`. For `offset_normal` and `offset_cauchy`, `mutation_scale` is multiplied by the range of the variable being mutated to obtain the standard deviation of the offset. For `offset_uniform`, the range of possible deviation amounts is $\pm 1/2 * (\text{mutation_scale} * \text{variable range})$.

offset_cauchy

- [mutation_type](#)

- [offset_uniform](#)
- [mutation_scale](#)

Scales mutation across range of parameter

Specification

Alias: none

Argument(s): REAL

Default: 0.15

Description

The `mutation_scale` is a fraction in the range [0, 1] and is meant to help control the amount of variation that takes place when a variable is mutated. Its behavior depends on the selected `mutation_type`. For `offset_normal` and `offset_cauchy`, `mutation_scale` is multiplied by the range of the variable being mutated to obtain the standard deviation of the offset. For `offset_uniform`, the range of possible deviation amounts is $\pm 1/2 * (\text{mutation_scale} * \text{variable range})$.

mutation_rate

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [mutation_type](#)
- [mutation_rate](#)

Set probability of a mutation

Specification

Alias: none

Argument(s): REAL

Default: 0.08

Description

All mutation types have a `mutation_rate`, which controls the number of mutations performed. For `replace_uniform` and all the `offset_*` types, the number of mutations performed is the product of `mutation_rate` and `population_size`. For `bit_random`, it's the product of the `mutation_rate`, number of design variables, and population size

seed

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [seed](#)

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)

Description

The random `seed` control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

convergence_tolerance

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

model_pointer

- [Keywords Area](#)
- [method](#)
- [moga](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                    0.1 0.2 0.6
                    0.1 0.2 0.6

  sample_type lhs
  distribution cumulative

model
  id_model = 'SURR'
  surrogate global,
  dace_method_pointer = 'DACE'
  polynomial quadratic

method
  id_method = 'DACE'
  model_pointer = 'DACE_M'
  sampling sample_type lhs
  samples = 121 seed = 5034 rng rnum2

model
  id_model = 'DACE_M'
  single
  interface_pointer = 'I1'

variables
  uniform_uncertain = 2
  lower_bounds = 0. 0.
  upper_bounds = 1. 1.
  descriptors = 'x1' 'x2'
```

```
interface
  id_interface = 'I1'
  system async evaluation_concurrency = 5
  analysis_driver = 'text_book'

responses
  response_functions = 3
  no_gradients
  no_hessians
```

	Optional	<code>model_pointer</code>	Identifier for model block to be used by a method

Description

`soga` stands for Single-objective Genetic Algorithm, which is a global optimization method that supports general constraints and a mixture of real and discrete variables. `soga` is part of the JEGA library.

Constraints `soga` can utilize linear constraints.

Configuration

The genetic algorithm configurations are:

1. fitness
2. replacement
3. convergence
4. initialization
5. crossover
6. mutation
7. population size

The pool of potential members is the current population and the current set of offspring. Choice of fitness assessors is strongly related to the type of replacement algorithm being used and can have a profound effect on the solutions selected for the next generation.

Stopping Criteria

The `soga` method respects the `max_iterations` and `max_function_evaluations` method independent controls to provide integer limits for the maximum number of generations and function evaluations, respectively.

The algorithm also stops when convergence is reached. This involves repeated assessment of the algorithm's progress in solving the problem, until some criterion is met.

Expected Outputs The `soga` method respects the `output` method independent control to vary the amount of information presented to the user during execution.

The final results are written to the Dakota tabular output. Additional information is also available - see the `log_file` and `print_each_pop` keywords.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the `hdf5` keyword, this method writes the following results to HDF5:

- [Best Parameters](#)
- [Best Objective Functions](#) (when `objective_functions` are specified)
- [Best Nonlinear Constraints](#)
- [Calibration](#) (when `calibration_terms` are specified)

Theory

The basic steps of the `soga` algorithm are as follows:

1. Initialize the population
2. Evaluate the population (calculate the values of the objective function and constraints for each population member)
3. Loop until converged, or stopping criteria reached
 - (a) Perform crossover
 - (b) Perform mutation
 - (c) Evaluate the new population
 - (d) Assess the fitness of each member in the population
 - (e) Replace the population with members selected to continue in the next generation
 - (f) Test for convergence

- [method](#)
- [soga](#)
- [fitness_type](#)
- [merit_function](#)

Balance goals of reducing objective function and satisfying constraints

Specification

Alias: none

Argument(s): none

Description

A `merit_function` is a function in constrained optimization that attempts to provide joint progress toward reducing the objective function and satisfying the constraints.

constraint_penalty

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [fitness_type](#)
- [constraint_penalty](#)

Multiplier for the penalty function

Specification

Alias: none

Argument(s): REAL

Default: 1.0

Description

The `merit_function` fitness assessor uses an exterior penalty function formulation to penalize infeasible designs. The specification allows the input of a `constraint_penalty` which is the multiplier to use on the constraint violations.

replacement_type

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [replacement_type](#)

Select a replacement type for JEGA methods

Specification

Alias: none

Argument(s): none

Default: elitist

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Replacement Type (Group 1)	elitist	Use the best designs to form a new population
			favor_feasible	Prioritize feasible designs
			roulette_wheel	Replace population
			unique_roulette_wheel	Replace population

Description

Replace the population with members selected to continue in the next generation. The pool of potential members is the current population and the current set of offspring. The `replacement_type` of `roulette_wheel` or `unique_roulette_wheel` may be used either with MOGA or SOGA problems however they are not recommended for use with MOGA. Given that the only two fitness assessors for MOGA are the `layer_rank` and `domination_count`, the recommended selector is the `below_limit` selector. The `below_limit` replacement will only keep designs that are dominated by fewer than a limiting number of other designs.

In `roulette_wheel` replacement, each design is conceptually allotted a portion of a wheel proportional to its fitness relative to the fitnesses of the other Designs. Then, portions of the wheel are chosen at random and the design occupying those portions are duplicated into the next population. Those Designs allotted larger portions

of the wheel are more likely to be selected (potentially many times). `unique_roulette_wheel` replacement is the same as `roulette_wheel` replacement, with the exception that a design may only be selected once. The `below_limit` selector attempts to keep all designs for which the negated fitness is below a certain limit. The values are negated to keep with the convention that higher fitness is better. The inputs to the `below_limit` selector are the limit as a real value, and a `shrinkage_percentage` as a real value. The `shrinkage_percentage` defines the minimum amount of selections that will take place if enough designs are available. It is interpreted as a percentage of the population size that must go on to the subsequent generation. To enforce this, `below_limit` makes all the selections it would make anyway and if that is not enough, it takes the remaining that it needs from the best of what is left (effectively raising its limit as far as it must to get the minimum number of selections). It continues until it has made enough selections. The `shrinkage_percentage` is designed to prevent extreme decreases in the population size at any given generation, and thus prevent a big loss of genetic diversity in a very short time. Without a shrinkage limit, a small group of "super" designs may appear and quickly cull the population down to a size on the order of the limiting value. In this case, all the diversity of the population is lost and it is expensive to re-diversify and spread the population. The

The `replacement_type` for a SOGA may be `roulette_wheel`, `unique_roulette_wheel`, `elitist`, or `favor_feasible`. The `elitist` selector simply chooses the required number of designs taking the most fit. For example, if 100 selections are requested, then the top 100 designs as ranked by fitness will be selected and the remaining will be discarded. The `favor_feasible` replacement type first considers feasibility as a selection criteria. If that does not produce a "winner" then it moves on to considering fitness value. Because of this, any fitness assessor used with the `favor_feasible` selector must only account objectives in the creation of fitness. Therefore, there is such a fitness assessor and it's use is enforced when the `favor_feasible` selector is chosen. In that case, and if the output level is set high enough, a message will be presented indicating that the `weighted_sum_only` fitness assessor will be used.

elitist

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [replacement_type](#)
- [elitist](#)

Use the best designs to form a new population

Specification

Alias: none

Argument(s): none

Description

The `elitist` (default) setting creates a new population using (a) the `replacement_size` best individuals from the current population, (b) and `population_size - replacement_size` individuals randomly selected from the newly generated individuals. It is possible in this case to lose a good solution from the newly generated individuals if it is not randomly selected for replacement; however, the default `new_solutions_generated` value is set such that the entire set of newly generated individuals will be selected for replacement.

favor_feasible

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [replacement_type](#)
- [favor_feasible](#)

Prioritize feasible designs

Specification

Alias: none

Argument(s): none

Description

This replacement operator will always prefer a more feasible design to a less feasible one. Beyond that, it favors solutions based on an assigned fitness value which must have been installed by the weighted sum only fitness assessor.

The `favor_feasible` replacement type first considers feasibility as a selection criteria. If that does not produce a "winner" then it moves on to considering fitness value. Because of this, any fitness assessor used with the `favor_feasible` selector must only account objectives in the creation of fitness. Therefore, there is such a fitness assessor and it's use is enforced when the `favor_feasible` selector is chosen. In that case, and if the output level is set high enough, a message will be presented indicating that the `weighted_sum_only` fitness assessor will be used.

roulette_wheel

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			percent_change	Define the convergence criterion for JEGA methods
	Optional		num_generations	Define the convergence criterion for JEGA methods

Description

The `convergence_type` called `average_fitness_tracker` keeps track of the average fitness in a population. If this average fitness does not change more than `percent_change` over some number of generations, `num_generations`, then the solution is reported as converged and the algorithm terminates.

See Also

These keywords may also be of interest:

- [best_fitness_tracker](#)
- **percent_change**
- [Keywords Area](#)
- [method](#)
- [soga](#)
- [convergence_type](#)
- [average_fitness_tracker](#)
- [percent_change](#)

Define the convergence criterion for JEGA methods

Specification

Alias: none

Argument(s): REAL

Default: 0.1

Description

The `percent_change` is the threshold beneath which convergence is attained whereby it is compared to the metric value computed.

num_generations

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [convergence_type](#)
- [average_fitness_tracker](#)
- [num_generations](#)

Define the convergence criterion for JEGA methods

Specification

Alias: none

Argument(s): INTEGER

Default: 10

Description

The `num_generations` is the number of generations over which the metric value should be tracked. Convergence will be attained if the recorded metric is below `percent_change` for `num_generations` consecutive generations.

max_iterations

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [max_iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: `fsu_cvt`, `local_reliability`: 25; `global_{reliability, interval_est, evidence}` / `efficient_global`: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

max_function_evaluations

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [max_function_evaluations](#)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

Default Behavior

Default value is 1000.

scaling

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the `method`, `variables`, and `responses` blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*_scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling
3. `auto` - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval $[0,1]$;
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into $[0,1]$.

4. `log` - logarithmic scaling

First, any characteristic values from the optional `*_scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*_scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- none, auto, log - optional
- value - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100
```

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value" "value" "value"
primary_scales = 1 1 100
```

population_size

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [population_size](#)

Set the initial population size in JEGA methods

Specification

Alias: none

Argument(s): INTEGER

Default: 50

Description

The number of designs in the initial population is specified by the `population_size`. Note that the `population_size` only sets the size of the initial population. The population size may vary in the JEGA methods according to the type of operators chosen for a particular optimization run.

Also note that some initializers may not strictly respect the initial population size. See the SOGA [flat_file](#) or MOGA [flat_file](#) initializer for an example.

log_file

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [log_file](#)

Specify the name of a log file

Specification

Alias: none

Argument(s): STRING

Default: JEGAGlobal.log

Description

New as of JEGA v2.0 is the introduction of the `log_file` specification. JEGA now uses a logging library to output messages and status to the user. JEGA can be configured at build time to log to both the console window and a text file, one or the other, or neither. The `log_file` input is a string name of a file into which to log. If the build was configured without file logging in JEGA, this input is ignored. If file logging is enabled and no `log_file` is specified, the default file name of JEGAGlobal.log is used.

print_each_pop

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [print_each_pop](#)

Print every population to a population file

Specification

Alias: none

Argument(s): none

Default: No printing

Description

New to JEGA v2.0 is the introduction of the `print_each_pop` specification. It serves as a flag and if supplied, the population at each generation will be printed to a file named "population<GEN#>.dat" where <GEN#> is the number of the current generation.

initialization_type

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [initialization_type](#)

Specify how to initialize the population

Specification

Alias: none

Argument(s): none

Default: `unique_random`

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Initialization Type (Group 1)	simple_random	Create random initial solutions
			unique_random	Create random initial solutions, but enforce uniqueness (default)
			flat_file	Read initial solutions from file

Description

The `initialization_type` defines how the initial population is created for the GA. There are three types:

1. `simple_random`
2. `unique_random` (default)
3. `flat_file`

Setting the size for the `flat_file` initializer has the effect of requiring a minimum number of designs to create. If this minimum number has not been created once the files are all read, the rest are created using the `unique_random` initializer and then the `simple_random` initializer if necessary.

simple_random

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [initialization_type](#)
- [simple_random](#)

Create random initial solutions

Specification

Alias: none

Argument(s): none

Description

`simple_random` creates initial solutions with random variable values according to a uniform random number distribution. It gives no consideration to any previously generated designs.

unique_random

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [initialization_type](#)
- [unique_random](#)

Create random initial solutions, but enforce uniqueness (default)

Specification

Alias: none

Argument(s): none

Description

`unique_random` is the same as `simple_random`, except that when a new solution is generated, it is checked against the rest of the solutions. If it duplicates any of them, it is rejected.

flat_file

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [initialization_type](#)
- [flat_file](#)

Read initial solutions from file

Specification

Alias: none

Argument(s): STRING

Description

`flat_file` allows the initial population to be read from a flat file. If `flat_file` is specified, a file name must be given.

Variables can be delimited in the flat file in any way you see fit with a few exceptions. The delimiter must be the same on any given line of input with the exception of leading and trailing whitespace. So a line could look like: 1.1, 2.2,3.3 for example but could not look like: 1.1, 2.2 3.3. The delimiter can vary from line to line within the file which can be useful if data from multiple sources is pasted into the same input file. The delimiter can be any string that does not contain any of the characters `.-dDeE` or any of the digits 0-9. The input will be read until the end of the file. The algorithm will discard any configurations for which it was unable to retrieve at least the number of design variables. The objective and constraint entries are not required but if ALL are present, they will be recorded and the design will be tagged as evaluated so that evaluators may choose not to re-evaluate them.

Setting the size for this initializer has the effect of requiring a minimum number of designs to create. If this minimum number has not been created once the files are all read, the rest are created using the `unique_random` initializer and then the `simple_random` initializer if necessary. If more designs are found in the initialization files than specified by the initial size, then the initial size is ignored and all designs read out of the files are kept in the initial population.

crossover_type

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [crossover_type](#)

Select a crossover type for JEGA methods

Specification

Alias: none

Argument(s): none

Default: `shuffle_random`

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required(<i>Choose One</i>)	Crossover Type (Group 1)	multi_point_binary	Use bit switching for crossover events
			multi_point_-parameterized_-binary	Use bit switching to crossover each design variable
			multi_point_real	Perform crossover in real valued genome

		shuffle_random	Perform crossover by choosing design variable(s)
	Optional	crossover_rate	Specify the probability of a crossover event

Description

There are many crossover types available. `multi_point_binary` crossover requires an integer number, N, of crossover points. This crossover type performs a bit switching crossover at N crossover points in the binary encoded genome of two designs. Thus, crossover may occur at any point along a solution chromosome (in the middle of a gene representing a design variable, for example). `multi_point_parameterized_binary` crossover is similar in that it performs a bit switching crossover routine at N crossover points. However, this crossover type performs crossover on each design variable individually. So the individual chromosomes are crossed at N locations. `multi_point_real` crossover performs a variable switching crossover routing at N crossover points in the real valued genome of two designs. In this scheme, crossover only occurs between design variables (chromosomes). Note that the standard solution chromosome representation in the JEGA algorithm is real encoded and can handle integer or real design variables. For any crossover types that use a binary representation, real variables are converted to long integers by multiplying the real number by 10^6 and then truncating. Note that this assumes a precision of only six decimal places. Discrete variables are represented as integers (indices within a list of possible values) within the algorithm and thus require no special treatment by the binary operators.

The final crossover type is `shuffle_random`. This crossover type performs crossover by choosing design variables at random from a specified number of parents enough times that the requested number of children are produced. For example, consider the case of 3 parents producing 2 children. This operator would go through and for each design variable, select one of the parents as the donor for the child. So it creates a random shuffle of the parent design variable values. The relative numbers of children and parents are controllable to allow for as much mixing as desired. The more parents involved, the less likely that the children will wind up exact duplicates of the parents.

All crossover types take a `crossover_rate`. The crossover rate is used to calculate the number of crossover operations that take place. The number of crossovers is equal to the rate * population_size.

`multi_point_binary`

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [crossover_type](#)
- [multi_point_binary](#)

Use bit switching for crossover events

Specification

Alias: none

Argument(s): INTEGER

Description

There are many crossover types available. `multi_point_binary` crossover requires an integer number, *N*, of crossover points. This crossover type performs a bit switching crossover at *N* crossover points in the binary encoded genome of two designs. Thus, crossover may occur at any point along a solution chromosome (in the middle of a gene representing a design variable, for example). `multi_point_parameterized_binary` crossover is similar in that it performs a bit switching crossover routine at *N* crossover points. However, this crossover type performs crossover on each design variable individually. So the individual chromosomes are crossed at *N* locations. `multi_point_real` crossover performs a variable switching crossover routing at *N* crossover points in the real valued genome of two designs. In this scheme, crossover only occurs between design variables (chromosomes). Note that the standard solution chromosome representation in the JEGA algorithm is real encoded and can handle integer or real design variables. For any crossover types that use a binary representation, real variables are converted to long integers by multiplying the real number by 10^6 and then truncating. Note that this assumes a precision of only six decimal places. Discrete variables are represented as integers (indices within a list of possible values) within the algorithm and thus require no special treatment by the binary operators.

`multi_point_parameterized_binary`

Number of offspring in random shuffle crossover

crossover_rate

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [crossover_type](#)
- [crossover_rate](#)

Specify the probability of a crossover event

Specification

Alias: none

Argument(s): REAL

Default: 0.8

Description

The `crossover_type` controls what approach is employed for combining parent genetic information to create offspring, and the `crossover_rate` specifies the probability of a crossover operation being performed to generate a new offspring. The SCOLIB EA method supports three forms of crossover, `two_point`, `blend`, and `uniform`, which generate a new individual through combinations of two parent individuals. Two-point crossover divides each parent into three regions, where offspring are created from the combination of the middle region from one parent and the end regions from the other parent. Since the SCOLIB EA does not utilize bit representations of variable values, the crossover points only occur on coordinate boundaries, never within the bits of a particular coordinate. Uniform crossover creates offspring through random combination of coordinates from the two parents. Blend crossover generates a new individual randomly along the multidimensional vector connecting the two parents.

mutation_type

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [mutation_type](#)

Select a mutation type for JEGA methods

Specification

Alias: none

Argument(s): none

Default: `replace_uniform`

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Mutation Type (Group 1)	bit_random	Mutate by flipping a random bit
			replace_uniform	Use uniformly distributed value over range of parameter
			offset_normal	Set mutation offset to use a normal distribution
			offset_cauchy	Use a Cauchy distribution for the mutation offset
	offset_uniform	Set mutation offset to use a uniform distribution		
	Optional		mutation_rate	Set probability of a mutation

Description

Five mutation types are available for selection by keyword: `replace_uniform`, `bit_random`, `offset_cauchy`, `offset_normal`, and `offset_uniform`. They are described in greater detail on their respective keyword pages.

The `offset_*` mutators all act by adding a random "offset" to a variable value. The random amount has a mean of zero in all cases. The size of the offset is controlled using the `mutation_scale` keyword, which is interpreted differently for each `offset_*` type.

The rate of mutations for all types is controlled using the `mutation_rate`. The rate is applied differently in each `mutation_type`.

bit_random

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [mutation_type](#)
- [bit_random](#)

Mutate by flipping a random bit

Specification

Alias: none

Argument(s): none

Description

The `bit_random` mutator introduces random variation by first converting a randomly chosen variable of a randomly chosen design into a binary string. It then flips a randomly chosen bit in the string from a 1 to a 0 or visa versa. In this mutation scheme, the resulting value has more probability of being similar to the original value.

replace_uniform

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [mutation_type](#)
- [replace_uniform](#)

Use uniformly distributed value over range of parameter

Specification

Alias: none

Argument(s): none

Description

`replace_uniform` introduces random variation by first randomly choosing a design variable of a randomly selected design and reassigning it to a random valid value for that variable. No consideration of the current value is given when determining the new value.

offset_normal

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [mutation_type](#)
- [offset_normal](#)

Set mutation offset to use a normal distribution

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			mutation_scale	Scales mutation across range of parameter

Description

The `offset_normal` mutator introduces random variation by adding a Gaussian random amount to a variable value. The random amount has a standard deviation dependent on the `mutation_scale`.

mutation_scale

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [mutation_type](#)
- [offset_normal](#)
- [mutation_scale](#)

Scales mutation across range of parameter

Specification

Alias: none

Argument(s): REAL

Default: 0.15

Description

The `mutation_scale` is a fraction in the range [0, 1] and is meant to help control the amount of variation that takes place when a variable is mutated. Its behavior depends on the selected `mutation_type`. For `offset_normal` and `offset_cauchy`, `mutation_scale` is multiplied by the range of the variable being mutated to obtain the standard deviation of the offset. For `offset_uniform`, the range of possible deviation amounts is $\pm 1/2 * (\text{mutation_scale} * \text{variable range})$.

`offset_cauchy`

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [mutation_type](#)
- [offset_cauchy](#)

Use a Cauchy distribution for the mutation offset

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword mutation_scale	Dakota Keyword Description Scales mutation across range of parameter

Description

The `offset_cauchy` mutator introduces random variation by adding a Cauchy random amount to a variable value. The random amount has a standard deviation dependent on the `mutation_scale`.

`mutation_scale`

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [mutation_type](#)
- [offset_cauchy](#)
- [mutation_scale](#)

Scales mutation across range of parameter

Specification

mutation_rate

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [mutation_type](#)
- [mutation_rate](#)

Set probability of a mutation

Specification

Alias: none

Argument(s): REAL

Default: 0.08

Description

All mutation types have a `mutation_rate`, which controls the number of mutations performed. For `replace_uniform` and all the `offset_*` types, the number of mutations performed is the product of `mutation_rate` and `population_size`. For `bit_random`, it's the product of the `mutation_rate`, number of design variables, and population size

seed

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [seed](#)

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)

Description

The random `seed` control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

convergence_tolerance

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

model_pointer

- [Keywords Area](#)
- [method](#)
- [soga](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                    0.1 0.2 0.6
                    0.1 0.2 0.6

  sample_type lhs

	Optional	model_pointer	Identifier for model block to be used by a method

Description

Pattern search techniques are nongradient-based optimization methods which use a set of offsets from the current iterate to locate improved points in the design space.

See the page [package scolib](#) for important information regarding all SCOLIB methods

`coliny_pattern_search` supports concurrency up to the size of the search pattern

Traditional pattern search methods search with a fixed pattern of search directions to try to find improvements to the current iterate. The SCOLIB pattern search methods generalize this simple algorithmic strategy to enable control of how the search pattern is adapted, as well as how each search pattern is evaluated. The `stochastic` and `synchronization` specifications denote how the trial points are evaluated. The `stochastic` specification indicates that the trial points are considered in a random order. For parallel pattern search, `synchronization` dictates whether the evaluations are scheduled using a `blocking` scheduler or a `nonblocking` scheduler. In the `blocking` case, all points in the pattern are evaluated (in parallel), and if the best of these trial points is an improving point, then it becomes the next iterate. These runs are reproducible, assuming use of the same seed in the `stochastic` case. In the `nonblocking` case, all points in the pattern may not be evaluated, since the first improving point found becomes the next iterate. Since the algorithm steps will be subject to parallel timing variabilities, these runs will not generally be repeatable. The `synchronization` specification has similar connotations for sequential pattern search. If `blocking` is specified, then each sequential iteration terminates after all trial points have been considered, and if `nonblocking` is specified, then each sequential iteration terminates after the first improving trial point is evaluated. In this release, both `blocking` and `nonblocking` specifications result in blocking behavior (except in the case where `exporatory_moves` below is set to `adaptive_pattern`). Nonblocking behavior will be re-enabled after some underlying technical issues have been resolved.

The particular form of the search pattern is controlled by the `pattern_basis` specification. If `pattern_basis` is `coordinate`, then the pattern search uses a plus and minus offset in each coordinate direction, for a total of $2n$ function evaluations in the pattern. This case is depicted in Figure 5.3 for three coordinate dimensions.

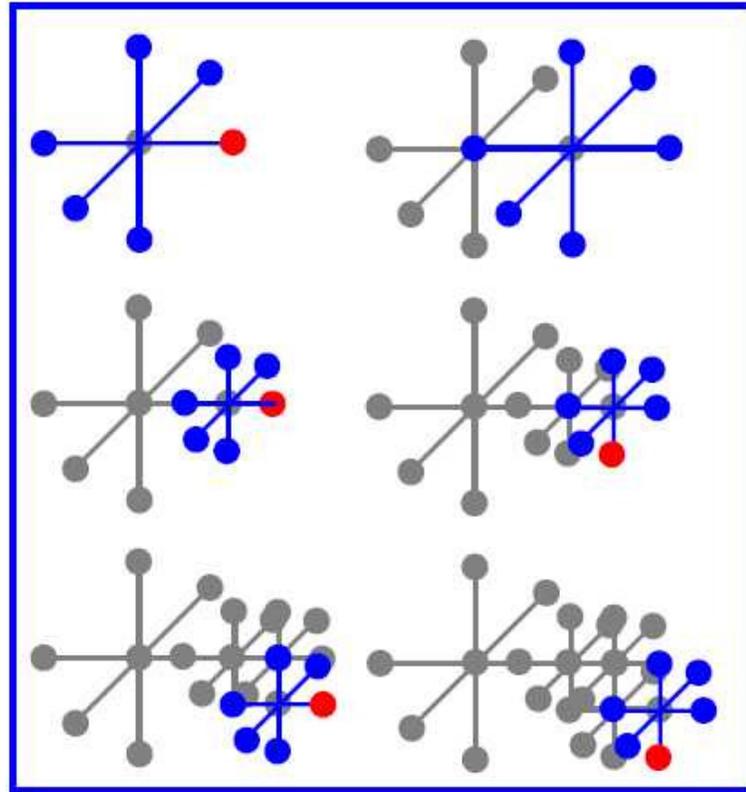

Figure 7.1: Depiction of coordinate pattern search algorithm

If `pattern_basis` is `simplex`, then pattern search uses a minimal positive basis simplex for the parameter space, for a total of $n+1$ function evaluations in the pattern. Note that the `simplex` pattern basis can be used for unbounded problems only. The `total_pattern_size` specification can be used to augment the basic coordinate and simplex patterns with additional function evaluations, and is particularly useful for parallel load balancing. For example, if some function evaluations in the pattern are dropped due to duplication or bound constraint interaction, then the `total_pattern_size` specification instructs the algorithm to generate new offsets to bring the total number of evaluations up to this consistent total.

The `exploratory_moves` specification controls how the search pattern is adapted. (The search pattern can be adapted after an improving trial point is found, or after all trial points in a search pattern have been found to be unimproving points.) The following exploratory moves selections are supported by SCOLIB:

- The `basic_pattern` case is the simple pattern search approach, which uses the same pattern in each iteration.
- The `multi_step` case examines each trial step in the pattern in turn. If a successful step is found, the pattern search continues examining trial steps about this new point. In this manner, the effects of multiple

successful steps are cumulative within a single iteration. This option does not support any parallelism and will result in a serial pattern search.

- The `adaptive_pattern` case invokes a pattern search technique that adaptively rescales the different search directions to maximize the number of redundant function evaluations. See[45] for details of this method. In preliminary experiments, this method had more robust performance than the standard `basic_pattern` case in serial tests. This option supports a limited degree of parallelism. After successful iterations (where the step length is not contracted), a parallel search will be performed. After unsuccessful iterations (where the step length is contracted), only a single evaluation is performed.

The `initial_delta` and `variable_tolerance` specifications provide the initial offset size and the threshold size at which to terminate the algorithm. For any dimension that has both upper and lower bounds, this step length will be internally rescaled to provide search steps of length `initial_delta * range * 0.1`. This rescaling does not occur for other dimensions, so search steps in those directions have length `initial_delta`. Note that the factor of 0.1 in the rescaling could result in an undesirably small initial step. This can be offset by providing a large `initial_delta`.

In general, pattern search methods can expand and contract their step lengths. SCOLIB pattern search methods contract the step length by the value `contraction_factor`, and they expand the step length by the value `(1/contraction_factor)`. The `expand_after_success` control specifies how many successful objective function improvements must occur with a specific step length prior to expansion of the step length, whereas the `no_expansion` flag instructs the algorithm to forgo pattern expansion altogether.

Finally, constraint infeasibility can be managed in a somewhat more sophisticated manner than the simple weighted penalty function. If the `constant_penalty` specification is used, then the simple weighted penalty scheme described above is used. Otherwise, the constraint penalty is adapted to the value `constraint_penalty/L`, where L is the the smallest step length used so far.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the `hdf5` keyword, this method writes the following results to HDF5:

- [Best Parameters](#)
- [Best Objective Functions](#) (when `objective_functions` are specified)
- [Best Nonlinear Constraints](#)
- [Calibration](#) (when `calibration_terms` are specified)

constant_penalty

- [Keywords Area](#)
- [method](#)
- [coliny_pattern_search](#)
- [constant_penalty](#)

Use a simple weighted penalty to manage feasibility

Specification

Alias: none

Argument(s): none

Default: algorithm dynamically adapts the constraint penalty

Description

Finally, constraint infeasibility can be managed in a somewhat more sophisticated manner than the simple weighted penalty function. If the `constant_penalty` specification is used, then the simple weighted penalty scheme described above is used. Otherwise, the constraint penalty is adapted to the value `constraint_penalty/L`, where `L` is the the smallest step length used so far.

no_expansion

- [Keywords Area](#)
- [method](#)
- [coliny_pattern_search](#)
- [no_expansion](#)

Don't allow expansion of the search pattern

Specification

Alias: none

Argument(s): none

Default: algorithm may expand pattern size

Description

In general, pattern search methods can expand and contract their step lengths. SCOLIB pattern search methods contract the step length by the value `contraction_factor`, and they expand the step length by the value `(1/contraction_factor)`. The `expand_after_success` control specifies how many successful objective function improvements must occur with a specific step length prior to expansion of the step length, whereas the `no_expansion` flag instructs the algorithm to forgo pattern expansion altogether.

expand_after_success

- [Keywords Area](#)
- [method](#)
- [coliny_pattern_search](#)
- [expand_after_success](#)

Set the factor by which a search pattern can be expanded

Specification

Alias: none

Argument(s): INTEGER

Default: 5

Description

In general, pattern search methods can expand and contract their step lengths. SCOLIB pattern search methods contract the step length by the value `contraction_factor`, and they expand the step length by the value $(1/\text{contraction_factor})$. The `expand_after_success` control specifies how many successful objective function improvements must occur with a specific step length prior to expansion of the step length, whereas the `no_expansion` flag instructs the algorithm to forgo pattern expansion altogether.

- [method](#)
- [coliny_pattern_search](#)
- [exploratory_moves](#)

Exploratory moves selection

Specification

Alias: none

Argument(s): none

Default: `basic_pattern`

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required(<i>Choose One</i>)	Exploration Mode (Group 1)	multi_step	Examine trial step around successful new point
			adaptive_pattern	Adaptively rescale search directions
			basic_pattern	Use the same search pattern every iteration

Description

The `exploratory_moves` specification controls how the search pattern is adapted. (The search pattern can be adapted after an improving trial point is found, or after all trial points in a search pattern have been found to be unimproving points.) The following exploratory moves selections are supported by SCOLIB:

multi_step

- [Keywords Area](#)
- [method](#)
- [coliny_pattern_search](#)

- [exploratory_moves](#)
- [multi_step](#)

Examine trial step around successful new point

Specification

Alias: none

Argument(s): none

Description

The `multi_step` case examines each trial step in the pattern in turn. If a successful step is found, the pattern search continues examining trial steps about this new point. In this manner, the effects of multiple successful steps are cumulative within a single iteration. This option does not support any parallelism and will result in a serial pattern

`adaptive_pattern`

- [Keywords Area](#)
- [method](#)
- [colony_pattern_search](#)
- [exploratory_moves](#)
- [adaptive_pattern](#)

Adaptively rescale search directions

Specification

Alias: none

Argument(s): none

Description

The `adaptive_pattern` case invokes a pattern search technique that adaptively rescales the different search directions to maximize the number of redundant function evaluations. See[45] for details of this method. In preliminary experiments, this method had more robust performance than the standard `basic_pattern` case in serial tests. This option supports a limited degree of parallelism. After successful iterations (where the step length is not contracted), a parallel search will be performed. After unsuccessful iterations (where the step length is contracted), only a single evaluation is performed.

`basic_pattern`

- [Keywords Area](#)
- [method](#)
- [colony_pattern_search](#)

- [exploratory_moves](#)
- [basic_pattern](#)

Use the same search pattern every iteration

Specification

Alias: none

Argument(s): none

Description

The `basic_pattern` case is the simple pattern search approach, which uses the same pattern in each iteration.

synchronization

- [Keywords Area](#)
- [method](#)
- [colony_pattern_search](#)
- [synchronization](#)

Select how Dakota schedules function evaluations in a pattern search

Specification

Alias: none

Argument(s): none

Default: nonblocking

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required(<i>Choose One</i>)	Synchronization (Group 1)	blocking	Evaluate all points in a pattern
			nonblocking	Evaluate points in the pattern until an improving point is found

Description

The `synchronization` specification can be used to specify the use of either `blocking` or `nonblocking` schedulers.

blocking

- [Keywords Area](#)
- [method](#)
- [coliny_pattern_search](#)
- [synchronization](#)
- [blocking](#)

Evaluate all points in a pattern

Specification

Alias: none

Argument(s): none

Description

In the `blocking` case, all points in the pattern are evaluated (in parallel), and if the best of these trial points is an improving point, then it becomes the next iterate. These runs are reproducible, assuming use of the same seed in the stochastic case.

nonblocking

- [Keywords Area](#)
- [method](#)
- [coliny_pattern_search](#)
- [synchronization](#)
- [nonblocking](#)

Evaluate points in the pattern until an improving point is found

Specification

Alias: none

Argument(s): none

Description

In the `nonblocking` case, all points in the pattern may not be evaluated. The first improving point found becomes the next iterate. Since the algorithm steps will be subject to parallel timing variabilities, these runs will not generally be repeatable.

contraction_factor

- [Keywords Area](#)
- [method](#)
- [coliny_pattern_search](#)
- [contraction_factor](#)

Amount by which step length is rescaled

Specification

Alias: none

Argument(s): REAL

Default: 0.5

Description

For pattern search methods, `contraction_factor` specifies the amount by which step length is rescaled after unsuccessful iterates, must be strictly between 0 and 1.

For methods that can expand the step length, the expansion is $1/\text{contraction_factor}$

constraint_penalty

- [Keywords Area](#)
- [method](#)
- [coliny_pattern_search](#)
- [constraint_penalty](#)

Multiplier for the penalty function

Specification

Alias: none

Argument(s): REAL

Default: 1.0

Description

Most SCOLIB optimizers treat constraints with a simple penalty scheme that adds `constraint_penalty` times the sum of squares of the constraint violations to the objective function. The default value of `constraint_penalty` is 1000.0, except for methods that dynamically adapt their constraint penalty, for which the default value is 1.0.

initial_delta

- [Keywords Area](#)
- [method](#)
- [coliny_pattern_search](#)
- [initial_delta](#)

Initial step size for derivative-free optimizers

Specification

Alias: none

Argument(s): REAL

Default: 1.0 (COBYLA), 0.1*range (PS, SW)

Description

The `initial_delta` keyword defines the size of the first search step in derivative-free optimization methods, specifically `asynch_pattern_search`, `coliny_cobyla`, `coliny_pattern_search`, `coliny_solis_wets`, and `mesh_adaptive_search`. It is applied in an absolute sense to all search directions.

Default Behavior

The default value is 1.0.

Usage Tips

It is recommended that `initial_delta` be the approximate distance from the initial point to the solution. If this distance is unknown, it is advisable to err on the side of choosing an `initial_delta` that is too large or to not specify it. Relative application of `initial_delta` is not available unless the user scales the problem accordingly.

Examples

Three example method input blocks appear below.

For `asynch_pattern_search`:

```
method
  asynch_pattern_search
    initial_delta = .5
    contraction_factor = 0.25
    merit_function merit1_smooth
    smoothing_factor = 1.0
    constraint_tolerance = 1.e-6
```

For `coliny_pattern_search`:

```
method
  coliny_pattern_search
    initial_delta = .2
    variable_tolerance = 1.e-4
    max_iterations 100
    solution_accuracy = 1.e-6
    seed = 1234
    max_function_evaluations = 1000
```

For `mesh_adaptive_search`

```
method
  mesh_adaptive_search
    initial_delta = 2.0
    seed = 1234
```

variable_tolerance

- [Keywords Area](#)
- [method](#)
- [coliny_pattern_search](#)
- [variable_tolerance](#)

Step length-based stopping criteria for derivative-free optimizers

Specification

Alias: none

Argument(s): REAL

Default: 1.0e-4 (COBYLA), 1.0e-5 (PS), 1.0e-6 (SW)

Description

The `variable_tolerance` keyword defines the minimum step length allowed by the optimizer and is used to determine convergence. It is applicable to `asynch_pattern_search`, `coliny_cobyala`, `coliny_pattern_search`, `coliny_solis_wets`, and `mesh_adaptive_search`.

Default Behavior

The default value varies according to method as follows:

- `asynch_pattern_search`: 1.0e-2
- `coliny_cobyala`: 1.0e-4
- `coliny_pattern_search`: 1.0e-5
- `coliny_solis_wets`: 1.0e-6
- `mesh_adaptive_search`: 1.0e-6

Usage Tips

It is recommended that `variable_tolerance` be set to a value for which changes of that scale in parameter values cause negligible changes in the objective function.

Examples

Three example method input blocks appear below.

For `asynch_pattern_search`:

```
method
  asynch_pattern_search
    contraction_factor = 0.25
    variable_tolerance = 1.e-4
    solution_target = 1.e-6
    max_function_evaluations 500
    constraint_tolerance 1.e-6
```

For `coliny_pattern_search`:

```
method
  coliny_pattern_search
    initial_delta = .2
    variable_tolerance = 1.e-4
    max_iterations 100
    solution_accuracy = 1.e-6
    seed = 1234
    max_function_evaluations = 1000
```

For `mesh_adaptive_search`

```
method
  mesh_adaptive_search
    variable_tolerance = 0.01
    seed = 1234
```

solution_target

- [Keywords Area](#)
- [method](#)
- [coliny_pattern_search](#)
- [solution_target](#)

Stopping criteria based on objective function value

Specification

Alias: `solution_accuracy`

Argument(s): REAL

Default: `-DBL_MAX`

Description

`solution_target` is a termination criterion. The algorithm will terminate when the function value falls below `solution_target`.

seed

- [Keywords Area](#)
- [method](#)
- [coliny_pattern_search](#)
- [seed](#)

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)

Description

The random `seed` control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

show_misc_options

- [Keywords Area](#)
- [method](#)
- [coliny_pattern_search](#)
- [show_misc_options](#)

Show algorithm parameters not exposed in Dakota input

Specification

Alias: none

Argument(s): none

Default: no dump of specification options

Description

All SCOLIB methods support the `show_misc_options` optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The `misc_options` optional specification provides a means for inputting additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

misc_options

- [Keywords Area](#)
- [method](#)
- [coliny_pattern_search](#)
- [misc_options](#)

Set method options not available through Dakota spec

Specification

Alias: none

Argument(s): STRINGLIST

Default: no misc options

Description

All SCOLIB methods support the `show_misc_options` optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The `misc_options` optional specification provides a means for inputting additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

max_iterations

- [Keywords Area](#)
- [method](#)
- [coliny_pattern_search](#)
- [max_iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: `fsu_cvt`, `local_reliability`: 25; `global_{reliability, interval_est, evidence}` / `efficient-global`: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_--iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

convergence_tolerance

- [Keywords Area](#)
- [method](#)
- [coliny_pattern_search](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)

- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

max_function_evaluations

- [Keywords Area](#)
- [method](#)
- [coliny_pattern_search](#)
- [max_function_evaluations](#)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

Default Behavior

Default value is 1000.

scaling

- [Keywords Area](#)
- [method](#)
- [coliny_pattern_search](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*_scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling
3. `auto` - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. `log` - logarithmic scaling

First, any characteristic values from the optional `*_scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- `none`, `auto`, `log` - optional
- `value` - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100
```

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value" "value" "value"
primary_scales = 1 1 100
```

model_pointer

- [Keywords Area](#)
- [method](#)
- [coliny_pattern_search](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                    0.1 0.2 0.6
                    0.1 0.2 0.6
  sample_type lhs
  distribution cumulative

model
  id_model = 'SURR'
  surrogate global,
  dace_method_pointer = 'DACE'
  polynomial quadratic

method
  id_method = 'DACE'

  sampling sample_type lhs
  samples = 121 seed = 5034 rng rnum2

model
  id_model = 'DACE_M'
  single
  interface_pointer = 'I1'

variables
  uniform_uncertain = 2
  lower_bounds = 0. 0.
  upper_bounds = 1. 1.
  descriptors = 'x1' 'x2'

interface
  id_interface = 'I1'
  system asynch evaluation_concurrency = 5
  analysis_driver = 'text_book'

responses
```

```

response_functions = 3
no_gradients
no_hessians

```

7.2.36 coliny_solis_wets

- [Keywords Area](#)
- [method](#)
- [coliny_solis_wets](#)

Simple greedy local search method

Topics

This keyword is related to the topics:

- [package_scolib](#)
- [package_coliny](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			contract_after_- failure	The number of unsuccessful cycles prior to contraction.
	Optional		no_expansion	Don't allow expansion of the search pattern
	Optional		expand_after_- success	Set the factor by which a search pattern can be expanded
	Optional		constant_penalty	Use a simple weighted penalty to manage feasibility

	Optional	contraction_factor	Amount by which step length is rescaled
	Optional	constraint_penalty	Multiplier for the penalty function
	Optional	initial_delta	Initial step size for derivative-free optimizers
	Optional	variable_tolerance	Step length-based stopping criteria for derivative-free optimizers
	Optional	solution_target	Stopping criteria based on objective function value
	Optional	seed	Seed of the random number generator
	Optional	show_misc_options	Show algorithm parameters not exposed in Dakota input
	Optional	misc_options	Set method options not available through Dakota spec
	Optional	max_iterations	Number of iterations allowed for optimizers and adaptive UQ methods
	Optional	convergence_tolerance	Stopping criterion based on objective function or statistics convergence

	Optional	max_function_- evaluations	Number of function evaluations allowed for optimizers
	Optional	scaling	Turn on scaling for variables, responses, and constraints
	Optional	model_pointer	Identifier for model block to be used by a method

Description

The Solis-Wets method is a simple greedy local search heuristic for continuous parameter spaces. Solis-Wets generates trial points using a multivariate normal distribution, and unsuccessful trial points are reflected about the current point to find a descent direction.

See the page [package_scolib](#) for important information regarding all SCOLIB methods

`coliny_solis_wets` is inherently serial, no concurrency is used.

These specifications have the same meaning as corresponding specifications for [coliny_pattern_search](#). Please see that page for specification details.

In particular, `coliny_solis_wets` supports dynamic rescaling of the step length, and dynamic rescaling of the constraint penalty. The only new specification is `contract_after_failure`, which specifies the number of unsuccessful cycles which must occur with a specific delta prior to contraction of the delta.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the [hdf5](#) keyword, this method writes the following results to HDF5:

- [Best Parameters](#)
- [Best Objective Functions](#) (when [objective_functions](#) are specified)
- [Best Nonlinear Constraints](#)
- [Calibration](#) (when [calibration_terms](#) are specified)

See Also

These keywords may also be of interest:

- [coliny_beta](#)
- [coliny_direct](#)
- [coliny_pattern_search](#)
- [coliny_cobyla](#)
- [coliny_ea](#)

contract_after_failure

- [Keywords Area](#)
- [method](#)
- [coliny_solis_wets](#)
- [contract_after_failure](#)

The number of unsuccessful cycles prior to contraction.

Specification

Alias: none

Argument(s): INTEGER

Default: 4*number of variables

Description

In particular, `coliny_solis_wets` supports dynamic rescaling of the step length, and dynamic rescaling of the constraint penalty. The only new specification is `contract_after_failure`, which specifies the number of unsuccessful cycles which must occur with a specific delta prior to contraction of the delta.

no_expansion

- [Keywords Area](#)
- [method](#)
- [coliny_solis_wets](#)
- [no_expansion](#)

Don't allow expansion of the search pattern

Specification

Alias: none

Argument(s): none

Default: algorithm may expand pattern size

Description

In general, pattern search methods can expand and contract their step lengths. SCOLIB pattern search methods contract the step length by the value `contraction_factor`, and they expand the step length by the value $(1/\text{contraction_factor})$. The `expand_after_success` control specifies how many successful objective function improvements must occur with a specific step length prior to expansion of the step length, whereas the `no_expansion` flag instructs the algorithm to forgo pattern expansion altogether.

expand_after_success

- [Keywords Area](#)
- [method](#)
- [coliny_solis_wets](#)
- [expand_after_success](#)

Set the factor by which a search pattern can be expanded

Specification

Alias: none

Argument(s): INTEGER

Default: 5

Description

In general, pattern search methods can expand and contract their step lengths. SCOLIB pattern search methods contract the step length by the value `contraction_factor`, and they expand the step length by the value $(1/\text{contraction_factor})$. The `expand_after_success` control specifies how many successful objective function improvements must occur with a specific step length prior to expansion of the step length, whereas the `no_expansion` flag instructs the algorithm to forgo pattern expansion altogether.

constant_penalty

- [Keywords Area](#)
- [method](#)
- [coliny_solis_wets](#)
- [constant_penalty](#)

Use a simple weighted penalty to manage feasibility

Specification

Alias: none

Argument(s): none

Default: algorithm dynamically adapts the constraint penalty

Description

Finally, constraint infeasibility can be managed in a somewhat more sophisticated manner than the simple weighted penalty function. If the `constant_penalty` specification is used, then the simple weighted penalty scheme described above is used. Otherwise, the constraint penalty is adapted to the value $\text{constraint_penalty}/L$, where L is the the smallest step length used so far.

contraction_factor

- [Keywords Area](#)
- [method](#)
- [coliny_solis_wets](#)
- [contraction_factor](#)

Amount by which step length is rescaled

Specification

Alias: none

Argument(s): REAL

Default: 0.5

Description

For pattern search methods, `contraction_factor` specifies the amount by which step length is rescaled after unsuccessful iterates, must be strictly between 0 and 1.

For methods that can expand the step length, the expansion is $1/\text{contraction_factor}$

constraint_penalty

- [Keywords Area](#)
- [method](#)
- [coliny_solis_wets](#)
- [constraint_penalty](#)

Multiplier for the penalty function

Specification

Alias: none

Argument(s): REAL

Default: 1.0

Description

Most SCOLIB optimizers treat constraints with a simple penalty scheme that adds `constraint_penalty` times the sum of squares of the constraint violations to the objective function. The default value of `constraint_penalty` is 1000.0, except for methods that dynamically adapt their constraint penalty, for which the default value is 1.0.

initial_delta

- [Keywords Area](#)
- [method](#)
- [coliny_solis_wets](#)
- [initial_delta](#)

Initial step size for derivative-free optimizers

Specification

Alias: none

Argument(s): REAL

Default: 1.0 (COBYLA), 0.1*range (PS, SW)

Description

The `initial_delta` keyword defines the size of the first search step in derivative-free optimization methods, specifically `asynch_pattern_search`, `coliny_cobyla`, `coliny_pattern_search`, `coliny_solis_wets`, and `mesh_adaptive_search`. It is applied in an absolute sense to all search directions.

Default Behavior

The default value is 1.0.

Usage Tips

It is recommended that `initial_delta` be the approximate distance from the initial point to the solution. If this distance is unknown, it is advisable to err on the side of choosing an `initial_delta` that is too large or to not specify it. Relative application of `initial_delta` is not available unless the user scales the problem accordingly.

Examples

Three example method input blocks appear below.

For `asynch_pattern_search`:

```
method
  asynch_pattern_search
    initial_delta = .5
    contraction_factor = 0.25
    merit_function merit1_smooth
    smoothing_factor = 1.0
    constraint_tolerance = 1.e-6
```

For `coliny_pattern_search`:

```
method
  coliny_pattern_search
    initial_delta = .2
    variable_tolerance = 1.e-4
    max_iterations 100
    solution_accuracy = 1.e-6
    seed = 1234
    max_function_evaluations = 1000
```

For `mesh_adaptive_search`

```
method
  mesh_adaptive_search
    initial_delta = 2.0
    seed = 1234
```

variable_tolerance

- [Keywords Area](#)
- [method](#)
- [coliny_solis_wets](#)
- [variable_tolerance](#)

Step length-based stopping criteria for derivative-free optimizers

Specification

Alias: none

Argument(s): REAL

Default: 1.0e-4 (COBYLA), 1.0e-5 (PS), 1.0e-6 (SW)

Description

The `variable_tolerance` keyword defines the minimum step length allowed by the optimizer and is used to determine convergence. It is applicable to `asynch_pattern_search`, `coliny_cobyala`, `coliny_pattern_search`, `coliny_solis_wets`, and `mesh_adaptive_search`.

Default Behavior

The default value varies according to method as follows:

- `asynch_pattern_search`: 1.0e-2
- `coliny_cobyala`: 1.0e-4
- `coliny_pattern_search`: 1.0e-5
- `coliny_solis_wets`: 1.0e-6
- `mesh_adaptive_search`: 1.0e-6

Usage Tips

It is recommended that `variable_tolerance` be set to a value for which changes of that scale in parameter values cause negligible changes in the objective function.

Examples

Three example method input blocks appear below.

For `asynch_pattern_search`:

```
method
  asynch_pattern_search
    contraction_factor = 0.25
    variable_tolerance = 1.e-4
    solution_target = 1.e-6
    max_function_evaluations 500
    constraint_tolerance 1.e-6
```

For `coliny_pattern_search`:

```
method
coliny_pattern_search
  initial_delta = .2
  variable_tolerance = 1.e-4
  max_iterations 100
  solution_accuracy = 1.e-6
  seed = 1234
  max_function_evaluations = 1000
```

For `mesh_adaptive_search`

```
method
mesh_adaptive_search
  variable_tolerance = 0.01
  seed = 1234
```

solution_target

- [Keywords Area](#)
- [method](#)
- [coliny_solis_wets](#)
- [solution_target](#)

Stopping criteria based on objective function value

Specification

Alias: `solution_accuracy`

Argument(s): REAL

Default: `-DBL_MAX`

Description

`solution_target` is a termination criterion. The algorithm will terminate when the function value falls below `solution_target`.

seed

- [Keywords Area](#)
- [method](#)
- [coliny_solis_wets](#)
- [seed](#)

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)

Description

The random `seed` control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

show_misc_options

- [Keywords Area](#)
- [method](#)
- [coliny_solis_wets](#)
- [show_misc_options](#)

Show algorithm parameters not exposed in Dakota input

Specification

Alias: none

Argument(s): none

Default: no dump of specification options

Description

All SCOLIB methods support the `show_misc_options` optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The `misc_options` optional specification provides a means for inputting additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

misc_options

- [Keywords Area](#)
- [method](#)
- [coliny_solis_wets](#)
- [misc_options](#)

Set method options not available through Dakota spec

Specification

Alias: none

Argument(s): STRINGLIST

Default: no misc options

Description

All SCOLIB methods support the `show_misc_options` optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The `misc_options` optional specification provides a means for inputting additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

max_iterations

- [Keywords Area](#)
- [method](#)
- [coliny_solis_wets](#)
- [max_iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: `fsu_cvt`, `local_reliability`: 25; `global_{reliability, interval_est, evidence}` / `efficient-global`: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_--iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

convergence_tolerance

- [Keywords Area](#)
- [method](#)
- [coliny_solis_wets](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)

- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

max_function_evaluations

- [Keywords Area](#)
- [method](#)
- [coliny_solis_wets](#)
- [max_function_evaluations](#)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

Default Behavior

Default value is 1000.

scaling

- [Keywords Area](#)
- [method](#)
- [coliny_solis_wets](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*_scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling
3. `auto` - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. `log` - logarithmic scaling

First, any characteristic values from the optional `*_scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- none, auto, log - optional
- value - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100
```

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value" "value" "value"
primary_scales = 1 1 100
```

model_pointer

- [Keywords Area](#)
- [method](#)
- [coliny_solis_wets](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                    0.1 0.2 0.6
                    0.1 0.2 0.6
  sample_type lhs
  distribution cumulative

model
  id_model = 'SURR'

Constrained Optimization BY Linear Approximations (COBYLA)

Topics

This keyword is related to the topics:

- [package_scolib](#)
- [package_coliny](#)
- [local_optimization_methods](#)
- [constrained](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			initial_delta	Reasonable initial changes to optimization variables
	Optional		variable_tolerance	Required or expected accuracy in optimization variables.
	Optional		solution_target	Stopping criteria based on objective function value

	Optional	seed	Seed of the random number generator
	Optional	show_misc_options	Show algorithm parameters not exposed in Dakota input
	Optional	misc_options	Set method options not available through Dakota spec
	Optional	max_iterations	Number of iterations allowed for optimizers and adaptive UQ methods
	Optional	convergence_-tolerance	Stopping criterion based on objective function or statistics convergence
	Optional	max_function_-evaluations	Number of function evaluations allowed for optimizers
	Optional	scaling	Turn on scaling for variables, responses, and constraints
	Optional	model_pointer	Identifier for model block to be used by a method

Description

The Constrained Optimization BY Linear Approximations (COBYLA) algorithm is an extension to the Nelder-Mead simplex algorithm for handling general linear/nonlinear constraints and is invoked using the `coliny_cobyala` group specification. The COBYLA algorithm employs linear approximations to the objective and constraint functions, the approximations being formed by linear interpolation at $N+1$ points in the space of the variables. We regard these interpolation points as vertices of a simplex. The step length parameter controls the size of the simplex and it is reduced automatically from `initial_delta` to `variable_tolerance`. One advantage that COBYLA has over many of its competitors is that it treats each constraint individually when calculating a change to the variables, instead of lumping the constraints together into a single penalty function.

See the page [package.scolib](#) for important information regarding all SCOLIB methods

`coliny_cobyala` is inherently serial.

Stopping Criteria

COBYLA currently only supports termination based on

- [max_function_evaluations](#)
- [solution_target](#)

Other method-independent stopping criteria (`max_iterations` and `convergence_tolerance`) will be ignored if set.

Known Bugs

The implementation of the `coliny_cobyala` optimization method is such that the best function value is not always returned to Dakota for reporting. The user is advised to look through the Dakota screen output or the tabular output file (if generated) to confirm what the best function value and corresponding parameter values are.

The `coliny_cobyala` optimization method does not always respect bound constraints when scaling is turned on.

Neither bug will be fixed, as maintaining third-party source code (such as COBYLA) is outside of the Dakota project scope.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the [hdf5](#) keyword, this method writes the following results to HDF5:

- [Best Parameters](#)
- [Best Objective Functions](#) (when [objective_functions](#) are specified)
- [Best Nonlinear Constraints](#)
- [Calibration](#) (when [calibration_terms](#) are specified)

See Also

These keywords may also be of interest:

- [coliny_beta](#)
- [coliny_direct](#)
- [coliny_pattern_search](#)
- [coliny_ea](#)
- [coliny_solis_wets](#)

initial_delta

- [Keywords Area](#)
- [method](#)
- [coliny_cobyala](#)
- [initial_delta](#)

Reasonable initial changes to optimization variables

Specification

Alias: none

Argument(s): REAL

Default: 1.0 (COBYLA), 0.1*range (PS, SW)

Description

`initial_delta` for COBYLA should be set to be a value that is reasonable for initial changes to the optimization variables. It represents a distance from the initial simplex within which linear approximation subproblems can be trusted to be sufficiently representative of the true problem. It is analogous to the initial trust-region size used in trust-region methods.

Default Behavior

The default value is 1.0.

variable_tolerance

- [Keywords Area](#)
- [method](#)
- [coliny_cobyala](#)
- [variable_tolerance](#)

Required or expected accuracy in optimization variables.

Specification

Alias: none

Argument(s): REAL

Default: 1.0e-4 (COBYLA), 1.0e-5 (PS), 1.0e-6 (SW)

Description

Unlike its use as a stopping criteria in other methods, `variable_tolerance` is used to communicate the accuracy of the optimization variables to COBYLA. It represents the minimum distance from the simplex within which linear approximation subproblems can be trusted to be sufficiently representative of the true problem. It is analogous to the minimum trust-region size used in trust-region methods. Note that, per COBYLA documentation, the level of accuracy is not guaranteed.

Default Behavior

The default value is 0.0001.

Additional Discussion

While `variable_tolerance` is not a stopping criteria for COBYLA, we note that it may have a side effect regarding convergence. In particular, if lower accuracy is required of the optimization variables, it may stop sooner than if higher accuracy is required.

solution_target

- [Keywords Area](#)
- [method](#)
- [coliny_cobyla](#)
- [solution_target](#)

Stopping criteria based on objective function value

Specification

Alias: solution_accuracy

Argument(s): REAL

Default: -DBL_MAX

Description

`solution_target` is a termination criterion. The algorithm will terminate when the function value falls below `solution_target`.

seed

- [Keywords Area](#)
- [method](#)
- [coliny_cobyla](#)
- [seed](#)

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)

Description

The random `seed` control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

show_misc_options

- [Keywords Area](#)
- [method](#)
- [coliny_cobyla](#)
- [show_misc_options](#)

Show algorithm parameters not exposed in Dakota input

Specification

Alias: none

Argument(s): none

Default: no dump of specification options

Description

All SCOLIB methods support the `show_misc_options` optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The `misc_options` optional specification provides a means for inputting additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

misc_options

- [Keywords Area](#)
- [method](#)
- [coliny_cobyla](#)
- [misc_options](#)

Set method options not available through Dakota spec

Specification

Alias: none

Argument(s): STRINGLIST

Default: no misc options

Description

All SCOLIB methods support the `show_misc_options` optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The `misc_options` optional specification provides a means for inputting additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

max.iterations

- [Keywords Area](#)
- [method](#)
- [coliny_cobyla](#)
- [max.iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: `fsu_cvt`, `local_reliability`: 25; `global_{reliability, interval_est, evidence}` / `efficient-global`: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

convergence_tolerance

- [Keywords Area](#)
- [method](#)
- [coliny_cobyla](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

max_function_evaluations

- [Keywords Area](#)
- [method](#)
- [coliny_cobyla](#)
- [max_function_evaluations](#)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

Default Behavior

Default value is 1000.

scaling

- [Keywords Area](#)
- [method](#)
- [coliny_cobyla](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*.scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling
3. `auto` - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. `log` - logarithmic scaling

First, any characteristic values from the optional `*_scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*_scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- `none`, `auto`, `log` - optional
- `value` - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * DBL_MIN$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100

responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

model_pointer

- [Keywords Area](#)
- [method](#)
- [coliny_cobyla](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which [model](#) block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a [model](#) block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```

environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                      0.1 0.2 0.6

	Optional	max_function_evaluations	Number of function evaluations allowed for optimizers
	Optional	scaling	Turn on scaling for variables, responses, and constraints
	Optional	model_pointer	Identifier for model block to be used by a method

Description

The Dividing RECTangles (DIRECT) optimization algorithm is a derivative free global optimization method that balances local search in promising regions of the design space with global search in unexplored regions. As shown in Figure 5.1, DIRECT adaptively subdivides the space of feasible design points so as to guarantee that iterates are generated in the neighborhood of a global minimum in finitely many iterations.

DIRECT” \image latex direct1.eps ”Design space partitioning with DIRECT” width=10cm

In practice, DIRECT has proven an effective heuristic for engineering design applications, for which it is able to quickly identify candidate solutions that can be further refined with fast local optimizers.

See the page [package_scolib](#) for important information regarding all SCOLIB methods

The DIRECT algorithm supports concurrency up to twice the number of variables being optimized.

DIRECT uses the `solution_target`, `constraint_penalty` and `show_misc_options` specifications that are described in [package_scolib](#). Note, however, that DIRECT uses a fixed penalty value for constraint violations (i.e. it is not dynamically adapted as is done in `coliny_pattern_search`).

Search Parameters

The `global_balance_parameter` controls how much global search is performed by only allowing a subregion to be subdivided if the size of the subregion divided by the size of the largest subregion is at least `global_balance_parameter`. Intuitively, this forces large subregions to be subdivided before the smallest subregions are refined. The `local_balance_parameter` provides a tolerance for estimating whether the smallest subregion can provide a sufficient decrease to be worth subdividing; the default value is a small value that is suitable for most applications.

Stopping Criteria

DIRECT can be terminated with:

- [max_function_evaluations](#)
- [max_iterations](#)
- [convergence_tolerance](#)
- [solution_target](#)
- [max_boxsize_limit](#)
- [min_boxsize_limit](#) - most effective in practice

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the [hdf5](#) keyword, this method writes the following results to HDF5:

- [Best Parameters](#)
- [Best Objective Functions](#) (when [objective_functions](#) are specified)
- [Best Nonlinear Constraints](#)
- [Calibration](#) (when [calibration_terms](#) are specified)

See Also

These keywords may also be of interest:

Determine how rectangles are subdivided

Specification

Alias: none

Argument(s): none

Default: major_dimension

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Divide Along (Group 1)	major_dimension	(default) Longest edge of subregion is subdivided
			all_dimensions	All dimensions are simultaneously subdivided

Description

The `division` specification determines how DIRECT subdivides each subregion of the search space.

If `division` is set to `major_dimension`, then the dimension representing the longest edge of the subregion is subdivided (this is the default). If `division` is set to `all_dimensions`, then all dimensions are simultaneously subdivided.

major_dimension

- [Keywords Area](#)
- [method](#)
- [coliny_direct](#)
- [division](#)
- [major_dimension](#)

(default) Longest edge of subregion is subdivided

Specification

Alias: none

Argument(s): none

Description

Longest edge of subregion is subdivided

all_dimensions

- [Keywords Area](#)
- [method](#)
- [coliny_direct](#)
- [division](#)

- [all_dimensions](#)

All dimensions are simultaneously subdivided

Specification

Alias: none

Argument(s): none

Description

All dimensions are simultaneously subdivided

global_balance_parameter

- [Keywords Area](#)
- [method](#)
- [coliny_direct](#)
- [global_balance_parameter](#)

Tolerance for whether a subregion is worth dividing

Specification

Alias: none

Argument(s): REAL

Default: 0.0

Description

The `global_balance_parameter` controls how much global search is performed by only allowing a subregion to be subdivided if the size of the subregion divided by the size of the largest subregion is at least `global_balance_parameter`. Intuitively, this forces large subregions to be subdivided before the smallest subregions are refined.

local_balance_parameter

- [Keywords Area](#)
- [method](#)
- [coliny_direct](#)
- [local_balance_parameter](#)

Tolerance for whether a subregion is worth dividing

Specification

Alias: none

Argument(s): REAL

Default: 1.e-8

Description

See parent page. The `local_balance_parameter` provides a tolerance for estimating whether the smallest subregion can provide a sufficient decrease to be worth subdividing; the default value is a small value that is suitable for most applications.

`max_boxsize_limit`

- [Keywords Area](#)
- [method](#)
- [coliny_direct](#)
- [max_boxsize_limit](#)

Stopping Criterion based on longest edge of hyperrectangle

Specification

Alias: none

Argument(s): REAL

Default: 0.0

Description

Each subregion considered by DIRECT has a **size**, which corresponds to the longest diagonal of the subregion.

`max_boxsize_limit` specification terminates DIRECT if the size of the largest subregion falls below this threshold.

`min_boxsize_limit`

- [Keywords Area](#)
- [method](#)
- [coliny_direct](#)
- [min_boxsize_limit](#)

Stopping Criterion based on shortest edge of hyperrectangle

Specification

Alias: none

Argument(s): REAL

Default: 1.0e-4

Description

`min_boxsize_limit` is a setting that terminates the optimization when the measure of a hyperrectangle S with $f(c(S)) = f_{\min}$ is less than `min_boxsize_limit`.

Each subregion considered by DIRECT has a **size**, which corresponds to the longest diagonal of the subregion.

`min_boxsize_limit` specification terminates DIRECT if the size of the smallest subregion falls below this threshold.

In practice, this specification is likely to be more effective at limiting DIRECT's search.

`constraint_penalty`

- [Keywords Area](#)
- [method](#)
- [coliny_direct](#)
- [constraint_penalty](#)

Multiplier for the penalty function

Specification

Alias: none

Argument(s): REAL

Default: 1000.0

Description

Most SCOLIB optimizers treat constraints with a simple penalty scheme that adds `constraint_penalty` times the sum of squares of the constraint violations to the objective function. The default value of `constraint_penalty` is 1000.0, except for methods that dynamically adapt their constraint penalty, for which the default value is 1.0.

`solution_target`

- [Keywords Area](#)
- [method](#)
- [coliny_direct](#)
- [solution_target](#)

Stopping criteria based on objective function value

Specification

Alias: `solution_accuracy`

Argument(s): REAL

Default: `-DBL_MAX`

Description

`solution_target` is a termination criterion. The algorithm will terminate when the function value falls below `solution_target`.

seed

- [Keywords Area](#)
- [method](#)
- [coliny_direct](#)
- [seed](#)

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)

Description

The random `seed` control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

show_misc_options

- [Keywords Area](#)
- [method](#)
- [coliny_direct](#)
- [show_misc_options](#)

Show algorithm parameters not exposed in Dakota input

Specification

Alias: none

Argument(s): none

Default: no dump of specification options

Description

All SCOLIB methods support the `show_misc_options` optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The `misc_options` optional specification provides a means for inputting additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

Set method options not available through Dakota spec

Specification

Alias: none

Argument(s): STRINGLIST

Default: no misc options

Description

All SCOLIB methods support the `show_misc_options` optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The `misc_options` optional specification provides a means for inputting additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

`max_iterations`

- [Keywords Area](#)
- [method](#)
- [coliny_direct](#)

- [max_iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: `fsu_cvt`, `local_reliability`: 25; `global_{reliability, interval_est, evidence}` / `efficient_global`: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

convergence_tolerance

- [Keywords Area](#)
- [method](#)
- [coliny_direct](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

max_function_evaluations

- [Keywords Area](#)
- [method](#)
- [coliny_direct](#)
- [max_function_evaluations](#)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

Default Behavior

Default value is 1000.

scaling

- [Keywords Area](#)
- [method](#)
- [coliny_direct](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*_scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling
3. `auto` - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. `log` - logarithmic scaling

First, any characteristic values from the optional `*_scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*_scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- `none`, `auto`, `log` - optional
- `value` - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100

responses
objective_functions 3
sense "maximize"
primary_scale_types = "value" "value" "value"
primary_scales = 1 1 100
```

model_pointer

- [Keywords Area](#)
- [method](#)
- [coliny_direct](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                      0.1 0.2 0.6
                      0.1 0.2 0.6

  sample_type lhs
  distribution cumulative

model
  id_model = 'SURR'
```

```

surrogate global,
dace_method_pointer = 'DACE'
polynomial quadratic

method
id_method = 'DACE'
model_pointer = 'DACE_M'
sampling sample_type lhs
samples = 121 seed = 5034 rng rnum2

model
id_model = 'DACE_M'
single
interface_pointer = 'I1'

variables
uniform_uncertain = 2
lower_bounds = 0. 0.
upper_bounds = 1. 1.
descriptors = 'x1' 'x2'

interface
id_interface = 'I1'
system asynch evaluation_concurrency = 5
analysis_driver = 'text_book'

responses
response_functions = 3
no_gradients
no_hessians

```

7.2.39 coliny_ea

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		population_size	Set the population size
	Optional		initialization_type	Specify how to initialize the population
	Optional		fitness_type	Select fitness type
	Optional		replacement_type	Select a replacement type for SCOLIB evolutionary algorithm (<i>coliny_ea</i>)
	Optional		crossover_rate	Specify the probability of a crossover event
	Optional		crossover_type	Select a crossover type
	Optional		mutation_rate	Set probability of a mutation
	Optional		mutation_type	Select a mutation type
	Optional		constraint_penalty	Multiplier for the penalty function
	Optional		solution_target	Stopping criteria based on objective function value
	Optional		seed	Seed of the random number generator
	Optional		show_misc_options	Show algorithm parameters not exposed in Dakota input
	Optional		misc_options	Set method options not available through Dakota spec

	Optional	<code>max_iterations</code>	Number of iterations allowed for optimizers and adaptive UQ methods
	Optional	<code>convergence_tolerance</code>	Stopping criterion based on objective function or statistics convergence
	Optional	<code>max_function_evaluations</code>	Number of function evaluations allowed for optimizers
	Optional	<code>scaling</code>	Turn on scaling for variables, responses, and constraints
	Optional	<code>model_pointer</code>	Identifier for model block to be used by a method

Description

Evolutionary Algorithm

See the page [package_scolib](#) for important information regarding all SCOLIB methods

`coliny_pattern_search` supports concurrency up to the size of the population

The random seed control provides a mechanism for making a stochastic optimization repeatable. That is, the use of the same random seed in identical studies will generate identical results. The `population_size` control specifies how many individuals will comprise the EA's population.

The `initialization_type` defines the type of initialization for the population of the EA. There are three types: `simple_random`, `unique_random`, and `flat_file`. `simple_random` creates initial solutions with random variable values according to a uniform random number distribution. It gives no consideration to any previously generated designs. The number of designs is specified by the `population_size`. `unique_random` is the same as `simple_random`, except that when a new solution is generated, it is checked against the rest of the solutions. If it duplicates any of them, it is rejected. `flat_file` allows the initial population to be read from a flat file. If `flat_file` is specified, a file name must be given.

The `fitness_type` controls how strongly differences in "fitness" (i.e., the objective function) are weighted in the process of selecting "parents" for crossover:

- the `linear_rank` setting uses a linear scaling of probability of selection based on the rank order of each individual's objective function within the population
- the `merit_function` setting uses a proportional scaling of probability of selection based on the relative value of each individual's objective function within the population

The `replacement_type` controls how current populations and newly generated individuals are combined to create a new population. Each of the `replacement_type` selections accepts an integer value, which is referred to below as the `replacement_size`.

- The `random` setting creates a new population using (a) `replacement_size` randomly selected individuals from the current population, and (b) `population_size - replacement_size` individuals randomly selected from among the newly generated individuals (the number of which is optionally specified using `new_solutions_generated`) that are created for each generation (using the selection, crossover, and mutation procedures).
- The `chc` setting creates a new population using (a) the `replacement_size` best individuals from the *combination* of the current population and the newly generated individuals, and (b) `population_size - replacement_size` individuals randomly selected from among the remaining individuals in this combined pool. The `chc` setting is the preferred selection for many engineering problems.
- The `elitist` (default) setting creates a new population using (a) the `replacement_size` best individuals from the current population, (b) and `population_size - replacement_size` individuals randomly selected from the newly generated individuals. It is possible in this case to lose a good solution from the newly generated individuals if it is not randomly selected for replacement; however, the default `new_solutions_generated` value is set such that the entire set of newly generated individuals will be selected for replacement.

Note that `new_solutions_generated` is not recognized by Dakota as a valid keyword unless `replacement_type` has been specified.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the `hdf5` keyword, this method writes the following results to HDF5:

- [Best Parameters](#)
- [Best Objective Functions](#) (when `objective_functions` are specified)
- [Best Nonlinear Constraints](#)
- [Calibration](#) (when `calibration_terms` are specified)

Theory

The basic steps of an evolutionary algorithm are depicted in Figure 5.2.

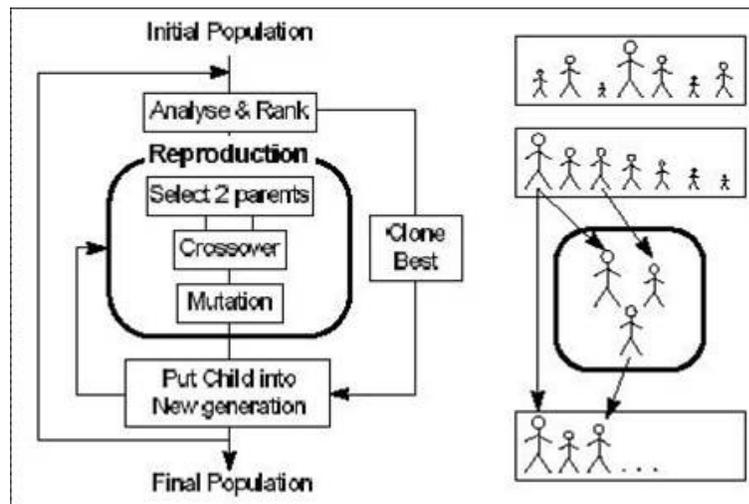

Figure 7.2: Depiction of evolutionary algorithm

They can be enumerated as follows:

1. Select an initial population randomly and perform function evaluations on these individuals
2. Perform selection for parents based on relative fitness
3. Apply crossover and mutation to generate new solutions generated new individuals from the selected parents
 - Apply crossover with a fixed probability from two selected parents
 - If crossover is applied, apply mutation to the newly generated individual with a fixed probability
 - If crossover is not applied, apply mutation with a fixed probability to a single selected parent
4. Perform function evaluations on the new individuals
5. Perform replacement to determine the new population
6. Return to step 2 and continue the algorithm until convergence criteria are satisfied or iteration limits are exceeded

population_size

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [population_size](#)

Set the population size

Specification

Alias: none

Argument(s): INTEGER

Default: 50

Description

The number of designs in the population is specified by the `population_size`.

initialization_type

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [initialization_type](#)

Specify how to initialize the population

Specification

Alias: none

Argument(s): none

Default: `unique_random`

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required(<i>Choose One</i>)	Initialization Type (Group 1)	simple_random	Create random initial solutions
			unique_random	Create random initial solutions, but enforce uniqueness (default)

			flat_file	Read initial solutions from file
--	--	--	---------------------------	----------------------------------

Description

The `initialization_type` defines how the initial population is created for the GA. There are three types:

1. `simple_random`
2. `unique_random` (default)
3. `flat_file`

Setting the size for the `flat_file` initializer has the effect of requiring a minimum number of designs to create. If this minimum number has not been created once the files are all read, the rest are created using the `unique_random` initializer and then the `simple_random` initializer if necessary.

simple_random

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [initialization_type](#)
- [simple_random](#)

Create random initial solutions

Specification

Alias: none

Argument(s): none

Description

`simple_random` creates initial solutions with random variable values according to a uniform random number distribution. It gives no consideration to any previously generated designs.

unique_random

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [initialization_type](#)
- [unique_random](#)

Create random initial solutions, but enforce uniqueness (default)

Specification

Alias: none

Argument(s): none

Description

`unique_random` is the same as `simple_random`, except that when a new solution is generated, it is checked against the rest of the solutions. If it duplicates any of them, it is rejected.

`flat_file`

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [initialization_type](#)
- [flat_file](#)

Read initial solutions from file

Specification

Alias: none

Argument(s): STRING

Description

`flat_file` allows the initial population to be read from a flat file. If `flat_file` is specified, a file name must be given.

`fitness_type`

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [fitness_type](#)

Select fitness type

Specification

Alias: none

Argument(s): none

Default: linear_rank

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Fitness Type (Group 1)	linear_rank	Set selection scaling
			merit_function	Balance goals of reducing objective function and satisfying constraints

Description

The `fitness_type` controls how strongly differences in "fitness" (i.e., the objective function) are weighted in the process of selecting "parents" for crossover. It has two options, `linear_rank` and `merit_function`.

`linear_rank`

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [fitness_type](#)
- [linear_rank](#)

Set selection scaling

Specification

Alias: none

Argument(s): none

Description

The `linear_rank` setting uses a linear scaling of probability of selection based on the rank order of each individual's objective function within the population

`merit_function`

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [fitness_type](#)
- [merit_function](#)

Balance goals of reducing objective function and satisfying constraints

Specification

Alias: none

Argument(s): none

Description

A `merit_function` is a function in constrained optimization that attempts to provide joint progress toward reducing the objective function and satisfying the constraints.

replacement_type

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [replacement_type](#)

Select a replacement type for SCOLIB evolutionary algorithm (`coliny_ea`)

Specification

Alias: none

Argument(s): none

Default: `elitist=1`

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Replacement Type (Group 1)	random	Create new population randomly
			chc	Create new population using replacement
			elitist	Use the best designs to form a new population
	Optional		new_solutions_ generated	Replace population with individuals chosen from population

Description

The `replacement_type` controls how current populations and newly generated individuals are combined to create a new population. Each of the `replacement_type` selections accepts an associated integer value, which is specified by the `replacement_size`:

The `random` setting creates a new population using (a) `replacement_size` randomly selected individuals from the current population, and (b) `population_size - replacement_size` individuals randomly

selected from among the newly generated individuals (the number of which is optionally specified using `new_solutions_generated`) that are created for each generation (using the selection, crossover, and mutation procedures).

The `chc` setting creates a new population using (a) the `replacement_size` best individuals from the combination of the current population and the newly generated individuals, and (b) `population_size - replacement_size` individuals randomly selected from among the remaining individuals in this combined pool. The `chc` setting is the preferred selection for many engineering problems.

The `elitist` (default) setting creates a new population using (a) the `replacement_size` best individuals from the current population, (b) and `population_size - replacement_size` individuals randomly selected from the newly generated individuals. It is possible in this case to lose a good solution from the newly generated individuals if it is not randomly selected for replacement; however, the default `new_solutions_generated` value is set such that the entire set of newly generated individuals will be selected for replacement.

Note that `new_solutions_generated` is not recognized by Dakota as a valid keyword unless `replacement_type` has been specified.

random

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [replacement_type](#)
- [random](#)

Create new population randomly

Specification

Alias: none

Argument(s): INTEGER

Description

The `replacement_type` controls how current populations and newly generated individuals are combined to create a new population. Each of the `replacement_type` selections accepts an integer value, which is referred as the `replacement_size`:

The `random` setting creates a new population using:

- `replacement_size` randomly selected individuals from the current population, and
- `population_size - replacement_size` individuals randomly selected from among the newly generated individuals (the number of which is optionally specified using `new_solutions_generated`) that are created for each generation (using the selection, crossover, and mutation procedures).

chc

- [Keywords Area](#)
- [method](#)

- [coliny_ea](#)
- [replacement_type](#)
- [chc](#)

Create new population using replacement

Specification

Alias: none

Argument(s): INTEGER

Description

The `replacement_type` controls how current populations and newly generated individuals are combined to create a new population. Each of the `replacement_type` selections accepts an integer value, which is referred as the `replacement_size`:

The `chc` setting creates a new population using (a) the `replacement_size` best individuals from the *combination* of the current population and the newly generated individuals, and (b) `population_size - replacement_size` individuals randomly selected from among the remaining individuals in this combined pool. The `chc` setting is the preferred selection for many engineering problems.

elitist

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [replacement_type](#)
- [elitist](#)

Use the best designs to form a new population

Specification

Alias: none

Argument(s): INTEGER

Description

The `elitist` (default) setting creates a new population using (a) the `replacement_size` best individuals from the current population, (b) and `population_size - replacement_size` individuals randomly selected from the newly generated individuals. It is possible in this case to lose a good solution from the newly generated individuals if it is not randomly selected for replacement; however, the default `new_solutions_generated` value is set such that the entire set of newly generated individuals will be selected for replacement.

new_solutions_generated

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [replacement_type](#)
- [new_solutions_generated](#)

Replace population with individuals chosen from population

Specification

Alias: none

Argument(s): INTEGER

Default: population_size - replacement_size

Description

- The random setting creates a new population using (a) replacement_size randomly selected individuals from the current population, and (b) population_size - replacement_size individuals randomly selected from among the newly generated individuals (the number of which is optionally specified using new_solutions_generated) that are created for each generation (using the selection, crossover, and mutation procedures).

crossover_rate

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [crossover_rate](#)

Specify the probability of a crossover event

Specification

Alias: none

Argument(s): REAL

Default: 0.8

Description

The `crossover_type` controls what approach is employed for combining parent genetic information to create offspring, and the `crossover_rate` specifies the probability of a crossover operation being performed to generate a new offspring. The SCOLIB EA method supports three forms of crossover, `two_point`, `blend`, and `uniform`, which generate a new individual through combinations of two parent individuals. Two-point crossover divides each parent into three regions, where offspring are created from the combination of the middle region from one parent and the end regions from the other parent. Since the SCOLIB EA does not utilize bit representations of variable values, the crossover points only occur on coordinate boundaries, never within the bits of a particular coordinate. Uniform crossover creates offspring through random combination of coordinates from the two parents. Blend crossover generates a new individual randomly along the multidimensional vector connecting the two parents.

`crossover_type`

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [crossover_type](#)

Select a crossover type

Specification

Alias: none

Argument(s): none

Default: `two_point`

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required(<i>Choose One</i>)	Crossover Type (Group 1)	<code>two_point</code>	Combine middle of one parent with end of another
			<code>blend</code>	Random blend of parents
			<code>uniform</code>	Randomly combine coordinates from parents

Description

The `crossover_type` controls what approach is employed for combining parent genetic information to create offspring. The SCOLIB EA method supports three forms of crossover, `two_point`, `blend`, and `uniform`, which generate a new individual through combinations of two parent individuals.

two_point

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [crossover_type](#)
- [two_point](#)

Combine middle of one parent with end of another

Specification

Alias: none

Argument(s): none

Description

Two-point crossover divides each parent into three regions, where offspring are created from the combination of the middle region from one parent and the end regions from the other parent. Since the SCOLIB EA does not utilize bit representations of variable values, the crossover points only occur on coordinate boundaries, never within the bits of a particular coordinate.

blend

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [crossover_type](#)
- [blend](#)

Random blend of parents

Specification

Alias: none

Argument(s): none

Description

blend crossover generates a new individual randomly along the multidimensional vector connecting the two parents.

uniform

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [crossover_type](#)
- [uniform](#)

Randomly combine coordinates from parents

Specification

Alias: none

Argument(s): none

Description

Uniform crossover creates offspring through random combination of coordinates from the two parents.

mutation_rate

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [mutation_rate](#)

Set probability of a mutation

Specification

Alias: none

Argument(s): REAL

Default: 1.0

Description

The `mutation_rate` controls the probability of mutation being performed on an individual, both for new individuals generated by crossover (if crossover occurs) and for individuals from the existing population. It is the fraction of trial points that are mutated in a given iteration and therefore must be specified to be between 0 and 1.

mutation_type

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [mutation_type](#)

Select a mutation type

Specification

Alias: none

Argument(s): none

Default: `offset_normal`

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required(<i>Choose One</i>)	Mutation Type (Group 1)	replace_uniform	Replace coordinate with randomly generated value
			offset_normal	Set mutation offset to use a normal distribution
			offset_cauchy	Use a Cauchy distribution for the mutation offset
			offset_uniform	Set mutation offset to use a uniform distribution
	Optional		non_adaptive	Disable self-adaptive mutation

Description

The `mutation_type` controls what approach is employed in randomly modifying continuous design variables within the EA population. Each of the mutation methods generates coordinate-wise changes to individuals, usually by adding a random variable to a given coordinate value (an `offset_*` mutation), but also by replacing a given coordinate value with a random variable (a `replace_*` mutation).

Discrete design variables are always mutated using the `offset_uniform` method.

`replace_uniform`

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [mutation_type](#)
- [replace_uniform](#)

Replace coordinate with randomly generated value

Specification

Alias: none

Argument(s): none

Description

The `replace_uniform` mutation type generates a replacement value for a coordinate using a uniformly distributed value over the total range for that coordinate.

offset_normal

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [mutation_type](#)
- [offset_normal](#)

Set mutation offset to use a normal distribution

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		mutation_scale	Scales mutation across range of parameter
	Optional		mutation_range	Set uniform offset control for discrete parameters

Description

The `offset_normal` type is an "offset" mutation that adds a 0-mean random variable with a normal uniform distribution to the existing coordinate value. The offset is limited in magnitude by `mutation_scale`.

mutation_scale

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [mutation_type](#)
- [offset_normal](#)
- [mutation_scale](#)

Scales mutation across range of parameter

Specification

Alias: none

Argument(s): REAL

Default: 0.1

Description

The `mutation_scale` specifies a scale factor which scales continuous mutation offsets; this is a fraction of the total range of each dimension, so `mutation_scale` is a relative value between 0 and 1.

mutation_range

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [mutation_type](#)
- [offset_normal](#)
- [mutation_range](#)

Set uniform offset control for discrete parameters

Specification

Alias: none

Argument(s): INTEGER

Default: 1

Description

The `mutation_range` is used to control `offset_uniform` mutation used for discrete parameters. The replacement discrete value is the original value plus or minus an integer value up to `mutation_range`.

offset_cauchy

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [mutation_type](#)
- [offset_cauchy](#)

Use a Cauchy distribution for the mutation offset

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		mutation_scale	Scales mutation across range of parameter
	Optional		mutation_range	Set uniform offset control for discrete parameters

Description

The `offset_cauchy` type is an "offset" mutation that adds a 0-mean random variable with a cauchy distribution to the existing coordinate value. The offset is limited in magnitude by `mutation_scale`.

mutation_scale

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [mutation_type](#)
- [offset_cauchy](#)
- [mutation_scale](#)

Scales mutation across range of parameter

Specification

Alias: none

Argument(s): REAL

Default: 0.1

Description

The `mutation_scale` specifies a scale factor which scales continuous mutation offsets; this is a fraction of the total range of each dimension, so `mutation_scale` is a relative value between 0 and 1.

mutation_range

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [mutation_type](#)
- [offset_cauchy](#)
- [mutation_range](#)

Set uniform offset control for discrete parameters

Specification

Alias: none

Argument(s): INTEGER

Default: 1

Description

The `mutation_range` is used to control `offset_uniform` mutation used for discrete parameters. The replacement discrete value is the original value plus or minus an integer value up to `mutation_range`.

`offset_uniform`

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [mutation_type](#)
- [offset_uniform](#)

Set mutation offset to use a uniform distribution

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			mutation_scale	Scales mutation across range of parameter
	Optional		mutation_range	Set uniform offset control for discrete parameters

Description

The `offset_uniform` type is an "offset" mutation that adds a 0-mean random variable with a uniform distribution to the existing coordinate value. The offset is limited in magnitude by `mutation_scale`

For discrete design variables, `offset_uniform` is always used, and `mutation_range` controls the magnitude of the mutation.

`mutation_scale`

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)

- [mutation_type](#)
- [offset_uniform](#)
- [mutation_scale](#)

Scales mutation across range of parameter

Specification

Alias: none

Argument(s): REAL

Default: 0.1

Description

The `mutation_scale` specifies a scale factor which scales continuous mutation offsets; this is a fraction of the total range of each dimension, so `mutation_scale` is a relative value between 0 and 1.

mutation_range

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [mutation_type](#)
- [offset_uniform](#)
- [mutation_range](#)

Set uniform offset control for discrete parameters

Specification

Alias: none

Argument(s): INTEGER

Default: 1

Description

The `mutation_range` is used to control `offset_uniform` mutation used for discrete parameters. The replacement discrete value is the original value plus or minus an integer value up to `mutation_range`.

non_adaptive

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [mutation_type](#)
- [non_adaptive](#)

Disable self-adaptive mutation

Specification

Alias: none

Argument(s): none

Default: Adaptive mutation

Description

The SCOLIB EA method uses self-adaptive mutation, which modifies the mutation scale dynamically. This mechanism is borrowed from EAs like evolution strategies. The `non_adaptive` flag can be used to deactivate the self-adaptation, which may facilitate a more global search.

Note that `non_adaptive` is not recognized by Dakota as a valid keyword unless `mutation_type` has been specified.

constraint_penalty

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [constraint_penalty](#)

Multiplier for the penalty function

Specification

Alias: none

Argument(s): REAL

Description

Most SCOLIB optimizers treat constraints with a simple penalty scheme that adds `constraint_penalty` times the sum of squares of the constraint violations to the objective function. The default value of `constraint_penalty` is 1000.0, except for methods that dynamically adapt their constraint penalty, for which the default value is 1.0.

solution_target

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [solution_target](#)

Stopping criteria based on objective function value

Specification

Alias: solution_accuracy

Argument(s): REAL

Default: -DBL_MAX

Description

solution_target is a termination criterion. The algorithm will terminate when the function value falls below solution_target.

seed

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [seed](#)

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)

Description

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

show_misc_options

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [show_misc_options](#)

Show algorithm parameters not exposed in Dakota input

Specification

Alias: none

Argument(s): none

Default: no dump of specification options

Description

All SCOLIB methods support the `show_misc_options` optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The `misc_options` optional specification provides a means for inputting additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

misc_options

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [misc_options](#)

Set method options not available through Dakota spec

Specification

Alias: none

Argument(s): STRINGLIST

Default: no misc options

Description

All SCOLIB methods support the `show_misc_options` optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The `misc_options` optional specification provides a means for inputting additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

max.iterations

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [max.iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: `fsu_cvt`, `local_reliability: 25`; `global_{reliability, interval_est, evidence} / efficient_global: 25*n`)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_--iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

convergence_tolerance

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

max_function_evaluations

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [max_function_evaluations](#)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

Default Behavior

Default value is 1000.

scaling

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*_scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling
3. `auto` - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. `log` - logarithmic scaling

First, any characteristic values from the optional `*_scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*_scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- `none`, `auto`, `log` - optional
- `value` - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100

responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

model_pointer

- [Keywords Area](#)
- [method](#)
- [coliny_ea](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which [model](#) block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a [model](#) block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```

environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
  samples = 10
  seed = 98765 rng rnum2
  response_levels = 0.1 0.2 0.6
                   0.1 0.2 0.6
                   0.1 0.2 0.6

  sample_type lhs
  distribution cumulative

model
  id_model = 'SURR'
  surrogate global,
  dace_method_pointer = 'DACE'
  polynomial quadratic

method
  id_method = 'DACE'
  model_pointer = 'DACE_M'
  sampling sample_type lhs
  samples = 121 seed = 5034 rng rnum2

model
  id_model = 'DACE_M'
  single
  interface_pointer = 'I1'

variables
  uniform_uncertain = 2
  lower_bounds = 0. 0.
  upper_bounds = 1. 1.
  descriptors = 'x1' 'x2'

interface
  id_interface = 'I1'
  system_async evaluation_concurrency = 5
  analysis_driver = 'text_book'

responses
  response_functions = 3
  no_gradients
  no_hessians

```

7.2.40 coliny_beta

- [Keywords Area](#)
- [method](#)
- [coliny_beta](#)

(Experimental) Coliny beta solver

Topics

This keyword is related to the topics:

- [package_scolib](#)
- [package_coliny](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Required	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		beta_solver_name	Use an in-development SCOLIB solver
	Optional		solution_target	Stopping criteria based on objective function value
	Optional		seed	Seed of the random number generator
	Optional		show_misc_options	Show algorithm parameters not exposed in Dakota input
	Optional		misc_options	Set method options not available through Dakota spec
	Optional		max_iterations	Number of iterations allowed for optimizers and adaptive UQ methods
	Optional		convergence_-tolerance	Stopping criterion based on objective function or statistics convergence

	Optional	max_function_- evaluations	Number of function evaluations allowed for optimizers
	Optional	scaling	Turn on scaling for variables, responses, and constraints
	Optional	model_pointer	Identifier for model block to be used by a method

Description

This method keyword allows testing of experimental (beta) Coliny (Scolib) optimization solvers during software development. It is intended primarily for developer use. Additional information on Coliny solvers is available at [package_scolib](#).

See Also

These keywords may also be of interest:

- [coliny_direct](#)

- [coliny_cobyla](#)
- [coliny_ea](#)
- [coliny_solis_wets](#)

beta_solver_name

- [Keywords Area](#)
- [method](#)
- [coliny_beta](#)
- [beta_solver_name](#)

Use an in-development SCOLIB solver

Specification

Alias: none

Argument(s): STRING

Description

This is a means of accessing new methods in SCOLIB before they are exposed through the Dakota interface. Seek help from a Dakota or SCOLIB developer or a Dakota developer.

solution_target

- [Keywords Area](#)
- [method](#)
- [coliny_beta](#)
- [solution_target](#)

Stopping criteria based on objective function value

Specification

Alias: solution_accuracy

Argument(s): REAL

Default: -DBL_MAX

Description

`solution_target` is a termination criterion. The algorithm will terminate when the function value falls below `solution_target`.

seed

- [Keywords Area](#)
- [method](#)
- [coliny_beta](#)
- [seed](#)

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)

Description

The random `seed` control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

show_misc_options

- [Keywords Area](#)
- [method](#)
- [coliny_beta](#)
- [show_misc_options](#)

Show algorithm parameters not exposed in Dakota input

Specification

Alias: none

Argument(s): none

Default: no dump of specification options

Description

All SCOLIB methods support the `show_misc_options` optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The `misc_options` optional specification provides a means for inputting additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

misc_options

- [Keywords Area](#)
- [method](#)
- [coliny_beta](#)
- [misc_options](#)

Set method options not available through Dakota spec

Specification

Alias: none

Argument(s): STRINGLIST

Default: no misc options

Description

All SCOLIB methods support the `show_misc_options` optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The `misc_options` optional specification provides a means for inputting additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

max_iterations

- [Keywords Area](#)
- [method](#)
- [coliny_beta](#)
- [max_iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: `fsu_cvt`, `local_reliability`: 25; `global_{reliability, interval_est, evidence}` / `efficient-global`: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_--iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

convergence_tolerance

- [Keywords Area](#)
- [method](#)
- [coliny_beta](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)

- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

max_function_evaluations

- [Keywords Area](#)
- [method](#)
- [coliny_beta](#)
- [max_function_evaluations](#)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

Default Behavior

Default value is 1000.

scaling

- [Keywords Area](#)
- [method](#)
- [coliny_beta](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*_scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling
3. `auto` - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval $[0,1]$;
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into $[0,1]$.

4. `log` - logarithmic scaling

First, any characteristic values from the optional `*_scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- none, auto, log - optional
- value - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100

responses
objective_functions 3
sense "maximize"
primary_scale_types = "value" "value" "value"
primary_scales = 1 1 100
```

	Optional	<code>regression_-diagnostics</code>	Turn on regression diagnostics
	Optional	<code>convergence_-tolerance</code>	Stopping criterion based on objective function or statistics convergence
	Optional	<code>max_iterations</code>	Number of iterations allowed for optimizers and adaptive UQ methods
	Optional	<code>speculative</code>	Compute speculative gradients
	Optional	<code>max_function_-evaluations</code>	Number of function evaluations allowed for optimizers
	Optional	<code>scaling</code>	Turn on scaling for variables, responses, and constraints
	Optional	<code>model_pointer</code>	Identifier for model block to be used by a method

Description

NL2SOL is available as `nl2sol` and addresses unconstrained and bound-constrained least squares problems. It uses a trust-region method (and thus can be viewed as a generalization of the Levenberg-Marquardt algorithm) and adaptively chooses between two Hessian approximations, the Gauss-Newton approximation alone and the Gauss-Newton approximation plus a quasi-Newton approximation to the rest of the Hessian. Even on small-residual problems, the latter Hessian approximation can be useful when the starting guess is far from the solution. On problems that are not over-parameterized (i.e., that do not involve more optimization variables than the data support), NL2SOL usually exhibits fast convergence.

Several internal NL2SOL convergence tolerances are adjusted in response to `function_precision`, which gives the relative precision to which responses are computed.

These tolerances may also be specified explicitly using:

- `convergence_tolerance` (NL2SOL's `rfctol`)
- `x_conv_tol` (NL2SOL's `xctol`)

- `absolute_conv_tol` (NL2SOL's `afctol`)
- `singular_conv_tol` (NL2SOL's `sctol`)
- `false_conv_tol` (NL2SOL's `xftol`)
- `initial_trust_radius` (NL2SOL's `lmax0`)

The internal NL2SOL defaults can be obtained for many of these controls by specifying the value -1. The internal defaults are often functions of machine epsilon (as limited by `function_precision`).

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the `hdf5` keyword, this method writes the following results to HDF5:

- [Best Parameters](#)
- [Best Nonlinear Constraints](#)
- [Calibration](#) (when `calibration_terms` are specified)
- [Parameter Confidence Intervals](#) (when `num_experiments` equals 1)

Examples

An example of `nl2sol` is given below, and is discussed in the User's Manual.

Note that in this usage of `calibration_terms`, the driver script `rosenbrock`, is returning "residuals", which the `nl2sol` method is attempting to minimize. Another use case is to provide a data file, which Dakota will attempt to match the model responses to. See [calibration_data_file](#). Finally, as of Dakota 6.2, the field data capability may be used with `nl2sol`. That is, the user can specify field simulation data and field experiment data, and Dakota will interpolate and provide the proper residuals for the calibration.

```
# Dakota Input File: rosen_opt_nls.in

Theory

NL2SOL has a variety of internal controls as described in AT&T Bell Labs CS TR 153 (<http://cm.bell-labs.com/cm/cs/cstr/153.ps.gz>). A number of existing Dakota controls (method independent controls and responses controls) are mapped into these NL2SOL internal controls. In particular, Dakota's `convergence_tolerance`, `max.iterations`, `max.function.evaluations`, and `fd.gradient.step.size` are mapped directly into NL2SOL's `rfctol`, `mxiter`, `mxfcal`, and `dltfdj` controls, respectively. In addition, Dakota's `fd.hessian.step.size` is mapped into both `delta0` and `dltfdc`, and Dakota's output verbosity is mapped into NL2SOL's `auxprt` and `outlev` (for normal/verbose/debug output, NL2SOL prints initial guess, final solution, solution statistics, nondefault values, and changes to the active bound constraint set on every iteration; for quiet output, NL2SOL prints only the initial guess and final solution; and for silent output, NL2SOL output is suppressed).

function_precision

- [Keywords Area](#)
- [method](#)
- [nl2sol](#)
- [function_precision](#)

Specify the maximum precision of the analysis code responses

Specification

Alias: none

Argument(s): REAL

Default: 1.0e-10

Description

The `function_precision` control provides the algorithm with an estimate of the accuracy to which the problem functions can be computed. This is used to prevent the algorithm from trying to distinguish between function values that differ by less than the inherent error in the calculation.

absolute_conv_tol

- [Keywords Area](#)
- [method](#)
- [nl2sol](#)
- [absolute_conv_tol](#)

Absolute convergence tolerance

Specification

Alias: none

Argument(s): REAL

Default: -1. (use NL2SOL internal default)

Description

`absolute_conv_tol` (NL2SOL's `afctol`) is the absolute function convergence tolerance (stop when half the sum of squares is less than `absolute_conv_tol`, which is mainly of interest on zero-residual test problems).

The internal default is a function of machine epsilon (as limited by `function_precision`). The default is selected with a value of -1.

x_conv_tol

- [Keywords Area](#)
- [method](#)
- [nl2sol](#)
- [x_conv_tol](#)

X-convergence tolerance

Specification

Alias: none

Argument(s): REAL

Default: -1. (use NL2SOL internal default)

Description

`x_conv_tol` maps to the internal NL2SOL control `xctol`. It is the X-convergence tolerance (scaled relative accuracy of the solution variables).

The internal default is a function of machine epsilon (as limited by `function_precision`). The default is selected with a value of -1.

singular_conv_tol

- [Keywords Area](#)
- [method](#)
- [nl2sol](#)
- [singular_conv_tol](#)

Singular convergence tolerance

Specification

Alias: none

Argument(s): REAL

Default: -1. (use NL2SOL internal default)

Description

`singular_conv_tol` (NL2SOL's `sctol`) is the singular convergence tolerance, which works in conjunction with [singular_radius](#) to test for underdetermined least-squares problems (stop when the relative reduction yet possible in the sum of squares appears less than `singular_conv_tol` for steps of scaled length at most [singular_radius](#)).

The internal default is a function of machine epsilon (as limited by `function_precision`). The default is selected with a value of -1.

singular_radius

- [Keywords Area](#)
- [method](#)
- [nl2sol](#)
- [singular_radius](#)

Singular radius

Specification

Alias: none

Argument(s): REAL

Default: -1. (use NL2SOL internal default of 1)

Description

`singular_radius` works in conjunction with [singular_conv_tol](#) to test for underdetermined least-squares problems (stop when the relative reduction yet possible in the sum of squares appears less than `singular_conv_tol` for steps of scaled length at most [singular_radius](#)).

The internal default results in the internal use of steps of length 1. The default is selected with a value of -1.

false_conv_tol

- [Keywords Area](#)
- [method](#)
- [nl2sol](#)
- [false_conv_tol](#)

False convergence tolerance

Specification

Alias: none

Argument(s): REAL

Default: -1. (use NL2SOL internal default)

Description

`false_conv_tol` (NL2SOL's `xf_tol`) is the false-convergence tolerance (stop with a suspicion of discontinuity when a more favorable stopping test is not satisfied and a step of scaled length at most `false_conv_tol` is not accepted)

The internal default is a function of machine epsilon (as limited by `function_precision`). The default is selected with a value of -1.

initial_trust_radius

- [Keywords Area](#)
- [method](#)
- [nl2sol](#)
- [initial_trust_radius](#)

Initial trust region radius

Specification

Alias: none

Argument(s): REAL

Default: -1. (use NL2SOL internal default of 1)

Description

`initial_trust_radius` specification (NL2SOL's `lmax0`) specifies the initial trust region radius for the algorithm.

The internal default results in the internal use of steps of length 1. The default is selected with a value of -1.

covariance

- [Keywords Area](#)
- [method](#)
- [nl2sol](#)
- [covariance](#)

Determine how the final covariance matrix is computed

Specification

Alias: none

Argument(s): INTEGER

Default: 0 (no covariance)

Description

`covariance` (NL2SOL's `covreq`) specifies whether and how NL2SOL computes a final covariance matrix.

The desired covariance approximation:

- 0 = default = none
- 1 or -1 ==> $\sigma^2 H^{-1} J^T J H^{-1}$
- 2 or -2 ==> $\sigma^2 H^{-1}$
- 3 or -3 ==> $\sigma^2 (J^T J)^{-1}$
- Negative values ==> estimate the final Hessian H by finite differences of function values only (using `fd_hessian_step_size`)
- Positive values ==> differences of gradients (using `fd_hessian_step_size`)

regression_diagnostics

- [Keywords Area](#)
- [method](#)
- [nl2sol](#)
- [regression_diagnostics](#)

Turn on regression diagnostics

Specification

Alias: none

Argument(s): none

Default: no regression diagnostics

Description

When `regression_diagnostics` (NL2SOL's `rdreq`) is specified and a positive-definite final Hessian approximation `H` is computed, NL2SOL computes and prints a regression diagnostic vector `RD` such that if omitting the i -th observation would cause α times the change in the solution that omitting the j -th observation would cause, then $RD[i] = |\alpha| RD[j]$. The finite-difference step-size tolerance affecting `H` is `fd_step_size` (NL2SOL's `delta0` and `dltfdc`).

convergence_tolerance

- [Keywords Area](#)
- [method](#)
- [nl2sol](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)

- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

max.iterations

- [Keywords Area](#)
- [method](#)
- [nl2sol](#)
- [max.iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: fsu_cvt, local_reliability: 25; global_{reliability, interval_est, evidence}/efficient-global: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

speculative

- [Keywords Area](#)
- [method](#)
- [nl2sol](#)
- [speculative](#)

Compute speculative gradients

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no speculation

Description

When performing gradient-based optimization in parallel, `speculative` gradients can be selected to address the load imbalance that can occur between gradient evaluation and line search phases. In a typical gradient-based optimization, the line search phase consists primarily of evaluating the objective function and any constraints at a trial point, and then testing the trial point for a sufficient decrease in the objective function value and/or constraint violation. If a sufficient decrease is not observed, then one or more additional trial points may be attempted sequentially. However, if the trial point is accepted then the line search phase is complete and the gradient evaluation phase begins. By speculating that the gradient information associated with a given line search trial point will be used later, additional coarse grained parallelism can be introduced by computing the gradient information (either by finite difference or analytically) in parallel, at the same time as the line search phase trial-point function values. This balances the total amount of computation to be performed at each design point and allows for efficient utilization of multiple processors. While the total amount of work performed will generally increase (since some speculative gradients will not be used when a trial point is rejected in the line search phase), the run time will usually decrease (since gradient evaluations needed at the start of each new optimization cycle were already performed in parallel during the line search phase). Refer to [14] for additional details. The speculative specification is implemented for the gradient-based optimizers in the DOT, CONMIN, and OPT++ libraries, and it can be used with dakota numerical or analytic gradient selections in the responses specification (refer to [responses](#) gradient section for information on these specifications). It should not be selected with vendor numerical gradients since vendor internal finite difference algorithms have not been modified for this purpose. In full-Newton approaches, the Hessian is also computed speculatively. NPSOL and NLSSOL do not support speculative gradients, as their gradient-based line search in user-supplied gradient mode (dakota numerical or analytic gradients) is a superior approach for load-balanced parallel execution.

The `speculative` specification enables speculative computation of gradient and/or Hessian information, where applicable, for parallel optimization studies. By speculating that the derivative information at the current point will be used later, the complete data set (all available gradient/Hessian information) can be computed on every function evaluation. While some of these computations will be wasted, the positive effects are a consistent parallel load balance and usually shorter wall clock time. The `speculative` specification is applicable only when parallelism in the gradient calculations can be exploited by Dakota (it will be ignored for vendor numerical gradients).

max_function_evaluations

- [Keywords Area](#)
- [method](#)
- [nl2sol](#)
- [max_function_evaluations](#)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

Default Behavior

Default value is 1000.

scaling

- [Keywords Area](#)
- [method](#)
- [nl2sol](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the `method`, `variables`, and `responses` blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*_scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling
3. `auto` - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval $[0,1]$;
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into $[0,1]$.

4. `log` - logarithmic scaling

First, any characteristic values from the optional `*_scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*_scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- none, auto, log - optional
- value - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100
```

```
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

model_pointer

- [Keywords Area](#)
- [method](#)
- [nl2sol](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which [model](#) block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a [model](#) block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                      0.1 0.2 0.6
                      0.1 0.2 0.6
  sample_type lhs
  distribution cumulative

model
  id_model = 'SURR'
  surrogate global,
  dace_method_pointer = 'DACE'
  polynomial quadratic

method
  id_method = 'DACE'
  model_pointer = 'DACE_M'
  sampling sample_type lhs
  samples = 121 seed = 5034 rng rnum2

model
  id_model = 'DACE_M'
  single
  interface_pointer = 'I1'

variables
  uniform_uncertain = 2
  lower_bounds = 0. 0.
  upper_bounds = 1. 1.
  descriptors = 'x1' 'x2'

interface
  id_interface = 'I1'
  system asynch evaluation_concurrency = 5
  analysis_driver = 'text_book'

responses
  response_functions = 3
  no_gradients
  no_hessians
```

7.2.42 nonlinear_cg

- [Keywords Area](#)

- [method](#)
- [nonlinear_cg](#)

(Experimental) nonlinear conjugate gradient optimization

Topics

This keyword is related to the topics:

- [local_optimization_methods](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			misc_options	Options for nonlinear CG optimizer
	Optional		convergence_-tolerance	Stopping criterion based on objective function or statistics convergence
	Optional		max_iterations	Number of iterations allowed for optimizers and adaptive UQ methods
	Optional		scaling	Turn on scaling for variables, responses, and constraints
	Optional		model_pointer	Identifier for model block to be used by a method

Description

This method is an incomplete experimental implementation of nonlinear conjugate gradient optimization, a local, gradient-based solver.

misc_options

- [Keywords Area](#)
- [method](#)
- [nonlinear_cg](#)
- [misc_options](#)

Options for nonlinear CG optimizer

Specification

Alias: none

Argument(s): STRINGLIST

Default: no misc options

Description

List of miscellaneous string options to pass to the experimental nonlinear CG solver (see NonlinearCGOptimizer.cpp in the Dakota source code for available controls). Includes controls for step sizes, linesearch control, convergence, etc.

convergence_tolerance

- [Keywords Area](#)
- [method](#)
- [nonlinear_cg](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

max.iterations

- [Keywords Area](#)
- [method](#)
- [nonlinear_cg](#)
- [max.iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: `fsu_cvt`, `local_reliability`: 25; `global_{reliability, interval_est, evidence}` / `efficient-global`: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_--iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

scaling

- [Keywords Area](#)
- [method](#)
- [nonlinear_cg](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*_scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling
3. `auto` - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. `log` - logarithmic scaling

First, any characteristic values from the optional `*_scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*_scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- `none`, `auto`, `log` - optional
- `value` - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100

responses
objective_functions 3
sense "maximize"
primary_scale_types = "value" "value" "value"
primary_scales = 1 1 100
```

model_pointer

- [Keywords Area](#)
- [method](#)
- [nonlinear_cg](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2

- [ncsu_direct](#)

Dividing RECTangles method

Topics

This keyword is related to the topics:

- [global_optimization_methods](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description

	Optional	solution_target	Specifies a globally optimal value toward which the optimizer should track
	Optional	min_boxsize_limit	Stopping Criterion based on shortest edge of hyperrectangle
	Optional	volume_boxsize_limit	Stopping criterion based on volume of search space
	Optional	convergence_tolerance	Stopping criterion based on objective function or statistics convergence
	Optional	max_iterations	Number of iterations allowed for optimizers and adaptive UQ methods
	Optional	max_function_evaluations	Number of function evaluations allowed for optimizers
	Optional	scaling	Turn on scaling for variables, responses, and constraints
	Optional	model_pointer	Identifier for model block to be used by a method

Description

North Carolina State University (NCSU) has an implementation of the DIRECT algorithm (Dividing RECTangles algorithm that is outlined in the SCOLIB method section above). This version is documented in [28] We have found that the NCSU DIRECT implementation works better and is more robust for some problems than `coliny_direct`. Currently, we maintain both versions of DIRECT in Dakota; in the future, we may deprecate one.

The NCSU DIRECT method is selected with `ncsu_direct`. We have tried to maintain consistency between the keywords in SCOLIB and NCSU implementation of DIRECT, but the algorithms have different parameters, so the keywords sometimes have slightly different meaning.

Stopping Criteria

The algorithm stops based on:

1. [max_iterations](#) - number of iterations
2. [max_function_evaluations](#) - number of function evaluations
3. [solution_target](#) and [convergence_tolerance](#)
4. [min_boxsize_limit](#)
5. [volume_boxsize_limit](#)

This method will always strictly respect the number of iterations, but may slightly exceed the number of function evaluations, as it will always explore all sub-rectangles at the current level.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the [hdf5](#) keyword, this method writes the following results to HDF5:

- [Best Parameters](#)
- [Best Objective Functions](#) (when [objective_functions](#) are specified)
- [Best Nonlinear Constraints](#)
- [Calibration](#) (when [calibration_terms](#) are specified)

See Also

These keywords may also be of interest:

- [coliny_direct](#)

solution_target

- [Keywords Area](#)
- [method](#)
- [ncsu_direct](#)
- [solution_target](#)

Specifies a globally optimal value toward which the optimizer should track

Specification

Alias: [solution_accuracy](#)

Argument(s): REAL

Default: 0

Description

The solution target specifies a goal toward which the optimizer should track.

This is used for test problems, when the true global minimum is known (call it `solution_target := fglobal`). Then, the optimization terminates when $100(f_{\min} - fglobal) / \max(1, \text{abs}(fglobal)) < \text{convergence_tolerance}$. The default for `fglobal` is $-1.0e100$ and the default for convergence tolerance is described at [convergence_tolerance](#).

min_boxsize_limit

- [Keywords Area](#)
- [method](#)
- [ncsu_direct](#)
- [min_boxsize_limit](#)

Stopping Criterion based on shortest edge of hyperrectangle

Specification

Alias: none

Argument(s): REAL

Default: 1.0e-4

Description

`min_boxsize_limit` is a setting that terminates the optimization when the measure of a hyperrectangle S with $f(c(S)) = f_{\min}$ is less than `min_boxsize_limit`.

Each subregion considered by DIRECT has a **size**, which corresponds to the longest diagonal of the subregion.

`min_boxsize_limit` specification terminates DIRECT if the size of the smallest subregion falls below this threshold.

In practice, this specification is likely to be more effective at limiting DIRECT's search.

volume_boxsize_limit

- [Keywords Area](#)
- [method](#)
- [ncsu_direct](#)
- [volume_boxsize_limit](#)

Stopping criterion based on volume of search space

Specification

Alias: none

Argument(s): REAL

Default: 1.0e-6

Description

`volume_boxsize_limit` is a setting that terminates the optimization when the volume of a hyperrectangle S with $f(c(S)) = f_{\min}$ is less than `volume_boxsize_limit` percent of the original hyperrectangle. Basically, `volume_boxsize_limit` stops the optimization when the volume of the particular rectangle which has f_{\min} is less than a certain percentage of the whole volume.

convergence_tolerance

- [Keywords Area](#)
- [method](#)
- [ncsu_direct](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

max_iterations

- [Keywords Area](#)
- [method](#)
- [ncsu_direct](#)
- [max_iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: fsu_cvt, local_reliability: 25; global_{reliability, interval_est, evidence} / efficient-global: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

max_function_evaluations

- [Keywords Area](#)
- [method](#)
- [ncsu_direct](#)
- [max_function_evaluations](#)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

Default Behavior

Default value is 1000.

scaling

- [Keywords Area](#)
- [method](#)
- [ncsu_direct](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*.scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling
3. `auto` - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. `log` - logarithmic scaling

First, any characteristic values from the optional `*_scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*_scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- `none`, `auto`, `log` - optional
- `value` - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100

responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

model_pointer

- [Keywords Area](#)
- [method](#)
- [ncsu_direct](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which [model](#) block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a [model](#) block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```

environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'

7.2.44 genie_opt_darts

- [Keywords Area](#)
- [method](#)
- [genie_opt_darts](#)

Voronoi-based high-dimensional global Lipschitzian optimization

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		seed	Seed of the random number generator
	Optional		max_function_--evaluations	Number of function evaluations allowed for optimizers
	Optional		scaling	Turn on scaling for variables, responses, and constraints
	Optional		model_pointer	Identifier for model block to be used by a method

Description

OPT-Darts method is a fast alternative to DIRECT for global Lipschitzian optimization purposes. Instead of hyperrectangular, OPT-Darts decomposes a high-dimensional domain into Voronoi cells, and places samples via stochastic blue noise instead of deterministic cell division.

To refine a cell, OPT-Darts first adds a new sample within it via spoke-dart sampling, then set the conflict radius to the cells inscribed hypersphere radius, to avoid adding a sample point that is too close to a prior sample, then divide that cell (and update its neighboring cells) via the approximate Delaunay graph, and use the computed witnesses to decide the next refinement candidate. These two steps replace the corresponding deterministic center-sample and rectangular cell division in DIRECT, respectively.

OPT-Darts is the first exact stochastic Lipschitzian optimization technique that combines the benefits of guaranteed convergence in [Jones et al. 1993] and high dimensional efficiency in [Spall 2005]. Computing blue noise and Voronoi regions has been intractable in high dimensions, and are being done within OPT-Darts using Spoke-Darts.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the [hdf5](#) keyword, this method writes the following results to HDF5:

- [Best Parameters](#)
- [Best Objective Functions](#) (when [objective_functions](#) are specified)
- [Calibration](#) (when [calibration_terms](#) are specified)

seed

- [Keywords Area](#)

- [method](#)
- [genie_opt_darts](#)
- [seed](#)

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)

Description

The random `seed` control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

7.2.45 genie_direct

- [Keywords Area](#)
- [method](#)
- [genie_direct](#)

Classical high-dimensional global Lipschitzian optimization Classical high-dimensional global Lipschitzian optimization

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			seed	Seed of the random number generator
	Optional		max_function_- evaluations	Number of function evaluations allowed for optimizers
	Optional		scaling	Turn on scaling for variables, responses, and constraints
	Optional		model_pointer	Identifier for model block to be used by a method

Description

DIRECT (DIviding RECTangles) partitions the domain into hyperrectangles and uses an iterative Lipschitzian optimization approach to search for a global optimal point.

DIRECT begins by scaling the domain into the unit hypercube by adopting a center-sampling strategy. The objective function is evaluated at the midpoint of the domain, where a lower bound is constructed. In one-dimension, the domain is tri-sected and two new center points are sampled. At each iteration (dividing and sampling), DIRECT identifies intervals that contain the best minimal value of the objective function found up to that point. This strategy of selecting and dividing gives DIRECT its performance and convergence properties compared to other deterministic methods.

The classical DIRECT method [Shubert 1972] has two limitations: poor scaling to high dimensions; and relying on a global K; whose exact value is often unknown. The enhanced DIRECT algorithm [Jones et al. 1993] generalizes [Shubert 1972] to higher dimensions and does not require knowledge of the Lipschitz constant.

- [method](#)
- [genie_direct](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*_scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling
3. `auto` - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. `log` - logarithmic scaling

First, any characteristic values from the optional `*_scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*_scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- `none`, `auto`, `log` - optional
- `value` - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100

responses
objective_functions 3
sense "maximize"
primary_scale_types = "value" "value" "value"
primary_scales = 1 1 100
```

model_pointer

- [Keywords Area](#)
- [method](#)
- [genie_direct](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                    0.1 0.2 0.6
                    0.1 0.2 0.6

  sample_type lhs
  distribution cumulative

model

	Optional		convergence_ tolerance	Expected improvement convergence tolerance
	Optional		x_conv_tol	x-convergence tolerance
	Optional		gaussian_process	Gaussian Process surrogate model
	Optional		use_derivatives	Use derivative data to construct surrogate models
	Optional		import_build_ points_file	File containing points you wish to use to build a surrogate
	Optional		export_approx_ points_file	Output file for evaluations of a surrogate model

	Optional	model_pointer	Identifier for model block to be used by a method
--	-----------------	-------------------------------	---

Description

The Efficient Global Optimization (EGO) method was first developed by Jones, Schonlau, and Welch[54]. In EGO, a stochastic response surface approximation for the objective function is developed based on some sample points from the "true" simulation.

Note that several major differences exist between our implementation and that of[54]. First, rather than using a branch and bound method to find the point which maximizes the EIF, we use the DIRECT global optimization method.

Second, we support both global optimization and global nonlinear least squares as well as general nonlinear constraints through abstraction and subproblem recasting.

The efficient global method is in prototype form. Currently, we do not expose any specification controls for the underlying Gaussian process model used or for the optimization of the expected improvement function (which is currently performed by the NCSU DIRECT algorithm using its internal defaults).

By default, EGO uses the Surfpack GP (Kriging) model, but the Dakota implementation may be selected instead. If `use_derivatives` is specified the GP model will be built using available derivative data (Surfpack GP only).

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the `hdf5` keyword, this method writes the following results to HDF5:

- [Best Parameters](#)
- [Best Objective Functions](#) (when `objective_functions` are specified)
- [Best Nonlinear Constraints](#)
- [Calibration](#) (when `calibration_terms` are specified)

Theory

The particular response surface used is a Gaussian process (GP). The GP allows one to calculate the prediction at a new input location as well as the uncertainty associated with that prediction. The key idea in EGO is to maximize the Expected Improvement Function (EIF). The EIF is used to select the location at which a new training point should be added to the Gaussian process model by maximizing the amount of improvement in the objective function that can be expected by adding that point. A point could be expected to produce an improvement in the objective function if its predicted value is better than the current best solution, or if the uncertainty in its prediction is such that the probability of it producing a better solution is high. Because the uncertainty is higher in regions of the design space with few observations, this provides a balance between exploiting areas of the design space that predict good solutions, and exploring areas where more information is needed. EGO trades off this "exploitation vs. exploration." The general procedure for these EGO-type methods is:

- Build an initial Gaussian process model of the objective function
- Find the point that maximizes the EIF. If the EIF value at this point is sufficiently small, stop.
- Evaluate the objective function at the point where the EIF is maximized. Update the Gaussian process model using this new point.
- Return to the previous step.

These keywords may also be of interest:

- [surrogate_based_local](#)
- [surrogate_based_global](#)

initial_samples

- [Keywords Area](#)
- [method](#)
- [efficient_global](#)
- [initial_samples](#)

Initial number of samples for sampling-based methods

Specification

Alias: none

Argument(s): INTEGER

Default: $(d+1)(d+2)/2$

Description

The `initial_samples` keyword is used to define the number of initial samples (i.e., randomly chosen sets of variable values) at which to execute a model. The initial samples may later be augmented in an iterative process.

Default Behavior

By default, Dakota will use the minimum number of samples required by the chosen method.

Usage Tips

To obtain linear sensitivities or to construct a linear response surface, at least $\text{dim}+1$ samples should be used, where "dim" is the number of variables. For sensitivities to quadratic terms or quadratic response surfaces, at least $(\text{dim}+1)(\text{dim}+2)/2$ samples are needed. For uncertainty quantification, we recommend at least $10*\text{dim}$ samples. For `variance_based_decomp`, we recommend hundreds to thousands of samples. Note that for `variance_based_decomp`, the number of simulations performed will be $N*(\text{dim}+2)$.

Examples

```
method
  sampling
    sample_type random
    initial_samples = 20
    refinement_samples = 5
```

seed

- [Keywords Area](#)
- [method](#)
- [efficient_global](#)

- [seed](#)

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)

Description

The random `seed` control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

max_iterations

- [Keywords Area](#)
- [method](#)
- [efficient_global](#)
- [max_iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: `fsu_cvt`, `local_reliability`: 25; `global_{reliability, interval_est, evidence}` / `efficient_global`: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

`convergence_tolerance`

- [Keywords Area](#)
- [method](#)
- [efficient_global](#)
- [convergence_tolerance](#)

Expected improvement convergence tolerance

Specification

Alias: none

Argument(s): REAL

Default: 1.e-12

Description

The Efficient Global Optimization method will terminate if the expected improvement is below the specified tolerance for two subsequent iterations.

`x_conv_tol`

- [Keywords Area](#)
- [method](#)
- [efficient_global](#)
- [x_conv_tol](#)

x-convergence tolerance

Specification

Alias: none

Argument(s): REAL

Default: 1.0e-8

Description

The Efficient Global Optimization method will terminate if the relative change in the best decision variables values x is less than the specified tolerance.

gaussian_process

- [Keywords Area](#)
- [method](#)
- [efficient_global](#)
- [gaussian_process](#)

Gaussian Process surrogate model

Specification

Alias: kriging

Argument(s): none

Default: Surfpack Gaussian process

Child Keywords:

	Required/ Optional Required (<i>Choose One</i>)	Description of Group GP Implementation (Group 1)	Dakota Keyword	Dakota Keyword Description
			surfpack	Use the Surfpack version of Gaussian Process surrogates
			dakota	Select the built in Gaussian Process surrogate

Description

Use the Gaussian process (GP) surrogate from Surfpack, which is specified using the [surfpack](#) keyword.

An alternate version of GP surrogates was available in prior versions of Dakota. **For now, both versions are supported but the `dakota` version is deprecated and intended to be removed in a future release.**

Known Issue: When using discrete variables, there have been sometimes significant differences in surrogate behavior observed across computing platforms in some cases. The cause has not yet been fully diagnosed and is currently under investigation. In addition, guidance on appropriate construction and use of surrogates with discrete variables is under development. In the meantime, users should therefore be aware that there is a risk of inaccurate results when using surrogates with discrete variables.

surfpack

- [Keywords Area](#)
- [method](#)
- [efficient_global](#)
- [gaussian_process](#)
- [surfpack](#)

Use the Surfpack version of Gaussian Process surrogates

Specification

Alias: none

Argument(s): none

Description

This keyword specifies the use of the Gaussian process that is incorporated in our surface fitting library called Surfpack.

Several user options are available:

1. Optimization methods:

Maximum Likelihood Estimation (MLE) is used to find the optimal values of the hyper-parameters governing the trend and correlation functions. By default the global optimization method DIRECT is used for MLE, but other options for the optimization method are available. See [optimization_method](#).

The total number of evaluations of the likelihood function can be controlled using the `max_trials` keyword followed by a positive integer. Note that the likelihood function does not require running the "truth" model, and is relatively inexpensive to compute.

2. Trend Function:

The GP models incorporate a parametric trend function whose purpose is to capture large-scale variations. See [trend](#).

3. Correlation Lengths:

Correlation lengths are usually optimized by Surfpack, however, the user can specify the lengths manually. See [correlation_lengths](#).

4. Ill-conditioning

One of the major problems in determining the governing values for a Gaussian process or Kriging model is the fact that the correlation matrix can easily become ill-conditioned when there are too many input points close together. Since the predictions from the Gaussian process model involve inverting the correlation matrix, ill-conditioning can lead to poor predictive capability and should be avoided.

Note that a sufficiently bad sample design could require correlation lengths to be so short that any interpolatory GP model would become inept at extrapolation and interpolation.

The `surfpack` model handles ill-conditioning internally by default, but behavior can be modified using

5. Gradient Enhanced Kriging (GEK).

The `use_derivatives` keyword will cause the Surfpack GP to be constructed from a combination of function value and gradient information (if available).

See notes in the Theory section.

Theory

Gradient Enhanced Kriging

Incorporating gradient information will only be beneficial if accurate and inexpensive derivative information is available, and the derivatives are not infinite or nearly so. Here "inexpensive" means that the cost of evaluating a function value plus gradient is comparable to the cost of evaluating only the function value, for example gradients computed by analytical, automatic differentiation, or continuous adjoint techniques. It is not cost effective to use derivatives computed by finite differences. In tests, GEK models built from finite difference derivatives were also significantly less accurate than those built from analytical derivatives. Note that GEK's correlation matrix tends to have a significantly worse condition number than Kriging for the same sample design.

This issue was addressed by using a pivoted Cholesky factorization of Kriging's correlation matrix (which is a small sub-matrix within GEK's correlation matrix) to rank points by how much unique information they contain. This reordering is then applied to whole points (the function value at a point immediately followed by gradient information at the same point) in GEK's correlation matrix. A standard non-pivoted Cholesky is then applied to the reordered GEK correlation matrix and a bisection search is used to find the last equation that meets the constraint on the (estimate of) condition number. The cost of performing pivoted Cholesky on Kriging's correlation matrix is usually negligible compared to the cost of the non-pivoted Cholesky factorization of GEK's correlation matrix. In tests, it also resulted in more accurate GEK models than when pivoted Cholesky or whole-point-block pivoted Cholesky was performed on GEK's correlation matrix.

dakota

- [Keywords Area](#)
- [method](#)
- [efficient_global](#)
- [gaussian_process](#)
- [dakota](#)

Select the built in Gaussian Process surrogate

Specification

Alias: none

Argument(s): none

Description

A second version of GP surrogates was available in prior versions of Dakota. **For now, both versions are supported but the `dakota` version is deprecated and intended to be removed in a future release.**

Historically these models were drastically different, but in Dakota 5.1, they became quite similar. They now differ in that the Surfpack GP has a richer set of features/options and tends to be more accurate than the Dakota version. Due to how the Surfpack GP handles ill-conditioned correlation matrices (which significantly contributes

to its greater accuracy), the Surfpack GP can be a factor of two or three slower than Dakota's. As of Dakota 5.2, the Surfpack implementation is the default in all contexts except Bayesian calibration.

More details on the `gaussian_process` dakota model can be found in[59].

Dakota's GP deals with ill-conditioning in two ways. First, when it encounters a non-invertible correlation matrix it iteratively increases the size of a "nugget," but in such cases the resulting approximation smooths rather than interpolates the data. Second, it has a `point_selection` option (default off) that uses a greedy algorithm to select a well-spaced subset of points prior to the construction of the GP. In this case, the GP will only interpolate the selected subset. Typically, one should not need point selection in trust-region methods because a small number of points are used to develop a surrogate within each trust region. Point selection is most beneficial when constructing with a large number of points, typically more than order one hundred, though this depends on the number of variables and spacing of the sample points.

This differs from the `point_selection` option of the Dakota GP which initially chooses a well-spaced subset of points and finds the correlation parameters that are most likely for that one subset.

use_derivatives

- [Keywords Area](#)
- [method](#)
- [efficient_global](#)
- [use_derivatives](#)

Use derivative data to construct surrogate models

Specification

Alias: none

Argument(s): none

Default: use function values only

Description

The `use_derivatives` flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, it's use with Surfpack Gaussian process is not recommended.

import_build_points_file

- [Keywords Area](#)
- [method](#)
- [efficient_global](#)
- [import_build_points_file](#)

File containing points you wish to use to build a surrogate

Specification

Alias: `import_points_file`

Argument(s): STRING

Default: no point import from a file

Child Keywords:

	Required/ Optional Optional(<i>Choose One</i>)	Description of Group Tabular Format (Group 1)	Dakota Keyword custom_annotated	Dakota Keyword Description Selects custom-annotated tabular file format
			annotated	Selects annotated tabular file format
			freeform	Selects freeform file format
	Optional		active_only	Import only active variables from tabular data file

Description

The `import_build_points_file` allows the user to specify a file that contains a list of points and truth model responses used to construct a surrogate model. These can be used by all methods that (explicitly, e.g. surrogate-based optimization, or implicitly, e.g. efficient global optimization) operate on a surrogate. In particular, these points and responses are used in place of truth model evaluations to construct the initial surrogate. When used to construct surrogate models or emulators these are often called build points or training data.

Default Behavior

By default, methods do not import points from a file.

Usage Tips

Dakota parses input files without regard to whitespace, but the `import_build_points_file` must be in one of three formats:

- `annotated` (default)
- `custom_annotated`
- `freeform`

Examples

```
method
  polynomial_chaos
    expansion_order = 4
    import_build_points_file = 'dakota_uq_rosenbrock_pce_import.annot.pts.dat'
```

`custom_annotated`

- [Keywords Area](#)

- [method](#)
- [efficient_global](#)
- [import_build_points_file](#)
- [custom_annotated](#)

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			header	Enable header row in custom-annotated tabular file
	Optional		eval_id	Enable evaluation ID column in custom-annotated tabular file
	Optional		interface_id	Enable interface ID column in custom-annotated tabular file

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether `header` row, `eval_id` column, and `interface_id` column appear in the tabular file, thus bridging `freeform` and (fully) annotated.

Default Behavior

The `annotated` format is the default for tabular export/import. To control which header row and columns are in the input/output, specify `custom_annotated`, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and `eval_id` (no `interface_id`), and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id      x1          x2          obj_fn  nln_ineq_con_1  nln_ineq_con_2
1             0.9          1.1          0.0002         0.26           0.76
2             0.90009      1.1 0.0001996404857  0.2601620081   0.759955
3             0.89991      1.1 0.0002003604863  0.2598380081   0.760045
...
```

Default: no interface_id column

Description

See description of parent `custom_annotated`

annotated

- [Keywords Area](#)
- [method](#)
- [efficient_global](#)
- [import_build_points_file](#)
- [annotated](#)

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The `annotated` keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include `interface_id`, specify `custom_annotated_header eval_id`
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export an annotated top-level tabular data file containing a header row, leading `eval_id` and `interface_id` columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated
```

Resulting tabular file:

```
%eval_id interface          x1          x2          obj_fn nln_ineq_con_1 nln_ineq_con_2
1          NO_ID            0.9         1.1         0.0002          0.26          0.76
2          NO_ID            0.90009     1.1 0.0001996404857 0.2601620081 0.759955
3          NO_ID            0.89991     1.1 0.0002003604863 0.2598380081 0.760045
...
```

freeform

- [Keywords Area](#)
- [method](#)
- [efficient_global](#)
- [import_build_points_file](#)
- [freeform](#)

Selects freeform file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The `annotated` format is the default for tabular export/import. To change this behavior, specify `freeform` in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to `annotated` format, though `freeform` remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- In `freeform`, the `num_rows` x `num_cols` total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

```
      0.9          1.1          0.0002          0.26          0.76
0.90009          1.1 0.0001996404857 0.2601620081 0.759955
0.89991          1.1 0.0002003604863 0.2598380081 0.760045
...
```

active_only

- [Keywords Area](#)
- [method](#)
- [efficient_global](#)
- [import_build_points_file](#)
- [active_only](#)

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

export_approx_points_file

- [Keywords Area](#)
- [method](#)
- [efficient_global](#)
- [export_approx_points_file](#)

Output file for evaluations of a surrogate model

Specification

Alias: export_points_file

Argument(s): STRING

Default: no point export to a file

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional (<i>Choose One</i>)	Tabular Format (Group 1)	custom_annotated	Selects custom-annotated tabular file format
			annotated	Selects annotated tabular file format
			freeform	Selects freeform file format

Description

The `export_approx_points_file` keyword allows the user to specify a file in which the points (input variable values) at which the surrogate model is evaluated and corresponding response values computed by the surrogate model will be written. The response values are the surrogate's predicted approximation to the truth model responses at those points.

Usage Tips

Dakota exports tabular data in one of three formats:

- `annotated` (default)
- `custom_annotated`
- `freeform`

custom_annotated

- [Keywords Area](#)
- [method](#)
- [efficient_global](#)

- [export_approx_points_file](#)
- [custom_annotated](#)

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			header	Enable header row in custom-annotated tabular file
	Optional		eval_id	Enable evaluation ID column in custom-annotated tabular file
	Optional		interface_id	Enable interface ID column in custom-annotated tabular file

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, `eval_id` column, and `interface_id` column appear in the tabular file, thus bridging `freeform` and (fully) `annotated`.

Default Behavior

The `annotated` format is the default for tabular export/import. To control which header row and columns are in the input/output, specify `custom_annotated`, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to `annotated` format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and `eval_id` (no `interface_id`), and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id      x1          x2          obj_fn nln_ineq_con_1 nln_ineq_con_2
1              0.9          1.1          0.0002          0.26          0.76
2              0.90009      1.1 0.0001996404857 0.2601620081 0.759955
3              0.89991      1.1 0.0002003604863 0.2598380081 0.760045
...
```

annotated

- [Keywords Area](#)
- [method](#)
- [efficient_global](#)
- [export_approx_points_file](#)
- [annotated](#)

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The `annotated` keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include `interface_id`, specify `custom_annotated_header eval_id`
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export an annotated top-level tabular data file containing a header row, leading `eval_id` and `interface_id` columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated
```

Resulting tabular file:

```
%eval_id interface          x1          x2          obj_fn nln_ineq_con_1 nln_ineq_con_2
1          NO_ID            0.9          1.1          0.0002          0.26          0.76

...
```

freeform

- [Keywords Area](#)
- [method](#)
- [efficient_global](#)
- [export_approx_points_file](#)
- [freeform](#)

Selects freeform file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The `annotated` format is the default for tabular export/import. To change this behavior, specify `freeform` in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to `annotated` format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- In `freeform`, the `num_rows` x `num_cols` total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

```
      0.9          1.1          0.0002          0.26          0.76
0.90009          1.1 0.0001996404857  0.2601620081  0.759955
0.89991          1.1 0.0002003604863  0.2598380081  0.760045

```

model_pointer

- [Keywords Area](#)
- [method](#)
- [efficient_global](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2

7.2.47 function_train_uq

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)

UQ method leveraging a functional tensor train surrogate model.

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			samples_on_- emulator	Number of samples at which to evaluate an emulator (surrogate)

	Optional	sample_type	Selection of sampling strategy
	Optional	seed	Seed of the random number generator
	Optional	fixed_seed	Reuses the same seed value for multiple random sampling sets
	Optional	rng	Selection of a random number generator
	Optional	probability_refinement	Allow refinement of probability and generalized reliability results using importance sampling
	Optional	final_moments	Output moments of the specified type and include them within the set of final statistics.
	Optional	response_levels	Values at which to estimate desired statistics for each response
	Optional	probability_levels	Specify probability levels at which to estimate the corresponding response value
	Optional	reliability_levels	Specify reliability levels at which the response values will be estimated

	Optional		gen_reliability_-levels	Specify generalized reliability levels at which to estimate the corresponding response value
	Optional		distribution	Selection of cumulative or complementary cumulative functions
	Optional		variance_based_-decomp	Activates global sensitivity analysis based on decomposition of response variance into main, interaction, and total effects
	Optional (Choose One)	Covariance Type (Group 1)	diagonal_-covariance	Display only the diagonal terms of the covariance matrix
			full_covariance	Display the full covariance matrix
	Optional		convergence_-tolerance	Placeholder keyword
	Optional		import_approx_-points_file	Filename for points at which to evaluate the PCE/SC surrogate
	Optional		export_approx_-points_file	Output file for evaluations of a surrogate model
	Optional		model_pointer	Identifier for model block to be used by a method

Description

Tensor train decompositions are approximations that exploit low rank structure in an input-output mapping. Refer to the `function_train` surrogate model for additional details.

Usage Tips

This method is mostly a generic UQ shell for the `function_train` surrogate model. Rank controls and

other function train specifics are managed in the model specification.

Examples

```
method,  
  function_train_uq  
  samples_on_emulator = 100000  
  variance_based_decomp  
  model_pointer = 'FT'
```

- [samples_on_emulator](#)

Number of samples at which to evaluate an emulator (surrogate)

Specification

Alias: samples

Argument(s): INTEGER

Description

How many approximate function evaluations to perform on the emulator model, e.g., to compute statistics

Default Behavior

The default number of samples is method-dependent.

Examples

Perform 10000 samples on the PCE approximation of the true model:

```
method  
  polynomial_chaos  
  quadrature_order = 2  
  samples_on_emulator = 10000
```

sample_type

- [method](#)
- [function_train_uq](#)
- [sample_type](#)

Selection of sampling strategy

Specification

Alias: none

Argument(s): none

Default: lhs

Child Keywords:

	Required/- Optional Required (<i>Choose One</i>)	Description of Group Sample Type (Group 1)	Dakota Keyword lhs	Dakota Keyword Description Uses Latin Hypercube Sampling (LHS) to sample variables
			random	Uses purely random Monte Carlo sampling to sample variables

Description

The `sample_type` keyword allows the user to select between two types of sampling: Monte Carlo (pure random) and Latin hypercube (stratified) sampling.

The incremental keywords are deprecated; instead use `samples` together with `refinement_samples`.

Default Behavior

If the `sample_type` keyword is present, it must be accompanied by `lhs` or `random`. In most contexts, `lhs` is the default (exception: `multilevel_sampling` uses Monte Carlo by default).

Examples

```
method
  sampling
    sample_type lhs
    samples = 20
    seed = 83921
```

lhs

- [Keywords Area](#)
- [method](#)

- [function_train_uq](#)
- [sample_type](#)
- [lhs](#)

Uses Latin Hypercube Sampling (LHS) to sample variables

Specification

Alias: none

Argument(s): none

Description

The `lhs` keyword invokes Latin Hypercube Sampling as the means of drawing samples of uncertain variables according to their probability distributions. This is a stratified, space-filling approach that selects variable values from a set of equi-probable bins.

Default Behavior

Latin Hypercube Sampling is the default sampling mode in most contexts (exception: `multilevel_sampling`). To explicitly specify LHS in the Dakota input file, the `lhs` keyword must appear in conjunction with the `sample_type` keyword.

Usage Tips

Latin Hypercube Sampling is very robust and can be applied to any problem. It is fairly effective at estimating the mean of model responses and linear correlations with a reasonably small number of samples relative to the number of variables.

Examples

```
method
  sampling
    sample_type lhs
    samples = 20
```

random

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [sample_type](#)
- [random](#)

Uses purely random Monte Carlo sampling to sample variables

Specification

Alias: none

Argument(s): none

Description

The `random` keyword invokes Monte Carlo sampling as the means of drawing samples of uncertain variables according to their probability distributions.

Default Behavior

In most contexts, Monte Carlo sampling is not the default sampling mode (exception: `multilevel_sampling`). To change this behavior, the `random` keyword must be specified in conjunction with the `sample_type` keyword.

Usage Tips

Monte Carlo sampling is more computationally expensive than Latin Hypercube Sampling as it requires a larger number of samples to accurately estimate statistics.

Examples

```
method
  sampling
    sample_type random
    samples = 200
```

seed

- [Keywords Area](#)
- [method](#)
- [function.train_uq](#)
- [seed](#)

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)

Description

The `random seed` control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

fixed_seed

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [fixed_seed](#)

Reuses the same seed value for multiple random sampling sets

Specification

Alias: none

Argument(s): none

Default: not fixed; pattern varies run-to-run

Description

The `fixed_seed` flag is relevant if multiple sampling sets will be generated over the course of a Dakota analysis. This occurs when using advance methods (e.g., surrogate-based optimization, optimization under uncertainty). The same seed value is reused for each of these multiple sampling sets, which can be important for reducing variability in the sampling results.

Default Behavior

The default behavior is to not use a fixed seed, as the repetition of the same sampling pattern can result in a modeling weakness that an optimizer could potentially exploit (resulting in actual reliabilities that are lower than the estimated reliabilities). For repeatable studies, the `seed` must also be specified.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    fixed_seed
```

rng

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [rng](#)

Selection of a random number generator

Specification

Alias: none

Argument(s): none

Default: Mersenne twister (mt19937)

Child Keywords:

	Required/ Optional Required(<i>Choose One</i>)	Description of Group RNG Algorithm (Group 1)	Dakota Keyword	Dakota Keyword Description
			mt19937	Generates random numbers using the Mersenne twister
			rnum2	Generates pseudo-random numbers using the Pecos package

Description

The `rng` keyword is used to indicate a choice of random number generator.

Default Behavior

If specified, the `rng` keyword must be accompanied by either `rnum2` (pseudo-random numbers) or `mt19937` (random numbers generated by the Mersenne twister). Otherwise, `mt19937`, the Mersenne twister is used by default.

Usage Tips

The default is recommended, as the Mersenne twister is a higher quality random number generator.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2
```

mt19937

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [rng](#)
- [mt19937](#)

Generates random numbers using the Mersenne twister

Specification

Alias: none

Argument(s): none

Description

The `mt19937` keyword directs Dakota to use the Mersenne twister to generate random numbers. Additional information can be found on wikipedia: http://en.wikipedia.org/wiki/Mersenne_twister.

Default Behavior

`mt19937` is the default random number generator. To specify it explicitly in the Dakota input file, however, it must be specified in conjunction with the `rng` keyword.

Usage Tips

Use of the Mersenne twister random number generator (`mt19937`) is recommended.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng mt19937
```

rnum2

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [rng](#)
- [rnum2](#)

Generates pseudo-random numbers using the Pecos package

Specification

Alias: none

Argument(s): none

Description

The `rnum2` keyword directs Dakota to use pseudo-random numbers generated by the Pecos package.

Default Behavior

`rnum2` is not used by default. To change this behavior, it must be specified in conjunction with the `rng` keyword.

Usage Tips

Use of the Mersenne twister random number generator (`mt19937`) is recommended over `rnum2`.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2
```

probability_refinement

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [probability_refinement](#)

Allow refinement of probability and generalized reliability results using importance sampling

Topics

This keyword is related to the topics:

- [reliability_methods](#)

Specification

Alias: sample_refinement

Argument(s): none

Default: no refinement

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Importance Sampling Approach (Group 1)	import	Sampling option
			adapt_import	Importance sampling option
			mm_adapt_import	Sampling option
	Optional		refinement_ samples	Number of samples used to refine a probability estimate or sampling design.

Description

The `probability_refinement` allows refinement of probability and generalized reliability results using importance sampling. If one specifies `probability_refinement`, there are some additional options. One can specify which type of importance sampling to use (`import`, `adapt_import`, or `mm_adapt_import`). Additionally, one can specify the number of refinement samples to use with `refinement_samples` and the seed to use with `seed`.

The `probability_refinement` density reweighting accounts originally was developed based on Gaussian distributions. It now accounts for additional non-Gaussian cases.

import

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [probability_refinement](#)
- [import](#)

Sampling option

Specification

Alias: none

Argument(s): none

Description

`import` centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level).

adapt_import

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [probability_refinement](#)
- [adapt_import](#)

Importance sampling option

Specification

Alias: none

Argument(s): none

Description

`adapt_import` centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level). This continues iteratively until the failure probability estimate converges.

mm_adapt_import

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [probability_refinement](#)
- [mm_adapt_import](#)

Sampling option

Specification

Alias: none

Argument(s): none

Description

`mm_adapt_import` starts with all of the samples located in the failure region to build a multimodal sampling density. First, it uses a small number of samples around each of the initial samples in the failure region. Note that these samples are allocated to the different points based on their relative probabilities of occurrence: more probable points get more samples. This early part of the approach is done to search for "representative" points. Once these are located, the multimodal sampling density is set and then `mm_adapt_import` proceeds similarly to `adapt_import` (sample until convergence).

refinement_samples

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [probability_refinement](#)
- [refinement_samples](#)

Number of samples used to refine a probability estimate or sampling design.

Specification

Alias: none

Argument(s): INTEGERLIST

Description

Probability estimate: Specify the (scalar) number of samples used to improve a probability estimate. If using uni-modal sampling all samples are assigned to the sampling center. If using multi-modal sampling the samples are split between multiple samples according to some internally computed weights.

Sampling design: Specify one or a sequence of refinement samples to augment the `initial_samples` in a sampling design.

final_moments

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [final_moments](#)

Output moments of the specified type and include them within the set of final statistics.

Specification

Alias: none

Argument(s): none

Default: standard

Child Keywords:

	Required/- Optional <i>Required(Choose One)</i>	Description of Group Objective Formulation (Group 1)	Dakota Keyword none	Dakota Keyword Description Omit moments from the set of final statistics.
			standard	Output standardized moments and include them within the set of final statistics.
			central	Output central moments and include them within the set of final statistics.

Description

When performing a nested study that may employ moment statistics on the inner loop, it can be desirable to control the type of these moments. The `final_moments` specification supports options of `none`, `standard` (default), or `central`, corresponding to omission of moments, standardized moments (mean, standard deviation, skewness, and excess kurtosis), or central moments (mean, variance, 3rd central, and 4th central).

The presence or omission of moment results in the final statistics influences the outer level mappings in the case of a nested study. For example, `final_moments none` can allow for a more compact specification of primary and/or secondary response mappings.

Examples

The following method specification overrides the default to print `central` moments and include them in the set of final statistics.

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments central
```

Overriding the default to none as follows:

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments none
```

allows associated nested model mappings to be simplified from:

```
model
  nested
    sub_method_pointer = 'UQ'
    primary_response_mapping = 0. 0. 1. 0. 0. 1. 0. 0. 0.
    secondary_response_mapping = 0. 0. 0. 0. 0. 0. 0. 0. 1.
```

to a more compact version focused only on the response level mappings (two leading zeros per response function for moment mappings have been removed):

```
model
  nested
    sub_method_pointer = 'UQ'
    primary_response_mapping = 1. 1. 0.
    secondary_response_mapping = 0. 0. 1.
```

none

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [final_moments](#)
- [none](#)

Omit moments from the set of final statistics.

Specification

Alias: none

Argument(s): none

Description

The omission of moment results from the final statistics can allow for a more compact definition of primary and/or secondary response mappings within a nested model specification.

Examples

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments none
```

standard

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [final_moments](#)
- [standard](#)

Output standardized moments and include them within the set of final statistics.

Specification

Alias: none

Argument(s): none

Description

Output standardized moments (mean, standard deviation, skewness, and excess kurtosis) and include the first two within the set of final statistics to be used at a higher level (e.g., optimization under uncertainty, mixed aleatory-epistemic UQ). This inclusion of moment results affects the primary and/or secondary response mappings in a nested model specification.

Examples

The following method specification overrides the default to print `central` moments and include them in the set of final statistics.

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments standard
```

central

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [final_moments](#)
- [central](#)

Output central moments and include them within the set of final statistics.

Specification

Alias: none

Argument(s): none

Description

Output central moments (mean, variance, 3rd central, and 4th central) and include the first two within the set of final statistics to be used at a higher level (e.g., optimization under uncertainty, mixed aleatory-epistemic U-Q). This inclusion of moment results affects the primary and/or secondary response mappings in a nested model specification.

Examples

The following method specification overrides the default to print `central` moments and include them in the set of final statistics.

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments central
```

response_levels

- [Keywords Area](#)
- [method](#)
- [function.train_uq](#)
- [response_levels](#)

Values at which to estimate desired statistics for each response

Specification

Alias: none

Argument(s): REALLIST

Default: No CDF/CCDF probabilities/reliabilities to compute

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			<code>num_response_ levels</code>	Number of values at which to estimate desired statistics for each response

	Optional	<code>compute</code>	Selection of statistics to compute at each response level
--	-----------------	----------------------	---

Description

The `response_levels` specification provides the target response values for which to compute probabilities, reliabilities, or generalized reliabilities (forward mapping).

Default Behavior

If `response_levels` are not specified, no statistics will be computed. If they are, probabilities will be computed by default.

Expected Outputs

If `response_levels` are specified, Dakota will create two tables in the standard output: a Probability Density function (PDF) histogram and a Cumulative Distribution Function (CDF) table. The PDF histogram has the lower and upper endpoints of each bin and the corresponding density of that bin. Note that the PDF histogram has bins defined by the `probability_levels` and/or `response_levels` in the Dakota input file. If there are not very many levels, the histogram will be coarse. Dakota does not do anything to optimize the bin size or spacing. The CDF table has the list of response levels and the corresponding probability that the response value is less than or equal to each response level threshold.

Usage Tips

The `num_response_levels` is used to specify which arguments of the `response_level` correspond to which response.

Examples

For example, specifying a `response_level` of 52.3 followed with `compute probabilities` will result in the calculation of the probability that the response value is less than or equal to 52.3, given the uncertain distributions on the inputs.

For an example with multiple responses, the following specification

```
response_levels = 1. 2. .1 .2 .3 .4 10. 20. 30.
num_response_levels = 2 4 3
```

would assign the first two response levels (1., 2.) to response function 1, the next four response levels (.1, .2, .3, .4) to response function 2, and the final three response levels (10., 20., 30.) to response function 3. If the `num_response_levels` key were omitted from this example, then the response levels would be evenly distributed among the response functions (three levels each in this case).

The Dakota input file below specifies a sampling method with response levels of interest.

```
method,
  sampling,
  samples = 100 seed = 1
  complementary distribution
  response_levels = 3.6e+11 4.0e+11 4.4e+11
                   6.0e+04 6.5e+04 7.0e+04
                   3.5e+05 4.0e+05 4.5e+05

variables,
  normal_uncertain = 2
  means             = 248.89, 593.33
  std_deviations    = 12.4, 29.7
  descriptors       = 'TF1n' 'TF2n'
```

```

uniform_uncertain = 2
  lower_bounds      = 199.3, 474.63
  upper_bounds      = 298.5, 712.
  descriptors        = 'TF1u' 'TF2u'
weibull_uncertain = 2
  alphas             = 12., 30.
  betas              = 250., 590.
  descriptors        = 'TF1w' 'TF2w'
histogram_bin_uncertain = 2
  num_pairs          = 3      4
  abscissas          = 5 8 10 .1 .2 .3 .4

  4.5000000000e+05  0.0000000000e+00

```

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

A forward mapping involves computing the belief and plausibility probability level for a specified response level.

num_response_levels

- [Keywords Area](#)
- [method](#)
- [function.train.uq](#)
- [response_levels](#)
- [num_response_levels](#)

Number of values at which to estimate desired statistics for each response

Specification

Alias: none

Argument(s): INTEGERLIST

Default: response_levels evenly distributed among response functions

Description

The `num_response_levels` keyword allows the user to specify the number of response values, for each response, at which estimated statistics are of interest. Statistics that can be computed are probabilities and reliabilities, both according to either a cumulative distribution function or a complementary cumulative distribution function.

Default Behavior

If `num_response_levels` is not specified, the `response_levels` will be evenly distributed among the responses.

Expected Outputs

The specific output will be determined by the type of statistics that are specified. In a general sense, the output will be a list of response level-statistic pairs that show the estimated value of the desired statistic for each response level specified.

Examples

```
method
  sampling
    samples = 100
    seed = 34785
    num_response_levels = 1 1 1
    response_levels = 0.5 0.5 0.5
```

compute

- [Keywords Area](#)
- [method](#)
- [function.train_uq](#)
- [response_levels](#)
- [compute](#)

Selection of statistics to compute at each response level

Specification

Alias: none

Argument(s): none

Default: probabilities

Child Keywords:

	Required/- Optional Required(<i>Choose One</i>)	Description of Group Statistics to Compute (Group 1)	Dakota Keyword probabilities	Dakota Keyword Description Computes probabilities associated with response levels
			reliabilities	Computes reliabilities associated with response levels

		gen_reliabilities	Computes generalized reliabilities associated with response levels
	Optional	system	Compute system reliability (series or parallel)

Description

The `compute` keyword is used to select which forward stastical mapping is calculated at each response level.

Default Behavior

If `response_levels` is not specified, no statistics are computed. If `response_levels` is specified but `compute` is not, probabilities will be computed by default. If both `response_levels` and `compute` are specified, then one of the following must be specified: `probabilities`, `reliabilities`, or `gen_reliabilities`.

Expected Output

The type of statistics specified by `compute` will be reported for each response level.

Usage Tips

CDF/CCDF probabilities are calculated for specified response levels using a simple binning approach.

CDF/CCDF reliabilities are calculated for specified response levels by computing the number of sample standard deviations separating the sample mean from the response level.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                    6.0e+04 6.5e+04 7.0e+04
                    3.5e+05 4.0e+05 4.5e+05
    compute reliabilities
```

probabilities

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [response_levels](#)
- [compute](#)
- [probabilities](#)

Computes probabilities associated with response levels

Specification

Alias: none

Argument(s): none

Description

The `probabilities` keyword directs Dakota to compute the probability that the model response will be below (cumulative) or above (complementary cumulative) a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the probabilities are computed by default. To explicitly specify it in the Dakota input file, though, the `probabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-probability pairs that give the probability that the model response will be below or above the corresponding response level, depending on the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                    6.0e+04 6.5e+04 7.0e+04
                    3.5e+05 4.0e+05 4.5e+05
    compute probabilities
```

reliabilities

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [response_levels](#)
- [compute](#)
- [reliabilities](#)

Computes reliabilities associated with response levels

Specification

Alias: none

Argument(s): none

Description

The `reliabilities` keyword directs Dakota to compute reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the reliabilities are not computed by default. To change this behavior, the `reliabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-reliability pairs according to the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                    6.0e+04 6.5e+04 7.0e+04
                    3.5e+05 4.0e+05 4.5e+05
    compute reliabilities
```

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [response_levels](#)
- [compute](#)
- [gen_reliabilities](#)

Computes generalized reliabilities associated with response levels

Specification

Alias: none

Argument(s): none

Description

The `gen_reliabilities` keyword directs Dakota to compute generalized reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the generalized reliabilities are not computed by default. To change this behavior, the `gen_reliabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-generalized reliability pairs according to the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                    6.0e+04 6.5e+04 7.0e+04
                    3.5e+05 4.0e+05 4.5e+05
    compute gen_reliabilities
```

system

Compute system reliability (series or parallel)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Required(<i>Choose One</i>)	Description of Group System Reliability Mode (Group 1)	Dakota Keyword	Dakota Keyword Description
			series	Aggregate response statistics assuming a series system
			parallel	Aggregate response statistics assuming a parallel system

Description

With the system probability/reliability option, statistics for specified `response_levels` are calculated and reported assuming the response functions combine either in series or parallel to produce a total system response.

For a series system, the system fails when any one component (response) fails. The probability of failure is the complement of the product of the individual response success probabilities.

For a parallel system, the system fails only when all components (responses) fail. The probability of failure is the product of the individual response failure probabilities.

probability_levels

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [probability_levels](#)

Specify probability levels at which to estimate the corresponding response value

Specification

Alias: none

Argument(s): REALLIST

Default: No CDF/CCDF response levels to compute

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			num_probability_- levels	Specify which probability_- levels correspond to which response

Description

Response levels are calculated for specified CDF/CCDF probabilities by indexing into a sorted samples array (the response levels computed are not interpolated and will correspond to one of the sampled values).

Expected Output

If `probability_levels` are specified, Dakota will create two tables in the standard output: a Probability Density function (PDF) histogram and a Cumulative Distribution Function (CDF) table. The PDF histogram has the lower and upper endpoints of each bin and the corresponding density of that bin. Note that the PDF histogram has bins defined by the `probability_levels` and/or `response_levels` in the Dakota input file. If there are not very many levels, the histogram will be coarse. Dakota does not do anything to optimize the bin size or spacing. The CDF table has the list of response levels and the corresponding probability that the response value is less than or equal to each response level threshold.

Examples

The Dakota input file below specifies a sampling method with probability levels of interest.

```
method,
  sampling,
  samples = 100 seed = 1
  complementary distribution
  probability_levels = 1. .66 .33 0.
                    1. .8 .5 0.
                    1. .3 .2 0.

variables,
  normal_uncertain = 2
  means             = 248.89, 593.33
```

```

std_deviations = 12.4, 29.7

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).

- [function_train_uq](#)
- [reliability_levels](#)
- [num_reliability_levels](#)

Specify which `reliability_levels` correspond to which response

Specification

Alias: none

Argument(s): INTEGERLIST

Default: reliability_levels evenly distributed among response functions

Description

See parent page

gen_reliability_levels

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [gen_reliability_levels](#)

Specify generalized reliability levels at which to estimate the corresponding response value

Specification

Alias: none

Argument(s): REALLIST

Default: No CDF/CCDF response levels to compute

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			num_gen_- reliability_levels	Specify which gen_- reliability_- levels correspond to which response

Description

Response levels are calculated for specified generalized reliabilities by indexing into a sorted samples array (the response levels computed are not interpolated and will correspond to one of the sampled values).

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).

num_gen_reliability_levels

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [gen_reliability_levels](#)
- [num_gen_reliability_levels](#)

Specify which `gen_reliability_levels` correspond to which response

Specification

Alias: none

Argument(s): INTEGERLIST

Default: `gen_reliability_levels` evenly distributed among response functions

Description

See parent page

distribution

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [distribution](#)

Selection of cumulative or complementary cumulative functions

Specification

Alias: none

Argument(s): none

Default: cumulative (CDF)

Child Keywords:

	Required/ Optional Required(<i>Choose One</i>)	Description of Group Distribution Type (CDF/CCDF) (Group 1)	Dakota Keyword	Dakota Keyword Description
			cumulative	Computes statistics according to cumulative functions

			complementary	Computes statistics according to complementary cumulative functions
--	--	--	-------------------------------	---

Description

The `distribution` keyword allows the user to select between a cumulative distribution/belief/plausibility function and a complementary cumulative distribution/belief/plausibility function. This choice affects how probabilities and reliability indices are reported.

Default Behavior

If the `distribution` keyword is present, it must be accompanied by either `cumulative` or `complementary`. Otherwise, a cumulative distribution will be used by default.

Expected Outputs

Output will be a set of model response-probability pairs determined according to the choice of distribution. The choice of distribution also defines the sign of the reliability or generalized reliability indices.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

cumulative

- [Keywords Area](#)
- [method](#)
- [function.train.uq](#)
- [distribution](#)
- [cumulative](#)

Computes statistics according to cumulative functions

Specification

Alias: none

Argument(s): none

Description

Statistics on model responses will be computed according to a cumulative distribution/belief/plausibility function.

Default Behavior

By default, a cumulative distribution/belief/plausibility function will be used. To explicitly specify it in the Dakota input file, however, the `cumulative` keyword must appear in conjunction with the `distribution` keyword.

Expected Outputs

Output will be a set of model response-probability pairs determined according to a cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls below given response thresholds.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

complementary

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [distribution](#)
- [complementary](#)

Computes statistics according to complementary cumulative functions

Specification

Alias: none

Argument(s): none

Description

Statistics on model responses will be computed according to a complementary cumulative distribution/belief/plausibility function.

Default Behavior

By default, a complementary cumulative distribution/belief/plausibility function will not be used. To change that behavior, the `complementary` keyword must be appear in conjunction with the `distribution` keyword.

Expected Outputs

Output will be a set of model response-probability pairs determined according to a complementary cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls above given response thresholds.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    distribution complementary
```

variance_based_decomp

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [variance_based_decomp](#)

Activates global sensitivity analysis based on decomposition of response variance into main, interaction, and total effects

Specification

Alias: none

Argument(s): none

Default: no variance-based decomposition

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			interaction_order	Specify the maximum number of variables allowed in an interaction when reporting interaction metrics.
	Optional		drop_tolerance	Suppresses output of sensitivity indices with values lower than this tolerance

Description

Dakota can calculate sensitivity indices through variance-based decomposition using the keyword `variance_based_decomp`. This approach decomposes main, interaction, and total effects in order to identify the most important variables and combinations of variables in contributing to the variance of output quantities of interest.

Default Behavior

Because of processing overhead and output volume, `variance_based_decomp` is inactive by default, unless required for dimension-adaptive refinement using Sobol' indices.

Expected Outputs

When `variance_based_decomp` is specified, sensitivity indices for main effects, total effects, and any interaction effects will be reported. Each of these effects represents the percent contribution to the variance in the model response, where main effects include the aggregated set of *univariate* terms for each individual variable, interaction effects represent the set of *mixed* terms (the complement of the univariate set), and total effects represent the *complete* set of terms (univariate and mixed) that contain each individual variable. The aggregated set of main and interaction sensitivity indices will sum to one, whereas the sum of total effects sensitivity indices will be greater than one due to redundant counting of mixed terms.

Usage Tips

An important consideration is that the number of possible interaction terms grows exponentially with dimension and expansion order. To mitigate this, both in terms of compute time and output volume, possible interaction effects are suppressed whenever no contributions are present due to the particular form of an expansion. In addition, the `interaction_order` and `drop_tolerance` controls can further limit the computational and output requirements.

Examples

```
method,
  polynomial_chaos # or stoch_collocation
  sparse_grid_level = 3
  variance_based_decomp interaction_order = 2
```

Theory

In this context, we take sensitivity analysis to be global, not local as when calculating derivatives of output variables with respect to input variables. Our definition is similar to that of [75]: "The study of how uncertainty in the output of a model can be apportioned to different sources of uncertainty in the model input."

Variance based decomposition is a way of using sets of samples to understand how the variance of the output behaves, with respect to each input variable. A larger value of the sensitivity index, S_i , means that the uncertainty in the input variable i has a larger effect on the variance of the output. More details on the calculations and interpretation of the sensitivity indices can be found in [89].

interaction_order

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [variance_based_decomp](#)
- [interaction_order](#)

Specify the maximum number of variables allowed in an interaction when reporting interaction metrics.

Specification

Alias: none

Argument(s): INTEGER

Default: Unrestricted (VBD includes all interaction orders present in the expansion)

Description

The `interaction_order` option has been added to allow suppression of higher-order interactions, since the output volume (and memory and compute consumption) of these results could be extensive for high dimensional problems (note: the previous `univariate_effects` specification is equivalent to `interaction_order = 1` in the current specification). Similar to suppression of interactions is the covariance control, which can be selected to be `diagonal_covariance` or `full_covariance`, with the former supporting suppression of the off-diagonal covariance terms (to again save compute and memory resources and reduce output volume)

drop_tolerance

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [variance_based_decomp](#)
- [drop_tolerance](#)

Suppresses output of sensitivity indices with values lower than this tolerance

Specification

Alias: none

Argument(s): REAL

Default: All VBD indices displayed

Description

The `drop_tolerance` keyword allows the user to specify a value below which sensitivity indices generated by `variance_based_decomp` are not displayed.

Default Behavior

By default, all sensitivity indices generated by `variance_based_decomp` are displayed.

Usage Tips

For `polynomial_chaos`, which outputs main, interaction, and total effects by default, the `univariate_effects` may be a more appropriate option. It allows suppression of the interaction effects since the output volume of these results can be prohibitive for high dimensional problems. Similar to suppression of these interactions is the covariance control, which can be selected to be `diagonal_covariance` or `full_covariance`, with the former supporting suppression of the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

Examples

```
method,
sampling
  sample_type lhs
  samples = 100
  variance_based_decomp
  drop_tolerance = 0.001
```

diagonal_covariance

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [diagonal_covariance](#)

Display only the diagonal terms of the covariance matrix

Specification

Alias: none

Argument(s): none

Default: diagonal_covariance for response vector > 10; else full_covariance

Description

With a large number of responses, the covariance matrix can be very large. `diagonal_covariance` is used to suppress the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

full_covariance

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [full_covariance](#)

Display the full covariance matrix

Specification

Alias: none

Argument(s): none

Description

With a large number of responses, the covariance matrix can be very large. `full_covariance` is used to force Dakota to output the full covariance matrix.

convergence_tolerance

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [convergence_tolerance](#)

Placeholder keyword

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

This general UQ control is not currently implemented in `function_train_uq`

import_approx_points_file

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [import_approx_points_file](#)

Filename for points at which to evaluate the PCE/SC surrogate

Specification

Alias: none

Argument(s): STRING

Default: no point import from a file

Child Keywords:

	Required/- Optional <i>Optional(Choose One)</i>	Description of Group Tabular Format (Group 1)	Dakota Keyword custom_annotated	Dakota Keyword Description Selects custom-annotated tabular file format
			annotated	Selects annotated tabular file format
			freeform	Selects freeform file format
	Optional		active_only	Import only active variables from tabular data file

Description

Default Behavior No import of points at which to evaluate the surrogate.

Expected Output The PCE/SC surrogate model will be evaluated at the list of points (input variable values) provided in the file and results tabulated and/or statistics computed at them, depending on the method context.

Examples

```
method
  polynomial_chaos
    expansion_order = 4
    import_approx_points_file = 'import.mcmc_annot.dat'
    annotated
```

custom_annotated

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [import_approx_points_file](#)
- [custom_annotated](#)

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			header	Enable header row in custom-annotated tabular file
	Optional		eval_id	Enable evaluation ID column in custom-annotated tabular file
	Optional		interface_id	Enable interface ID column in custom-annotated tabular file

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, `eval_id` column, and `interface_id` column appear in the tabular file, thus bridging `freeform` and (fully) `annotated`.

Default Behavior

The `annotated` format is the default for tabular export/import. To control which header row and columns are in the input/output, specify `custom_annotated`, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and `eval_id` (no `interface_id`), and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id      x1          x2          obj_fn  nln_ineq_con_1  nln_ineq_con_2
1             0.9          1.1          0.0002          0.26           0.76
2             0.90009      1.1 0.0001996404857  0.2601620081    0.759955

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The `annotated` keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include `interface_id`, specify `custom_annotated_header eval_id`
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export an annotated top-level tabular data file containing a header row, leading `eval_id` and `interface_id` columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated
```

Resulting tabular file:

```
%eval_id interface          x1          x2          obj_fn nln_ineq_con_1 nln_ineq_con_2
1          NO_ID            0.9         1.1         0.0002          0.26          0.76
2          NO_ID            0.90009     1.1 0.0001996404857 0.2601620081 0.759955

...
```

freeform

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [import_approx_points_file](#)
- [freeform](#)

Selects freeform file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The `annotated` format is the default for tabular export/import. To change this behavior, specify `freeform` in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to `annotated` format, though `freeform` remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- In `freeform`, the `num_rows` x `num_cols` total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

```
      0.9          1.1          0.0002          0.26          0.76
0.90009          1.1 0.0001996404857  0.2601620081  0.759955
0.89991          1.1 0.0002003604863  0.2598380081  0.760045
...
```

active_only

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [import_approx_points_file](#)
- [active_only](#)

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

export_approx_points_file

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [export_approx_points_file](#)

Output file for evaluations of a surrogate model

Specification

Alias: export_points_file

Argument(s): STRING

Default: no point export to a file

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional (<i>Choose One</i>)	Tabular Format (Group 1)	custom_annotated	Selects custom-annotated tabular file format
			annotated	Selects annotated tabular file format
			freeform	Selects freeform file format

Description

The `export_approx_points_file` keyword allows the user to specify a file in which the points (input variable values) at which the surrogate model is evaluated and corresponding response values computed by the surrogate model will be written. The response values are the surrogate's predicted approximation to the truth model responses at those points.

Usage Tips

Dakota exports tabular data in one of three formats:

- `annotated` (default)
- `custom_annotated`
- `freeform`

custom_annotated

freeform

- [Keywords Area](#)
- [method](#)
- [function_train_uq](#)
- [export_approx_points_file](#)
- [freeform](#)

Selects freeform file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The `annotated` format is the default for tabular export/import. To change this behavior, specify `freeform` in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to `annotated` format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- In `freeform`, the `num_rows` x `num_cols` total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

```

      0.9          1.1          0.0002          0.26          0.76
0.90009          1.1 0.0001996404857  0.2601620081  0.759955
0.89991          1.1 0.0002003604863  0.2598380081  0.760045
...

```

model_pointer

- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

Description

The polynomial chaos expansion (PCE) is a general framework for the approximate representation of random response functions in terms of finite-dimensional series expansions in standardized random variables

$$R = \sum_{i=0}^P \alpha_i \Psi_i(\xi)$$

where α_i is a deterministic coefficient, Ψ_i is a multidimensional orthogonal polynomial and ξ is a vector of standardized random variables. An important distinguishing feature of the methodology is that the functional relationship between random inputs and outputs is captured, not merely the output statistics as in the case of many nondeterministic methodologies.

Basis polynomial family (Group 1)

Group 1 keywords are used to select the type of basis, Ψ_i , of the expansion. Three approaches may be employed:

- Wiener: employs standard normal random variables in a transformed probability space, corresponding to Hermite orthogonal basis polynomials (see [wiener](#)).
- Askey: employs standard normal, standard uniform, standard exponential, standard beta, and standard gamma random variables in a transformed probability space, corresponding to Hermite, Legendre, Laguerre, Jacobi, and generalized Laguerre orthogonal basis polynomials, respectively (see [askey](#)).
- Extended (default if no option is selected): The Extended option avoids the use of any nonlinear variable transformations by augmenting the Askey approach with numerically-generated orthogonal polynomials for non-Askey probability density functions. Extended polynomial selections replace each of the sub-optimal Askey basis selections for bounded normal, lognormal, bounded lognormal, loguniform, triangular, gumbel, frechet, weibull, and bin-based histogram.

For supporting correlated random variables, certain fallbacks must be implemented.

- The Extended option is the default and supports only Gaussian correlations.
- If needed to support prescribed correlations (not under user control), the Extended and Askey options will fall back to the Wiener option *on a per variable basis*. If the prescribed correlations are also unsupported by Wiener expansions, then Dakota will exit with an error.

Refer to [variable_support](#) for additional information on supported variable types, with and without correlation.

Coefficient estimation approach (Group 2)

To obtain the coefficients α_i of the expansion, seven options are provided:

1. multidimensional integration by a tensor-product of Gaussian quadrature rules (specified with `quadrature_order`, and, optionally, `dimension_preference`).
2. multidimensional integration by the Smolyak sparse grid method (specified with `sparse_grid_level` and, optionally, `dimension_preference`)
3. multidimensional integration by Stroud cubature rules and extensions as specified with `cubature_integrand`.
4. multidimensional integration by Latin hypercube sampling (specified with `expansion_order` and `expansion_samples`).
5. linear regression (specified with `expansion_order` and either `collocation_points` or `collocation_ratio`), using either over-determined (least squares) or under-determined (compressed sensing) approaches.
6. orthogonal least interpolation (specified with `orthogonal_least_interpolation` and `collocation_points`)
7. coefficient import from a file (specified with `import_expansion_file`). The expansion can be comprised of a general set of expansion terms, as indicated by the multi-index annotation within the file.

It is important to note that, for polynomial chaos using a single model fidelity, `quadrature_order`, `sparse_grid_level`, and `expansion_order` are scalar inputs used for a single expansion estimation. These scalars can be augmented with a `dimension_preference` to support anisotropy across the random dimension set. This differs from the use of sequence arrays in advanced use cases such as multilevel and multifidelity polynomial chaos, where multiple grid resolutions can be employed across a model hierarchy.

Active Variables

The default behavior is to form expansions over aleatory uncertain continuous variables. To form expansions over a broader set of variables, one needs to specify `active` followed by `state`, `epistemic`, `design`, or `all` in the variables specification block.

For continuous design, continuous state, and continuous epistemic uncertain variables included in the expansion, Legendre chaos bases are used to model the bounded intervals for these variables. However, these variables are not assumed to have any particular probability distribution, only that they are independent variables. Moreover, when probability integrals are evaluated, only the aleatory random variable domain is integrated, leaving behind a polynomial relationship between the statistics and the remaining design/state/epistemic variables.

Covariance type (Group 3)

These two keywords are used to specify how this method computes, stores, and outputs the covariance of the responses. In particular, the diagonal covariance option is provided for reducing post-processing overhead and output volume in high dimensional applications.

Optional Keywords regarding method outputs

Each of these sampling specifications refer to sampling on the PCE approximation for the purposes of generating approximate statistics.

- `sample_type`
- `samples`
- `seed`
- `fixed_seed`
- `rng`
- `probability_refinement`
- `distribution`
- `reliability_levels`
- `response_levels`
- `probability_levels`
- `gen_reliability_levels`

which should be distinguished from simulation sampling for generating the PCE coefficients as described in options 4, 5, and 6 above (although these options will share the `sample_type`, `seed`, and `rng` settings, if provided).

When using the `probability_refinement` control, the number of refinement samples is not under the user's control (these evaluations are approximation-based, so management of this expense is less critical). This option allows for refinement of probability and generalized reliability results using importance sampling.

Usage Tips

If n is small (e.g., two or three), then tensor-product Gaussian quadrature is quite effective and can be the preferred choice. For moderate to large n (e.g., five or more), tensor-product quadrature quickly becomes too expensive and the sparse grid and regression approaches are preferred. Random sampling for coefficient estimation is generally not recommended due to its slow convergence rate. For incremental studies, approaches 4 and 5 support reuse of previous samples through the `incremental_lhs` and `reuse_points` specifications, respectively.

In the quadrature and sparse grid cases, growth rates for nested and non-nested rules can be synchronized for consistency. For a non-nested Gauss rule used within a sparse grid, linear one-dimensional growth rules of $m = 2l + 1$ are used to enforce odd quadrature orders, where l is the grid level and m is the number of points in the rule. The precision of this Gauss rule is then $i = 2m - 1 = 4l + 1$. For nested rules, order growth with level is typically exponential; however, the default behavior is to restrict the number of points to be the lowest order rule that is available that meets the one-dimensional precision requirement implied by either a level l for a sparse grid ($i = 4l + 1$) or an order m for a tensor grid ($i = 2m - 1$). This behavior is known as

”restricted growth” or ”delayed sequences.” To override this default behavior in the case of sparse grids, the `unrestricted` keyword can be used; it cannot be overridden for tensor grids using nested rules since it also provides a mapping to the available nested rule quadrature orders. An exception to the default usage of restricted growth is the `dimension_adaptive_p_refinement_generalized` sparse grid case described previously, since the ability to evolve the index sets of a sparse grid in an unstructured manner eliminates the motivation for restricting the exponential growth of nested rules.

Additional Resources

Dakota provides access to PCE methods through the `NonDPolynomialChaos` class. Refer to the Uncertainty Quantification Capabilities chapter of the Users Manual[4] and the Stochastic Expansion Methods chapter of the Theory Manual[6] for additional information on the PCE algorithm.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the `hdf5` keyword, this method writes the following results to HDF5:

- [Integration and Expansion Moments](#)
- [Probability Density](#)
- [Level Mappings](#)
- [Variance-Based Decomposition \(Sobol’ Indices\)](#)

Examples

```
method,  
  polynomial_chaos

Automatic polynomial order refinement

Specification

Alias: none

Argument(s): none

Default: no refinement

Child Keywords:

	Required/ Optional Required(<i>Choose One</i>)	Description of Group p-refinement Type (Group 1)	Dakota Keyword uniform	Dakota Keyword Description Refine an expansion uniformly in all dimensions.
			dimension_- adaptive	Perform anisotropic expansion refinement by preferentially adapting in dimensions that are detected to have higher 'importance'.

Description

The `p_refinement` keyword specifies the usage of automated polynomial order refinement, which can be either `uniform` or `dimension_adaptive`.

The `dimension_adaptive` option is supported for the tensor-product quadrature and Smolyak sparse grid options and `uniform` is supported for tensor and sparse grids as well as regression approaches (`collocation_points` or `collocation_ratio`).

Each of these refinement cases makes use of the `max_iterations` and `convergence_tolerance` method independent controls. The former control limits the number of refinement iterations, and the latter control terminates refinement when the two-norm of the change in the response covariance matrix (or, in goal-oriented approaches, the two-norm of change in the statistical quantities of interest (QOI)) falls below the tolerance.

The `dimension_adaptive` case can be further specified to utilize `sobol`, `decay`, or generalized refinement controls. The former two cases employ anisotropic tensor/sparse grids in which the anisotropic dimension preference (leading to anisotropic integrations/expansions with differing refinement levels for different random dimensions) is determined using either total Sobol' indices from variance-based decomposition (`sobol`

case: high indices result in high dimension preference) or using spectral coefficient decay rates from a rate estimation technique similar to Richardson extrapolation (decay case: low decay rates result in high dimension preference). In these two cases as well as the `uniform` refinement case, the `quadrature_order` or `sparse_grid_level` are ramped by one on each refinement iteration until either of the two convergence controls is satisfied. For the `uniform` refinement case with regression approaches, the `expansion_order` is ramped by one on each iteration while the oversampling ratio (either defined by `collocation_ratio` or inferred from `collocation_points` based on the initial expansion) is held fixed. Finally, the `generalized_dimension_adaptive` case is the default adaptive approach; it refers to the generalized sparse grid algorithm, a greedy approach in which candidate index sets are evaluated for their impact on the statistical QOI, the most influential sets are selected and used to generate additional candidates, and the index set frontier of a sparse grid is evolved in an unstructured and goal-oriented manner (refer to User's Manual PCE descriptions for additional specifics).

For the case of `p_refinement` or the case of an explicit nested override, Gauss-Hermite rules are replaced with Genz-Keister nested rules and Gauss-Legendre rules are replaced with Gauss-Patterson nested rules, both of which exchange lower integrand precision for greater point reuse.

uniform

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [p_refinement](#)
- [uniform](#)

Refine an expansion uniformly in all dimensions.

Specification

Alias: none

Argument(s): none

Description

The `quadrature_order` or `sparse_grid_level` are ramped by one on each refinement iteration until either of the two convergence controls is satisfied. For the `uniform` refinement case with regression approaches, the `expansion_order` is ramped by one on each iteration while the oversampling ratio (either defined by `collocation_ratio` or inferred from `collocation_points` based on the initial expansion) is held fixed.

dimension_adaptive

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)

Maximum number of expansion refinement iterations

Specification

Alias: none

Argument(s): INTEGER

Default: 100

Description

Limits the number of times the expansion can be refined under various refinement strategies.

Examples

```
method,
  polynomial_chaos
    dimension_adaptive generalized
  p_refinement
    max_refinement_iterations = 20
    convergence_tol = 1.e-4
  sparse_grid_level = 1
```

quadrature_order

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [quadrature_order](#)

Order for tensor-products of Gaussian quadrature rules

Specification

Alias: none

Argument(s): INTEGER

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			dimension_- preference	A set of weights specifying the relative importance of each uncertain variable (dimension)

	Optional(<i>Choose One</i>)	Quadrature Rule Nesting (Group 1)	nested	Enforce use of nested quadrature rules if available
			non_nested	Enforce use of non-nested quadrature rules

Description

Multidimensional integration by a tensor-product of Gaussian quadrature rules (specified with `quadrature_order`, and, optionally, `dimension_preference`). The default rule selection is to employ `non_nested` Gauss rules including Gauss-Hermite (for normals or transformed normals), Gauss-Legendre (for uniforms or transformed uniforms), Gauss-Jacobi (for betas), Gauss-Laguerre (for exponentials), generalized Gauss-Laguerre (for gammas), and numerically-generated Gauss rules (for other distributions when using an Extended basis). For the case of `p_refinement` or the case of an explicit `nested` override, Gauss-Hermite rules are replaced with Genz-Keister nested rules and Gauss-Legendre rules are replaced with Gauss-Patterson nested rules, both of which exchange lower integrand precision for greater point reuse. By specifying a `dimension_preference`, where higher preference leads to higher order polynomial resolution, the tensor grid may be rendered anisotropic. The dimension specified to have highest preference will be set to the specified `quadrature_order` and all other dimensions will be reduced in proportion to their reduced preference; any non-integral portion is truncated. To synchronize with tensor-product integration, a tensor-product expansion is used, where the order p_i of the expansion in each dimension is selected to be half of the integrand precision available from the rule in use, rounded down. In the case of non-nested Gauss rules with integrand precision $2m_i - 1$, p_i is one less than the quadrature order m_i in each dimension (a one-dimensional expansion contains the same number of terms, $p + 1$, as the number of Gauss points). The total number of terms, N , in a tensor-product expansion involving n uncertain input variables is

$$N = 1 + P = \prod_{i=1}^n (p_i + 1)$$

In some advanced use cases (e.g., multifidelity UQ), multiple grid resolutions can be employed; for this reason, the `quadrature_order` specification supports an array input.

Usage Tips

For most use cases, this keyword will specify a single integer order. In more advanced UQ studies with hierarchical models, the list of integers can apply to different models and/or model levels

`dimension_preference`

- [Keywords Area](#)
- [method](#)

Level to use in sparse grid integration or interpolation

Specification

Alias: none

Argument(s): INTEGER

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			<code>dimension_- preference</code>	A set of weights specifying the relative importance of each uncertain variable (dimension)
	Optional(<i>Choose One</i>)	Quadrature Rule Growth (Group 1)	<code>restricted</code>	Restrict the growth rates for nested and non-nested rules can be synchronized for consistency.
			<code>unrestricted</code>	Override the default restriction of growth rates for nested and non-nested rules that are by default synchronized for consistency.
	Optional(<i>Choose One</i>)	Quadrature Rule Nesting (Group 2)	<code>nested</code>	Enforce use of nested quadrature rules if available
			<code>non_nested</code>	Enforce use of non-nested quadrature rules

Description

Multi-dimensional integration by the Smolyak sparse grid method (specified with `sparse_grid_level` and, optionally, `dimension_preference`). The underlying one-dimensional integration rules are the same as for the tensor-product quadrature case; however, the default rule selection is nested for sparse grids (Genz-Keister for normals/transformed normals and Gauss-Patterson for uniforms/transformed uniforms). This default can be overridden with an explicit `non_nested` specification (resulting in Gauss-Hermite for normals/transformed normals and Gauss-Legendre for uniforms/transformed uniforms). As for tensor quadrature, the `dimension_preference` specification enables the use of anisotropic sparse grids (refer to the PCE description in the User's Manual for the anisotropic index set constraint definition). Similar to anisotropic tensor grids, the dimension with greatest preference will have resolution at the full `sparse_grid_level` and all other dimension resolutions will be reduced in proportion to their reduced preference. For PCE with either isotropic or anisotropic sparse grids, a summation of tensor-product expansions is used, where each anisotropic tensor-product quadrature rule underlying the sparse grid construction results in its own anisotropic tensor-product expansion as described in case 1. These anisotropic tensor-product expansions are summed into a sparse PCE using the standard Smolyak summation (again, refer to the User's Manual for additional details). As for `quadrature_order`, the `sparse_grid_level` specification admits an array input for enabling specification of multiple grid resolutions used by certain advanced solution methodologies.

Usage Tips

This keyword can be used when using sparse grid integration to calculate PCE coefficients or when generating samples for sparse grid collocation.

For most use cases, this keyword will specify a single integer level. In more advanced UQ studies with hierarchical models, the list of integers can apply to different models and/or model levels

dimension_preference

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [sparse_grid_level](#)
- [dimension_preference](#)

A set of weights specifying the relative importance of each uncertain variable (dimension)

Specification

Alias: none

Argument(s): REALLIST

Default: isotropic grids

Description

A set of weights specifying the relative importance of each uncertain variable (dimension). Using this specification leads to anisotropic integrations with differing refinement levels for different random dimensions.

- [sobol](#)
- [decay](#)

restricted

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [sparse_grid_level](#)
- [restricted](#)

Restrict the growth rates for nested and non-nested rules can be synchronized for consistency.

Specification

Alias: none

Argument(s): none

Default: restricted (except for generalized sparse grids)

Description

In the quadrature and sparse grid cases, growth rates for nested and non-nested rules can be synchronized for consistency. For a non-nested Gauss rule used within a sparse grid, linear one-dimensional growth rules of $m = 2l + 1$ are used to enforce odd quadrature orders, where l is the grid level and m is the number of points in the rule. The precision of this Gauss rule is then $i = 2m - 1 = 4l + 1$. For nested rules, order growth with level is typically exponential; however, the default behavior is to restrict the number of points to be the lowest order rule that is available that meets the one-dimensional precision requirement implied by either a level l for a sparse grid ($i = 4l + 1$) or an order m for a tensor grid ($i = 2m - 1$). This behavior is known as "restricted growth" or "delayed sequences." To override this default behavior in the case of sparse grids, the `unrestricted` keyword can be used; it cannot be overridden for tensor grids using nested rules since it also provides a mapping to the available nested rule quadrature orders. An exception to the default usage of restricted growth is the `dimension_adaptive_p_refinement` generalized sparse grid case described previously, since the ability to evolve the index sets of a sparse grid in an unstructured manner eliminates the motivation for restricting the exponential growth of nested rules.

cubature_integrand

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [cubature_integrand](#)

Cubature using Stroud rules and their extensions

Specification

Alias: none

Argument(s): INTEGER

Description

Multi-dimensional integration by Stroud cubature rules [79] and extensions [93], as specified with `cubature_integrand`. A total-order expansion is used, where the isotropic order p of the expansion is half of the integrand order, rounded down. The total number of terms N for an isotropic total-order expansion of order p over n variables is given by

$$N = 1 + P = 1 + \sum_{s=1}^p \frac{1}{s!} \prod_{r=0}^{s-1} (n+r) = \frac{(n+p)!}{n!p!}$$

Since the maximum integrand order is currently five for normal and uniform and two for all other types, at most second- and first-order expansions, respectively, will be used. As a result, cubature is primarily useful for global sensitivity analysis, where the Sobol' indices will provide main effects and, at most, two-way interactions. In addition, the random variable set must be independent and identically distributed (*iid*), so the use of `askey` or `wiener` transformations may be required to create *iid* variable sets in the transformed space (as well as to allow usage of the higher order cubature rules for normal and uniform). Note that global sensitivity analysis often assumes uniform bounded regions, rather than precise probability distributions, so the *iid* restriction would not be problematic in that case.

expansion_order

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [expansion_order](#)

The (initial) order of a polynomial expansion

Specification

Alias: none

Argument(s): INTEGER

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional	Group 1	dimension_- preference	A set of weights specifying the relative importance of each uncertain variable (dimension)
	Required(<i>Choose One</i>)		basis_type	Specify the type of truncation to be used with a Polynomial Chaos Expansion.
			collocation_points	Number of collocation points to estimate PCE coefficients
			collocation_ratio	Set the number of points used to build a PCE via regression to be proportional to the number of terms in the expansion.
			expansion_samples	Number of simulation samples to estimate the PCE coefficients
	Optional		import_build_- points_file	File containing points you wish to use to build a surrogate

Description

When the `expansion_order` for a polynomial chaos expansion is specified, the coefficients may be computed by integration based on random samples or by regression using either random or sub-sampled tensor product quadrature points.

Multidimensional integration by Latin hypercube sampling (specified with `expansion_samples`). In this case, the expansion order p cannot be inferred from the numerical integration specification and it is necessary to provide an `expansion_order` to specify p for a total-order expansion.

Linear regression (specified with either `collocation_points` or `collocation_ratio`). A total-order expansion is used and must be specified using `expansion_order` as described in the previous option. To avoid requiring the user to calculate N from n and p , the `collocation_ratio` allows for specification of a constant factor applied to N (e.g., `collocation_ratio = 2`. produces `samples = 2N`). In addition, the default linear relationship with N can be overridden using a real-valued exponent specified using `ratio_order`. In this

case, the number of samples becomes cN^o where c is the `collocation_ratio` and o is the `ratio_order`. The `use_derivatives` flag informs the regression approach to include derivative matching equations (limited to gradients at present) in the least squares solutions, enabling the use of fewer collocation points for a given expansion order and dimension (number of points required becomes $\frac{cN^o}{n+1}$). When admissible, a constrained least squares approach is employed in which response values are first reproduced exactly and error in reproducing response derivatives is minimized. Two collocation grid options are supported: the default is Latin hypercube sampling ("point collocation"), and an alternate approach of "probabilistic collocation" is also available through inclusion of the `tensor_grid` keyword. In this alternate case, the collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

If `collocation_points` or `collocation_ratio` is specified, the PCE coefficients will be determined by regression. If no regression specification is provided, appropriate defaults are defined. Specifically SVD-based least-squares will be used for solving over-determined systems and under-determined systems will be solved using LASSO. For the situation when the number of function values is smaller than the number of terms in a PCE, but the total number of samples including gradient values is greater than the number of terms, the resulting over-determined system will be solved using equality constrained least squares. Technical information on the various methods listed below can be found in the Linear regression section of the Theory Manual. Some of the regression methods (OMP, LASSO, and LARS) are able to produce a set of possible PCE coefficient vectors (see the Linear regression section in the Theory Manual). If cross validation is inactive, then only one solution, consistent with the `noise_tolerance`, will be returned. If cross validation is active, Dakota will choose between possible coefficient vectors found internally by the regression method across the set of expansion orders (1,...,`expansion_order`) and the set of specified noise tolerances and return the one with the lowest cross validation error indicator.

Usage Tips

For most use cases, this keyword will specify a single integer order. In more advanced UQ studies with hierarchical models, the list of integers can apply to different models and/or model levels

	Optional	noise_only	Restrict the cross validation process to estimating only the best noise tolerance.
--	-----------------	----------------------------	--

Description

Use cross validation to choose the 'best' polynomial degree of a polynomial chaos expansion. 10 fold cross validation is used to estimate the cross validation error of a total-order polynomial expansion for orders 1 through to order. The order chosen is the one that produces the lowest cross validation error. If there are not enough points to perform 10 fold cross validation then one-at-a-time cross validation will be performed.

noise_only

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [expansion_order](#)
- [collocation_points](#)
- [cross_validation](#)
- [noise_only](#)

Restrict the cross validation process to estimating only the best noise tolerance.

Specification

Alias: none

Argument(s): none

Default: false

Description

By default, cross validation estimates both the best noise tolerance and the best candidate basis order. For reasons of reducing computational cost by reducing the number of candidate solves, the user may wish to restrict this process to estimating only the best noise tolerance.

Generally speaking, computing the best noise tolerance through cross validation mitigates issues with overfitting the data. Computing the best candidate basis order can also mitigate overfitting, while also controlling levels of mutual coherence resulting from high-order Vandermonde-like matrix systems.

ratio_order

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [expansion_order](#)
- [collocation_points](#)
- [ratio_order](#)

Specify a non-linear the relationship between the expansion order of a polynomial chaos expansion and the number of samples that will be used to compute the PCE coefficients.

Specification

Alias: none

Argument(s): REAL

Default: 1.

Description

When using regression type methods (specified with either `collocation_points` or `collocation_ratio`), a total-order expansion can be specified using `expansion_order`. To avoid requiring the user to calculate N from n and p , the `collocation_ratio` allows for specification of a constant factor applied to N (e.g., `collocation_ratio = 2` produces $\text{samples} = 2N$). In addition, the default linear relationship with N can be overridden using a real-valued exponent specified using `ratio_order`. In this case, the number of samples becomes cN^o where c is the `collocation_ratio` and o is the `ratio_order`.

use_derivatives

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [expansion_order](#)
- [collocation_points](#)
- [use_derivatives](#)

Use derivative data to construct surrogate models

Specification

Alias: none

Argument(s): none

Default: use function values only

Description

The `use_derivatives` flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, its use with Surfpack Gaussian process is not recommended.

tensor_grid

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [expansion_order](#)
- [collocation_points](#)
- [tensor_grid](#)

Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.

Specification

Alias: none

Argument(s): none

Default: regression with LHS sample set (point collocation)

Description

The collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

reuse_points

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [expansion_order](#)
- [collocation_points](#)
- [reuse_points](#)

This describes the behavior of reuse of points in constructing polynomial chaos expansion models.

Specification

Alias: reuse_samples

Argument(s): none

Default: no sample reuse in coefficient estimation

Description

The `reuse_points` option controls the reuse behavior of points for various types of polynomial chaos expansions, including: `collocation_points`, `collocation_ratio`, `expansion_samples`, or `orthogonal_least_interpolation`. If any of these approaches are specified to create a set of points for the polynomial chaos expansion, one can specify `reuse_points` so that any points that have been previously generated (for example, from the `import_points` file) can be reused.

max_solver_iterations

			basis_pursuit-denoising	Compute the coefficients of a polynomial expansion by solving the Basis Pursuit Denoising ℓ_1 -minimization problem using second order cone optimization.

		least_angle_regression	Compute the coefficients of a polynomial expansion by using the greedy least angle regression (LAR) method.
		least_absolute_shrinkage	Compute the coefficients of a polynomial expansion by using the LASSO problem.
	Optional	cross_validation	Use cross validation to choose the 'best' polynomial order of a polynomial chaos expansion.
	Optional	ratio_order	Specify a non-linear the relationship between the expansion order of a polynomial chaos expansion and the number of samples that will be used to compute the PCE coefficients.
	Optional	use_derivatives	Use derivative data to construct surrogate models
	Optional	tensor_grid	Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.

	Optional	reuse_points	This describes the behavior of reuse of points in constructing polynomial chaos expansion models. Maximum iterations in determining polynomial coefficients
	Optional	max_solver_ iterations	

Description

Set the number of points used to build a PCE via regression to be proportional to the number of terms in the expansion. To avoid requiring the user to calculate N from n and p , the `collocation_ratio` allows for specification of a constant factor applied to N (e.g., `collocation_ratio = 2` produces `samples = 2N`). In addition, the default linear relationship with N can be overridden using a real-valued exponent specified using `ratio_order`. In this case, the number of samples becomes cN^o where c is the `collocation_ratio` and o is the `ratio_order`. The `use_derivatives` flag informs the regression approach to include derivative matching equations (limited to gradients at present) in the least squares solutions, enabling the use of fewer collocation points for a given expansion order and dimension (number of points required becomes $\frac{cN^o}{n+1}$).

least_squares

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [expansion_order](#)
- [collocation_ratio](#)
- [least_squares](#)

Compute the coefficients of a polynomial expansion using least squares

Specification

Alias: none

Argument(s): none

Default: svd

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
--	-----------------------	-------------------------	----------------	-------------------------------

	Optional (Choose One)	LSQ Regression Approach (Group 1)	svd	Calculate the coefficients of a polynomial chaos expansion using the singular value decomposition.
			equality_-constrained	Calculate the coefficients of a polynomial chaos expansion using equality constrained least squares.

Description

Compute the coefficients of a polynomial expansion using least squares. Specifically SVD-based least-squares will be used for solving over-determined systems. For the situation when the number of function values is smaller than the number of terms in a PCE, but the total number of samples including gradient values is greater than the number of terms, the resulting over-determined system will be solved using equality constrained least squares

svd

- [Keywords Area](#)
- [method](#)
- [polynomial.chaos](#)
- [expansion_order](#)
- [collocation_ratio](#)
- [least_squares](#)
- [svd](#)

Calculate the coefficients of a polynomial chaos expansion using the singular value decomposition.

Specification

Alias: none

Argument(s): none

Description

Calculate the coefficients of a polynomial chaos expansion using the singular value decomposition. When the number of model runs exceeds the number of terms in the PCE, the solution returned will be the least-squares solution, otherwise the solution will be the minimum norm solution computed using the pseudo-inverse.

equality_constrained

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			noise_tolerance	The noise tolerance used when performing cross validation in the presence of noise or truncation errors.
	Optional		l2_penalty	The l_2 penalty used when performing compressed sensing with elastic net.

Description

Compute the coefficients of a polynomial expansion by using the LASSO problem.

noise_tolerance

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [expansion_order](#)
- [collocation_ratio](#)
- [least_absolute_shrinkage](#)
- [noise_tolerance](#)

The noise tolerance used when performing cross validation in the presence of noise or truncation errors.

Specification

Alias: none

Argument(s): REALLIST

Default: 1e-3 for BPDN, 0. otherwise (algorithms run until termination)

Description

The noise tolerance used when performing cross validation in the presence of noise or truncation errors.

l2_penalty

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [expansion_order](#)
- [collocation_ratio](#)
- [least_absolute_shrinkage](#)
- [l2_penalty](#)

The l_2 penalty used when performing compressed sensing with elastic net.

Specification

Alias: none

Argument(s): REAL

Default: 0. (reverts to standard LASSO formulation)

Description

The l_2 penalty used when performing compressed sensing with elastic net.

cross_validation

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [expansion_order](#)
- [collocation_ratio](#)
- [cross_validation](#)

Use cross validation to choose the 'best' polynomial order of a polynomial chaos expansion.

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description

	Optional	noise_only	Restrict the cross validation process to estimating only the best noise tolerance.
--	-----------------	----------------------------	--

Description

Use cross validation to choose the 'best' polynomial degree of a polynomial chaos expansion. 10 fold cross validation is used to estimate the cross validation error of a total-order polynomial expansion for orders 1 through to order. The order chosen is the one that produces the lowest cross validation error. If there are not enough points to perform 10 fold cross validation then one-at-a-time cross validation will be performed.

noise_only

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [expansion_order](#)
- [collocation_ratio](#)
- [cross_validation](#)
- [noise_only](#)

Restrict the cross validation process to estimating only the best noise tolerance.

Specification

Alias: none

Argument(s): none

Default: false

Description

By default, cross validation estimates both the best noise tolerance and the best candidate basis order. For reasons of reducing computational cost by reducing the number of candidate solves, the user may wish to restrict this process to estimating only the best noise tolerance.

Generally speaking, computing the best noise tolerance through cross validation mitigates issues with overfitting the data. Computing the best candidate basis order can also mitigate overfitting, while also controlling levels of mutual coherence resulting from high-order Vandermonde-like matrix systems.

ratio_order

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [expansion_order](#)
- [collocation_ratio](#)
- [ratio_order](#)

Specify a non-linear the relationship between the expansion order of a polynomial chaos expansion and the number of samples that will be used to compute the PCE coefficients.

Specification

Alias: none

Argument(s): REAL

Default: 1.

Description

When using regression type methods (specified with either `collocation_points` or `collocation_ratio`), a total-order expansion can be specified using `expansion_order`. To avoid requiring the user to calculate N from n and p , the `collocation_ratio` allows for specification of a constant factor applied to N (e.g., `collocation_ratio = 2` produces $\text{samples} = 2N$). In addition, the default linear relationship with N can be overridden using a real-valued exponent specified using `ratio_order`. In this case, the number of samples becomes cN^o where c is the `collocation_ratio` and o is the `ratio_order`.

use_derivatives

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [expansion_order](#)
- [collocation_ratio](#)
- [use_derivatives](#)

Use derivative data to construct surrogate models

Specification

Alias: none

Argument(s): none

Default: use function values only

Description

The `use_derivatives` flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, it's use with Surfpack Gaussian process is not recommended.

tensor_grid

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [expansion_order](#)
- [collocation_ratio](#)
- [tensor_grid](#)

Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.

Specification

Alias: none

Argument(s): none

Default: regression with LHS sample set (point collocation)

Description

The collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

reuse_points

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [expansion_order](#)
- [collocation_ratio](#)
- [reuse_points](#)

This describes the behavior of reuse of points in constructing polynomial chaos expansion models.

Specification

Alias: reuse_samples

Argument(s): none

Default: no sample reuse in coefficient estimation

Description

The `reuse_points` option controls the reuse behavior of points for various types of polynomial chaos expansions, including: `collocation_points`, `collocation_ratio`, `expansion_samples`, or `orthogonal_least_interpolation`. If any of these approaches are specified to create a set of points for the polynomial chaos expansion, one can specify `reuse_points` so that any points that have been previously generated (for example, from the `import_points` file) can be reused.

max_solver_iterations

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [expansion_order](#)
- [collocation_ratio](#)
- [max_solver_iterations](#)

Maximum iterations in determining polynomial coefficients

Specification

Alias: none

Argument(s): INTEGER

Default: 100

Description

When using an iterative polynomial coefficient estimation approach, e.g., cross-validation-based solvers, limits the maximum iterations in the coefficient solver.

expansion_samples

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [expansion_order](#)
- [expansion_samples](#)

Number of simulation samples to estimate the PCE coefficients

Specification

Alias: none

Argument(s): INTEGER

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			reuse_points	This describes the behavior of reuse of points in constructing polynomial chaos expansion models.
	Optional		incremental_lhs	(Deprecated keyword) Augments an existing Latin Hypercube Sampling (LHS) study

Description

In this case, the expansion order p cannot be inferred from the numerical integration specification and it is necessary to provide an `expansion_order` to specify p for a total-order expansion.

Usage Tips

For most use cases, this keyword will specify a single integer number of samples. In more advanced UQ studies with hierarchical models, the list of integers can apply to different models and/or model levels

reuse_points

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [expansion_order](#)
- [expansion_samples](#)
- [reuse_points](#)

This describes the behavior of reuse of points in constructing polynomial chaos expansion models.

Specification

Alias: reuse_samples

Argument(s): none

Default: no sample reuse in coefficient estimation

Description

The `reuse_points` option controls the reuse behavior of points for various types of polynomial chaos expansions, including: `collocation_points`, `collocation_ratio`, `expansion_samples`, or `orthogonal_least_interpolation`. If any of these approaches are specified to create a set of points for the polynomial chaos expansion, one can specify `reuse_points` so that any points that have been previously generated (for example, from the `import_points` file) can be reused.

incremental_lhs

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [expansion_order](#)
- [expansion_samples](#)
- [incremental_lhs](#)

(Deprecated keyword) Augments an existing Latin Hypercube Sampling (LHS) study

Specification

Alias: none

Argument(s): none

Default: no sample reuse in coefficient estimation

Description

This keyword is deprecated. Instead specify `sample_type lhs` with `refinement_samples`.

An incremental random sampling approach will augment an existing random sampling study with `refinement_samples` to get better estimates of mean, variance, and percentiles. The number of `refinement_samples` in each refinement level must result in twice the number of previous samples.

Typically, this approach is used when you have an initial study with sample size $N1$ and you want to perform an additional $N1$ samples. Ideally, a Dakota restart file containing the initial $N1$ samples, so only $N1$ (instead of $2 \times N1$) potentially expensive function evaluations will be performed.

This process can be extended by repeatedly doubling the `refinement_samples`:

```
method
  sampling
    seed = 1337
    samples = 50
    refinement_samples = 50 100 200 400 800
```

Usage Tips

The incremental approach is useful if it is uncertain how many simulations can be completed within available time.

See the examples below and the [Usage](#) and [Restarting Dakota Studies](#) pages.

Examples

Suppose an initial study is conducted using `sample_type lhs` with `samples = 50`. A follow-on study uses a new input file where `samples = 50`, and `refinement_samples = 50`, resulting in 50 reused samples (from restart) and 50 new random samples. The 50 new samples will be combined with the 50 previous samples to generate a combined sample of size 100 for the analysis.

One way to ensure the restart file is saved is to specify a non-default name, via a command line option:

```
dakota -input LHS_50.in -write_restart LHS_50.rst
```

which uses the input file:

```
# LHS_50.in

environment
  tabular_data
    tabular_data_file = 'LHS_50.dat'

method
  sampling
    seed = 1337
    sample_type lhs
    samples = 50

model
  single

variables
  uniform_uncertain = 2
  descriptors = 'input1' 'input2'
  lower_bounds = -2.0 -2.0
  upper_bounds = 2.0 2.0

interface
  analysis_drivers 'text_book'
  fork

responses
  response_functions = 1
  no_gradients
  no_hessians
```

and the restart file is written to `LHS_50.rst`.

Then an incremental LHS study can be run with:

```
dakota -input LHS_100.in -read_restart LHS_50.rst -write_restart LHS_100.rst
```

where `LHS_100.in` is shown below, and `LHS_50.rst` is the restart file containing the results of the previous LHS study. In the example input files for the initial and incremental studies, the values for `seed` match. This ensures that the initial 50 samples generated in both runs are the same.

```
# LHS_100.in

environment
  tabular_data
    tabular_data_file = 'LHS_100.dat'

method
  sampling
    seed = 1337
    sample_type incremental_lhs
    samples = 50
```

```

refinement_samples = 50

model
  single

variables
  uniform_uncertain = 2
  descriptors = 'input1' 'input2'
  lower_bounds = -2.0 -2.0
  upper_bounds = 2.0 2.0

interface
  analysis_drivers 'text_book'
  fork

responses
  response_functions = 1
  no_gradients
  no_hessians

```

The user will get 50 new LHS samples which maintain both the correlation and stratification of the original LHS sample. The new samples will be combined with the original samples to generate a combined sample of size 100.

import_build_points_file

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [expansion_order](#)
- [import_build_points_file](#)

File containing points you wish to use to build a surrogate

Specification

Alias: import_points_file

Argument(s): STRING

Default: no point import from a file

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional (<i>Choose One</i>)	Tabular Format (Group 1)	custom_annotated	Selects custom-annotated tabular file format

		annotated	Selects annotated tabular file format
		freeform	Selects freeform file format
	Optional	active_only	Import only active variables from tabular data file

Description

The `import_build_points_file` allows the user to specify a file that contains a list of points and truth model responses used to construct a surrogate model. These can be used by all methods that (explicitly, e.g. surrogate-based optimization, or implicitly, e.g. efficient global optimization) operate on a surrogate. In particular, these points and responses are used in place of truth model evaluations to construct the initial surrogate. When used to construct surrogate models or emulators these are often called build points or training data.

Default Behavior

By default, methods do not import points from a file.

Usage Tips

Dakota parses input files without regard to whitespace, but the `import_build_points_file` must be in one of three formats:

- `annotated` (default)
- `custom_annotated`
- `freeform`

Examples

```
method
  polynomial_chaos
    expansion_order = 4
    import_build_points_file = 'dakota_uq_rosenbrock_pce_import.annot.pts.dat'
```

custom_annotated

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [expansion_order](#)
- [import_build_points_file](#)
- [custom_annotated](#)

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			header	Enable header row in custom-annotated tabular file
	Optional		eval_id	Enable evaluation ID column in custom-annotated tabular file
	Optional		interface_id	Enable interface ID column in custom-annotated tabular file

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, `eval_id` column, and `interface_id` column appear in the tabular file, thus bridging `freeform` and (fully) annotated.

Default Behavior

The `annotated` format is the default for tabular export/import. To control which header row and columns are in the input/output, specify `custom_annotated`, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface-id), and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id      x1          x2          obj_fn  nln_ineq_con_1  nln_ineq_con_2
1              0.9          1.1          0.0002          0.26          0.76
2              0.90009        1.1 0.0001996404857  0.2601620081    0.759955

- [interface_id](#)

Enable interface ID column in custom-annotated tabular file

Specification

Alias: none

Argument(s): none

Default: no interface_id column

Description

See description of parent `custom_annotated`

annotated

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [expansion_order](#)
- [import_build_points_file](#)
- [annotated](#)

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include `interface_id`, specify `custom_annotated` header `eval_id`
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export an annotated top-level tabular data file containing a header row, leading `eval_id` and `interface_id` columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated
```

Resulting tabular file:

```
%eval_id interface          x1          x2          obj_fn nln_ineq_con_1 nln_ineq_con_2
1          NO_ID           0.9          1.1          0.0002          0.26          0.76
2          NO_ID           0.90009      1.1 0.0001996404857 0.2601620081 0.759955

freeform

- [Keywords Area](#)
- [method](#)
- [polynomial.chaos](#)
- [expansion_order](#)
- [import_build_points_file](#)
- [freeform](#)

Selects freeform file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The `annotated` format is the default for tabular export/import. To change this behavior, specify `freeform` in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- In `freeform`, the `num_rows` x `num_cols` total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

```

          0.9          1.1          0.0002          0.26          0.76
0.90009      1.1 0.0001996404857  0.2601620081  0.759955
0.89991      1.1 0.0002003604863  0.2598380081  0.760045
...

```

active_only

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [expansion_order](#)
- [import_build_points_file](#)
- [active_only](#)

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

orthogonal_least_interpolation

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [orthogonal_least_interpolation](#)

Build a polynomial chaos expansion from simulation samples using orthogonal least interpolation.

Specification

Alias: least_interpolation oli

Argument(s): none

Child Keywords:

	Required/ Optional Required	Description of Group	Dakota Keyword	Dakota Keyword Description
			collocation_points	Specify the number of collocation points used to estimate PCE coefficients using orthogonal least interpolation
	Optional		tensor_grid	Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.
	Optional		reuse_points	This describes the behavior of reuse of points in constructing polynomial chaos expansion models.
	Optional		import_build_points_file	File containing points you wish to use to build a surrogate

Description

Build a polynomial chaos expansion from simulation samples using orthogonal least interpolation. Unlike the other regression methods `expansion_order` cannot be set. OLI will produce the lowest degree polynomial that interpolates the data

collocation_points

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [orthogonal_least_interpolation](#)
- [collocation_points](#)

Specify the number of collocation points used to estimate PCE coefficients using orthogonal least interpolation

Specification

Alias: none

Argument(s): INTEGER

Description

Specify the number of collocation points used to estimate PCE coefficients using orthogonal least interpolation

tensor_grid

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [orthogonal_least_interpolation](#)
- [tensor_grid](#)

Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.

Specification

Alias: none

Argument(s): INTEGERLIST

Default: regression with LHS sample set (point collocation)

Description

The collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

reuse_points

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [orthogonal_least_interpolation](#)
- [reuse_points](#)

This describes the behavior of reuse of points in constructing polynomial chaos expansion models.

Specification

Alias: reuse_samples

Argument(s): none

Default: no sample reuse in coefficient estimation

Description

The `reuse_points` option controls the reuse behavior of points for various types of polynomial chaos expansions, including: `collocation_points`, `collocation_ratio`, `expansion_samples`, or `orthogonal_least_interpolation`. If any of these approaches are specified to create a set of points for the polynomial chaos expansion, one can specify `reuse_points` so that any points that have been previously generated (for example, from the `import_points` file) can be reused.

import_build_points_file

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [orthogonal_least_interpolation](#)
- [import_build_points_file](#)

File containing points you wish to use to build a surrogate

Specification

Alias: import_points_file

Argument(s): STRING

Default: no point import from a file

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description

	Optional(<i>Choose One</i>)	Tabular Format (Group 1)	custom_annotated	Selects custom-annotated tabular file format
			annotated	Selects annotated tabular file format
			freeform	Selects freeform file format
	Optional		active_only	Import only active variables from tabular data file

Description

The `import_build_points_file` allows the user to specify a file that contains a list of points and truth model responses used to construct a surrogate model. These can be used by all methods that (explicitly, e.g. surrogate-based optimization, or implicitly, e.g. efficient global optimization) operate on a surrogate. In particular, these points and responses are used in place of truth model evaluations to construct the initial surrogate. When used to construct surrogate models or emulators these are often called build points or training data.

Default Behavior

By default, methods do not import points from a file.

Usage Tips

Dakota parses input files without regard to whitespace, but the `import_build_points_file` must be in one of three formats:

- `annotated` (default)
- `custom_annotated`
- `freeform`

Examples

```
method
  polynomial_chaos
    expansion_order = 4
    import_build_points_file = 'dakota_uq_rosenbrock_pce_import.annot.pts.dat'
```

custom_annotated

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [orthogonal_least_interpolation](#)
- [import_build_points_file](#)
- [custom_annotated](#)

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			header	Enable header row in custom-annotated tabular file
	Optional		eval_id	Enable evaluation ID column in custom-annotated tabular file
	Optional		interface_id	Enable interface ID column in custom-annotated tabular file

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, `eval_id` column, and `interface_id` column appear in the tabular file, thus bridging `freeform` and (fully) annotated.

Default Behavior

The `annotated` format is the default for tabular export/import. To control which header row and columns are in the input/output, specify `custom_annotated`, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface-id), and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id      x1          x2          obj_fn  nln_ineq_con_1  nln_ineq_con_2
1             0.9          1.1          0.0002         0.26          0.76
2             0.90009      1.1 0.0001996404857  0.2601620081    0.759955

annotated

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [orthogonal_least_interpolation](#)
- [import_build_points_file](#)
- [annotated](#)

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include `interface_id`, specify `custom_annotated` header `eval_id`
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export an annotated top-level tabular data file containing a header row, leading `eval_id` and `interface_id` columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated
```

Resulting tabular file:

```
%eval_id interface          x1          x2          obj_fn nln_ineq_con_1 nln_ineq_con_2
1          NO_ID            0.9          1.1          0.0002          0.26          0.76
2          NO_ID            0.90009      1.1 0.0001996404857 0.2601620081 0.759955
3          NO_ID            0.89991      1.1 0.0002003604863 0.2598380081 0.760045
...
```

freeform

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [orthogonal_least_interpolation](#)
- [import_build_points_file](#)
- [freeform](#)

Selects freeform file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The `annotated` format is the default for tabular export/import. To change this behavior, specify `freeform` in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- In `freeform`, the `num_rows` x `num_cols` total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

```

          0.9          1.1          0.0002          0.26          0.76

```

active_only

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [orthogonal_least_interpolation](#)
- [import_build_points_file](#)
- [active_only](#)

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

import_expansion_file

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [import_expansion_file](#)

Build a Polynomial Chaos Expansion (PCE) by import coefficients and a multi-index from a file

Specification

Alias: none

Argument(s): STRING

Description

The coefficients can be specified in an arbitrary order. The multi-index provided is used to generate a sparse expansion that consists only of the indices corresponding to the non-zero coefficients provided in the file.

askey

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [askey](#)

Select the standardized random variables (and associated basis polynomials) from the Askey family that best match the user-specified random variables.

Specification

Alias: none

Argument(s): none

Default: extended (Askey + numerically-generated)

Description

The Askey option employs standard normal, standard uniform, standard exponential, standard beta, and standard gamma random variables in a transformed probability space. These selections correspond to Hermite, Legendre, Laguerre, Jacobi, and generalized Laguerre orthogonal polynomials, respectively.

Specific mappings for the basis polynomials are based on a closest match criterion, and include Hermite for normal (optimal) as well as bounded normal, lognormal, bounded lognormal, gumbel, frechet, and weibull (sub-optimal); Legendre for uniform (optimal) as well as loguniform, triangular, and bin-based histogram (sub-optimal); Laguerre for exponential (optimal); Jacobi for beta (optimal); and generalized Laguerre for gamma (optimal).

These keywords may also be of interest:

- [polynomial.chaos](#)
- [wiener](#)

wiener

- [Keywords Area](#)
- [method](#)
- [polynomial.chaos](#)
- [wiener](#)

Use standard normal random variables (along with Hermite orthogonal basis polynomials) when transforming to a standardized probability space.

Specification

Alias: none

Argument(s): none

Default: extended (Askey + numerically-generated)

Description

The Wiener option employs standard normal random variables in a transformed probability space, corresponding to a Hermite orthogonal polynomial basis. This is the same nonlinear variable transformation used by local and global reliability methods (and therefore has the same variable support).

See Also

These keywords may also be of interest:

- [polynomial.chaos](#)
- [askey](#)

normalized

- [Keywords Area](#)
- [method](#)
- [polynomial.chaos](#)
- [normalized](#)

The normalized specification requests output of PCE coefficients that correspond to normalized orthogonal basis polynomials

Specification

Alias: none

Argument(s): none

Default: PCE coefficients correspond to unnormalized basis polynomials

Description

The normalized specification requests output of PCE coefficients that correspond to normalized orthogonal basis polynomials

export_expansion_file

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [export_expansion_file](#)

Export the coefficients and multi-index of a Polynomial Chaos Expansion (PCE) to a file

Specification

Alias: none

Argument(s): STRING

Description

Export the coefficients and multi-index of a Polynomial Chaos Expansion (PCE) to a file. The multi-index written will be sparse. Specifically the expansion will consists only of the indices corresponding to the non-zero coefficients of the PCE.

samples_on_emulator

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [samples_on_emulator](#)

Number of samples at which to evaluate an emulator (surrogate)

Specification

Alias: samples

Argument(s): INTEGER

Description

How many approximate function evaluations to perform on the emulator model, e.g., to compute statistics

Default Behavior

The default number of samples is method-dependent.

Examples

Perform 10000 samples on the PCE approximation of the true model:

```
method
  polynomial_chaos
    quadrature_order = 2
    samples_on_emulator = 10000
```

sample_type

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [sample_type](#)

Selection of sampling strategy

Specification

Alias: none

Argument(s): none

Default: lhs

Child Keywords:

	Required/ Optional Required(<i>Choose One</i>)	Description of Group Sample Type (Group 1)	Dakota Keyword	Dakota Keyword Description
			lhs	Uses Latin Hypercube Sampling (LHS) to sample variables
			random	Uses purely random Monte Carlo sampling to sample variables

Description

The `sample_type` keyword allows the user to select between two types of sampling: Monte Carlo (pure random) and Latin hypercube (stratified) sampling.

The incremental keywords are deprecated; instead use `samples` together with `refinement_samples`.

Default Behavior

If the `sample_type` keyword is present, it must be accompanied by `lhs` or `random`. In most contexts, `lhs` is the default (exception: `multilevel_sampling` uses Monte Carlo by default).

Examples

```
method
  sampling
    sample_type lhs
    samples = 20
    seed = 83921
```

lhs

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [sample_type](#)
- [lhs](#)

Uses Latin Hypercube Sampling (LHS) to sample variables

Specification

Alias: none

Argument(s): none

Description

The `lhs` keyword invokes Latin Hypercube Sampling as the means of drawing samples of uncertain variables according to their probability distributions. This is a stratified, space-filling approach that selects variable values from a set of equi-probable bins.

Default Behavior

Latin Hypercube Sampling is the default sampling mode in most contexts (exception: `multilevel_sampling`). To explicitly specify LHS in the Dakota input file, the `lhs` keyword must appear in conjunction with the `sample_type` keyword.

Usage Tips

Latin Hypercube Sampling is very robust and can be applied to any problem. It is fairly effective at estimating the mean of model responses and linear correlations with a reasonably small number of samples relative to the number of variables.

Examples

```
method
  sampling
    sample_type lhs
    samples = 20
```

random

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)

- [sample_type](#)
- [random](#)

Uses purely random Monte Carlo sampling to sample variables

Specification

Alias: none

Argument(s): none

Description

The `random` keyword invokes Monte Carlo sampling as the means of drawing samples of uncertain variables according to their probability distributions.

Default Behavior

In most contexts, Monte Carlo sampling is not the default sampling mode (exception: `multilevel_sampling`). To change this behavior, the `random` keyword must be specified in conjunction with the `sample_type` keyword.

Usage Tips

Monte Carlo sampling is more computationally expensive than Latin Hypercube Sampling as it requires a larger number of samples to accurately estimate statistics.

Examples

```
method
  sampling
    sample_type random
  samples = 200
```

seed

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [seed](#)

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)

Description

The random `seed` control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

fixed_seed

- [Keywords Area](#)
- [method](#)
- [polynomial.chaos](#)
- [fixed_seed](#)

Reuses the same seed value for multiple random sampling sets

Specification

Alias: none

Argument(s): none

Default: not fixed; pattern varies run-to-run

Description

The `fixed_seed` flag is relevant if multiple sampling sets will be generated over the course of a Dakota analysis. This occurs when using advance methods (e.g., surrogate-based optimization, optimization under uncertainty). The same seed value is reused for each of these multiple sampling sets, which can be important for reducing variability in the sampling results.

Default Behavior

The default behavior is to not use a fixed seed, as the repetition of the same sampling pattern can result in a modeling weakness that an optimizer could potentially exploit (resulting in actual reliabilities that are lower than the estimated reliabilities). For repeatable studies, the `seed` must also be specified.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    fixed_seed
```

rng

- [Keywords Area](#)
- [method](#)
- [polynomial.chaos](#)
- [rng](#)

Selection of a random number generator

Specification

Alias: none

Argument(s): none

Default: Mersenne twister (mt19937)

Child Keywords:

	Required/ Optional Required(<i>Choose One</i>)	Description of Group RNG Algorithm (Group 1)	Dakota Keyword mt19937	Dakota Keyword Description Generates random numbers using the Mersenne twister
			rnum2	Generates pseudo-random numbers using the Pecos package

Description

The `rng` keyword is used to indicate a choice of random number generator.

Default Behavior

If specified, the `rng` keyword must be accompanied by either `rnum2` (pseudo-random numbers) or `mt19937` (random numbers generated by the Mersenne twister). Otherwise, `mt19937`, the Mersenne twister is used by default.

Usage Tips

The default is recommended, as the Mersenne twister is a higher quality random number generator.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
```

```
seed = 98765
rng rnum2
```

mt19937

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [rng](#)
- [mt19937](#)

Generates random numbers using the Mersenne twister

Specification

Alias: none

Argument(s): none

Description

The `mt19937` keyword directs Dakota to use the Mersenne twister to generate random numbers. Additional information can be found on wikipedia: http://en.wikipedia.org/wiki/Mersenne_twister.

Default Behavior

`mt19937` is the default random number generator. To specify it explicitly in the Dakota input file, however, it must be specified in conjunction with the `rng` keyword.

Usage Tips

Use of the Mersenne twister random number generator (`mt19937`) is recommended.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng mt19937
```

rnum2

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [rng](#)
- [rnum2](#)

Generates pseudo-random numbers using the Pecos package

Specification

Alias: none

Argument(s): none

Description

The `rnum2` keyword directs Dakota to use pseudo-random numbers generated by the Pecos package.

Default Behavior

`rnum2` is not used by default. To change this behavior, it must be specified in conjunction with the `rng` keyword.

Usage Tips

Use of the Mersenne twister random number generator (`mt19937`) is recommended over `rnum2`.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2
```

probability_refinement

- [Keywords Area](#)
- [method](#)
- [polynomial.chaos](#)
- [probability_refinement](#)

Allow refinement of probability and generalized reliability results using importance sampling

Topics

This keyword is related to the topics:

- [reliability_methods](#)

Specification

Alias: `sample_refinement`

Argument(s): none

Default: no refinement

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description

	Required (<i>Choose One</i>)	Importance Sampling Approach (Group 1)	import	Sampling option
			adapt_import	Importance sampling option
	Optional		mm_adapt_import_refinement_samples	Sampling option Number of samples used to refine a probability estimate or sampling design.

Description

The `probability_refinement` allows refinement of probability and generalized reliability results using importance sampling. If one specifies `probability_refinement`, there are some additional options. One can specify which type of importance sampling to use (`import`, `adapt_import`, or `mm_adapt_import`). Additionally, one can specify the number of refinement samples to use with `refinement_samples` and the seed to use with `seed`.

The `probability_refinement` density reweighting accounts originally was developed based on Gaussian distributions. It now accounts for additional non-Gaussian cases.

import

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [probability_refinement](#)
- [import](#)

Sampling option

Specification

Alias: none

Argument(s): none

Description

`import` centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level).

adapt_import

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)

- [probability_refinement](#)
- [adapt_import](#)

Importance sampling option

Specification

Alias: none

Argument(s): none

Description

`adapt_import` centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level). This continues iteratively until the failure probability estimate converges.

mm_adapt_import

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [probability_refinement](#)
- [mm_adapt_import](#)

Sampling option

Specification

Alias: none

Argument(s): none

Description

`mm_adapt_import` starts with all of the samples located in the failure region to build a multimodal sampling density. First, it uses a small number of samples around each of the initial samples in the failure region. Note that these samples are allocated to the different points based on their relative probabilities of occurrence: more probable points get more samples. This early part of the approach is done to search for "representative" points. Once these are located, the multimodal sampling density is set and then `mm_adapt_import` proceeds similarly to `adapt_import` (sample until convergence).

refinement_samples

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)

- [probability_refinement](#)
- [refinement_samples](#)

Number of samples used to refine a probability estimate or sampling design.

Specification

Alias: none

Argument(s): INTEGERLIST

Description

Probability estimate: Specify the (scalar) number of samples used to improve a probability estimate. If using uni-modal sampling all samples are assigned to the sampling center. If using multi-modal sampling the samples are split between multiple samples according to some internally computed weights.

Sampling design: Specify one or a sequence of refinement samples to augment the initial_samples in a sampling design.

final_moments

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [final_moments](#)

Output moments of the specified type and include them within the set of final statistics.

Specification

Alias: none

Argument(s): none

Default: standard

Child Keywords:

	Required/ Optional <i>Required(Choose One)</i>	Description of Group Objective Formulation (Group 1)	Dakota Keyword <i>none</i>	Dakota Keyword Description Omit moments from the set of final statistics.
			<i>standard</i>	Output standardized moments and include them within the set of final statistics.
			<i>central</i>	Output central moments and include them within the set of final statistics.

Description

When performing a nested study that may employ moment statistics on the inner loop, it can be desirable to control the type of these moments. The `final_moments` specification supports options of `none`, `standard` (default), or `central`, corresponding to omission of moments, standardized moments (mean, standard deviation, skewness, and excess kurtosis), or central moments (mean, variance, 3rd central, and 4th central).

The presence or omission of moment results in the final statistics influences the outer level mappings in the case of a nested study. For example, `final_moments none` can allow for a more compact specification of primary and/or secondary response mappings.

Examples

The following method specification overrides the default to print `central` moments and include them in the set of final statistics.

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments central
```

Overriding the default to `none` as follows:

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments none
```

allows associated nested model mappings to be simplified from:

```
model
  nested
    sub_method_pointer = 'UQ'
    primary_response_mapping = 0. 0. 1. 0. 0. 1. 0. 0. 0.
    secondary_response_mapping = 0. 0. 0. 0. 0. 0. 0. 0. 1.
```

to a more compact version focused only on the response level mappings (two leading zeros per response function for moment mappings have been removed):

```
model
  nested
    sub_method_pointer = 'UQ'
    primary_response_mapping = 1. 1. 0.
    secondary_response_mapping = 0. 0. 1.
```

none

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [final_moments](#)
- [none](#)

Omit moments from the set of final statistics.

Specification

Alias: none

Argument(s): none

Description

The omission of moment results from the final statistics can allow for a more compact definition of primary and/or secondary response mappings within a nested model specification.

Examples

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments none
```

standard

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [final_moments](#)
- [standard](#)

Output standardized moments and include them within the set of final statistics.

Specification

Alias: none

Argument(s): none

Description

Output standardized moments (mean, standard deviation, skewness, and excess kurtosis) and include the first two within the set of final statistics to be used at a higher level (e.g., optimization under uncertainty, mixed aleatory-epistemic UQ). This inclusion of moment results affects the primary and/or secondary response mappings in a nested model specification.

Examples

The following method specification overrides the default to print `central` moments and include them in the set of final statistics.

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments standard
```

central

- [Keywords Area](#)
- [method](#)
- [polynomial.chaos](#)
- [final_moments](#)
- [central](#)

Output central moments and include them within the set of final statistics.

Specification

Alias: none

Argument(s): none

Description

Output central moments (mean, variance, 3rd central, and 4th central) and include the first two within the set of final statistics to be used at a higher level (e.g., optimization under uncertainty, mixed aleatory-epistemic U-Q). This inclusion of moment results affects the primary and/or secondary response mappings in a nested model specification.

Examples

The following method specification overrides the default to print `central` moments and include them in the set of final statistics.

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments central
```

response_levels

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [response_levels](#)

Values at which to estimate desired statistics for each response

Specification

Alias: none

Argument(s): REALLIST

Default: No CDF/CCDF probabilities/reliabilities to compute

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			num_response_ - levels	Number of values at which to estimate desired statistics for each response
	Optional		compute	Selection of statistics to compute at each response level

Description

The `response_levels` specification provides the target response values for which to compute probabilities, reliabilities, or generalized reliabilities (forward mapping).

Default Behavior

If `response_levels` are not specified, no statistics will be computed. If they are, probabilities will be computed by default.

Expected Outputs

If `response_levels` are specified, Dakota will create two tables in the standard output: a Probability Density function (PDF) histogram and a Cumulative Distribution Function (CDF) table. The PDF histogram has

the lower and upper endpoints of each bin and the corresponding density of that bin. Note that the PDF histogram has bins defined by the `probability_levels` and/or `response_levels` in the Dakota input file. If there are not very many levels, the histogram will be coarse. Dakota does not do anything to optimize the bin size or spacing. The CDF table has the list of response levels and the corresponding probability that the response value is less than or equal to each response level threshold.

Usage Tips

The `num_response_levels` is used to specify which arguments of the `response_level` correspond to which response.

Examples

For example, specifying a `response_level` of 52.3 followed with `compute probabilities` will result in the calculation of the probability that the response value is less than or equal to 52.3, given the uncertain distributions on the inputs.

For an example with multiple responses, the following specification

```
response_levels = 1. 2. .1 .2 .3 .4 10. 20. 30.
num_response_levels = 2 4 3
```

would assign the first two response levels (1., 2.) to response function 1, the next four response levels (.1, .2, .3, .4) to response function 2, and the final three response levels (10., 20., 30.) to response function 3. If the `num_response_levels` key were omitted from this example, then the response levels would be evenly distributed among the response functions (three levels each in this case).

The Dakota input file below specifies a sampling method with response levels of interest.

```
method,
  sampling,
  samples = 100 seed = 1
  complementary distribution
  response_levels = 3.6e+11 4.0e+11 4.4e+11
                   6.0e+04 6.5e+04 7.0e+04
                   3.5e+05 4.0e+05 4.5e+05

variables,
  normal_uncertain = 2
  means             = 248.89, 593.33
  std_deviations    = 12.4, 29.7
  descriptors       = 'TF1n' 'TF2n'
  uniform_uncertain = 2
  lower_bounds      = 199.3, 474.63
  upper_bounds      = 298.5, 712.
  descriptors       = 'TF1u' 'TF2u'
  weibull_uncertain = 2
  alphas            = 12., 30.
  betas             = 250., 590.
  descriptors       = 'TF1w' 'TF2w'
  histogram_bin_uncertain = 2
  num_pairs         = 3 4
  abscissas         = 5 8 10 .1 .2 .3 .4
  counts            = 17 21 0 12 24 12 0
  descriptors       = 'TF1h' 'TF2h'
  histogram_point_uncertain
  real = 1
  num_pairs         = 2
  abscissas         = 3 4
  counts            = 1 1
  descriptors       = 'TF3h'
```

```

interface,
  system asynch evaluation_concurrency = 5
  analysis_driver = 'text_book'

responses,
  response_functions = 3
  no_gradients
  no_hessians

```

Given the above Dakota input file, the following excerpt from the output shows the PDF and CCDF generated. Note that the bounds on the bins of the PDF are the response values specified in the input file. The probability levels corresponding to those response values are shown in the CCDF.

Probability Density Function (PDF) histograms for each response function:

PDF for response_fn_1:

Bin Lower	Bin Upper	Density Value
2.7604749078e+11	3.6000000000e+11	5.3601733194e-12

6.0000000000e+04	6.1000000000e-01		
6.5000000000e+04	2.9000000000e-01		
7.0000000000e+04	9.0000000000e-02		

Complementary Cumulative Distribution Function (CCDF) for response_fn_3:

Response Level	Probability Level	Reliability Index	General Rel Index
3.5000000000e+05	5.2000000000e-01		
4.0000000000e+05	9.0000000000e-02		
4.5000000000e+05	0.0000000000e+00		

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

A forward mapping involves computing the belief and plausibility probability level for a specified response level.

num_response_levels

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [response_levels](#)
- [num_response_levels](#)

Number of values at which to estimate desired statistics for each response

Specification

Alias: none

Argument(s): INTEGERLIST

Default: response_levels evenly distributed among response functions

Description

The `num_response_levels` keyword allows the user to specify the number of response values, for each response, at which estimated statistics are of interest. Statistics that can be computed are probabilities and reliabilities, both according to either a cumulative distribution function or a complementary cumulative distribution function.

Default Behavior

If `num_response_levels` is not specified, the `response_levels` will be evenly distributed among the responses.

Expected Outputs

The specific output will be determined by the type of statistics that are specified. In a general sense, the output will be a list of response level-statistic pairs that show the estimated value of the desired statistic for each response level specified.

Examples

```
method
  sampling
    samples = 100
    seed = 34785
    num_response_levels = 1 1 1
    response_levels = 0.5 0.5 0.5
```

compute

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [response_levels](#)
- [compute](#)

Selection of statistics to compute at each response level

Specification

Alias: none

Argument(s): none

Default: probabilities

Child Keywords:

	Required/- Optional <i>Required(Choose One)</i>	Description of Group Statistics to Compute (Group 1)	Dakota Keyword probabilities	Dakota Keyword Description Computes probabilities associated with response levels
			reliabilities	Computes reliabilities associated with response levels
			gen_reliabilities	Computes generalized reliabilities associated with response levels
	Optional		system	Compute system reliability (series or parallel)

Description

The `compute` keyword is used to select which forward stastical mapping is calculated at each response level.

Default Behavior

If `response_levels` is not specified, no statistics are computed. If `response_levels` is specified but `compute` is not, probabilities will be computed by default. If both `response_levels` and `compute` are specified, then on of the following must be specified: `probabilities`, `reliabilities`, or `gen_reliabilities`.

Expected Output

The type of statistics specified by `compute` will be reported for each response level.

Usage Tips

CDF/CCDF probabilities are calculated for specified response levels using a simple binning approach.

CDF/CCDF reliabilities are calculated for specified response levels by computing the number of sample standard deviations separating the sample mean from the response level.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                    6.0e+04 6.5e+04 7.0e+04
                    3.5e+05 4.0e+05 4.5e+05
    compute reliabilities
```

probabilities

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [response_levels](#)
- [compute](#)
- [probabilities](#)

Computes probabilities associated with response levels

Specification

Alias: none

Argument(s): none

Description

The `probabilities` keyword directs Dakota to compute the probability that the model response will be below (cumulative) or above (complementary cumulative) a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the probabilities are computed by default. To explicitly specify it in the Dakota input file, though, the `probabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-probability pairs that give the probability that the model response will be below or above the corresponding response level, depending on the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                    6.0e+04 6.5e+04 7.0e+04
                    3.5e+05 4.0e+05 4.5e+05
    compute probabilities
```

reliabilities

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [response_levels](#)
- [compute](#)
- [reliabilities](#)

Computes reliabilities associated with response levels

Specification

Alias: none

Argument(s): none

Description

The `reliabilities` keyword directs Dakota to compute reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the reliabilities are not computed by default. To change this behavior, the `reliabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-reliability pairs according to the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                    6.0e+04 6.5e+04 7.0e+04
                    3.5e+05 4.0e+05 4.5e+05
    compute reliabilities
```

gen_reliabilities

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [response_levels](#)
- [compute](#)
- [gen_reliabilities](#)

Computes generalized reliabilities associated with response levels

Specification

Alias: none

Argument(s): none

Description

The `gen_reliabilities` keyword directs Dakota to compute generalized reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the generalized reliabilities are not computed by default. To change this behavior, the `gen_reliabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-generalized reliability pairs according to the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                    6.0e+04 6.5e+04 7.0e+04
                    3.5e+05 4.0e+05 4.5e+05
    compute gen_reliabilities
```

system

- [response_levels](#)
- [compute](#)
- [system](#)

Compute system reliability (series or parallel)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	System Reliability Mode (Group 1)	series	Aggregate response statistics assuming a series system
			parallel	Aggregate response statistics assuming a parallel system

Description

With the system probability/reliability option, statistics for specified `response_levels` are calculated and reported assuming the response functions combine either in series or parallel to produce a total system response.

For a series system, the system fails when any one component (response) fails. The probability of failure is the complement of the product of the individual response success probabilities.

For a parallel system, the system fails only when all components (responses) fail. The probability of failure is the product of the individual response failure probabilities.

series

probability_levels

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [probability_levels](#)

Specify probability levels at which to estimate the corresponding response value

Specification

Alias: none

Argument(s): REALLIST

Default: No CDF/CCDF response levels to compute

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			num_probability_levels	Specify which probability_levels correspond to which response

Description

Response levels are calculated for specified CDF/CCDF probabilities by indexing into a sorted samples array (the response levels computed are not interpolated and will correspond to one of the sampled values).

Expected Output

If `probability_levels` are specified, Dakota will create two tables in the standard output: a Probability Density function (PDF) histogram and a Cumulative Distribution Function (CDF) table. The PDF histogram has the lower and upper endpoints of each bin and the corresponding density of that bin. Note that the PDF histogram has bins defined by the `probability_levels` and/or `response_levels` in the Dakota input file. If there are not very many levels, the histogram will be coarse. Dakota does not do anything to optimize the bin size or spacing. The CDF table has the list of response levels and the corresponding probability that the response value is less than or equal to each response level threshold.

Examples

The Dakota input file below specifies a sampling method with probability levels of interest.

```
method,
  sampling,
  samples = 100 seed = 1
  complementary distribution
  probability_levels = 1. .66 .33 0.
                    1. .8 .5 0.
                    1. .3 .2 0.

variables,
  normal_uncertain = 2
  means            = 248.89, 593.33
  std_deviations   = 12.4, 29.7
  descriptors      = 'TF1n' 'TF2n'
  uniform_uncertain = 2
  lower_bounds     = 199.3, 474.63
  upper_bounds     = 298.5, 712.
  descriptors      = 'TF1u' 'TF2u'
  weibull_uncertain = 2

Given the above Dakota input file, the following excerpt from the output shows the PDF and CCDF generated. Note that the bounds on the bins of the PDF are the response values that correspond the probability levels specified in the input file. Those response values are also shown in the CCDF.

Probability Density Function (PDF) histograms for each response function:

PDF for response_fn_1:

Bin Lower	Bin Upper	Density Value

4.4111498127e+05	0.0000000000e+00		

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).

num_probability_levels

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [probability_levels](#)
- [num_probability_levels](#)

Specify which `probability_levels` correspond to which response

Specification

distribution

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [distribution](#)

Selection of cumulative or complementary cumulative functions

Specification

Alias: none

Argument(s): none

Default: cumulative (CDF)

Child Keywords:

	Required/- Optional Required <i>(Choose One)</i>	Description of Group Distribution Type (CDF/CCDF) (Group 1)	Dakota Keyword	Dakota Keyword Description
			cumulative	Computes statistics according to cumulative functions
			complementary	Computes statistics according to complementary cumulative functions

Description

The `distribution` keyword allows the user to select between a cumulative distribution/belief/plausibility function and a complementary cumulative distribution/belief/plausibility function. This choice affects how probabilities and reliability indices are reported.

Default Behavior

If the `distribution` keyword is present, it must be accompanied by either `cumulative` or `complementary`. Otherwise, a cumulative distribution will be used by default.

Expected Outputs

Output will be a set of model response-probability pairs determined according to the choice of distribution. The choice of distribution also defines the sign of the reliability or generalized reliability indices.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

cumulative

- [Keywords Area](#)
- [method](#)
- [polynomial.chaos](#)
- [distribution](#)
- [cumulative](#)

Computes statistics according to cumulative functions

Specification

Alias: none

Argument(s): none

Description

Statistics on model responses will be computed according to a cumulative distribution/belief/plausibility function.

Default Behavior

By default, a cumulative distribution/belief/plausibility function will be used. To explicitly specify it in the Dakota input file, however, the `cumulative` keyword must be appear in conjunction with the `distribution` keyword.

Expected Outputs

Output will be a set of model response-probability pairs determined according to a cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls below given response thresholds.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

complementary

- [Keywords Area](#)
- [method](#)
- [polynomial.chaos](#)
- [distribution](#)
- [complementary](#)

Computes statistics according to complementary cumulative functions

Specification

Alias: none

Argument(s): none

Description

Statistics on model responses will be computed according to a complementary cumulative distribution/belief/plausibility function.

Default Behavior

By default, a complementary cumulative distribution/belief/plausibility function will not be used. To change that behavior, the `complementary` keyword must be appear in conjunction with the `distribution` keyword.

Expected Outputs

Output will be a set of model response-probability pairs determined according to a complementary cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls above given response thresholds.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    distribution complementary
```

variance_based_decomp

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [variance_based_decomp](#)

Activates global sensitivity analysis based on decomposition of response variance into main, interaction, and total effects

Specification

Alias: none

Argument(s): none

Default: no variance-based decomposition

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		<code>interaction_order</code>	Specify the maximum number of variables allowed in an interaction when reporting <i>interaction metrics</i>
	Optional		<code>drop_tolerance</code>	Suppresses output of sensitivity indices with values lower than this tolerance

Description

Dakota can calculate sensitivity indices through variance-based decomposition using the keyword `variance_based_decomp`. This approach decomposes main, interaction, and total effects in order to identify the most important variables and combinations of variables in contributing to the variance of output quantities of interest.

Default Behavior

Because of processing overhead and output volume, `variance_based_decomp` is inactive by default, unless required for dimension-adaptive refinement using Sobol' indices.

Expected Outputs

When `variance_based_decomp` is specified, sensitivity indices for main effects, total effects, and any interaction effects will be reported. Each of these effects represents the percent contribution to the variance in the model response, where main effects include the aggregated set of *univariate* terms for each individual variable, interaction effects represent the set of *mixed* terms (the complement of the univariate set), and total effects represent the *complete* set of terms (univariate and mixed) that contain each individual variable. The aggregated set of main and interaction sensitivity indices will sum to one, whereas the sum of total effects sensitivity indices will be greater than one due to redundant counting of mixed terms.

Usage Tips

An important consideration is that the number of possible interaction terms grows exponentially with dimension and expansion order. To mitigate this, both in terms of compute time and output volume, possible interaction effects are suppressed whenever no contributions are present due to the particular form of an expansion. In addition, the `interaction_order` and `drop_tolerance` controls can further limit the computational and output requirements.

Examples

```
method,
    polynomial_chaos # or stoch_collocation
    sparse_grid_level = 3
    variance_based_decomp interaction_order = 2
```

Theory

In this context, we take sensitivity analysis to be global, not local as when calculating derivatives of output variables with respect to input variables. Our definition is similar to that of [75]: "The study of how uncertainty in the output of a model can be apportioned to different sources of uncertainty in the model input."

Variance based decomposition is a way of using sets of samples to understand how the variance of the output behaves, with respect to each input variable. A larger value of the sensitivity index, S_i , means that the uncertainty in the input variable i has a larger effect on the variance of the output. More details on the calculations and interpretation of the sensitivity indices can be found in[89].

interaction_order

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [variance_based_decomp](#)
- [interaction_order](#)

Specify the maximum number of variables allowed in an interaction when reporting interaction metrics.

Specification

Alias: none

Argument(s): INTEGER

Default: Unrestricted (VBD includes all interaction orders present in the expansion)

Description

The `interaction_order` option has been added to allow suppression of higher-order interactions, since the output volume (and memory and compute consumption) of these results could be extensive for high dimensional problems (note: the previous `univariate_effects` specification is equivalent to `interaction_order = 1` in the current specification). Similar to suppression of interactions is the covariance control, which can be selected to be `diagonal_covariance` or `full_covariance`, with the former supporting suppression of the off-diagonal covariance terms (to again save compute and memory resources and reduce output volume)

drop_tolerance

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [variance_based_decomp](#)
- [drop_tolerance](#)

Suppresses output of sensitivity indices with values lower than this tolerance

Specification

Alias: none

Argument(s): REAL

Default: All VBD indices displayed

Description

The `drop_tolerance` keyword allows the user to specify a value below which sensitivity indices generated by `variance_based_decomp` are not displayed.

Default Behavior

By default, all sensitivity indices generated by `variance_based_decomp` are displayed.

Usage Tips

For `polynomial_chaos`, which outputs main, interaction, and total effects by default, the `univariate_effects` may be a more appropriate option. It allows suppression of the interaction effects since the output volume of these results can be prohibitive for high dimensional problems. Similar to suppression of these interactions is the covariance control, which can be selected to be `diagonal_covariance` or `full_covariance`, with the former supporting suppression of the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

Examples

```
method,
  sampling
  sample_type lhs
  samples = 100
  variance_based_decomp
  drop_tolerance = 0.001
```

diagonal_covariance

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [diagonal_covariance](#)

Display only the diagonal terms of the covariance matrix

Specification

Alias: none

Argument(s): none

Default: `diagonal_covariance` for response vector > 10; else `full_covariance`

Description

With a large number of responses, the covariance matrix can be very large. `diagonal_covariance` is used to suppress the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

full_covariance

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)

- [full_covariance](#)

Display the full covariance matrix

Specification

Alias: none

Argument(s): none

Description

With a large number of responses, the covariance matrix can be very large. `full_covariance` is used to force Dakota to output the full covariance matrix.

`convergence_tolerance`

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

import_approx_points_file

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [import_approx_points_file](#)

Filename for points at which to evaluate the PCE/SC surrogate

Specification

Alias: none

Argument(s): STRING

Default: no point import from a file

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional(<i>Choose One</i>)	Tabular Format (Group 1)	custom_annotated	Selects custom-annotated tabular file format
			annotated	Selects annotated tabular file format
			freeform	Selects freeform file format
	Optional		active_only	Import only active variables from tabular data file

Description

Default Behavior No import of points at which to evaluate the surrogate.

Expected Output The PCE/SC surrogate model will be evaluated at the list of points (input variable values) provided in the file and results tabulated and/or statistics computed at them, depending on the method context.

Examples

```
method
  polynomial_chaos
  expansion_order = 4
  import_approx_points_file = 'import.mcmc_annot.dat'
  annotated
```

custom_annotated

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [import_approx_points_file](#)
- [custom_annotated](#)

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			header	Enable header row in custom-annotated tabular file
	Optional		eval_id	Enable evaluation ID column in custom-annotated tabular file

	Optional	interface_id	Enable interface ID column in custom-annotated tabular file
--	-----------------	------------------------------	---

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, `eval_id` column, and `interface_id` column appear in the tabular file, thus bridging `freeform` and (fully) annotated.

Default Behavior

The `annotated` format is the default for tabular export/import. To control which header row and columns are in the input/output, specify `custom_annotated`, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and `eval_id` (no `interface_id`), and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id      x1          x2          obj_fn  nln_ineq_con_1  nln_ineq_con_2
1             0.9          1.1          0.0002      0.26           0.76
2             0.90009      1.1 0.0001996404857  0.2601620081  0.759955
3             0.89991      1.1 0.0002003604863  0.2598380081  0.760045
...
```

Description

See description of parent `custom_annotated`

annotated

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [import_approx_points_file](#)
- [annotated](#)

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The `annotated` keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include `interface_id`, specify `custom_annotated` header `eval_id`
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export an annotated top-level tabular data file containing a header row, leading `eval_id` and `interface_id` columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated
```

Resulting tabular file:

```
%eval_id interface          x1          x2          obj_fn nln_ineq_con_1 nln_ineq_con_2
1          NO_ID            0.9         1.1         0.0002          0.26          0.76
2          NO_ID            0.90009    1.1 0.0001996404857 0.2601620081 0.759955

```

freeform

- [Keywords Area](#)
- [method](#)
- [polynomial.chaos](#)
- [import_approx_points_file](#)
- [freeform](#)

Selects freeform file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The `annotated` format is the default for tabular export/import. To change this behavior, specify `freeform` in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to `annotated` format, though `freeform` remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- In `freeform`, the `num_rows` x `num_cols` total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

```
      0.9          1.1          0.0002          0.26          0.76
0.90009          1.1 0.0001996404857  0.2601620081  0.759955
0.89991          1.1 0.0002003604863  0.2598380081  0.760045
...
```

- [active_only](#)

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

export_approx_points_file

- [Keywords Area](#)
- [method](#)
- [polynomial.chaos](#)
- [export_approx_points_file](#)

Output file for evaluations of a surrogate model

Specification

Alias: export_points_file

Argument(s): STRING

Default: no point export to a file

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional (<i>Choose One</i>)	Tabular Format (Group 1)	custom_annotated	Selects custom-annotated tabular file format
			annotated	Selects annotated tabular file format
			freeform	Selects freeform file format

Description

The `export_approx_points_file` keyword allows the user to specify a file in which the points (input variable values) at which the surrogate model is evaluated and corresponding response values computed by the surrogate model will be written. The response values are the surrogate's predicted approximation to the truth model responses at those points.

Usage Tips

Dakota exports tabular data in one of three formats:

- `annotated` (default)
- `custom_annotated`
- `freeform`

custom_annotated

- [Keywords Area](#)
- [method](#)
- [polynomial.chaos](#)

- [export_approx_points_file](#)
- [custom_annotated](#)

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			header	Enable header row in custom-annotated tabular file
	Optional		eval_id	Enable evaluation ID column in custom-annotated tabular file
	Optional		interface_id	Enable interface ID column in custom-annotated tabular file

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, `eval_id` column, and `interface_id` column appear in the tabular file, thus bridging `freeform` and (fully) `annotated`.

Default Behavior

The `annotated` format is the default for tabular export/import. To control which header row and columns are in the input/output, specify `custom_annotated`, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to `annotated` format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and `eval_id` (no `interface_id`), and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id      x1          x2          obj_fn nln_ineq_con_1 nln_ineq_con_2
1             0.9          1.1          0.0002          0.26          0.76
2             0.90009      1.1 0.0001996404857 0.2601620081 0.759955
3             0.89991      1.1 0.0002003604863 0.2598380081 0.760045
...
```

annotated

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [export_approx_points_file](#)
- [annotated](#)

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The `annotated` keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include `interface_id`, specify `custom_annotated_header eval_id`
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export an annotated top-level tabular data file containing a header row, leading `eval_id` and `interface_id` columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated
```

Resulting tabular file:

```
%eval_id interface          x1          x2          obj_fn nln_ineq_con_1 nln_ineq_con_2
1          NO_ID            0.9          1.1          0.0002          0.26          0.76
2          NO_ID            0.90009      1.1 0.0001996404857 0.2601620081 0.759955

...
```

freeform

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [export_approx_points_file](#)
- [freeform](#)

Selects freeform file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The `annotated` format is the default for tabular export/import. To change this behavior, specify `freeform` in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to `annotated` format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- In `freeform`, the `num_rows` x `num_cols` total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

```

      0.9          1.1          0.0002          0.26          0.76
0.90009          1.1 0.0001996404857  0.2601620081  0.759955
0.89991          1.1 0.0002003604863  0.2598380081  0.760045
...

```

model_pointer

- [Keywords Area](#)
- [method](#)
- [polynomial_chaos](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

Multifidelity uncertainty quantification using polynomial chaos expansions

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		p_refinement	Automatic polynomial order refinement

	Optional		max_refinement_-\niterations	Maximum number of expansion refinement iterations
	Optional		allocation_control	Sample allocation approach for multifidelity polynomial chaos and multifidelity stochastic collocation
	Optional		discrepancy_-\nemulation	Formulation for emulation of model discrepancies.
	Required (<i>Choose One</i>)	Chaos Coefficient Estimation Approach (Group 1)	quadrature_order_-\nsequence	Order for tensor-products of Gaussian quadrature rules
			sparse_grid_level_-\nsequence	Level to use in sparse grid integration or interpolation
			expansion_order_-\nsequence	The (initial) order of a polynomial expansion
			orthogonal_least_-\ninterpolation	Build a polynomial chaos expansion from simulation samples using orthogonal least interpolation.

	Optional <i>(Choose One)</i>	Basis Polynomial Family (Group 2)	askey	Select the standardized random variables (and associated basis polynomials) from the Askey family that best match the user-specified random variables.
			wiener	Use standard normal random variables (along with Hermite orthogonal basis polynomials) when transforming to a standardized probability space.
	Optional		normalized	The normalized specification requests output of PCE coefficients that correspond to normalized orthogonal basis polynomials
	Optional		export_expansion_-file	Export the coefficients and multi-index of a Polynomial Chaos Expansion (PCE) to a file
	Optional		samples_on_-emulator	Number of samples at which to evaluate an emulator (surrogate)

	Optional	sample_type	Selection of sampling strategy
	Optional	seed	Seed of the random number generator
	Optional	fixed_seed	Reuses the same seed value for multiple random sampling sets
	Optional	rng	Selection of a random number generator
	Optional	probability_refinement	Allow refinement of probability and generalized reliability results using importance sampling
	Optional	final_moments	Output moments of the specified type and include them within the set of final statistics.
	Optional	response_levels	Values at which to estimate desired statistics for each response
	Optional	probability_levels	Specify probability levels at which to estimate the corresponding response value
	Optional	reliability_levels	Specify reliability levels at which the response values will be estimated

	Optional		gen_reliability_- levels	Specify generalized reliability levels at which to estimate the corresponding response value
	Optional		distribution	Selection of cumulative or complementary cumulative functions
	Optional		variance_based_- decomp	Activates global sensitivity analysis based on decomposition of response variance into main, interaction, and total effects
	Optional (Choose One)	Covariance Type (Group 3)	diagonal_- covariance	Display only the diagonal terms of the covariance matrix
			full_covariance	Display the full covariance matrix
	Optional		convergence_- tolerance	Stopping criterion based on objective function or statistics convergence
	Optional		import_approx_- points_file	Filename for points at which to evaluate the PCE/SC surrogate
	Optional		export_approx_- points_file	Output file for evaluations of a surrogate model

	Optional	<code>model_pointer</code>	Identifier for model block to be used by a method
--	-----------------	----------------------------	---

Description

As described in [polynomial_chaos](#), the polynomial chaos expansion (PCE) is a general framework for the approximate representation of random response functions in terms of series expansions in standardized random variables:

$$R = \sum_{i=0}^P \alpha_i \Psi_i(\xi)$$

where α_i is a deterministic coefficient, Ψ_i is a multidimensional orthogonal polynomial and ξ is a vector of standardized random variables.

In the multilevel and multifidelity cases, we decompose this expansion into several constituent expansions, one per model form or solution control level. In a bi-fidelity case with low-fidelity (LF) and high-fidelity (HF) models and an additive discrepancy approach, we have:

$$R = \sum_{i=0}^{P^{LF}} \alpha_i^{LF} \Psi_i(\xi) + \sum_{i=0}^{P^{HF}} \delta_i \Psi_i(\xi)$$

where δ_i is a coefficient for the discrepancy expansion.

The same specification options are available as described in [polynomial_chaos](#) with one key difference: many of the coefficient estimation inputs change from a scalar input for a single expansion to a *sequence* specification for a low-fidelity expansion followed by multiple discrepancy expansions.

To obtain the coefficients α_i and δ_i for each of the expansions, the following options are provided:

1. multidimensional integration by a tensor-product of Gaussian quadrature rules (specified with `quadrature_order_sequence`, and, optionally, `dimension_preference`).
2. multidimensional integration by the Smolyak sparse grid method (specified with `sparse_grid_level_sequence` and, optionally, `dimension_preference`)
3. multidimensional integration by Latin hypercube sampling (specified with `expansion_order_sequence` and `expansion_samples_sequence`).
4. linear regression (specified with `expansion_order_sequence` and either `collocation_points_sequence` or `collocation_ratio`), using either over-determined (least squares) or under-determined (compressed sensing) approaches.
5. orthogonal least interpolation (specified with `orthogonal_least_interpolation` and `collocation_points_sequence`)

It is important to note that, while `quadrature_order_sequence`, `sparse_grid_level_sequence`, `expansion_order_sequence`, `expansion_samples_sequence`, and `collocation_points_sequence` are array inputs, only one scalar from these arrays is active at a time for a particular expansion estimation. In order to specify anisotropy in resolution across the random variable set, a `dimension_preference` specification can be used to augment scalar specifications for quadrature order, sparse grid level, and expansion order.

Multifidelity UQ using PCE requires that the model selected for iteration by the method specification is a multifidelity surrogate model (see [hierarchical](#)), which defines an `ordered_model_sequence` (see [hierarchical](#)). Two types of hierarchies are supported: (i) a hierarchy of model forms composed from more than one model

within the `ordered_model_sequence`, or (ii) a hierarchy of discretization levels comprised from a single model within the `ordered_model_sequence` which in turn specifies a `solution_level_control` (see [solution_level_control](#)).

In both cases, an expansion will first be formed for the low fidelity model or coarse discretization, using the first value within the coefficient estimation sequence, along with any specified refinement strategy. Second, expansions are formed for one or more model discrepancies (the difference between response results if `additive correction` or the ratio of results if `multiplicative correction`), using all subsequent values in the coefficient estimation sequence (if the sequence does not provide a new value, then the previous value is reused) along with any specified refinement strategy. The number of discrepancy expansions is determined by the number of model forms or discretization levels in the hierarchy.

After formation and refinement of the constituent expansions, each of the expansions is combined (added or multiplied) into an expansion that approximates the high fidelity model, from which the final set of statistics are generated. For polynomial chaos expansions, this high fidelity expansion can differ significantly in form from the low fidelity and discrepancy expansions, particularly in the `multiplicative` case where it is expanded to include all of the basis products.

Additional Resources

Dakota provides access to multifidelity PCE methods through the `NonDMultilevelPolynomialChaos` class. Refer to the Stochastic Expansion Methods chapter of the Theory Manual[6] for additional information on the Multifidelity PCE algorithm.

Automatic polynomial order refinement

Specification

Alias: none

Argument(s): none

Default: no refinement

Child Keywords:

	Required/ Optional Required (<i>Choose One</i>)	Description of Group p-refinement Type (Group 1)	Dakota Keyword	Dakota Keyword Description
			uniform	Refine an expansion uniformly in all dimensions.
			dimension_- adaptive	Perform anisotropic expansion refinement by preferentially adapting in dimensions that are detected to have higher 'importance'.

Description

The `p_refinement` keyword specifies the usage of automated polynomial order refinement, which can be either `uniform` or `dimension_adaptive`.

The `dimension_adaptive` option is supported for the tensor-product quadrature and Smolyak sparse grid options and `uniform` is supported for tensor and sparse grids as well as regression approaches (`collocation_points` or `collocation_ratio`).

Each of these refinement cases makes use of the `max_iterations` and `convergence_tolerance` method independent controls. The former control limits the number of refinement iterations, and the latter control terminates refinement when the two-norm of the change in the response covariance matrix (or, in goal-oriented approaches, the two-norm of change in the statistical quantities of interest (QOI)) falls below the tolerance.

The `dimension_adaptive` case can be further specified to utilize `sobol`, `decay`, or generalized refinement controls. The former two cases employ anisotropic tensor/sparse grids in which the anisotropic dimension preference (leading to anisotropic integrations/expansions with differing refinement levels for different random dimensions) is determined using either total Sobol' indices from variance-based decomposition (`sobol`

case: high indices result in high dimension preference) or using spectral coefficient decay rates from a rate estimation technique similar to Richardson extrapolation (decay case: low decay rates result in high dimension preference). In these two cases as well as the `uniform` refinement case, the `quadrature_order` or `sparse_grid_level` are ramped by one on each refinement iteration until either of the two convergence controls is satisfied. For the `uniform` refinement case with regression approaches, the `expansion_order` is ramped by one on each iteration while the oversampling ratio (either defined by `collocation_ratio` or inferred from `collocation_points` based on the initial expansion) is held fixed. Finally, the `generalized_dimension_adaptive` case is the default adaptive approach; it refers to the generalized sparse grid algorithm, a greedy approach in which candidate index sets are evaluated for their impact on the statistical QOI, the most influential sets are selected and used to generate additional candidates, and the index set frontier of a sparse grid is evolved in an unstructured and goal-oriented manner (refer to User's Manual PCE descriptions for additional specifics).

For the case of `p_refinement` or the case of an explicit nested override, Gauss-Hermite rules are replaced with Genz-Keister nested rules and Gauss-Legendre rules are replaced with Gauss-Patterson nested rules, both of which exchange lower integrand precision for greater point reuse.

uniform

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [p_refinement](#)
- [uniform](#)

Refine an expansion uniformly in all dimensions.

Specification

Alias: none

Argument(s): none

Description

The `quadrature_order` or `sparse_grid_level` are ramped by one on each refinement iteration until either of the two convergence controls is satisfied. For the `uniform` refinement case with regression approaches, the `expansion_order` is ramped by one on each iteration while the oversampling ratio (either defined by `collocation_ratio` or inferred from `collocation_points` based on the initial expansion) is held fixed.

dimension_adaptive

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [p_refinement](#)
- [dimension_adaptive](#)

Perform anisotropic expansion refinement by preferentially adapting in dimensions that are detected to have higher 'importance'.

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Required (<i>Choose One</i>)	Description of Group Dimension Adaptivity Estimation Approach (Group 1)	Dakota Keyword	Dakota Keyword Description
			sobol	Estimate dimension preference for automated refinement of stochastic expansion using total Sobol' sensitivity indices.
			decay	Estimate spectral coefficient decay rates to guide dimension-adaptive refinement.
			generalized	Use the generalized sparse grid dimension adaptive algorithm to refine a sparse grid approximation of stochastic expansion.

Description

Perform anisotropic expansion refinement by preferentially adapting in dimensions that are detected to hold higher 'importance' in resolving statistical quantities of interest.

Dimension importance must be estimated as part of the refinement process. Techniques include either [sobol](#) or [generalized](#) for stochastic collocation and either [sobol](#), [decay](#), or [generalized](#) for polynomial chaos. Each of these automated refinement approaches makes use of the `max_iterations` and `convergence_tolerance` iteration controls.

sobol

- [p_refinement](#)
- [dimension_adaptive](#)
- [decay](#)

Estimate spectral coefficient decay rates to guide dimension-adaptive refinement.

Specification

Alias: none

Argument(s): none

Description

Estimate spectral coefficient decay rates from a rate estimation technique similar to Richardson extrapolation. These decay rates are used to guide dimension-adaptive refinement, where slower decay rates result in higher dimension preference.

Examples

```
method,
    polynomial_chaos
    sparse_grid_level = 3
    dimension_adaptive p_refinement decay
    max_iterations = 20
    convergence_tol = 1.e-4
```

generalized

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [p_refinement](#)
- [dimension_adaptive](#)
- [generalized](#)

Use the generalized sparse grid dimension adaptive algorithm to refine a sparse grid approximation of stochastic expansion.

Specification

Alias: none

Argument(s): none

Description

The generalized sparse grid algorithm is a greedy approach in which candidate index sets are evaluated for their impact on the statistical QOI, the most influential sets are selected and used to generate additional candidates, and the index set frontier of a sparse grid is evolved in an unstructured and goal-oriented manner (refer to User's Manual PCE descriptions for additional specifics).

Examples

```
method,
    polynomial_chaos
    sparse_grid_level = 3
    dimension_adaptive p_refinement generalized
    max_iterations = 20
    convergence_tol = 1.e-4
```

max_refinement_iterations

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [max_refinement_iterations](#)

Maximum number of expansion refinement iterations

Specification

Alias: none

Argument(s): INTEGER

Default: 100

Description

Limits the number of times the expansion can be refined under various refinement strategies.

Examples

```
method,
  polynomial_chaos
  dimension_adaptive generalized
  p_refinement
  max_refinement_iterations = 20
  convergence_tol = 1.e-4
  sparse_grid_level = 1
```

allocation_control

- [method](#)
- [multifidelity_polynomial_chaos](#)
- [allocation_control](#)

Sample allocation approach for multifidelity polynomial chaos and multifidelity stochastic collocation

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/- Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required(<i>Choose One</i>)	Multifidelity Sample Allocation Control (Group 1)	greedy	Sample allocation based on greedy refinement within multi- level/multifidelity polynomial chaos

Description

Multifidelity polynomial chaos and multifidelity stochastic collocation can optionally employ a greedy sample allocation strategy, where adaptive refinement spans multiple level candidates. The default, when `allocation_control` is not specified, is to compute or adapt separately for each model fidelity.

greedy

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [allocation_control](#)
- [greedy](#)

Sample allocation based on greedy refinement within multilevel/multifidelity polynomial chaos

Specification

Alias: none

Argument(s): none

Description

Multilevel and multifidelity polynomial chaos both support greedy refinement strategies, spanning regression and projection approaches for computing expansion coefficients. The key idea is that each level of the model hierarchy being approximated can generate one or more candidates for refinement. These candidates are competed against each other within a unified competition, and the candidate that induces the largest change in the statistical QoI (response covariance by default, or results of any $z/p/\beta/\beta^*$ level mappings when specified), normalized by relative cost of evaluating the candidate, is selected and then used to generate additional candidates for consideration at its model level.

Examples

The following example of greedy multilevel regression starts from a zeroth-order reference expansion (a constant) for each level, and generates candidate refinements for each level that are competed in a greedy competition. The number of new samples for the incremented candidate expansion order is determined from the collocation ratio. In this case, the number of candidates for each level is limited to one uniform refinement of the current expansion order.

```
method,
  model_pointer = 'HIERARCH'
  multilevel_polynomial_chaos # or multifidelity
  allocation_control greedy
  p_refinement uniform
  expansion_order_sequence = 0
  collocation_ratio = .9 seed = 160415
  orthogonal_matching_pursuit
  convergence_tolerance 1.e-2
```

The next example employs generalized sparse grids within a greedy multilevel competition. Each modeling level starts from a level 0 reference grid (a single point) and generates multiple admissible index set candidates. The full set of candidates across all model levels is competed within a unified greedy competition, where the greedy selection metric is the induced change in the statistical QoI, normalized by the aggregate simulation cost of the index set candidate. In this case, there are multiple candidates for each model level and the number of candidates grows rapidly with random dimension and grid level.

```

method,
  model_pointer = 'HIERARCH'
  multilevel_polynomial_chaos # or multifidelity
  allocation_control greedy
  p_refinement dimension_adaptive generalized
  sparse_grid_level_sequence = 0 unrestricted
  convergence_tolerance 1.e-8

```

Default: distinct

Child Keywords:

	Required/ Optional Required (<i>Choose One</i>)	Description of Group Discrepancy Emulation Approach (Group 1)	Dakota Keyword distinct	Dakota Keyword Description Distinct formulation for emulation of model discrepancies.
			recursive	Recursive formulation for emulation of model discrepancies.

Description

In many uncertainty quantification approaches, model discrepancies are emulated using, e.g., polynomial chaos, stochastic collocation, or Gaussian process models. Two formulations are available for this emulation:

1. `distinct` emulation (default), in which we directly approximate the difference or ratio between the evaluations of two models or solution levels.
2. `recursive` emulation (experimental option), in which we approximate a difference or ratio among the new model evaluation and the emulator approximation of the previous model.

The latter approach is a form of hierarchical emulation in which we emulate the surplus between the previous emulator and the new modeling level. This approach has a few advantages: (i) it reduces bias by correcting for emulation errors that occur at previous levels, and (ii) it does not require paired model evaluations for each discrepancy level, which reduces cost, allows for disparate sample points, and simplifies data imports.

On the other hand, its primary disadvantage is that the aggregate emulation is only as good as its weakest link, in that a poor emulator recovery can create difficulty in accurately resolving discrepancies that are recursively dependent on it. Thus, the `distinct` approach may tend to be more expensive in exchange for greater robustness.

Examples

```
method,
    multilevel_polynomial_chaos
    expansion_order_sequence = 2
    collocation_ratio = .9
    orthogonal_matching_pursuit
    discrepancy_emulation recursive

Order for tensor-products of Gaussian quadrature rules

Specification

Alias: none

Argument(s): INTEGERLIST

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			dimension_- preference	A set of weights specifying the relative importance of each uncertain variable (dimension)

	Optional(<i>Choose One</i>)	Quadrature Rule Nesting (Group 1)	nested	Enforce use of nested quadrature rules if available
			non_nested	Enforce use of non-nested quadrature rules

Description

Multidimensional integration by a tensor-product of Gaussian quadrature rules (specified with `quadrature_order`, and, optionally, `dimension_preference`). The default rule selection is to employ `non_nested` Gauss rules including Gauss-Hermite (for normals or transformed normals), Gauss-Legendre (for uniforms or transformed uniforms), Gauss-Jacobi (for betas), Gauss-Laguerre (for exponentials), generalized Gauss-Laguerre (for gammas), and numerically-generated Gauss rules (for other distributions when using an Extended basis). For the case of `p_refinement` or the case of an explicit `nested` override, Gauss-Hermite rules are replaced with Genz-Keister nested rules and Gauss-Legendre rules are replaced with Gauss-Patterson nested rules, both of which exchange lower integrand precision for greater point reuse. By specifying a `dimension_preference`, where higher preference leads to higher order polynomial resolution, the tensor grid may be rendered anisotropic. The dimension specified to have highest preference will be set to the specified `quadrature_order` and all other dimensions will be reduced in proportion to their reduced preference; any non-integral portion is truncated. To synchronize with tensor-product integration, a tensor-product expansion is used, where the order p_i of the expansion in each dimension is selected to be half of the integrand precision available from the rule in use, rounded down. In the case of non-nested Gauss rules with integrand precision $2m_i - 1$, p_i is one less than the quadrature order m_i in each dimension (a one-dimensional expansion contains the same number of terms, $p + 1$, as the number of Gauss points). The total number of terms, N , in a tensor-product expansion involving n uncertain input variables is

$$N = 1 + P = \prod_{i=1}^n (p_i + 1)$$

In some advanced use cases (e.g., multifidelity UQ), multiple grid resolutions can be employed; for this reason, the `quadrature_order` specification supports an array input.

Usage Tips

For most use cases, this keyword will specify a single integer order. In more advanced UQ studies with hierarchical models, the list of integers can apply to different models and/or model levels

Level to use in sparse grid integration or interpolation

Specification

Alias: none

Argument(s): INTEGERLIST

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional (Choose One)	Quadrature Rule Growth (Group 1)	dimension_- preference restricted	A set of weights specifying the relative importance of each uncertain variable (dimension) Restrict the growth rates for nested and non-nested rules can be synchronized for consistency.
			unrestricted	Override the default restriction of growth rates for nested and non-nested rules that are by default synchronized for consistency.
	Optional (Choose One)	Quadrature Rule Nesting (Group 2)	nested	Enforce use of nested quadrature rules if available
			non_nested	Enforce use of non-nested quadrature rules

Description

Multi-dimensional integration by the Smolyak sparse grid method (specified with `sparse_grid_level` and, optionally, `dimension_preference`). The underlying one-dimensional integration rules are the same as for the tensor-product quadrature case; however, the default rule selection is nested for sparse grids (Genz-Keister for normals/transformed normals and Gauss-Patterson for uniforms/transformed uniforms). This default can be overridden with an explicit `non_nested` specification (resulting in Gauss-Hermite for normals/transformed normals and Gauss-Legendre for uniforms/transformed uniforms). As for tensor quadrature, the `dimension_preference` specification enables the use of anisotropic sparse grids (refer to the PCE description in the User's Manual for the anisotropic index set constraint definition). Similar to anisotropic tensor grids, the dimension with greatest preference will have resolution at the full `sparse_grid_level` and all other dimension resolutions will be reduced in proportion to their reduced preference. For PCE with either isotropic or anisotropic sparse grids, a summation of tensor-product expansions is used, where each anisotropic tensor-product quadrature rule underlying the sparse grid construction results in its own anisotropic tensor-product expansion as described in case 1. These anisotropic tensor-product expansions are summed into a sparse PCE using the standard Smolyak summation (again, refer to the User's Manual for additional details). As for `quadrature_order`, the `sparse_grid_level` specification admits an array input for enabling specification of multiple grid resolutions used by certain advanced solution methodologies.

Usage Tips

This keyword can be used when using sparse grid integration to calculate PCE coefficients or when generating samples for sparse grid collocation.

For most use cases, this keyword will specify a single integer level. In more advanced UQ studies with hierarchical models, the list of integers can apply to different models and/or model levels

restricted

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [sparse_grid_level_sequence](#)
- [restricted](#)

Restrict the growth rates for nested and non-nested rules can be synchronized for consistency.

Specification

Alias: none

Argument(s): none

Default: restricted (except for generalized sparse grids)

Description

In the quadrature and sparse grid cases, growth rates for nested and non-nested rules can be synchronized for consistency. For a non-nested Gauss rule used within a sparse grid, linear one-dimensional growth rules of $m = 2l + 1$ are used to enforce odd quadrature orders, where l is the grid level and m is the number of points in the rule. The precision of this Gauss rule is then $i = 2m - 1 = 4l + 1$. For nested rules, order growth with level is typically exponential; however, the default behavior is to restrict the number of points to be the lowest order rule that is available that meets the one-dimensional precision requirement implied by either a level l for a sparse grid ($i = 4l + 1$) or an order m for a tensor grid ($i = 2m - 1$). This behavior is known as "restricted growth" or "delayed sequences." To override this default behavior in the case of sparse grids, the `unrestricted` keyword can be used; it cannot be overridden for tensor grids using nested rules since it also provides a mapping to the available nested rule quadrature orders. An exception to the default usage of restricted growth is the `dimension_adaptive_p_refinement` generalized sparse grid case described previously, since the ability to evolve the index sets of a sparse grid in an unstructured manner eliminates the motivation for restricting the exponential growth of nested rules.

	Optional	<code>import_build_- points_file</code>	File containing points you wish to use to build a surrogate

Description

When the `expansion_order` for a polynomial chaos expansion is specified, the coefficients may be computed by integration based on random samples or by regression using either random or sub-sampled tensor product quadrature points.

Multidimensional integration by Latin hypercube sampling (specified with `expansion_samples`). In this case, the expansion order p cannot be inferred from the numerical integration specification and it is necessary to provide an `expansion_order` to specify p for a total-order expansion.

Linear regression (specified with either `collocation_points` or `collocation_ratio`). A total-order expansion is used and must be specified using `expansion_order` as described in the previous option. To avoid requiring the user to calculate N from n and p , the `collocation_ratio` allows for specification of a constant factor applied to N (e.g., `collocation_ratio = 2`. produces `samples = 2N`). In addition, the default linear relationship with N can be overridden using a real-valued exponent specified using `ratio_order`. In this case, the number of samples becomes cN^o where c is the `collocation_ratio` and o is the `ratio_order`. The `use_derivatives` flag informs the regression approach to include derivative matching equations (limited to gradients at present) in the least squares solutions, enabling the use of fewer collocation points for a given expansion order and dimension (number of points required becomes $\frac{cN^o}{n+1}$). When admissible, a constrained least squares approach is employed in which response values are first reproduced exactly and error in reproducing response derivatives is minimized. Two collocation grid options are supported: the default is Latin hypercube sampling ("point collocation"), and an alternate approach of "probabilistic collocation" is also available through inclusion of the `tensor_grid` keyword. In this alternate case, the collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

If `collocation_points` or `collocation_ratio` is specified, the PCE coefficients will be determined by regression. If no regression specification is provided, appropriate defaults are defined. Specifically SVD-based least-squares will be used for solving over-determined systems and under-determined systems will be solved using LASSO. For the situation when the number of function values is smaller than the number of terms in a PCE, but the total number of samples including gradient values is greater than the number of terms, the resulting over-determined system will be solved using equality constrained least squares. Technical information on the various methods listed below can be found in the Linear regression section of the Theory Manual. Some of the regression methods (OMP, LASSO, and LARS) are able to produce a set of possible PCE coefficient vectors (see the Linear regression section in the Theory Manual). If cross validation is inactive, then only one solution, consistent with the `noise_tolerance`, will be returned. If cross validation is active, Dakota will choose between possible coefficient vectors found internally by the regression method across the set of expansion orders (1,...,`expansion_order`) and the set of specified noise tolerances and return the one with the lowest cross validation error indicator.

Usage Tips

For most use cases, this keyword will specify a single integer order. In more advanced UQ studies with hierarchical models, the list of integers can apply to different models and/or model levels

Argument(s): REAL

Default: 0. (reverts to standard LASSO formulation)

Description

The l_2 penalty used when performing compressed sensing with elastic net.

cross_validation

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_points_sequence](#)
- [cross_validation](#)

Use cross validation to choose the 'best' polynomial order of a polynomial chaos expansion.

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description

	Optional	noise_only	Restrict the cross validation process to estimating only the best noise tolerance.
--	-----------------	----------------------------	--

Description

Use cross validation to choose the 'best' polynomial degree of a polynomial chaos expansion. 10 fold cross validation is used to estimate the cross validation error of a total-order polynomial expansion for orders 1 through to order. The order chosen is the one that produces the lowest cross validation error. If there are not enough points to perform 10 fold cross validation then one-at-a-time cross validation will be performed.

noise_only

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_points_sequence](#)
- [cross_validation](#)
- [noise_only](#)

Restrict the cross validation process to estimating only the best noise tolerance.

Specification

Alias: none

Argument(s): none

Default: false

Description

By default, cross validation estimates both the best noise tolerance and the best candidate basis order. For reasons of reducing computational cost by reducing the number of candidate solves, the user may wish to restrict this process to estimating only the best noise tolerance.

Generally speaking, computing the best noise tolerance through cross validation mitigates issues with overfitting the data. Computing the best candidate basis order can also mitigate overfitting, while also controlling levels of mutual coherence resulting from high-order Vandermonde-like matrix systems.

ratio_order

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_points_sequence](#)
- [ratio_order](#)

Specify a non-linear the relationship between the expansion order of a polynomial chaos expansion and the number of samples that will be used to compute the PCE coefficients.

Specification

Alias: none

Argument(s): REAL

Default: 1.

Description

When using regression type methods (specified with either `collocation_points` or `collocation_ratio`), a total-order expansion can be specified using `expansion_order`. To avoid requiring the user to calculate N from n and p), the `collocation_ratio` allows for specification of a constant factor applied to N (e.g., `collocation_ratio = 2.` produces $\text{samples} = 2N$). In addition, the default linear relationship with N can be overridden using a real-valued exponent specified using `ratio_order`. In this case, the number of samples becomes cN^o where c is the `collocation_ratio` and o is the `ratio_order`.

use_derivatives

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_points_sequence](#)
- [use_derivatives](#)

Use derivative data to construct surrogate models

Specification

Alias: none

Argument(s): none

Default: use function values only

Description

The `use_derivatives` flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, its use with Surfpack Gaussian process is not recommended.

tensor_grid

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_points_sequence](#)
- [tensor_grid](#)

Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.

Specification

Alias: none

Argument(s): none

Default: regression with LHS sample set (point collocation)

Description

The collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

reuse_points

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_points_sequence](#)
- [reuse_points](#)

This describes the behavior of reuse of points in constructing polynomial chaos expansion models.

Specification

Alias: reuse_samples

Argument(s): none

Default: no sample reuse in coefficient estimation

Description

The `reuse_points` option controls the reuse behavior of points for various types of polynomial chaos expansions, including: `collocation_points`, `collocation_ratio`, `expansion_samples`, or `orthogonal_least_interpolation`. If any of these approaches are specified to create a set of points for the polynomial chaos expansion, one can specify `reuse_points` so that any points that have been previously generated (for example, from the `import_points` file) can be reused.

max_solver_iterations

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_points_sequence](#)
- [max_solver_iterations](#)

Maximum iterations in determining polynomial coefficients

Specification

Alias: none

Argument(s): INTEGER

Default: 100

Description

When using an iterative polynomial coefficient estimation approach, e.g., cross-validation-based solvers, limits the maximum iterations in the coefficient solver.

collocation_ratio

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_ratio](#)

Set the number of points used to build a PCE via regression to be proportional to the number of terms in the expansion.

Specification

Alias: none

Argument(s): REAL

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional (<i>Choose One</i>)	Regression Algorithm (Group 1)	least_squares	Compute the coefficients of a polynomial expansion using least squares
			orthogonal-matching-pursuit	Compute the coefficients of a polynomial expansion using orthogonal matching pursuit (OMP)
			basis_pursuit	Compute the coefficients of a polynomial expansion by solving the Basis Pursuit ℓ_1 -minimization problem using linear programming.
			basis_pursuit-denoising	Compute the coefficients of a polynomial expansion by solving the Basis Pursuit Denoising ℓ_1 -minimization problem using second order cone optimization.

		least_angle_regression	Compute the coefficients of a polynomial expansion by using the greedy least angle regression (LAR) method.
		least_absolute_shrinkage	Compute the coefficients of a polynomial expansion by using the LASSO problem.
	Optional	cross_validation	Use cross validation to choose the 'best' polynomial order of a polynomial chaos expansion.
	Optional	ratio_order	Specify a non-linear the relationship between the expansion order of a polynomial chaos expansion and the number of samples that will be used to compute the PCE coefficients.
	Optional	use_derivatives	Use derivative data to construct surrogate models
	Optional	tensor_grid	Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.

	Optional	reuse_points	This describes the behavior of reuse of points in constructing polynomial chaos expansion models. Maximum iterations in determining polynomial coefficients
	Optional	max_solver_ iterations	

Description

Set the number of points used to build a PCE via regression to be proportional to the number of terms in the expansion. To avoid requiring the user to calculate N from n and p , the `collocation_ratio` allows for specification of a constant factor applied to N (e.g., `collocation_ratio = 2` produces `samples = 2N`). In addition, the default linear relationship with N can be overridden using a real-valued exponent specified using `ratio_order`. In this case, the number of samples becomes cN^o where c is the `collocation_ratio` and o is the `ratio_order`. The `use_derivatives` flag informs the regression approach to include derivative matching equations (limited to gradients at present) in the least squares solutions, enabling the use of fewer collocation points for a given expansion order and dimension (number of points required becomes $\frac{cN^o}{n+1}$).

least_squares

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_ratio](#)
- [least_squares](#)

Compute the coefficients of a polynomial expansion using least squares

Specification

Alias: none

Argument(s): none

Default: svd

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
--	-----------------------	-------------------------	----------------	-------------------------------

	Optional (Choose One)	LSQ Regression Approach (Group 1)	svd	Calculate the coefficients of a polynomial chaos expansion using the singular value decomposition.
			equality_-constrained	Calculate the coefficients of a polynomial chaos expansion using equality constrained least squares.

Description

Compute the coefficients of a polynomial expansion using least squares. Specifically SVD-based least-squares will be used for solving over-determined systems. For the situation when the number of function values is smaller than the number of terms in a PCE, but the total number of samples including gradient values is greater than the number of terms, the resulting over-determined system will be solved using equality constrained least squares

svd

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_ratio](#)
- [least_squares](#)
- [svd](#)

Calculate the coefficients of a polynomial chaos expansion using the singular value decomposition.

Specification

Alias: none

Argument(s): none

Description

Calculate the coefficients of a polynomial chaos expansion using the singular value decomposition. When the number of model runs exceeds the number of terms in the PCE, the solution returned will be the least-squares solution, otherwise the solution will be the minimum norm solution computed using the pseudo-inverse.

equality_constrained

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_ratio](#)
- [least_squares](#)
- [equality_constrained](#)

Calculate the coefficients of a polynomial chaos expansion using equality constrained least squares.

Specification

Alias: none

Argument(s): none

Description

Calculate the coefficients of a polynomial chaos expansion using equality constrained least squares.

orthogonal_matching_pursuit

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_ratio](#)
- [orthogonal_matching_pursuit](#)

Compute the coefficients of a polynomial expansion using orthogonal matching pursuit (OMP)

Specification

Alias: omp

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description

	Optional	noise_tolerance	The noise tolerance used when performing cross validation in the presence of noise or truncation errors.
--	-----------------	---------------------------------	--

Description

Compute the coefficients of a polynomial expansion using orthogonal matching pursuit (OMP). Orthogonal matching pursuit (OMP) is a greedy algorithm that is useful when solving underdetermined linear systems.

Specification

Alias: none

Argument(s): REALLIST

Default: 1e-3 for BPDN, 0. otherwise (algorithms run until termination)

Description

The noise tolerance used when performing cross validation in the presence of noise or truncation errors.

l2_penalty

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_ratio](#)
- [least_absolute_shrinkage](#)
- [l2_penalty](#)

The l_2 penalty used when performing compressed sensing with elastic net.

Specification

Alias: none

Argument(s): REAL

Default: 0. (reverts to standard LASSO formulation)

Description

The l_2 penalty used when performing compressed sensing with elastic net.

cross_validation

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_ratio](#)
- [cross_validation](#)

Use cross validation to choose the 'best' polynomial order of a polynomial chaos expansion.

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description

	Optional	noise_only	Restrict the cross validation process to estimating only the best noise tolerance.
--	-----------------	----------------------------	--

Description

Use cross validation to choose the 'best' polynomial degree of a polynomial chaos expansion. 10 fold cross validation is used to estimate the cross validation error of a total-order polynomial expansion for orders 1 through to order. The order chosen is the one that produces the lowest cross validation error. If there are not enough points to perform 10 fold cross validation then one-at-a-time cross validation will be performed.

noise_only

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_ratio](#)
- [cross_validation](#)
- [noise_only](#)

Restrict the cross validation process to estimating only the best noise tolerance.

Specification

Alias: none

Argument(s): none

Default: false

Description

By default, cross validation estimates both the best noise tolerance and the best candidate basis order. For reasons of reducing computational cost by reducing the number of candidate solves, the user may wish to restrict this process to estimating only the best noise tolerance.

Generally speaking, computing the best noise tolerance through cross validation mitigates issues with overfitting the data. Computing the best candidate basis order can also mitigate overfitting, while also controlling levels of mutual coherence resulting from high-order Vandermonde-like matrix systems.

ratio_order

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_ratio](#)
- [ratio_order](#)

Specify a non-linear the relationship between the expansion order of a polynomial chaos expansion and the number of samples that will be used to compute the PCE coefficients.

Specification

Alias: none

Argument(s): REAL

Default: 1.

Description

When using regression type methods (specified with either `collocation_points` or `collocation_ratio`), a total-order expansion can be specified using `expansion_order`. To avoid requiring the user to calculate N from n and p , the `collocation_ratio` allows for specification of a constant factor applied to N (e.g., `collocation_ratio = 2` produces `samples = 2N`). In addition, the default linear relationship with N can be overridden using a real-valued exponent specified using `ratio_order`. In this case, the number of samples becomes cN^o where c is the `collocation_ratio` and o is the `ratio_order`.

use_derivatives

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_ratio](#)
- [use_derivatives](#)

Use derivative data to construct surrogate models

Specification

Alias: none

Argument(s): none

Default: use function values only

Description

The `use_derivatives` flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, it's use with Surfpack Gaussian process is not recommended.

tensor_grid

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_ratio](#)
- [tensor_grid](#)

Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.

Specification

Alias: none

Argument(s): none

Default: regression with LHS sample set (point collocation)

Description

The collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

reuse_points

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_ratio](#)
- [reuse_points](#)

This describes the behavior of reuse of points in constructing polynomial chaos expansion models.

Specification

Alias: reuse_samples

Argument(s): none

Default: no sample reuse in coefficient estimation

Description

The `reuse_points` option controls the reuse behavior of points for various types of polynomial chaos expansions, including: `collocation_points`, `collocation_ratio`, `expansion_samples`, or `orthogonal_least_interpolation`. If any of these approaches are specified to create a set of points for the polynomial chaos expansion, one can specify `reuse_points` so that any points that have been previously generated (for example, from the `import_points` file) can be reused.

max_solver_iterations

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_ratio](#)
- [max_solver_iterations](#)

Maximum iterations in determining polynomial coefficients

Specification

Alias: none

Argument(s): INTEGER

Default: 100

Description

When using an iterative polynomial coefficient estimation approach, e.g., cross-validation-based solvers, limits the maximum iterations in the coefficient solver.

expansion_samples_sequence

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [expansion_samples_sequence](#)

Number of simulation samples to estimate the PCE coefficients

Specification

Alias: none

Argument(s): INTEGERLIST

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			reuse_points	This describes the behavior of reuse of points in constructing polynomial chaos expansion models.
	Optional		incremental_lhs	(Deprecated keyword) Augments an existing Latin Hypercube Sampling (LHS) study

Description

In this case, the expansion order p cannot be inferred from the numerical integration specification and it is necessary to provide an `expansion_order` to specify p for a total-order expansion.

Usage Tips

For most use cases, this keyword will specify a single integer number of samples. In more advanced UQ studies with hierarchical models, the list of integers can apply to different models and/or model levels

reuse_points

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [expansion_samples_sequence](#)
- [reuse_points](#)

This describes the behavior of reuse of points in constructing polynomial chaos expansion models.

Specification

Alias: reuse_samples

Argument(s): none

Default: no sample reuse in coefficient estimation

Description

The `reuse_points` option controls the reuse behavior of points for various types of polynomial chaos expansions, including: `collocation_points`, `collocation_ratio`, `expansion_samples`, or `orthogonal_least_interpolation`. If any of these approaches are specified to create a set of points for the polynomial chaos expansion, one can specify `reuse_points` so that any points that have been previously generated (for example, from the `import_points` file) can be reused.

incremental_lhs

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [expansion_samples_sequence](#)
- [incremental_lhs](#)

(Deprecated keyword) Augments an existing Latin Hypercube Sampling (LHS) study

Specification

Alias: none

Argument(s): none

Default: no sample reuse in coefficient estimation

Description

This keyword is deprecated. Instead specify `sample_type lhs` with `refinement_samples`.

An incremental random sampling approach will augment an existing random sampling study with `refinement_samples` to get better estimates of mean, variance, and percentiles. The number of `refinement_samples` in each refinement level must result in twice the number of previous samples.

Typically, this approach is used when you have an initial study with sample size $N1$ and you want to perform an additional $N1$ samples. Ideally, a Dakota restart file containing the initial $N1$ samples, so only $N1$ (instead of $2 \times N1$) potentially expensive function evaluations will be performed.

This process can be extended by repeatedly doubling the `refinement_samples`:

```
method
  sampling
    seed = 1337
    samples = 50
    refinement_samples = 50 100 200 400 800
```

Usage Tips

The incremental approach is useful if it is uncertain how many simulations can be completed within available time.

See the examples below and the [Usage](#) and [Restarting Dakota Studies](#) pages.

Examples

Suppose an initial study is conducted using `sample_type lhs` with `samples = 50`. A follow-on study uses a new input file where `samples = 50`, and `refinement_samples = 50`, resulting in 50 reused samples (from restart) and 50 new random samples. The 50 new samples will be combined with the 50 previous samples to generate a combined sample of size 100 for the analysis.

One way to ensure the restart file is saved is to specify a non-default name, via a command line option:

```
dakota -input LHS_50.in -write_restart LHS_50.rst
```

which uses the input file:

```
# LHS_50.in

environment
  tabular_data
    tabular_data_file = 'LHS_50.dat'

method
  sampling
    seed = 1337
    sample_type lhs
    samples = 50

model
  single

variables
  uniform_uncertain = 2
  descriptors = 'input1' 'input2'
  lower_bounds = -2.0 -2.0
  upper_bounds = 2.0 2.0

interface
  analysis_drivers 'text_book'
  fork

responses
  response_functions = 1
  no_gradients
  no_hessians
```

and the restart file is written to `LHS_50.rst`.

Then an incremental LHS study can be run with:

```
dakota -input LHS_100.in -read_restart LHS_50.rst -write_restart LHS_100.rst
```

where `LHS_100.in` is shown below, and `LHS_50.rst` is the restart file containing the results of the previous LHS study. In the example input files for the initial and incremental studies, the values for `seed` match. This ensures that the initial 50 samples generated in both runs are the same.

```
# LHS_100.in

environment
  tabular_data
    tabular_data_file = 'LHS_100.dat'

method
  sampling
    seed = 1337
    sample_type incremental_lhs
    samples = 50
```

```

    refinement_samples = 50

model
  single

variables
  uniform_uncertain = 2
  descriptors = 'input1' 'input2'
  lower_bounds = -2.0 -2.0
  upper_bounds = 2.0 2.0

interface
  analysis_drivers 'text_book'
  fork

responses
  response_functions = 1
  no_gradients
  no_hessians

```

The user will get 50 new LHS samples which maintain both the correlation and stratification of the original LHS sample. The new samples will be combined with the original samples to generate a combined sample of size 100.

import_build_points_file

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [import_build_points_file](#)

File containing points you wish to use to build a surrogate

Specification

Alias: import_points_file

Argument(s): STRING

Default: no point import from a file

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional (<i>Choose One</i>)	Tabular Format (Group 1)	custom_annotated	Selects custom-annotated tabular file format

		annotated	Selects annotated tabular file format
		freeform	Selects freeform file format
	Optional	active_only	Import only active variables from tabular data file

Description

The `import_build_points_file` allows the user to specify a file that contains a list of points and truth model responses used to construct a surrogate model. These can be used by all methods that (explicitly, e.g. surrogate-based optimization, or implicitly, e.g. efficient global optimization) operate on a surrogate. In particular, these points and responses are used in place of truth model evaluations to construct the initial surrogate. When used to construct surrogate models or emulators these are often called build points or training data.

Default Behavior

By default, methods do not import points from a file.

Usage Tips

Dakota parses input files without regard to whitespace, but the `import_build_points_file` must be in one of three formats:

- `annotated` (default)
- `custom_annotated`
- `freeform`

Examples

```
method
  polynomial_chaos
    expansion_order = 4
    import_build_points_file = 'dakota_uq_rosenbrock_pce_import.annot.pts.dat'
```

custom_annotated

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [import_build_points_file](#)
- [custom_annotated](#)

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			header	Enable header row in custom-annotated tabular file
	Optional		eval_id	Enable evaluation ID column in custom-annotated tabular file
	Optional		interface_id	Enable interface ID column in custom-annotated tabular file

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, `eval_id` column, and `interface_id` column appear in the tabular file, thus bridging `freeform` and (fully) annotated.

Default Behavior

The `annotated` format is the default for tabular export/import. To control which header row and columns are in the input/output, specify `custom_annotated`, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface-id), and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id      x1          x2          obj_fn  nln_ineq_con_1  nln_ineq_con_2
1              0.9          1.1          0.0002          0.26          0.76

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include `interface_id`, specify `custom_annotated` header `eval_id`
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export an annotated top-level tabular data file containing a header row, leading `eval_id` and `interface_id` columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated
```

Resulting tabular file:

```
%eval_id interface          x1          x2          obj_fn nln_ineq_con_1 nln_ineq_con_2
1          NO_ID            0.9          1.1          0.0002          0.26          0.76

- [freeform](#)

Selects freeform file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The `annotated` format is the default for tabular export/import. To change this behavior, specify `freeform` in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- In `freeform`, the `num_rows` x `num_cols` total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

```
      0.9          1.1          0.0002          0.26          0.76
0.90009      1.1 0.0001996404857  0.2601620081  0.759955

- [method](#)
- [multifidelity_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [import_build_points_file](#)
- [active_only](#)

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

orthogonal_least_interpolation

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [orthogonal_least_interpolation](#)

Build a polynomial chaos expansion from simulation samples using orthogonal least interpolation.

Specification

Alias: least_interpolation oli

Argument(s): none

Child Keywords:

	Required/ Optional Required	Description of Group	Dakota Keyword	Dakota Keyword Description
			collocation_points- _sequence	Specify the number of collocation points used to estimate PCE coefficients using orthogonal least interpolation
	Optional		tensor_grid	Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.
	Optional		reuse_points	This describes the behavior of reuse of points in constructing polynomial chaos expansion models.
	Optional		import_build- points_file	File containing points you wish to use to build a surrogate

Description

Build a polynomial chaos expansion from simulation samples using orthogonal least interpolation. Unlike the other regression methods `expansion_order` cannot be set. OLI will produce the lowest degree polynomial that interpolates the data

collocation_points_sequence

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [orthogonal_least_interpolation](#)
- [collocation_points_sequence](#)

Specify the number of collocation points used to estimate PCE coefficients using orthogonal least interpolation

Specification

Alias: none

Argument(s): INTEGERLIST

Description

Specify the number of collocation points used to estimate PCE coefficients using orthogonal least interpolation

tensor_grid

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [orthogonal_least_interpolation](#)
- [tensor_grid](#)

Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.

Specification

Alias: none

Argument(s): INTEGERLIST

Default: regression with LHS sample set (point collocation)

Description

The collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

reuse_points

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [orthogonal_least_interpolation](#)
- [reuse_points](#)

This describes the behavior of reuse of points in constructing polynomial chaos expansion models.

Specification

Alias: reuse_samples

Argument(s): none

Default: no sample reuse in coefficient estimation

Description

The `reuse_points` option controls the reuse behavior of points for various types of polynomial chaos expansions, including: `collocation_points`, `collocation_ratio`, `expansion_samples`, or `orthogonal_least_interpolation`. If any of these approaches are specified to create a set of points for the polynomial chaos expansion, one can specify `reuse_points` so that any points that have been previously generated (for example, from the `import_points` file) can be reused.

import_build_points_file

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [orthogonal_least_interpolation](#)
- [import_build_points_file](#)

File containing points you wish to use to build a surrogate

Specification

Alias: import_points_file

Argument(s): STRING

Default: no point import from a file

Child Keywords:

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

askey

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [askey](#)

Select the standardized random variables (and associated basis polynomials) from the Askey family that best match the user-specified random variables.

Specification

Alias: none

Argument(s): none

Default: extended (Askey + numerically-generated)

Description

The Askey option employs standard normal, standard uniform, standard exponential, standard beta, and standard gamma random variables in a transformed probability space. These selections correspond to Hermite, Legendre, Laguerre, Jacobi, and generalized Laguerre orthogonal polynomials, respectively.

Specific mappings for the basis polynomials are based on a closest match criterion, and include Hermite for normal (optimal) as well as bounded normal, lognormal, bounded lognormal, gumbel, frechet, and weibull (sub-optimal); Legendre for uniform (optimal) as well as loguniform, triangular, and bin-based histogram (sub-optimal); Laguerre for exponential (optimal); Jacobi for beta (optimal); and generalized Laguerre for gamma (optimal).

Argument(s): none

Default: extended (Askey + numerically-generated)

Description

The Wiener option employs standard normal random variables in a transformed probability space, corresponding to a Hermite orthogonal polynomial basis. This is the same nonlinear variable transformation used by local and global reliability methods (and therefore has the same variable support).

See Also

These keywords may also be of interest:

- [polynomial_chaos](#)
- [askey](#)

normalized

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [normalized](#)

The normalized specification requests output of PCE coefficients that correspond to normalized orthogonal basis polynomials

Specification

Alias: none

Argument(s): none

Default: PCE coefficients correspond to unnormalized basis polynomials

Description

The normalized specification requests output of PCE coefficients that correspond to normalized orthogonal basis polynomials

export_expansion_file

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [export_expansion_file](#)

Export the coefficients and multi-index of a Polynomial Chaos Expansion (PCE) to a file

Specification

Alias: none

Argument(s): STRING

Description

Export the coefficients and multi-index of a Polynomial Chaos Expansion (PCE) to a file. The multi-index written will be sparse. Specifically the expansion will consist only of the indices corresponding to the non-zero coefficients of the PCE.

samples_on_emulator

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [samples_on_emulator](#)

Number of samples at which to evaluate an emulator (surrogate)

Specification

Alias: samples

Argument(s): INTEGER

Description

How many approximate function evaluations to perform on the emulator model, e.g., to compute statistics

Default Behavior

The default number of samples is method-dependent.

Examples

Perform 10000 samples on the PCE approximation of the true model:

```
method
  polynomial_chaos
    quadrature_order = 2
    samples_on_emulator = 10000
```

sample_type

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [sample_type](#)

Selection of sampling strategy

Specification

Alias: none

Argument(s): none

Default: lhs

Child Keywords:

	Required/ Optional Required (<i>Choose One</i>)	Description of Group Sample Type (Group 1)	Dakota Keyword	Dakota Keyword Description
			lhs	Uses Latin Hypercube Sampling (LHS) to sample variables
			random	Uses purely random Monte Carlo sampling to sample variables

Description

The `sample_type` keyword allows the user to select between two types of sampling: Monte Carlo (pure random) and Latin hypercube (stratified) sampling.

The incremental keywords are deprecated; instead use `samples` together with `refinement_samples`.

Default Behavior

If the `sample_type` keyword is present, it must be accompanied by `lhs` or `random`. In most contexts, `lhs` is the default (exception: `multilevel_sampling` uses Monte Carlo by default).

Examples

```
method
  sampling
    sample_type lhs
    samples = 20
    seed = 83921
```

lhs

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [sample_type](#)
- [lhs](#)

Uses Latin Hypercube Sampling (LHS) to sample variables

Specification

Alias: none

Argument(s): none

Description

The `lhs` keyword invokes Latin Hypercube Sampling as the means of drawing samples of uncertain variables according to their probability distributions. This is a stratified, space-filling approach that selects variable values from a set of equi-probable bins.

Default Behavior

Latin Hypercube Sampling is the default sampling mode in most contexts (exception: `multilevel_sampling`). To explicitly specify LHS in the Dakota input file, the `lhs` keyword must appear in conjunction with the `sample_type` keyword.

Usage Tips

Latin Hypercube Sampling is very robust and can be applied to any problem. It is fairly effective at estimating the mean of model responses and linear correlations with a reasonably small number of samples relative to the number of variables.

Examples

```
method
  sampling
    sample_type lhs
    samples = 20
```

random

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [sample_type](#)
- [random](#)

Uses purely random Monte Carlo sampling to sample variables

Specification

Alias: none

Argument(s): none

Description

The `random` keyword invokes Monte Carlo sampling as the means of drawing samples of uncertain variables according to their probability distributions.

Default Behavior

In most contexts, Monte Carlo sampling is not the default sampling mode (exception: `multilevel_sampling`). To change this behavior, the `random` keyword must be specified in conjunction with the `sample_type` keyword.

Usage Tips

Monte Carlo sampling is more computationally expensive than Latin Hypercube Sampling as it requires a larger number of samples to accurately estimate statistics.

Examples

```
method
  sampling
    sample_type random
    samples = 200
```

seed

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [seed](#)

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)

Description

The random `seed` control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

fixed_seed

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)

- [fixed_seed](#)

Reuses the same seed value for multiple random sampling sets

Specification

Alias: none

Argument(s): none

Default: not fixed; pattern varies run-to-run

Description

The `fixed_seed` flag is relevant if multiple sampling sets will be generated over the course of a Dakota analysis. This occurs when using advance methods (e.g., surrogate-based optimization, optimization under uncertainty). The same seed value is reused for each of these multiple sampling sets, which can be important for reducing variability in the sampling results.

Default Behavior

The default behavior is to not use a fixed seed, as the repetition of the same sampling pattern can result in a modeling weakness that an optimizer could potentially exploit (resulting in actual reliabilities that are lower than the estimated reliabilities). For repeatable studies, the `seed` must also be specified.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    fixed_seed
```

rng

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [rng](#)

Selection of a random number generator

Specification

Alias: none

Argument(s): none

Default: Mersenne twister (mt19937)

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description

	Required (<i>Choose One</i>)	RNG Algorithm (Group 1)	mt19937	Generates random numbers using the Mersenne twister
			rnum2	Generates pseudo-random numbers using the Pecos package

Description

The `rng` keyword is used to indicate a choice of random number generator.

Default Behavior

If specified, the `rng` keyword must be accompanied by either `rnum2` (pseudo-random numbers) or `mt19937` (random numbers generated by the Mersenne twister). Otherwise, `mt19937`, the Mersenne twister is used by default.

Usage Tips

The default is recommended, as the Mersenne twister is a higher quality random number generator.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2
```

mt19937

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [rng](#)
- [mt19937](#)

Generates random numbers using the Mersenne twister

Specification

Alias: none

Argument(s): none

Description

The `mt19937` keyword directs Dakota to use the Mersenne twister to generate random numbers. Additional information can be found on wikipedia: http://en.wikipedia.org/wiki/Mersenne_twister.

Default Behavior

`mt19937` is the default random number generator. To specify it explicitly in the Dakota input file, however, it must be specified in conjunction with the `rng` keyword.

Usage Tips

Use of the Mersenne twister random number generator (`mt19937`) is recommended.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng mt19937
```

rnum2

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [rng](#)
- [rnum2](#)

Generates pseudo-random numbers using the Pecos package

Specification

Alias: none

Argument(s): none

Description

The `rnum2` keyword directs Dakota to use pseudo-random numbers generated by the Pecos package.

Default Behavior

`rnum2` is not used by default. To change this behavior, it must be specified in conjunction with the `rng` keyword.

Usage Tips

Use of the Mersenne twister random number generator (`mt19937`) is recommended over `rnum2`.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2
```

probability_refinement

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [probability_refinement](#)

Allow refinement of probability and generalized reliability results using importance sampling

Topics

This keyword is related to the topics:

- [reliability_methods](#)

Specification

Alias: sample_refinement

Argument(s): none

Default: no refinement

Child Keywords:

	Required/ Optional	Description of Group Importance Sampling Approach (Group 1)	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)		import	Sampling option
			adapt_import	Importance sampling option
			mm_adapt_import	Sampling option
	Optional		refinement_ samples	Number of samples used to refine a probabily estimate or sampling design.

Description

The `probability_refinement` allows refinement of probability and generalized reliability results using importance sampling. If one specifies `probability_refinement`, there are some additional options. One can specify which type of importance sampling to use (`import`, `adapt_import`, or `mm_adapt_import`). Additionally, one can specify the number of refinement samples to use with `refinement_samples` and the seed to use with `seed`.

The `probability_refinement` density reweighting accounts originally was developed based on Gaussian distributions. It now accounts for additional non-Gaussian cases.

import

- [Keywords Area](#)
- [method](#)

- [multifidelity_polynomial_chaos](#)
- [probability_refinement](#)
- [import](#)

Sampling option

Specification

Alias: none

Argument(s): none

Description

`import` centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level).

adapt_import

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [probability_refinement](#)
- [adapt_import](#)

Importance sampling option

Specification

Alias: none

Argument(s): none

Description

`adapt_import` centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level). This continues iteratively until the failure probability estimate converges.

mm_adapt_import

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [probability_refinement](#)
- [mm_adapt_import](#)

Sampling option

Specification

Alias: none

Argument(s): none

Description

`mm_adapt_import` starts with all of the samples located in the failure region to build a multimodal sampling density. First, it uses a small number of samples around each of the initial samples in the failure region. Note that these samples are allocated to the different points based on their relative probabilities of occurrence: more probable points get more samples. This early part of the approach is done to search for "representative" points. Once these are located, the multimodal sampling density is set and then `mm_adapt_import` proceeds similarly to `adapt_import` (sample until convergence).

refinement_samples

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [probability_refinement](#)
- [refinement_samples](#)

Number of samples used to refine a probability estimate or sampling design.

Specification

Alias: none

Argument(s): INTEGERLIST

Description

Probability estimate: Specify the (scalar) number of samples used to improve a probability estimate. If using uni-modal sampling all samples are assigned to the sampling center. If using multi-modal sampling the samples are split between multiple samples according to some internally computed weights.

Sampling design: Specify one or a sequence of refinement samples to augment the `initial_samples` in a sampling design.

final_moments

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [final_moments](#)

Output moments of the specified type and include them within the set of final statistics.

Specification

Alias: none

Argument(s): none

Default: standard

Child Keywords:

	Required/ Optional Required (<i>Choose One</i>)	Description of Group Objective Formulation (Group 1)	Dakota Keyword	Dakota Keyword Description
			none	Omit moments from the set of final statistics.
			standard	Output standardized moments and include them within the set of final statistics.
			central	Output central moments and include them within the set of final statistics.

Description

When performing a nested study that may employ moment statistics on the inner loop, it can be desirable to control the type of these moments. The `final_moments` specification supports options of `none`, `standard` (default), or `central`, corresponding to omission of moments, standardized moments (mean, standard deviation, skewness, and excess kurtosis), or central moments (mean, variance, 3rd central, and 4th central).

The presence or omission of moment results in the final statistics influences the outer level mappings in the case of a nested study. For example, `final_moments none` can allow for a more compact specification of primary and/or secondary response mappings.

Examples

The following method specification overrides the default to print `central` moments and include them in the set of final statistics.

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments central
```

Overriding the default to `none` as follows:

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments none
```

allows associated nested model mappings to be simplified from:

```
model
  nested
    sub_method_pointer = 'UQ'
    primary_response_mapping = 0. 0. 1. 0. 0. 1. 0. 0. 0.
    secondary_response_mapping = 0. 0. 0. 0. 0. 0. 0. 0. 1.
```

to a more compact version focused only on the response level mappings (two leading zeros per response function for moment mappings have been removed):

```
model
  nested
    sub_method_pointer = 'UQ'
    primary_response_mapping = 1. 1. 0.
    secondary_response_mapping = 0. 0. 1.
```

none

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [final_moments](#)
- [none](#)

Omit moments from the set of final statistics.

Specification

Alias: none

Argument(s): none

Description

The omission of moment results from the final statistics can allow for a more compact definition of primary and/or secondary response mappings within a nested model specification.

Examples

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments none
```

standard

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [final_moments](#)
- [standard](#)

Output standardized moments and include them within the set of final statistics.

Specification

Alias: none

Argument(s): none

Description

Output standardized moments (mean, standard deviation, skewness, and excess kurtosis) and include the first two within the set of final statistics to be used at a higher level (e.g., optimization under uncertainty, mixed aleatory-epistemic UQ). This inclusion of moment results affects the primary and/or secondary response mappings in a nested model specification.

Examples

The following method specification overrides the default to print `central` moments and include them in the set of final statistics.

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments standard
```

central

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [final_moments](#)
- [central](#)

Output central moments and include them within the set of final statistics.

Specification

Alias: none

Argument(s): none

Description

Output central moments (mean, variance, 3rd central, and 4th central) and include the first two within the set of final statistics to be used at a higher level (e.g., optimization under uncertainty, mixed aleatory-epistemic UQ). This inclusion of moment results affects the primary and/or secondary response mappings in a nested model specification.

Examples

The following method specification overrides the default to print `central` moments and include them in the set of final statistics.

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments central
```

response_levels

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [response_levels](#)

Values at which to estimate desired statistics for each response

Specification

Alias: none

Argument(s): REALLIST

Default: No CDF/CCDF probabilities/reliabilities to compute

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			num_response_ levels	Number of values at which to estimate desired statistics for each response
	Optional		compute	Selection of statistics to compute at each response level

Description

The `response_levels` specification provides the target response values for which to compute probabilities, reliabilities, or generalized reliabilities (forward mapping).

Default Behavior

If `response_levels` are not specified, no statistics will be computed. If they are, probabilities will be computed by default.

Expected Outputs

If `response_levels` are specified, Dakota will create two tables in the standard output: a Probability Density function (PDF) histogram and a Cumulative Distribution Function (CDF) table. The PDF histogram has

the lower and upper endpoints of each bin and the corresponding density of that bin. Note that the PDF histogram has bins defined by the `probability_levels` and/or `response_levels` in the Dakota input file. If there are not very many levels, the histogram will be coarse. Dakota does not do anything to optimize the bin size or spacing. The CDF table has the list of response levels and the corresponding probability that the response value is less than or equal to each response level threshold.

Usage Tips

The `num_response_levels` is used to specify which arguments of the `response_level` correspond to which response.

Examples

For example, specifying a `response_level` of 52.3 followed with `compute probabilities` will result in the calculation of the probability that the response value is less than or equal to 52.3, given the uncertain distributions on the inputs.

For an example with multiple responses, the following specification

```
response_levels = 1. 2. .1 .2 .3 .4 10. 20. 30.
num_response_levels = 2 4 3
```

would assign the first two response levels (1., 2.) to response function 1, the next four response levels (.1, .2, .3, .4) to response function 2, and the final three response levels (10., 20., 30.) to response function 3. If the `num_response_levels` key were omitted from this example, then the response levels would be evenly distributed among the response functions (three levels each in this case).

The Dakota input file below specifies a sampling method with response levels of interest.

```
method,
  sampling,
  samples = 100 seed = 1
  complementary distribution
  response_levels = 3.6e+11 4.0e+11 4.4e+11
                   6.0e+04 6.5e+04 7.0e+04
                   3.5e+05 4.0e+05 4.5e+05

variables,
  normal_uncertain = 2
  means            = 248.89, 593.33
  std_deviations  = 12.4, 29.7
  descriptors      = 'TF1n' 'TF2n'
  uniform_uncertain = 2
  lower_bounds    = 199.3, 474.63
  upper_bounds    = 298.5, 712.
  descriptors      = 'TF1u' 'TF2u'
  weibull_uncertain = 2
  alphas          = 12., 30.
  betas           = 250., 590.
  descriptors      = 'TF1w' 'TF2w'
  histogram_bin_uncertain = 2
  num_pairs       = 3 4
  abscissas       = 5 8 10 .1 .2 .3 .4
  counts          = 17 21 0 12 24 12 0
  descriptors      = 'TF1h' 'TF2h'
  histogram_point_uncertain
  real = 1
  num_pairs       = 2
  abscissas       = 3 4
  counts          = 1 1
  descriptors      = 'TF3h'
```

```

interface,
  system_async_evaluation_concurrency = 5
  analysis_driver = 'text_book'

responses,
  response_functions = 3
  no_gradients
  no_hessians

```

Given the above Dakota input file, the following excerpt from the output shows the PDF and CCDF generated. Note that the bounds on the bins of the PDF are the response values specified in the input file. The probability levels corresponding to those response values are shown in the CCDF.

Probability Density Function (PDF) histograms for each response function:

PDF for response_fn_1:

3.5000000000e+05	5.2000000000e-01		
4.0000000000e+05	9.0000000000e-02		
4.5000000000e+05	0.0000000000e+00		

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

A forward mapping involves computing the belief and plausibility probability level for a specified response level.

num_response_levels

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [response_levels](#)
- [num_response_levels](#)

Number of values at which to estimate desired statistics for each response

Specification

Alias: none

Argument(s): INTEGERLIST

Default: response_levels evenly distributed among response functions

Description

The `num_response_levels` keyword allows the user to specify the number of response values, for each response, at which estimated statistics are of interest. Statistics that can be computed are probabilities and reliabilities, both according to either a cumulative distribution function or a complementary cumulative distribution function.

Default Behavior

If `num_response_levels` is not specified, the `response_levels` will be evenly distributed among the responses.

Expected Outputs

The specific output will be determined by the type of statistics that are specified. In a general sense, the output will be a list of response level-statistic pairs that show the estimated value of the desired statistic for each response level specified.

Examples

```
method
  sampling
    samples = 100
    seed = 34785
    num_response_levels = 1 1 1
    response_levels = 0.5 0.5 0.5
```

compute

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [response_levels](#)
- [compute](#)

Selection of statistics to compute at each response level

Specification

Alias: none

Argument(s): none

Default: probabilities

Child Keywords:

	Required/- Optional <i>Required(Choose One)</i>	Description of Group Statistics to Compute (Group 1)	Dakota Keyword probabilities	Dakota Keyword Description Computes probabilities associated with response levels
			reliabilities	Computes reliabilities associated with response levels
			gen_reliabilities	Computes generalized reliabilities associated with response levels
	Optional		system	Compute system reliability (series or parallel)

Description

The `compute` keyword is used to select which forward stastical mapping is calculated at each response level.

Default Behavior

If `response_levels` is not specified, no statistics are computed. If `response_levels` is specified but `compute` is not, probabilities will be computed by default. If both `response_levels` and `compute` are specified, then on of the following must be specified: `probabilities`, `reliabilities`, or `gen_reliabilities`.

Expected Output

The type of statistics specified by `compute` will be reported for each response level.

Usage Tips

CDF/CCDF probabilities are calculated for specified response levels using a simple binning approach.

CDF/CCDF reliabilities are calculated for specified response levels by computing the number of sample standard deviations separating the sample mean from the response level.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                    6.0e+04 6.5e+04 7.0e+04
                    3.5e+05 4.0e+05 4.5e+05
    compute reliabilities
```

probabilities

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [response_levels](#)
- [compute](#)
- [probabilities](#)

Computes probabilities associated with response levels

Specification

Alias: none

Argument(s): none

Description

The `probabilities` keyword directs Dakota to compute the probability that the model response will be below (cumulative) or above (complementary cumulative) a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the probabilities are computed by default. To explicitly specify it in the Dakota input file, though, the `probabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-probability pairs that give the probability that the model response will be below or above the corresponding response level, depending on the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                    6.0e+04 6.5e+04 7.0e+04
                    3.5e+05 4.0e+05 4.5e+05
    compute probabilities
```

reliabilities

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [response_levels](#)
- [compute](#)
- [reliabilities](#)

Computes reliabilities associated with response levels

Specification

Alias: none

Argument(s): none

Description

The `reliabilities` keyword directs Dakota to compute reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the reliabilities are not computed by default. To change this behavior, the `reliabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-reliability pairs according to the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                    6.0e+04 6.5e+04 7.0e+04
                    3.5e+05 4.0e+05 4.5e+05
    compute reliabilities
```

gen_reliabilities

- [method](#)
- [multifidelity_polynomial_chaos](#)
- [response_levels](#)
- [compute](#)
- [gen_reliabilities](#)

Computes generalized reliabilities associated with response levels

Specification

Alias: none

Argument(s): none

Description

The `gen_reliabilities` keyword directs Dakota to compute generalized reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the generalized reliabilities are not computed by default. To change this behavior, the `gen_reliabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-generalized reliability pairs according to the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                    6.0e+04 6.5e+04 7.0e+04
                    3.5e+05 4.0e+05 4.5e+05
    compute gen_reliabilities
```

system

- [Keywords Area](#)

- [system](#)

Compute system reliability (series or parallel)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	System Reliability Mode (Group 1)	series	Aggregate response statistics assuming a series system
			parallel	Aggregate response statistics assuming a parallel system

Description

With the system probability/reliability option, statistics for specified `response_levels` are calculated and reported assuming the response functions combine either in series or parallel to produce a total system response.

For a series system, the system fails when any one component (response) fails. The probability of failure is the complement of the product of the individual response success probabilities.

For a parallel system, the system fails only when all components (responses) fail. The probability of failure is the product of the individual response failure probabilities.

series

- [Keywords Area](#)
- [method](#)

probability_levels

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [probability_levels](#)

Specify probability levels at which to estimate the corresponding response value

Specification

Alias: none

Argument(s): REALLIST

Default: No CDF/CCDF response levels to compute

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			num_probability_levels	Specify which probability_levels correspond to which response

Description

Response levels are calculated for specified CDF/CCDF probabilities by indexing into a sorted samples array (the response levels computed are not interpolated and will correspond to one of the sampled values).

Expected Output

If `probability_levels` are specified, Dakota will create two tables in the standard output: a Probability Density function (PDF) histogram and a Cumulative Distribution Function (CDF) table. The PDF histogram has the lower and upper endpoints of each bin and the corresponding density of that bin. Note that the PDF histogram has bins defined by the `probability_levels` and/or `response_levels` in the Dakota input file. If there are not very many levels, the histogram will be coarse. Dakota does not do anything to optimize the bin size or spacing. The CDF table has the list of response levels and the corresponding probability that the response value is less than or equal to each response level threshold.

Examples

The Dakota input file below specifies a sampling method with probability levels of interest.

```
method,
  sampling,
  samples = 100 seed = 1
  complementary distribution
  probability_levels = 1. .66 .33 0.
                    1. .8 .5 0.
                    1. .3 .2 0.

variables,
  normal_uncertain = 2
  means            = 248.89, 593.33

4.4111498127e+05	0.0000000000e+00		

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).

distribution

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [distribution](#)

Selection of cumulative or complementary cumulative functions

Specification

Alias: none

Argument(s): none

Default: cumulative (CDF)

Child Keywords:

	Required/ Optional Required(<i>Choose One</i>)	Description of Group Distribution Type (CDF/CCDF) (Group 1)	Dakota Keyword	Dakota Keyword Description
			cumulative	Computes statistics according to cumulative functions
			complementary	Computes statistics according to complementary cumulative functions

Description

The `distribution` keyword allows the user to select between a cumulative distribution/belief/plausibility function and a complementary cumulative distribution/belief/plausibility function. This choice affects how probabilities and reliability indices are reported.

Default Behavior

If the `distribution` keyword is present, it must be accompanied by either `cumulative` or `complementary`. Otherwise, a cumulative distribution will be used by default.

Expected Outputs

Output will be a set of model response-probability pairs determined according to the choice of distribution. The choice of distribution also defines the sign of the reliability or generalized reliability indices.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

cumulative

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [distribution](#)
- [cumulative](#)

Computes statistics according to cumulative functions

Specification

Alias: none

Argument(s): none

Description

Statistics on model responses will be computed according to a cumulative distribution/belief/plausibility function.

Default Behavior

By default, a cumulative distribution/belief/plausibility function will be used. To explicitly specify it in the Dakota input file, however, the `cumulative` keyword must be appear in conjunction with the `distribution` keyword.

Expected Outputs

Output will be a set of model response-probability pairs determined according to a cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls below given response thresholds.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

complementary

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [distribution](#)
- [complementary](#)

Computes statistics according to complementary cumulative functions

Specification

Alias: none

Argument(s): none

Description

Statistics on model responses will be computed according to a complementary cumulative distribution/belief/plausibility function.

Default Behavior

By default, a complementary cumulative distribution/belief/plausibility function will not be used. To change that behavior, the `complementary` keyword must appear in conjunction with the `distribution` keyword.

Expected Outputs

Output will be a set of model response-probability pairs determined according to a complementary cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls above given response thresholds.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    distribution complementary
```

`variance_based_decomp`

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [variance_based_decomp](#)

Activates global sensitivity analysis based on decomposition of response variance into main, interaction, and total effects

Specification

Alias: none

Argument(s): none

Default: no variance-based decomposition

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		<code>interaction_order</code>	Specify the maximum number of variables allowed in an interaction when reporting <i>interaction metrics</i>
	Optional		<code>drop_tolerance</code>	Suppresses output of sensitivity indices with values lower than this tolerance

Description

Dakota can calculate sensitivity indices through variance-based decomposition using the keyword `variance_based_decomp`. This approach decomposes main, interaction, and total effects in order to identify the most important variables and combinations of variables in contributing to the variance of output quantities of interest.

Default Behavior

Because of processing overhead and output volume, `variance_based_decomp` is inactive by default, unless required for dimension-adaptive refinement using Sobol' indices.

Expected Outputs

When `variance_based_decomp` is specified, sensitivity indices for main effects, total effects, and any interaction effects will be reported. Each of these effects represents the percent contribution to the variance in the model response, where main effects include the aggregated set of *univariate* terms for each individual variable, interaction effects represent the set of *mixed* terms (the complement of the univariate set), and total effects represent the *complete* set of terms (univariate and mixed) that contain each individual variable. The aggregated set of main and interaction sensitivity indices will sum to one, whereas the sum of total effects sensitivity indices will be greater than one due to redundant counting of mixed terms.

Usage Tips

An important consideration is that the number of possible interaction terms grows exponentially with dimension and expansion order. To mitigate this, both in terms of compute time and output volume, possible interaction effects are suppressed whenever no contributions are present due to the particular form of an expansion. In addition, the `interaction_order` and `drop_tolerance` controls can further limit the computational and output requirements.

Examples

```
method,
  polynomial_chaos # or stoch_collocation
  sparse_grid_level = 3
  variance_based_decomp interaction_order = 2
```

Theory

In this context, we take sensitivity analysis to be global, not local as when calculating derivatives of output variables with respect to input variables. Our definition is similar to that of [75]: "The study of how uncertainty in the output of a model can be apportioned to different sources of uncertainty in the model input."

Variance based decomposition is a way of using sets of samples to understand how the variance of the output behaves, with respect to each input variable. A larger value of the sensitivity index, S_i , means that the uncertainty in the input variable i has a larger effect on the variance of the output. More details on the calculations and interpretation of the sensitivity indices can be found in[89].

interaction_order

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [variance_based_decomp](#)
- [interaction_order](#)

Specify the maximum number of variables allowed in an interaction when reporting interaction metrics.

Specification

Alias: none

Argument(s): INTEGER

Default: Unrestricted (VBD includes all interaction orders present in the expansion)

Description

The interaction_order option has been added to allow suppression of higher-order interactions, since the output volume (and memory and compute consumption) of these results could be extensive for high dimensional problems (note: the previous univariate_effects specification is equivalent to interaction_order = 1 in the current specification). Similar to suppression of interactions is the covariance control, which can be selected to be diagonal_covariance or full_covariance, with the former supporting suppression of the off-diagonal covariance terms (to again save compute and memory resources and reduce output volume)

drop_tolerance

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [variance_based_decomp](#)
- [drop_tolerance](#)

Suppresses output of sensitivity indices with values lower than this tolerance

Specification

Alias: none

Argument(s): REAL

Default: All VBD indices displayed

Description

The `drop_tolerance` keyword allows the user to specify a value below which sensitivity indices generated by `variance_based_decomp` are not displayed.

Default Behavior

By default, all sensitivity indices generated by `variance_based_decomp` are displayed.

Usage Tips

For `polynomial_chaos`, which outputs main, interaction, and total effects by default, the `univariate_effects` may be a more appropriate option. It allows suppression of the interaction effects since the output volume of these results can be prohibitive for high dimensional problems. Similar to suppression of these interactions is the covariance control, which can be selected to be `diagonal_covariance` or `full_covariance`, with the former supporting suppression of the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

Examples

```
method,
  sampling
  sample_type lhs
  samples = 100
  variance_based_decomp
  drop_tolerance = 0.001
```

diagonal_covariance

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [diagonal_covariance](#)

Display only the diagonal terms of the covariance matrix

Specification

Alias: none

Argument(s): none

Default: `diagonal_covariance` for response vector > 10; else `full_covariance`

Description

With a large number of responses, the covariance matrix can be very large. `diagonal_covariance` is used to suppress the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

full_covariance

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)

- [full_covariance](#)

Display the full covariance matrix

Specification

Alias: none

Argument(s): none

Description

With a large number of responses, the covariance matrix can be very large. `full_covariance` is used to force Dakota to output the full covariance matrix.

convergence_tolerance

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

import_approx_points_file

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [import_approx_points_file](#)

Filename for points at which to evaluate the PCE/SC surrogate

Specification

Alias: none

Argument(s): STRING

Default: no point import from a file

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional(<i>Choose One</i>)	Tabular Format (Group 1)	custom_annotated	Selects custom-annotated tabular file format
			annotated	Selects annotated tabular file format
			freeform	Selects freeform file format
	Optional		active_only	Import only active variables from tabular data file

Description

Default Behavior No import of points at which to evaluate the surrogate.

Expected Output The PCE/SC surrogate model will be evaluated at the list of points (input variable values) provided in the file and results tabulated and/or statistics computed at them, depending on the method context.

Examples

```
method
  polynomial_chaos
    expansion_order = 4
  import_approx_points_file = 'import.mcmc_annot.dat'
  annotated
```

custom_annotated

- [multifidelity_polynomial_chaos](#)
- [import_approx_points_file](#)
- [custom_annotated](#)

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			header	Enable header row in custom-annotated tabular file
	Optional		eval_id	Enable evaluation ID column in custom-annotated tabular file

	Optional	interface_id	Enable interface ID column in custom-annotated tabular file
--	-----------------	------------------------------	---

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, `eval_id` column, and `interface_id` column appear in the tabular file, thus bridging `freeform` and (fully) annotated.

Default Behavior

The `annotated` format is the default for tabular export/import. To control which header row and columns are in the input/output, specify `custom_annotated`, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and `eval_id` (no `interface_id`), and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id      x1          x2          obj_fn  nln_ineq_con_1  nln_ineq_con_2
1              0.9          1.1          0.0002          0.26          0.76
2              0.90009        1.1 0.0001996404857  0.2601620081  0.759955
3              0.89991        1.1 0.0002003604863  0.2598380081  0.760045
...
```

- [annotated](#)

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The `annotated` keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include `interface_id`, specify `custom_annotated` header `eval_id`
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export an annotated top-level tabular data file containing a header row, leading `eval_id` and `interface_id` columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated
```

Resulting tabular file:

```
%eval_id interface          x1          x2          obj_fn nln_ineq_con_1 nln_ineq_con_2
1          NO_ID            0.9          1.1          0.0002          0.26          0.76

```

freeform

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [import_approx_points_file](#)
- [freeform](#)

Selects freeform file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The `annotated` format is the default for tabular export/import. To change this behavior, specify `freeform` in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to `annotated` format, though `freeform` remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- In `freeform`, the `num_rows` x `num_cols` total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

```
      0.9          1.1          0.0002          0.26          0.76
0.90009        1.1 0.0001996404857  0.2601620081  0.759955
0.89991        1.1 0.0002003604863  0.2598380081  0.760045
...
```

active_only

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [import_approx_points_file](#)
- [active_only](#)

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

export_approx_points_file

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [export_approx_points_file](#)

Output file for evaluations of a surrogate model

Specification

Alias: export_points_file

Argument(s): STRING

Default: no point export to a file

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional(<i>Choose One</i>)	Tabular Format (Group 1)	custom_annotated	Selects custom-annotated tabular file format
			annotated	Selects annotated tabular file format
			freeform	Selects freeform file format

Description

The `export_approx_points_file` keyword allows the user to specify a file in which the points (input variable values) at which the surrogate model is evaluated and corresponding response values computed by the surrogate model will be written. The response values are the surrogate's predicted approximation to the truth model responses at those points.

Usage Tips

Dakota exports tabular data in one of three formats:

- annotated (default)
- custom_annotated
- freeform

custom_annotated

- [Keywords Area](#)

model_pointer

- [Keywords Area](#)
- [method](#)
- [multifidelity_polynomial_chaos](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'

			full_covariance	Display the full covariance matrix
	Optional		convergence_-tolerance	Stopping criterion based on objective function or statistics convergence
	Optional		import_approx_-points_file	Filename for points at which to evaluate the PCE/SC surrogate
	Optional		export_approx_-points_file	Output file for evaluations of a surrogate model
	Optional		model_pointer	Identifier for model block to be used by a method

Description

As described in [polynomial_chaos](#), the polynomial chaos expansion (PCE) is a general framework for the approximate representation of random response functions in terms of series expansions in standardized random variables:

$$R = \sum_{i=0}^P \alpha_i \Psi_i(\xi)$$

where α_i is a deterministic coefficient, Ψ_i is a multidimensional orthogonal polynomial and ξ is a vector of standardized random variables.

In the multilevel and multifidelity cases, we decompose this expansion into several constituent expansions, one per model form or solution control level. In a bi-fidelity case with low-fidelity (LF) and high-fidelity (HF) models, we have:

$$R = \sum_{i=0}^{P^{LF}} \alpha_i^{LF} \Psi_i(\xi) + \sum_{i=0}^{P^{HF}} \delta_i \Psi_i(\xi)$$

where δ_i is a coefficient for the discrepancy expansion.

For the case of regression-based PCE (least squares, compressed sensing, or orthogonal least interpolation), an optimal sample allocation procedure can be applied for the resolution of each level within a multilevel sampling procedure as in [multilevel_sampling](#). The core difference is that a Monte Carlo estimator of the statistics is replaced with a PCE-based estimator of the statistics, requiring approximation of the variance of these estimators.

Initial prototypes for multilevel PCE can be explored using `dakota/share/dakota/test/dakota_uq_diffusion_mlpce.in`, and will be stabilized in future releases.

Additional Resources

Dakota provides access to multilevel PCE methods through the `NonDMultilevelPolynomialChaos` class. Refer to the Stochastic Expansion Methods chapter of the Theory Manual[6] for additional information on the Multilevel PCE algorithm.

Examples

```
method,
  multilevel_polynomial_chaos

Argument(s): INTEGERLIST

Description

The pilot sample provides initial estimates of variance and/or correlation within the first iteration of a multilevel and/or control variate approach.

Default Behavior

100 samples per model fidelity and/or discretization level.

Usage Tips

The number of specified values can be none (default values used for all fidelities and levels), one (all fidelities and levels use the same specified value), the number of discretization levels for every model (each model uses the same discretization level profile), or the aggregate number of discretization levels for all models (samples for each discretization level are distinct for each model).

Sample allocation approach for multilevel polynomial chaos

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Required (<i>Choose One</i>)	Description of Group Multilevel Sample Allocation Control (Group 1)	Dakota Keyword estimator_variance	Dakota Keyword Description Variance of mean estimator within multilevel polynomial chaos
			rip_sampling	Sample allocation based on restricted isometry property (RIP) within multilevel polynomial chaos

			greedy	Sample allocation based on greedy refinement within multi-level/multifidelity polynomial chaos
--	--	--	------------------------	--

Description

Multilevel polynomial chaos requires a sample allocation strategy. Three options are currently available:

- greedy refinement (sparse grids, tensor grids, regression)
- allocation based on assuming a convergence rate for the estimator variance (for regression only)
- restricted isometry property (RIP) (for compressed sensing only)

The greedy approach is generally preferred over assuming a convergence rate for the estimator variance or allocating samples based on the restricted isometry property (RIP) for compressed sensing.

estimator_variance

- [method](#)
- [multilevel_polynomial_chaos](#)
- [allocation_control](#)
- [estimator_variance](#)

Variance of mean estimator within multilevel polynomial chaos

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		estimator_rate	Rate of convergence of mean estimator within multilevel polynomial chaos

Description

Multilevel Monte Carlo performs optimal resource allocation based on a known estimator variance for the mean statistic:

$$\text{Var}[\hat{Q}] = \frac{\sigma_Q^2}{N}$$

Replacing the simple ensemble average estimator in Monte Carlo with a polynomial chaos estimator results in a different and unknown relationship between the estimator variance and the number of samples. In one approach to multilevel PCE, we can employ a parameterized estimator variance:

$$\text{Var}[\hat{Q}] = \frac{\sigma_Q^2}{\gamma N^\kappa}$$

for free parameters γ and κ , with default values that may be overridden as part of this specification block.

This approach is supported for regression-based PCE approaches (over-determined least squares, under-determined compressed sensing, or orthogonal least interpolation).

In practice, it can be challenging to estimate a smooth convergence rate for estimator variance in the presence of abrupt transitions in the quality of sparse recoveries. As a result, sample allocation by greedy refinement is generally preferred.

Examples

This example starts with sparse recovery for a second-order candidate expansion at each level. As the number of samples is adapted for each level, as dictated by the convergence of the estimator variance, the candidate expansion order is incremented as needed in order to synchronize with the specified collocation ratio.

```
method,
  model_pointer = 'HIERARCH'
  multilevel_polynomial_chaos
  orthogonal_matching_pursuit
  expansion_order_sequence = 2
  pilot_samples = 10
  collocation_ratio = .9
  allocation_control
    estimator_variance estimator_rate = 2.5
  seed = 1237
  convergence_tolerance = .01
```

estimator_rate

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [allocation_control](#)
- [estimator_variance](#)
- [estimator_rate](#)

Rate of convergence of mean estimator within multilevel polynomial chaos

Specification

Alias: none

Argument(s): REAL

Default: 2

Description

Multilevel Monte Carlo performs optimal resource allocation based on a known estimator variance for the mean statistic:

$$\text{Var}[\hat{Q}] = \frac{\sigma_Q^2}{N}$$

Replacing the simple ensemble average estimator in Monte Carlo with a polynomial chaos estimator results in a different and unknown relationship between the estimator variance and the number of samples. In one approach to multilevel PCE, we can employ a parameterized estimator variance:

$$\text{Var}[\hat{Q}] = \frac{\sigma_Q^2}{\gamma N^\kappa}$$

for free parameters γ and κ .

The default values are $\gamma = 1$ and $\kappa = 2$ (adopts a more aggressive sample profile by assuming a faster convergence rate than Monte Carlo). This advanced specification option allows to user to specify κ , overriding the default.

rip_sampling

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [allocation_control](#)
- [rip_sampling](#)

Sample allocation based on restricted isometry property (RIP) within multilevel polynomial chaos

Specification

Alias: none

Argument(s): none

Description

Multilevel polynomial chaos with compressed sensing may allocate the number of samples per level based on the restricted isometry property (RIP), applied to recovery at level l :

$$N_l \geq s_l \log^3(s_l) L_l \log(C_l)$$

for sparsity s , cardinality C , and mutual coherence L . The adaptive algorithm starts from a pilot sample, shapes the profile based on observed sparsity, and iterates until convergence. In practice, RIP sampling levels are

quite conservative, and a collocation ratio constraint ($N_l \leq rC_l$, where r defaults to 2) must be enforced on the profile.

The algorithm relies on observed sparsity, it is appropriate for use with regularized solvers for compressed sensing. It employs orthogonal matching pursuit (OMP) by default and automatically activates cross-validation in order to choose the best noise parameter value for the recovery.

This capability is **experimental**. Sample allocation by greedy refinement is generally preferred.

Examples

This example starts with sparse recovery for a second-order candidate expansion at each level. As the number of samples is adapted for each level, as dictated by the number of sparse coefficient sets recovered for each level, the candidate expansion order is incremented as needed in order to synchronize with the specified collocation ratio.

```
method,
  model_pointer = 'HIERARCH'
  multilevel_polynomial_chaos
    orthogonal_matching_pursuit
    expansion_order_sequence = 2
    pilot_samples = 10
    collocation_ratio = .9
    allocation_control rip_sampling
    seed = 1237
    convergence_tolerance = .01
```

greedy

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [allocation_control](#)
- [greedy](#)

Sample allocation based on greedy refinement within multilevel/multifidelity polynomial chaos

Specification

Alias: none

Argument(s): none

Description

Multilevel and multifidelity polynomial chaos both support greedy refinement strategies, spanning regression and projection approaches for computing expansion coefficients. The key idea is that each level of the model hierarchy being approximated can generate one or more candidates for refinement. These candidates are competed against each other within a unified competition, and the candidate that induces the largest change in the statistical QoI (response covariance by default, or results of any $z/p/\beta/\beta^*$ level mappings when specified), normalized by relative cost of evaluating the candidate, is selected and then used to generate additional candidates for consideration at its model level.

Examples

The following example of greedy multilevel regression starts from a zeroth-order reference expansion (a constant) for each level, and generates candidate refinements for each level that are competed in a greedy competition. The number of new samples for the incremented candidate expansion order is determined from the collocation ratio. In this case, the number of candidates for each level is limited to one uniform refinement of the current expansion order.

```
method,
  model_pointer = 'HIERARCH'
  multilevel_polynomial_chaos # or multifidelity
  allocation_control greedy
  p_refinement uniform
  expansion_order_sequence = 0
  collocation_ratio = .9 seed = 160415
  orthogonal_matching_pursuit
  convergence_tolerance 1.e-2
```

The next example employs generalized sparse grids within a greedy multilevel competition. Each modeling level starts from a level 0 reference grid (a single point) and generates multiple admissible index set candidates. The full set of candidates across all model levels is competed within a unified greedy competition, where the greedy selection metric is the induced change in the statistical QoI, normalized by the aggregate simulation cost of the index set candidate. In this case, there are multiple candidates for each model level and the number of candidates grows rapidly with random dimension and grid level.

```
method,
  model_pointer = 'HIERARCH'
  multilevel_polynomial_chaos # or multifidelity
  allocation_control greedy
  p_refinement dimension_adaptive generalized
  sparse_grid_level_sequence = 0 unrestricted
  convergence_tolerance 1.e-8
```

discrepancy_emulation

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description

	Required(Choose One)	Discrepancy Emulation Approach (Group 1)	distinct	Distinct formulation for emulation of model discrepancies.
			recursive	Recursive formulation for emulation of model discrepancies.

Description

In many uncertainty quantification approaches, model discrepancies are emulated using, e.g., polynomial chaos, stochastic collocation, or Gaussian process models. Two formulations are available for this emulation:

1. `distinct` emulation (default), in which we directly approximate the difference or ratio between the evaluations of two models or solution levels.
2. `recursive` emulation (experimental option), in which we approximate a difference or ratio among the new model evaluation and the emulator approximation of the previous model.

The latter approach is a form of hierarchical emulation in which we emulate the surplus between the previous emulator and the new modeling level. This approach has a few advantages: (i) it reduces bias by correcting for emulation errors that occur at previous levels, and (ii) it does not require paired model evaluations for each discrepancy level, which reduces cost, allows for disparate sample points, and simplifies data imports.

On the other hand, its primary disadvantage is that the aggregate emulation is only as good as its weakest link, in that a poor emulator recovery can create difficulty in accurately resolving discrepancies that are recursively dependent on it. Thus, the `distinct` approach may tend to be more expensive in exchange for greater robustness.

Examples

```
method,
    multilevel_polynomial_chaos
    expansion_order_sequence = 2
    collocation_ratio = .9
    orthogonal_matching_pursuit
    discrepancy_emulation recursive
```

The (initial) order of a polynomial expansion

Specification

Alias: none

Argument(s): INTEGERLIST

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		<code>dimension_- preference</code>	A set of weights specifying the relative importance of each uncertain variable (dimension)
			<code>basis_type</code>	Specify the type of truncation to be used with a Polynomial Chaos Expansion.
	Required(<i>Choose One</i>)	Group 1	<code>collocation_points_ _sequence</code>	Number of collocation points to estimate PCE coefficients
			<code>collocation_ratio</code>	Set the number of points used to build a PCE via regression to be proportional to the number of terms in the expansion.
			<code>expansion_ samples_sequence</code>	Number of simulation samples to estimate the PCE coefficients
	Optional		<code>import_build_ points_file</code>	File containing points you wish to use to build a surrogate

Description

When the `expansion_order` for a polynomial chaos expansion is specified, the coefficients may be computed by integration based on random samples or by regression using either random or sub-sampled tensor product quadrature points.

Multidimensional integration by Latin hypercube sampling (specified with `expansion_samples`). In this case, the expansion order p cannot be inferred from the numerical integration specification and it is necessary to provide an `expansion_order` to specify p for a total-order expansion.

Linear regression (specified with either `collocation_points` or `collocation_ratio`). A total-order expansion is used and must be specified using `expansion_order` as described in the previous option. To avoid requiring the user to calculate N from n and p , the `collocation_ratio` allows for specification of a constant factor applied to N (e.g., `collocation_ratio = 2`. produces $\text{samples} = 2N$). In addition, the default linear relationship with N can be overridden using a real-valued exponent specified using `ratio_order`. In this case, the number of samples becomes cN^o where c is the `collocation_ratio` and o is the `ratio_order`. The `use_derivatives` flag informs the regression approach to include derivative matching equations (limited to gradients at present) in the least squares solutions, enabling the use of fewer collocation points for a given expansion order and dimension (number of points required becomes $\frac{cN^o}{n+1}$). When admissible, a constrained least squares approach is employed in which response values are first reproduced exactly and error in reproducing response derivatives is minimized. Two collocation grid options are supported: the default is Latin hypercube sampling ("point collocation"), and an alternate approach of "probabilistic collocation" is also available through inclusion of the `tensor_grid` keyword. In this alternate case, the collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

If `collocation_points` or `collocation_ratio` is specified, the PCE coefficients will be determined by regression. If no regression specification is provided, appropriate defaults are defined. Specifically SVD-based least-squares will be used for solving over-determined systems and under-determined systems will be solved using LASSO. For the situation when the number of function values is smaller than the number of terms in a PCE, but the total number of samples including gradient values is greater than the number of terms, the resulting over-determined system will be solved using equality constrained least squares. Technical information on the various methods listed below can be found in the Linear regression section of the Theory Manual. Some of the regression methods (OMP, LASSO, and LARS) are able to produce a set of possible PCE coefficient vectors (see the Linear regression section in the Theory Manual). If cross validation is inactive, then only one solution, consistent with the `noise_tolerance`, will be returned. If cross validation is active, Dakota will choose between possible coefficient vectors found internally by the regression method across the set of expansion orders ($1, \dots, \text{expansion_order}$) and the set of specified noise tolerances and return the one with the lowest cross validation error indicator.

Usage Tips

For most use cases, this keyword will specify a single integer order. In more advanced UQ studies with hierarchical models, the list of integers can apply to different models and/or model levels

dimension_preference

- [l2_penalty](#)

The l_2 penalty used when performing compressed sensing with elastic net.

Specification

Alias: none

Argument(s): REAL

Default: 0. (reverts to standard LASSO formulation)

Description

The l_2 penalty used when performing compressed sensing with elastic net.

cross_validation

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_points_sequence](#)
- [cross_validation](#)

Use cross validation to choose the 'best' polynomial order of a polynomial chaos expansion.

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description

	Optional	noise_only	Restrict the cross validation process to estimating only the best noise tolerance.
--	-----------------	----------------------------	--

Description

Use cross validation to choose the 'best' polynomial degree of a polynomial chaos expansion. 10 fold cross validation is used to estimate the cross validation error of a total-order polynomial expansion for orders 1 through to order. The order chosen is the one that produces the lowest cross validation error. If there are not enough points to perform 10 fold cross validation then one-at-a-time cross validation will be performed.

noise_only

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_points_sequence](#)
- [cross_validation](#)
- [noise_only](#)

Restrict the cross validation process to estimating only the best noise tolerance.

Specification

Alias: none

Argument(s): none

Default: false

Description

By default, cross validation estimates both the best noise tolerance and the best candidate basis order. For reasons of reducing computational cost by reducing the number of candidate solves, the user may wish to restrict this process to estimating only the best noise tolerance.

Generally speaking, computing the best noise tolerance through cross validation mitigates issues with overfitting the data. Computing the best candidate basis order can also mitigate overfitting, while also controlling levels of mutual coherence resulting from high-order Vandermonde-like matrix systems.

ratio_order

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_points_sequence](#)
- [ratio_order](#)

Specify a non-linear the relationship between the expansion order of a polynomial chaos expansion and the number of samples that will be used to compute the PCE coefficients.

Specification

Alias: none

Argument(s): REAL

Default: 1.

Description

When using regression type methods (specified with either `collocation_points` or `collocation_ratio`), a total-order expansion can be specified using `expansion_order`. To avoid requiring the user to calculate N from n and p), the `collocation_ratio` allows for specification of a constant factor applied to N (e.g., `collocation_ratio = 2` produces $\text{samples} = 2N$). In addition, the default linear relationship with N can be overridden using a real-valued exponent specified using `ratio_order`. In this case, the number of samples becomes cN^o where c is the `collocation_ratio` and o is the `ratio_order`.

use_derivatives

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_points_sequence](#)
- [use_derivatives](#)

Use derivative data to construct surrogate models

Specification

Alias: none

Argument(s): none

Default: use function values only

Description

The `use_derivatives` flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, its use with Surfpack Gaussian process is not recommended.

tensor_grid

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_points_sequence](#)
- [tensor_grid](#)

Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.

Specification

Alias: none

Argument(s): none

Default: regression with LHS sample set (point collocation)

Description

The collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

reuse_points

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_points_sequence](#)
- [reuse_points](#)

This describes the behavior of reuse of points in constructing polynomial chaos expansion models.

Specification

Alias: reuse_samples

Argument(s): none

Default: no sample reuse in coefficient estimation

Description

The `reuse_points` option controls the reuse behavior of points for various types of polynomial chaos expansions, including: `collocation_points`, `collocation_ratio`, `expansion_samples`, or `orthogonal_least_interpolation`. If any of these approaches are specified to create a set of points for the polynomial chaos expansion, one can specify `reuse_points` so that any points that have been previously generated (for example, from the `import_points` file) can be reused.

max_solver_iterations

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_points_sequence](#)
- [max_solver_iterations](#)

Maximum iterations in determining polynomial coefficients

Specification

Alias: none

Argument(s): INTEGER

Default: 100

Description

When using an iterative polynomial coefficient estimation approach, e.g., cross-validation-based solvers, limits the maximum iterations in the coefficient solver.

collocation_ratio

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_ratio](#)

Set the number of points used to build a PCE via regression to be proportional to the number of terms in the expansion.

Specification**Alias:** none**Argument(s):** REAL**Child Keywords:**

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional (<i>Choose One</i>)	Regression Algorithm (Group 1)	least_squares	Compute the coefficients of a polynomial expansion using least squares
			orthogonal-matching-pursuit	Compute the coefficients of a polynomial expansion using orthogonal matching pursuit (OMP)

			basis_pursuit-denoising	Compute the coefficients of a polynomial expansion by solving the Basis Pursuit Denoising ℓ_1 -minimization problem using second order cone optimization.

		least_angle_-regression	Compute the coefficients of a polynomial expansion by using the greedy least angle regression (LAR) method.
		least_absolute_-shrinkage	Compute the coefficients of a polynomial expansion by using the LASSO problem.
	Optional	cross_validation	Use cross validation to choose the 'best' polynomial order of a polynomial chaos expansion.
	Optional	ratio_order	Specify a non-linear the relationship between the expansion order of a polynomial chaos expansion and the number of samples that will be used to compute the PCE coefficients.
	Optional	use_derivatives	Use derivative data to construct surrogate models
	Optional	tensor_grid	Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.

	Optional	reuse_points	This describes the behavior of reuse of points in constructing polynomial chaos expansion models. Maximum iterations in determining polynomial coefficients
	Optional	max_solver_ iterations	

Description

Set the number of points used to build a PCE via regression to be proportional to the number of terms in the expansion. To avoid requiring the user to calculate N from n and p, the collocation_ratio allows for specification of a constant factor applied to N (e.g., collocation_ratio = 2. produces samples = 2N). In addition, the default linear relationship with N can be overridden using a real-valued exponent specified using ratio_order. In this case, the number of samples becomes cN^o where c is the collocation_ratio and o is the ratio_order. The use_derivatives flag informs the regression approach to include derivative matching equations (limited to gradients at present) in the least squares solutions, enabling the use of fewer collocation points for a given expansion order and dimension (number of points required becomes $\frac{cN^o}{n+1}$).

least_squares

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_ratio](#)
- [least_squares](#)

Compute the coefficients of a polynomial expansion using least squares

Specification

Alias: none

Argument(s): none

Default: svd

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
--	-----------------------	-------------------------	----------------	-------------------------------

	Optional (Choose One)	LSQ Regression Approach (Group 1)	svd	Calculate the coefficients of a polynomial chaos expansion using the singular value decomposition.
			equality_-constrained	Calculate the coefficients of a polynomial chaos expansion using equality constrained least squares.

Description

Compute the coefficients of a polynomial expansion using least squares. Specifically SVD-based least-squares will be used for solving over-determined systems. For the situation when the number of function values is smaller than the number of terms in a PCE, but the total number of samples including gradient values is greater than the number of terms, the resulting over-determined system will be solved using equality constrained least squares

svd

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_ratio](#)
- [least_squares](#)
- [svd](#)

Calculate the coefficients of a polynomial chaos expansion using the singular value decomposition.

Specification

Alias: none

Argument(s): none

Description

Calculate the coefficients of a polynomial chaos expansion using the singular value decomposition. When the number of model runs exceeds the number of terms in the PCE, the solution returned will be the least-squares solution, otherwise the solution will be the minimum norm solution computed using the pseudo-inverse.

equality_constrained

- [Keywords Area](#)
- [method](#)

- [collocation_ratio](#)
- [least_absolute_shrinkage](#)
- [l2_penalty](#)

The l_2 penalty used when performing compressed sensing with elastic net.

Specification

Alias: none

Argument(s): REAL

Default: 0. (reverts to standard LASSO formulation)

Description

The l_2 penalty used when performing compressed sensing with elastic net.

cross_validation

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_ratio](#)
- [cross_validation](#)

Use cross validation to choose the 'best' polynomial order of a polynomial chaos expansion.

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description

	Optional	noise_only	Restrict the cross validation process to estimating only the best noise tolerance.
--	-----------------	----------------------------	--

Description

Use cross validation to choose the 'best' polynomial degree of a polynomial chaos expansion. 10 fold cross validation is used to estimate the cross validation error of a total-order polynomial expansion for orders 1 through to order. The order chosen is the one that produces the lowest cross validation error. If there are not enough points to perform 10 fold cross validation then one-at-a-time cross validation will be performed.

noise_only

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_ratio](#)
- [cross_validation](#)
- [noise_only](#)

Restrict the cross validation process to estimating only the best noise tolerance.

Specification

Alias: none

Argument(s): none

Default: false

Description

By default, cross validation estimates both the best noise tolerance and the best candidate basis order. For reasons of reducing computational cost by reducing the number of candidate solves, the user may wish to restrict this process to estimating only the best noise tolerance.

Generally speaking, computing the best noise tolerance through cross validation mitigates issues with overfitting the data. Computing the best candidate basis order can also mitigate overfitting, while also controlling levels of mutual coherence resulting from high-order Vandermonde-like matrix systems.

ratio_order

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_ratio](#)
- [ratio_order](#)

Specify a non-linear the relationship between the expansion order of a polynomial chaos expansion and the number of samples that will be used to compute the PCE coefficients.

Specification

Alias: none

Argument(s): REAL

Default: 1.

Description

When using regression type methods (specified with either `collocation_points` or `collocation_ratio`), a total-order expansion can be specified using `expansion_order`. To avoid requiring the user to calculate N from n and p , the `collocation_ratio` allows for specification of a constant factor applied to N (e.g., `collocation_ratio = 2` produces $\text{samples} = 2N$). In addition, the default linear relationship with N can be overridden using a real-valued exponent specified using `ratio_order`. In this case, the number of samples becomes cN^o where c is the `collocation_ratio` and o is the `ratio_order`.

use_derivatives

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_ratio](#)
- [use_derivatives](#)

Use derivative data to construct surrogate models

Specification

Alias: none

Argument(s): none

Default: use function values only

Description

The `use_derivatives` flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, it's use with Surfpack Gaussian process is not recommended.

tensor_grid

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_ratio](#)
- [tensor_grid](#)

Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.

Specification

Alias: none

Argument(s): none

Default: regression with LHS sample set (point collocation)

Description

The collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

reuse_points

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_ratio](#)
- [reuse_points](#)

This describes the behavior of reuse of points in constructing polynomial chaos expansion models.

Specification

Alias: reuse_samples

Argument(s): none

Default: no sample reuse in coefficient estimation

Description

The `reuse_points` option controls the reuse behavior of points for various types of polynomial chaos expansions, including: `collocation_points`, `collocation_ratio`, `expansion_samples`, or `orthogonal_least_interpolation`. If any of these approaches are specified to create a set of points for the polynomial chaos expansion, one can specify `reuse_points` so that any points that have been previously generated (for example, from the `import_points` file) can be reused.

max_solver_iterations

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [collocation_ratio](#)
- [max_solver_iterations](#)

Maximum iterations in determining polynomial coefficients

Specification

Alias: none

Argument(s): INTEGER

Default: 100

Description

When using an iterative polynomial coefficient estimation approach, e.g., cross-validation-based solvers, limits the maximum iterations in the coefficient solver.

expansion_samples_sequence

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [expansion_samples_sequence](#)

Number of simulation samples to estimate the PCE coefficients

Specification

Alias: none

Argument(s): INTEGERLIST

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			reuse_points	This describes the behavior of reuse of points in constructing polynomial chaos expansion models.
	Optional		incremental_lhs	(Deprecated keyword) Augments an existing Latin Hypercube Sampling (LHS) study

Description

In this case, the expansion order p cannot be inferred from the numerical integration specification and it is necessary to provide an `expansion_order` to specify p for a total-order expansion.

Usage Tips

For most use cases, this keyword will specify a single integer number of samples. In more advanced UQ studies with hierarchical models, the list of integers can apply to different models and/or model levels

reuse_points

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [expansion_samples_sequence](#)
- [reuse_points](#)

This describes the behavior of reuse of points in constructing polynomial chaos expansion models.

Specification

Alias: reuse_samples

Argument(s): none

Default: no sample reuse in coefficient estimation

Description

The `reuse_points` option controls the reuse behavior of points for various types of polynomial chaos expansions, including: `collocation_points`, `collocation_ratio`, `expansion_samples`, or `orthogonal_least_interpolation`. If any of these approaches are specified to create a set of points for the polynomial chaos expansion, one can specify `reuse_points` so that any points that have been previously generated (for example, from the `import_points` file) can be reused.

incremental_lhs

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [expansion_samples_sequence](#)
- [incremental_lhs](#)

(Deprecated keyword) Augments an existing Latin Hypercube Sampling (LHS) study

Specification

Alias: none

Argument(s): none

Default: no sample reuse in coefficient estimation

Description

This keyword is deprecated. Instead specify `sample_type lhs` with `refinement_samples`.

An incremental random sampling approach will augment an existing random sampling study with `refinement_samples` to get better estimates of mean, variance, and percentiles. The number of `refinement_samples` in each refinement level must result in twice the number of previous samples.

Typically, this approach is used when you have an initial study with sample size $N1$ and you want to perform an additional $N1$ samples. Ideally, a Dakota restart file containing the initial $N1$ samples, so only $N1$ (instead of $2 \times N1$) potentially expensive function evaluations will be performed.

This process can be extended by repeatedly doubling the `refinement_samples`:

```
method
  sampling
    seed = 1337
    samples = 50
    refinement_samples = 50 100 200 400 800
```

Usage Tips

The incremental approach is useful if it is uncertain how many simulations can be completed within available time.

See the examples below and the [Usage](#) and [Restarting Dakota Studies](#) pages.

Examples

Suppose an initial study is conducted using `sample_type lhs` with `samples = 50`. A follow-on study uses a new input file where `samples = 50`, and `refinement_samples = 50`, resulting in 50 reused samples (from restart) and 50 new random samples. The 50 new samples will be combined with the 50 previous samples to generate a combined sample of size 100 for the analysis.

One way to ensure the restart file is saved is to specify a non-default name, via a command line option:

```
dakota -input LHS_50.in -write_restart LHS_50.rst
```

which uses the input file:

```
# LHS_50.in

environment
  tabular_data
    tabular_data_file = 'LHS_50.dat'

method
  sampling
    seed = 1337
    sample_type lhs
    samples = 50

model
  single

variables
  uniform_uncertain = 2
  descriptors = 'input1' 'input2'
  lower_bounds = -2.0 -2.0
  upper_bounds = 2.0 2.0

interface
  analysis_drivers 'text_book'
  fork

responses
  response_functions = 1
  no_gradients
  no_hessians
```

and the restart file is written to `LHS_50.rst`.

Then an incremental LHS study can be run with:

```
dakota -input LHS_100.in -read_restart LHS_50.rst -write_restart LHS_100.rst
```

where `LHS_100.in` is shown below, and `LHS_50.rst` is the restart file containing the results of the previous LHS study. In the example input files for the initial and incremental studies, the values for `seed` match. This ensures that the initial 50 samples generated in both runs are the same.

```
# LHS_100.in

environment
  tabular_data
    tabular_data_file = 'LHS_100.dat'

method
  sampling
    seed = 1337
    sample_type incremental_lhs
    samples = 50
```

```

    refinement_samples = 50

model
  single

variables
  uniform_uncertain = 2
  descriptors = 'input1' 'input2'
  lower_bounds = -2.0 -2.0
  upper_bounds = 2.0 2.0

interface
  analysis_drivers 'text_book'
  fork

responses
  response_functions = 1
  no_gradients
  no_hessians

```

The user will get 50 new LHS samples which maintain both the correlation and stratification of the original LHS sample. The new samples will be combined with the original samples to generate a combined sample of size 100.

import_build_points_file

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [import_build_points_file](#)

File containing points you wish to use to build a surrogate

Specification

Alias: import_points_file

Argument(s): STRING

Default: no point import from a file

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional (<i>Choose One</i>)	Tabular Format (Group 1)	custom_annotated	Selects custom-annotated tabular file format

		annotated	Selects annotated tabular file format
		freeform	Selects freeform file format
	Optional	active_only	Import only active variables from tabular data file

Description

The `import_build_points_file` allows the user to specify a file that contains a list of points and truth model responses used to construct a surrogate model. These can be used by all methods that (explicitly, e.g. surrogate-based optimization, or implicitly, e.g. efficient global optimization) operate on a surrogate. In particular, these points and responses are used in place of truth model evaluations to construct the initial surrogate. When used to construct surrogate models or emulators these are often called build points or training data.

Default Behavior

By default, methods do not import points from a file.

Usage Tips

Dakota parses input files without regard to whitespace, but the `import_build_points_file` must be in one of three formats:

- `annotated` (default)
- `custom_annotated`
- `freeform`

Examples

```
method
  polynomial_chaos
    expansion_order = 4
    import_build_points_file = 'dakota_uq_rosenbrock_pce_import.annot.pts.dat'
```

custom_annotated

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [import_build_points_file](#)
- [custom_annotated](#)

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			header	Enable header row in custom-annotated tabular file
	Optional		eval_id	Enable evaluation ID column in custom-annotated tabular file
	Optional		interface_id	Enable interface ID column in custom-annotated tabular file

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, `eval_id` column, and `interface_id` column appear in the tabular file, thus bridging `freeform` and (fully) annotated.

Default Behavior

The `annotated` format is the default for tabular export/import. To control which header row and columns are in the input/output, specify `custom_annotated`, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface-id), and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id      x1          x2          obj_fn  nln_ineq_con_1  nln_ineq_con_2
1              0.9          1.1          0.0002          0.26          0.76
2              0.90009      1.1 0.0001996404857  0.2601620081      0.759955
3              0.89991      1.1 0.0002003604863  0.2598380081      0.760045
...
```

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include `interface_id`, specify `custom_annotated` header `eval_id`
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export an annotated top-level tabular data file containing a header row, leading `eval_id` and `interface_id` columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated
```

Resulting tabular file:

```
%eval_id interface          x1          x2          obj_fn nln_ineq_con_1 nln_ineq_con_2
1          NO_ID            0.9          1.1          0.0002          0.26          0.76

- [freeform](#)

Selects freeform file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The `annotated` format is the default for tabular export/import. To change this behavior, specify `freeform` in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- In `freeform`, the `num_rows` x `num_cols` total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

```
      0.9          1.1          0.0002          0.26          0.76
0.90009      1.1 0.0001996404857  0.2601620081  0.759955

```

active_only

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [expansion_order_sequence](#)
- [import_build_points_file](#)
- [active_only](#)

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

orthogonal_least_interpolation

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [orthogonal_least_interpolation](#)

Build a polynomial chaos expansion from simulation samples using orthogonal least interpolation.

Specification

Alias: least_interpolation oli

Argument(s): none

Child Keywords:

	Required/ Optional Required	Description of Group	Dakota Keyword	Dakota Keyword Description
			collocation_points- _sequence	Specify the number of collocation points used to estimate PCE coefficients using orthogonal least interpolation
	Optional		tensor_grid	Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.
	Optional		reuse_points	This describes the behavior of reuse of points in constructing polynomial chaos expansion models.
	Optional		import_build- points_file	File containing points you wish to use to build a surrogate

Description

Build a polynomial chaos expansion from simulation samples using orthogonal least interpolation. Unlike the other regression methods `expansion_order` cannot be set. OLI will produce the lowest degree polynomial that interpolates the data

collocation_points_sequence

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [orthogonal_least_interpolation](#)
- [collocation_points_sequence](#)

Specify the number of collocation points used to estimate PCE coefficients using orthogonal least interpolation

Specification

Alias: none

Argument(s): INTEGERLIST

Description

Specify the number of collocation points used to estimate PCE coefficients using orthogonal least interpolation

tensor_grid

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [orthogonal_least_interpolation](#)
- [tensor_grid](#)

Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.

Specification

Alias: none

Argument(s): INTEGERLIST

Default: regression with LHS sample set (point collocation)

Description

The collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

reuse_points

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [orthogonal_least_interpolation](#)
- [reuse_points](#)

This describes the behavior of reuse of points in constructing polynomial chaos expansion models.

Specification

Alias: reuse_samples

Argument(s): none

Default: no sample reuse in coefficient estimation

Description

The `reuse_points` option controls the reuse behavior of points for various types of polynomial chaos expansions, including: `collocation_points`, `collocation_ratio`, `expansion_samples`, or `orthogonal_least_interpolation`. If any of these approaches are specified to create a set of points for the polynomial chaos expansion, one can specify `reuse_points` so that any points that have been previously generated (for example, from the `import_points` file) can be reused.

import_build_points_file

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [orthogonal_least_interpolation](#)
- [import_build_points_file](#)

File containing points you wish to use to build a surrogate

Specification

Alias: import_points_file

Argument(s): STRING

Default: no point import from a file

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description

	Optional (Choose One)	Tabular Format (Group 1)	custom_annotated	Selects custom-annotated tabular file format
			annotated	Selects annotated tabular file format
			freeform	Selects freeform file format
	Optional		active_only	Import only active variables from tabular data file

Description

The `import_build_points_file` allows the user to specify a file that contains a list of points and truth model responses used to construct a surrogate model. These can be used by all methods that (explicitly, e.g. surrogate-based optimization, or implicitly, e.g. efficient global optimization) operate on a surrogate. In particular, these points and responses are used in place of truth model evaluations to construct the initial surrogate. When used to construct surrogate models or emulators these are often called build points or training data.

Default Behavior

By default, methods do not import points from a file.

Usage Tips

Dakota parses input files without regard to whitespace, but the `import_build_points_file` must be in one of three formats:

- `annotated` (default)
- `custom_annotated`
- `freeform`

Examples

```
method
  polynomial_chaos
    expansion_order = 4
    import_build_points_file = 'dakota_uq_rosenbrock_pce_import.annot.pts.dat'
```

custom_annotated

- [active_only](#)

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

askey

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [askey](#)

Select the standardized random variables (and associated basis polynomials) from the Askey family that best match the user-specified random variables.

Specification

Alias: none

Argument(s): none

Default: extended (Askey + numerically-generated)

Description

The Askey option employs standard normal, standard uniform, standard exponential, standard beta, and standard gamma random variables in a transformed probability space. These selections correspond to Hermite, Legendre, Laguerre, Jacobi, and generalized Laguerre orthogonal polynomials, respectively.

Specific mappings for the basis polynomials are based on a closest match criterion, and include Hermite for normal (optimal) as well as bounded normal, lognormal, bounded lognormal, gumbel, frechet, and weibull (sub-optimal); Legendre for uniform (optimal) as well as loguniform, triangular, and bin-based histogram (sub-optimal); Laguerre for exponential (optimal); Jacobi for beta (optimal); and generalized Laguerre for gamma (optimal).

normalized

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [normalized](#)

The normalized specification requests output of PCE coefficients that correspond to normalized orthogonal basis polynomials

Specification

Alias: none

Argument(s): none

Default: PCE coefficients correspond to unnormalized basis polynomials

Description

The normalized specification requests output of PCE coefficients that correspond to normalized orthogonal basis polynomials

export_expansion_file

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [export_expansion_file](#)

Export the coefficients and multi-index of a Polynomial Chaos Expansion (PCE) to a file

Specification

Alias: none

Argument(s): STRING

Description

Export the coefficients and multi-index of a Polynomial Chaos Expansion (PCE) to a file. The multi-index written will be sparse. Specifically the expansion will consist only of the indices corresponding to the non-zero coefficients of the PCE.

samples_on_emulator

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [samples_on_emulator](#)

Number of samples at which to evaluate an emulator (surrogate)

Specification

Alias: samples

Argument(s): INTEGER

Description

How many approximate function evaluations to perform on the emulator model, e.g., to compute statistics

Default Behavior

The default number of samples is method-dependent.

Examples

Perform 10000 samples on the PCE approximation of the true model:

```
method
  polynomial_chaos
    quadrature_order = 2
    samples_on_emulator = 10000
```

sample_type

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [sample_type](#)

Selection of sampling strategy

Specification

Alias: none

Argument(s): none

Default: lhs

Child Keywords:

	Required/ Optional Required (<i>Choose One</i>)	Description of Group Sample Type (Group 1)	Dakota Keyword	Dakota Keyword Description
			lhs	Uses Latin Hypercube Sampling (LHS) to sample variables
			random	Uses purely random Monte Carlo sampling to sample variables

Description

The `sample_type` keyword allows the user to select between two types of sampling: Monte Carlo (pure random) and Latin hypercube (stratified) sampling.

The incremental keywords are deprecated; instead use `samples` together with `refinement_samples`.

Default Behavior

If the `sample_type` keyword is present, it must be accompanied by `lhs` or `random`. In most contexts, `lhs` is the default (exception: `multilevel_sampling` uses Monte Carlo by default).

Examples

```
method
  sampling
    sample_type lhs
    samples = 20
    seed = 83921
```

lhs

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [sample_type](#)
- [lhs](#)

Uses Latin Hypercube Sampling (LHS) to sample variables

Specification

Alias: none

Argument(s): none

Description

The `lhs` keyword invokes Latin Hypercube Sampling as the means of drawing samples of uncertain variables according to their probability distributions. This is a stratified, space-filling approach that selects variable values from a set of equi-probable bins.

Default Behavior

Latin Hypercube Sampling is the default sampling mode in most contexts (exception: `multilevel_sampling`). To explicitly specify LHS in the Dakota input file, the `lhs` keyword must appear in conjunction with the `sample_type` keyword.

Usage Tips

Latin Hypercube Sampling is very robust and can be applied to any problem. It is fairly effective at estimating the mean of model responses and linear correlations with a reasonably small number of samples relative to the number of variables.

Examples

```
method
  sampling
    sample_type lhs
    samples = 20
```

random

- [method](#)
- [multilevel_polynomial_chaos](#)
- [sample_type](#)
- [random](#)

Uses purely random Monte Carlo sampling to sample variables

Specification

Alias: none

Argument(s): none

Description

The `random` keyword invokes Monte Carlo sampling as the means of drawing samples of uncertain variables according to their probability distributions.

Default Behavior

In most contexts, Monte Carlo sampling is not the default sampling mode (exception: `multilevel_sampling`). To change this behavior, the `random` keyword must be specified in conjunction with the `sample_type` keyword.

Usage Tips

Monte Carlo sampling is more computationally expensive than Latin Hypercube Sampling as it requires a larger number of samples to accurately estimate statistics.

Examples

```
method
  sampling
    sample_type random
    samples = 200
```

seed

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [seed](#)

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)

Description

The random `seed` control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

fixed_seed

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)

- [fixed_seed](#)

Reuses the same seed value for multiple random sampling sets

Specification

Alias: none

Argument(s): none

Default: not fixed; pattern varies run-to-run

Description

The `fixed_seed` flag is relevant if multiple sampling sets will be generated over the course of a Dakota analysis. This occurs when using advance methods (e.g., surrogate-based optimization, optimization under uncertainty). The same seed value is reused for each of these multiple sampling sets, which can be important for reducing variability in the sampling results.

Default Behavior

The default behavior is to not use a fixed seed, as the repetition of the same sampling pattern can result in a modeling weakness that an optimizer could potentially exploit (resulting in actual reliabilities that are lower than the estimated reliabilities). For repeatable studies, the `seed` must also be specified.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    fixed_seed
```

rng

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [rng](#)

Selection of a random number generator

Specification

Alias: none

Argument(s): none

Default: Mersenne twister (mt19937)

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description

	Required (<i>Choose One</i>)	RNG Algorithm (Group 1)	mt19937	Generates random numbers using the Mersenne twister
			rnum2	Generates pseudo-random numbers using the Pecos package

Description

The `rng` keyword is used to indicate a choice of random number generator.

Default Behavior

If specified, the `rng` keyword must be accompanied by either `rnum2` (pseudo-random numbers) or `mt19937` (random numbers generated by the Mersenne twister). Otherwise, `mt19937`, the Mersenne twister is used by default.

Usage Tips

The default is recommended, as the Mersenne twister is a higher quality random number generator.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2
```

mt19937

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [rng](#)
- [mt19937](#)

Generates random numbers using the Mersenne twister

Specification

Alias: none

Argument(s): none

Description

The `mt19937` keyword directs Dakota to use the Mersenne twister to generate random numbers. Additional information can be found on wikipedia: http://en.wikipedia.org/wiki/Mersenne_twister.

Default Behavior

`mt19937` is the default random number generator. To specify it explicitly in the Dakota input file, however, it must be specified in conjunction with the `rng` keyword.

Usage Tips

Use of the Mersenne twister random number generator (`mt19937`) is recommended.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng mt19937
```

rnum2

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [rng](#)
- [rnum2](#)

Generates pseudo-random numbers using the Pecos package

Specification

Alias: none

Argument(s): none

Description

The `rnum2` keyword directs Dakota to use pseudo-random numbers generated by the Pecos package.

Default Behavior

`rnum2` is not used by default. To change this behavior, it must be specified in conjunction with the `rng` keyword.

Usage Tips

Use of the Mersenne twister random number generator (`mt19937`) is recommended over `rnum2`.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2
```

probability_refinement

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [probability_refinement](#)

Allow refinement of probability and generalized reliability results using importance sampling

Topics

This keyword is related to the topics:

- [reliability_methods](#)

Specification

Alias: sample_refinement

Argument(s): none

Default: no refinement

Child Keywords:

	Required/ Optional	Description of Group Importance	Dakota Keyword	Dakota Keyword Description
	Required(<i>Choose One</i>)	Sampling Approach (Group 1)	import	Sampling option
			adapt_import	Importance sampling option
	Optional		mm_adapt_import	Sampling option
			refinement- samples	Number of samples used to refine a probabily estimate or sampling design.

Description

The `probability_refinement` allows refinement of probability and generalized reliability results using importance sampling. If one specifies `probability_refinement`, there are some additional options. One can specify which type of importance sampling to use (`import`, `adapt_import`, or `mm_adapt_import`). Additionally, one can specify the number of refinement samples to use with `refinement_samples` and the seed to use with `seed`.

The `probability_refinement` density reweighting accounts originally was developed based on Gaussian distributions. It now accounts for additional non-Gaussian cases.

import

- [Keywords Area](#)
- [method](#)

- [multilevel_polynomial_chaos](#)
- [probability_refinement](#)
- [import](#)

Sampling option

Specification

Alias: none

Argument(s): none

Description

`import` centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level).

adapt_import

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [probability_refinement](#)
- [adapt_import](#)

Importance sampling option

Specification

Alias: none

Argument(s): none

Description

`adapt_import` centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level). This continues iteratively until the failure probability estimate converges.

mm_adapt_import

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [probability_refinement](#)
- [mm_adapt_import](#)

Sampling option

Specification

Alias: none

Argument(s): none

Description

`mm_adapt_import` starts with all of the samples located in the failure region to build a multimodal sampling density. First, it uses a small number of samples around each of the initial samples in the failure region. Note that these samples are allocated to the different points based on their relative probabilities of occurrence: more probable points get more samples. This early part of the approach is done to search for "representative" points. Once these are located, the multimodal sampling density is set and then `mm_adapt_import` proceeds similarly to `adapt_import` (sample until convergence).

refinement_samples

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [probability_refinement](#)
- [refinement_samples](#)

Number of samples used to refine a probability estimate or sampling design.

Specification

Alias: none

Argument(s): INTEGERLIST

Description

Probability estimate: Specify the (scalar) number of samples used to improve a probability estimate. If using uni-modal sampling all samples are assigned to the sampling center. If using multi-modal sampling the samples are split between multiple samples according to some internally computed weights.

Sampling design: Specify one or a sequence of refinement samples to augment the `initial_samples` in a sampling design.

final_moments

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [final_moments](#)

Output moments of the specified type and include them within the set of final statistics.

Specification

Alias: none

Argument(s): none

Default: standard

Child Keywords:

	Required/ Optional Required (<i>Choose One</i>)	Description of Group Objective Formulation (Group 1)	Dakota Keyword	Dakota Keyword Description
			none	Omit moments from the set of final statistics.
			standard	Output standardized moments and include them within the set of final statistics.
			central	Output central moments and include them within the set of final statistics.

Description

When performing a nested study that may employ moment statistics on the inner loop, it can be desirable to control the type of these moments. The `final_moments` specification supports options of `none`, `standard` (default), or `central`, corresponding to omission of moments, standardized moments (mean, standard deviation, skewness, and excess kurtosis), or central moments (mean, variance, 3rd central, and 4th central).

The presence or omission of moment results in the final statistics influences the outer level mappings in the case of a nested study. For example, `final_moments none` can allow for a more compact specification of primary and/or secondary response mappings.

Examples

The following method specification overrides the default to print `central` moments and include them in the set of final statistics.

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments central
```

Overriding the default to `none` as follows:

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments none
```

allows associated nested model mappings to be simplified from:

```
model
  nested
    sub_method_pointer = 'UQ'
    primary_response_mapping = 0. 0. 1. 0. 0. 1. 0. 0. 0.
    secondary_response_mapping = 0. 0. 0. 0. 0. 0. 0. 0. 1.
```

to a more compact version focused only on the response level mappings (two leading zeros per response function for moment mappings have been removed):

```
model
  nested
    sub_method_pointer = 'UQ'
    primary_response_mapping = 1. 1. 0.
    secondary_response_mapping = 0. 0. 1.
```

none

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [final_moments](#)
- [none](#)

Omit moments from the set of final statistics.

Specification

Alias: none

Argument(s): none

Description

The omission of moment results from the final statistics can allow for a more compact definition of primary and/or secondary response mappings within a nested model specification.

Examples

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments none
```

standard

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [final_moments](#)
- [standard](#)

Output standardized moments and include them within the set of final statistics.

Specification

Alias: none

Argument(s): none

Description

Output standardized moments (mean, standard deviation, skewness, and excess kurtosis) and include the first two within the set of final statistics to be used at a higher level (e.g., optimization under uncertainty, mixed aleatory-epistemic UQ). This inclusion of moment results affects the primary and/or secondary response mappings in a nested model specification.

Examples

The following method specification overrides the default to print `central` moments and include them in the set of final statistics.

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments standard
```

central

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [final_moments](#)
- [central](#)

Output central moments and include them within the set of final statistics.

Specification

Alias: none

Argument(s): none

Description

Output central moments (mean, variance, 3rd central, and 4th central) and include the first two within the set of final statistics to be used at a higher level (e.g., optimization under uncertainty, mixed aleatory-epistemic UQ). This inclusion of moment results affects the primary and/or secondary response mappings in a nested model specification.

Examples

The following method specification overrides the default to print `central` moments and include them in the set of final statistics.

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments central
```

response_levels

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [response_levels](#)

Values at which to estimate desired statistics for each response

Specification

Alias: none

Argument(s): REALLIST

Default: No CDF/CCDF probabilities/reliabilities to compute

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			num_response_ levels	Number of values at which to estimate desired statistics for each response
	Optional		compute	Selection of statistics to compute at each response level

Description

The `response_levels` specification provides the target response values for which to compute probabilities, reliabilities, or generalized reliabilities (forward mapping).

Default Behavior

If `response_levels` are not specified, no statistics will be computed. If they are, probabilities will be computed by default.

Expected Outputs

If `response_levels` are specified, Dakota will create two tables in the standard output: a Probability Density function (PDF) histogram and a Cumulative Distribution Function (CDF) table. The PDF histogram has

the lower and upper endpoints of each bin and the corresponding density of that bin. Note that the PDF histogram has bins defined by the `probability_levels` and/or `response_levels` in the Dakota input file. If there are not very many levels, the histogram will be coarse. Dakota does not do anything to optimize the bin size or spacing. The CDF table has the list of response levels and the corresponding probability that the response value is less than or equal to each response level threshold.

Usage Tips

The `num_response_levels` is used to specify which arguments of the `response_level` correspond to which response.

Examples

For example, specifying a `response_level` of 52.3 followed with `compute probabilities` will result in the calculation of the probability that the response value is less than or equal to 52.3, given the uncertain distributions on the inputs.

For an example with multiple responses, the following specification

```
response_levels = 1. 2. .1 .2 .3 .4 10. 20. 30.
num_response_levels = 2 4 3
```

would assign the first two response levels (1., 2.) to response function 1, the next four response levels (.1, .2, .3, .4) to response function 2, and the final three response levels (10., 20., 30.) to response function 3. If the `num_response_levels` key were omitted from this example, then the response levels would be evenly distributed among the response functions (three levels each in this case).

The Dakota input file below specifies a sampling method with response levels of interest.

```
method,
  sampling,
  samples = 100 seed = 1
  complementary distribution
  response_levels = 3.6e+11 4.0e+11 4.4e+11
                   6.0e+04 6.5e+04 7.0e+04
                   3.5e+05 4.0e+05 4.5e+05

variables,
  normal_uncertain = 2
  means            = 248.89, 593.33
  std_deviations  = 12.4, 29.7
  descriptors      = 'TF1n' 'TF2n'
  uniform_uncertain = 2
  lower_bounds    = 199.3, 474.63
  upper_bounds    = 298.5, 712.
  descriptors     = 'TF1u' 'TF2u'
  weibull_uncertain = 2
  alphas          = 12., 30.
  betas           = 250., 590.
  descriptors     = 'TF1w' 'TF2w'
  histogram_bin_uncertain = 2
  num_pairs      = 3 4
  abscissas     = 5 8 10 .1 .2 .3 .4
  counts        = 17 21 0 12 24 12 0
  descriptors   = 'TF1h' 'TF2h'
  histogram_point_uncertain
  real = 1
  num_pairs  = 2
  abscissas  = 3 4
  counts     = 1 1
  descriptors = 'TF3h'
```

```

interface,
  system_async_evaluation_concurrency = 5
  analysis_driver = 'text_book'

responses,
  response_functions = 3
  no_gradients
  no_hessians

```

Given the above Dakota input file, the following excerpt from the output shows the PDF and CCDF generated. Note that the bounds on the bins of the PDF are the response values specified in the input file. The probability levels corresponding to those response values are shown in the CCDF.

Probability Density Function (PDF) histograms for each response function:

PDF for response_fn_1:

6.5000000000e+04	2.9000000000e-01		
7.0000000000e+04	9.0000000000e-02		

Complementary Cumulative Distribution Function (CCDF) for response_fn_3:

Response Level	Probability Level	Reliability Index	General Rel Index
3.5000000000e+05	5.2000000000e-01		
4.0000000000e+05	9.0000000000e-02		
4.5000000000e+05	0.0000000000e+00		

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

A forward mapping involves computing the belief and plausibility probability level for a specified response level.

num_response_levels

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [response_levels](#)
- [num_response_levels](#)

Number of values at which to estimate desired statistics for each response

Specification

Alias: none

Argument(s): INTEGERLIST

Default: response_levels evenly distributed among response functions

Description

The `num_response_levels` keyword allows the user to specify the number of response values, for each response, at which estimated statistics are of interest. Statistics that can be computed are probabilities and reliabilities, both according to either a cumulative distribution function or a complementary cumulative distribution function.

Default Behavior

If `num_response_levels` is not specified, the `response_levels` will be evenly distributed among the responses.

Expected Outputs

The specific output will be determined by the type of statistics that are specified. In a general sense, the output will be a list of response level-statistic pairs that show the estimated value of the desired statistic for each response level specified.

Examples

```
method
  sampling
    samples = 100
    seed = 34785
    num_response_levels = 1 1 1
    response_levels = 0.5 0.5 0.5
```

compute

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [response_levels](#)
- [compute](#)

Selection of statistics to compute at each response level

Specification

Alias: none

Argument(s): none

Default: probabilities

Child Keywords:

	Required/- Optional <i>Required(Choose One)</i>	Description of Group Statistics to Compute (Group 1)	Dakota Keyword probabilities	Dakota Keyword Description Computes probabilities associated with response levels
			reliabilities	Computes reliabilities associated with response levels
			gen_reliabilities	Computes generalized reliabilities associated with response levels
	Optional		system	Compute system reliability (series or parallel)

Description

The `compute` keyword is used to select which forward stastical mapping is calculated at each response level.

Default Behavior

If `response_levels` is not specified, no statistics are computed. If `response_levels` is specified but `compute` is not, probabilities will be computed by default. If both `response_levels` and `compute` are specified, then on of the following must be specified: `probabilities`, `reliabilities`, or `gen_reliabilities`.

Expected Output

The type of statistics specified by `compute` will be reported for each response level.

Usage Tips

CDF/CCDF probabilities are calculated for specified response levels using a simple binning approach.

CDF/CCDF reliabilities are calculated for specified response levels by computing the number of sample standard deviations separating the sample mean from the response level.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
  complementary distribution
  response_levels = 3.6e+11 4.0e+11 4.4e+11
                   6.0e+04 6.5e+04 7.0e+04
                   3.5e+05 4.0e+05 4.5e+05
  compute reliabilities
```

probabilities

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [response_levels](#)
- [compute](#)
- [probabilities](#)

Computes probabilities associated with response levels

Specification

Alias: none

Argument(s): none

Description

The `probabilities` keyword directs Dakota to compute the probability that the model response will be below (cumulative) or above (complementary cumulative) a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the probabilities are computed by default. To explicitly specify it in the Dakota input file, though, the `probabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-probability pairs that give the probability that the model response will be below or above the corresponding response level, depending on the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                    6.0e+04 6.5e+04 7.0e+04
                    3.5e+05 4.0e+05 4.5e+05
    compute probabilities
```

reliabilities

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [response_levels](#)
- [compute](#)
- [reliabilities](#)

Computes reliabilities associated with response levels

Specification

Alias: none

Argument(s): none

Description

The `reliabilities` keyword directs Dakota to compute reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the reliabilities are not computed by default. To change this behavior, the `reliabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-reliability pairs according to the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                    6.0e+04 6.5e+04 7.0e+04
                    3.5e+05 4.0e+05 4.5e+05
    compute reliabilities
```

gen_reliabilities

- [compute](#)
- [gen_reliabilities](#)

Computes generalized reliabilities associated with response levels

Specification

Alias: none

Argument(s): none

Description

The `gen_reliabilities` keyword directs Dakota to compute generalized reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the generalized reliabilities are not computed by default. To change this behavior, the `gen_reliabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-generalized reliability pairs according to the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                    6.0e+04 6.5e+04 7.0e+04
                    3.5e+05 4.0e+05 4.5e+05
    compute gen_reliabilities
```

system

- [compute](#)
- [system](#)

Compute system reliability (series or parallel)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	System Reliability Mode (Group 1)	series	Aggregate response statistics assuming a series system
			parallel	Aggregate response statistics assuming a parallel system

Description

With the system probability/reliability option, statistics for specified `response_levels` are calculated and reported assuming the response functions combine either in series or parallel to produce a total system response.

For a series system, the system fails when any one component (response) fails. The probability of failure is the complement of the product of the individual response success probabilities.

For a parallel system, the system fails only when all components (responses) fail. The probability of failure is the product of the individual response failure probabilities.

probability_levels

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [probability_levels](#)

Specify probability levels at which to estimate the corresponding response value

Specification

Alias: none

Argument(s): REALLIST

Default: No CDF/CCDF response levels to compute

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			num_probability_levels	Specify which probability_levels correspond to which response

Description

Response levels are calculated for specified CDF/CCDF probabilities by indexing into a sorted samples array (the response levels computed are not interpolated and will correspond to one of the sampled values).

Expected Output

If `probability_levels` are specified, Dakota will create two tables in the standard output: a Probability Density function (PDF) histogram and a Cumulative Distribution Function (CDF) table. The PDF histogram has the lower and upper endpoints of each bin and the corresponding density of that bin. Note that the PDF histogram has bins defined by the `probability_levels` and/or `response_levels` in the Dakota input file. If there are not very many levels, the histogram will be coarse. Dakota does not do anything to optimize the bin size or spacing. The CDF table has the list of response levels and the corresponding probability that the response value is less than or equal to each response level threshold.

Examples

The Dakota input file below specifies a sampling method with probability levels of interest.

```
method,
  sampling,
  samples = 100 seed = 1
  complementary distribution
  probability_levels = 1. .66 .33 0.

3.8100966235e+05	2.0000000000e-01		
4.4111498127e+05	0.0000000000e+00		

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).

distribution

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [distribution](#)

Selection of cumulative or complementary cumulative functions

Specification

Alias: none

Argument(s): none

Default: cumulative (CDF)

Child Keywords:

	Required/- Optional Required(<i>Choose One</i>)	Description of Group Distribution Type (CDF/CCDF) (Group 1)	Dakota Keyword	Dakota Keyword Description
			cumulative	Computes statistics according to cumulative functions
			complementary	Computes statistics according to complementary cumulative functions

Description

The `distribution` keyword allows the user to select between a cumulative distribution/belief/plausibility function and a complementary cumulative distribution/belief/plausibility function. This choice affects how probabilities and reliability indices are reported.

Default Behavior

If the `distribution` keyword is present, it must be accompanied by either `cumulative` or `complementary`. Otherwise, a cumulative distribution will be used by default.

Expected Outputs

Output will be a set of model response-probability pairs determined according to the choice of distribution. The choice of distribution also defines the sign of the reliability or generalized reliability indices.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

cumulative

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [distribution](#)
- [cumulative](#)

Computes statistics according to cumulative functions

Specification

Alias: none

Argument(s): none

Description

Statistics on model responses will be computed according to a cumulative distribution/belief/plausibility function.

Default Behavior

By default, a cumulative distribution/belief/plausibility function will be used. To explicitly specify it in the Dakota input file, however, the `cumulative` keyword must be appear in conjunction with the `distribution` keyword.

Expected Outputs

Output will be a set of model response-probability pairs determined according to a cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls below given response thresholds.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

complementary

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [distribution](#)
- [complementary](#)

Computes statistics according to complementary cumulative functions

Specification

Alias: none

Argument(s): none

Description

Statistics on model responses will be computed according to a complementary cumulative distribution/belief/plausibility function.

Default Behavior

By default, a complementary cumulative distribution/belief/plausibility function will not be used. To change that behavior, the `complementary` keyword must appear in conjunction with the `distribution` keyword.

Expected Outputs

Output will be a set of model response-probability pairs determined according to a complementary cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls above given response thresholds.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    distribution complementary
```

`variance_based_decomp`

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [variance_based_decomp](#)

Activates global sensitivity analysis based on decomposition of response variance into main, interaction, and total effects

Specification

Alias: none

Argument(s): none

Default: no variance-based decomposition

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			<code>interaction_order</code>	Specify the maximum number of variables allowed in an interaction when reporting <i>interaction metrics</i>
	Optional		<code>drop_tolerance</code>	Suppresses output of sensitivity indices with values lower than this tolerance

Description

Dakota can calculate sensitivity indices through variance-based decomposition using the keyword `variance_based_decomp`. This approach decomposes main, interaction, and total effects in order to identify the most important variables and combinations of variables in contributing to the variance of output quantities of interest.

Default Behavior

Because of processing overhead and output volume, `variance_based_decomp` is inactive by default, unless required for dimension-adaptive refinement using Sobol' indices.

Expected Outputs

When `variance_based_decomp` is specified, sensitivity indices for main effects, total effects, and any interaction effects will be reported. Each of these effects represents the percent contribution to the variance in the model response, where main effects include the aggregated set of *univariate* terms for each individual variable, interaction effects represent the set of *mixed* terms (the complement of the univariate set), and total effects represent the *complete* set of terms (univariate and mixed) that contain each individual variable. The aggregated set of main and interaction sensitivity indices will sum to one, whereas the sum of total effects sensitivity indices will be greater than one due to redundant counting of mixed terms.

Usage Tips

An important consideration is that the number of possible interaction terms grows exponentially with dimension and expansion order. To mitigate this, both in terms of compute time and output volume, possible interaction effects are suppressed whenever no contributions are present due to the particular form of an expansion. In addition, the `interaction_order` and `drop_tolerance` controls can further limit the computational and output requirements.

Examples

```
method,
  polynomial_chaos # or stoch_collocation
  sparse_grid_level = 3
  variance_based_decomp interaction_order = 2
```

Theory

In this context, we take sensitivity analysis to be global, not local as when calculating derivatives of output variables with respect to input variables. Our definition is similar to that of [75]: "The study of how uncertainty in the output of a model can be apportioned to different sources of uncertainty in the model input."

Variance based decomposition is a way of using sets of samples to understand how the variance of the output behaves, with respect to each input variable. A larger value of the sensitivity index, S_i , means that the uncertainty in the input variable i has a larger effect on the variance of the output. More details on the calculations and interpretation of the sensitivity indices can be found in[89].

interaction_order

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [variance_based_decomp](#)
- [interaction_order](#)

Specify the maximum number of variables allowed in an interaction when reporting interaction metrics.

Specification

Alias: none

Argument(s): INTEGER

Default: Unrestricted (VBD includes all interaction orders present in the expansion)

Description

The `interaction_order` option has been added to allow suppression of higher-order interactions, since the output volume (and memory and compute consumption) of these results could be extensive for high dimensional problems (note: the previous `univariate_effects` specification is equivalent to `interaction_order = 1` in the current specification). Similar to suppression of interactions is the covariance control, which can be selected to be `diagonal_covariance` or `full_covariance`, with the former supporting suppression of the off-diagonal covariance terms (to again save compute and memory resources and reduce output volume)

drop_tolerance

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [variance_based_decomp](#)
- [drop_tolerance](#)

Suppresses output of sensitivity indices with values lower than this tolerance

Specification

Alias: none

Argument(s): REAL

Default: All VBD indices displayed

Description

The `drop_tolerance` keyword allows the user to specify a value below which sensitivity indices generated by `variance_based_decomp` are not displayed.

Default Behavior

By default, all sensitivity indices generated by `variance_based_decomp` are displayed.

Usage Tips

For `polynomial_chaos`, which outputs main, interaction, and total effects by default, the `univariate_effects` may be a more appropriate option. It allows suppression of the interaction effects since the output volume of these results can be prohibitive for high dimensional problems. Similar to suppression of these interactions is the covariance control, which can be selected to be `diagonal_covariance` or `full_covariance`, with the former supporting suppression of the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

Examples

```
method,
  sampling
  sample_type lhs
  samples = 100
  variance_based_decomp
  drop_tolerance = 0.001
```

diagonal_covariance

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [diagonal_covariance](#)

Display only the diagonal terms of the covariance matrix

Specification

Alias: none

Argument(s): none

Default: `diagonal_covariance` for response vector > 10; else `full_covariance`

Description

With a large number of responses, the covariance matrix can be very large. `diagonal_covariance` is used to suppress the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

full_covariance

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)

- [full_covariance](#)

Display the full covariance matrix

Specification

Alias: none

Argument(s): none

Description

With a large number of responses, the covariance matrix can be very large. `full_covariance` is used to force Dakota to output the full covariance matrix.

convergence_tolerance

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

import_approx_points_file

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [import_approx_points_file](#)

Filename for points at which to evaluate the PCE/SC surrogate

Specification

Alias: none

Argument(s): STRING

Default: no point import from a file

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional(<i>Choose One</i>)	Tabular Format (Group 1)	custom_annotated	Selects custom-annotated tabular file format
			annotated	Selects annotated tabular file format
			freeform	Selects freeform file format
	Optional		active_only	Import only active variables from tabular data file

Description

Default Behavior No import of points at which to evaluate the surrogate.

Expected Output The PCE/SC surrogate model will be evaluated at the list of points (input variable values) provided in the file and results tabulated and/or statistics computed at them, depending on the method context.

Examples

```
method
  polynomial_chaos
  expansion_order = 4
  import_approx_points_file = 'import.mcmc_annot.dat'
  annotated
```

custom_annotated

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [import_approx_points_file](#)
- [custom_annotated](#)

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			header	Enable header row in custom-annotated tabular file
	Optional		eval_id	Enable evaluation ID column in custom-annotated tabular file

	Optional	interface_id	Enable interface ID column in custom-annotated tabular file
--	-----------------	------------------------------	---

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, `eval_id` column, and `interface_id` column appear in the tabular file, thus bridging `freeform` and (fully) annotated.

Default Behavior

The `annotated` format is the default for tabular export/import. To control which header row and columns are in the input/output, specify `custom_annotated`, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and `eval_id` (no `interface_id`), and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id      x1          x2          obj_fn  nln_ineq_con_1  nln_ineq_con_2
1              0.9          1.1          0.0002          0.26          0.76
2              0.90009      1.1 0.0001996404857  0.2601620081  0.759955
3              0.89991      1.1 0.0002003604863  0.2598380081  0.760045
...
```

- [multilevel_polynomial_chaos](#)
- [import_approx_points_file](#)
- [annotated](#)

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The `annotated` keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include `interface_id`, specify `custom_annotated` header `eval_id`
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export an annotated top-level tabular data file containing a header row, leading `eval_id` and `interface_id` columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated
```

Resulting tabular file:

```
%eval_id interface          x1          x2          obj_fn nln_ineq_con_1 nln_ineq_con_2
1          NO_ID            0.9          1.1          0.0002          0.26          0.76
2          NO_ID            0.90009      1.1 0.0001996404857 0.2601620081 0.759955
3          NO_ID            0.89991      1.1 0.0002003604863 0.2598380081 0.760045
...
```

freeform

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [import_approx_points_file](#)
- [freeform](#)

Selects freeform file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The `annotated` format is the default for tabular export/import. To change this behavior, specify `freeform` in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to `annotated` format, though `freeform` remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- In `freeform`, the `num_rows` x `num_cols` total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

```
      0.9          1.1          0.0002          0.26          0.76
0.90009          1.1 0.0001996404857 0.2601620081 0.759955
0.89991          1.1 0.0002003604863 0.2598380081 0.760045
...
```

active_only

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [import_approx_points_file](#)
- [active_only](#)

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

export_approx_points_file

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)
- [export_approx_points_file](#)

Output file for evaluations of a surrogate model

Specification

Alias: export_points_file

Argument(s): STRING

Default: no point export to a file

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional(<i>Choose One</i>)	Tabular Format (Group 1)	custom_annotated	Selects custom-annotated tabular file format
			annotated	Selects annotated tabular file format
			freeform	Selects freeform file format

Description

The `export_approx_points_file` keyword allows the user to specify a file in which the points (input variable values) at which the surrogate model is evaluated and corresponding response values computed by the surrogate model will be written. The response values are the surrogate's predicted approximation to the truth model responses at those points.

Usage Tips

Dakota exports tabular data in one of three formats:

- `annotated` (default)
- `custom_annotated`
- `freeform`

custom_annotated

- [Keywords Area](#)
- [method](#)
- [multilevel_polynomial_chaos](#)

- [export_approx_points_file](#)
- [custom_annotated](#)

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			header	Enable header row in custom-annotated tabular file
	Optional		eval_id	Enable evaluation ID column in custom-annotated tabular file
	Optional		interface_id	Enable interface ID column in custom-annotated tabular file

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether `header` row, `eval_id` column, and `interface_id` column appear in the tabular file, thus bridging `freeform` and (fully) `annotated`.

Default Behavior

The `annotated` format is the default for tabular export/import. To control which header row and columns are in the input/output, specify `custom_annotated`, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to `annotated` format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and `eval_id` (no `interface_id`), and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id      x1          x2          obj_fn nln_ineq_con_1 nln_ineq_con_2
1             0.9          1.1          0.0002          0.26          0.76
2             0.90009      1.1 0.0001996404857 0.2601620081 0.759955

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```

	Optional	model_pointer	Identifier for model block to be used by a method

Description

Stochastic collocation is a general framework for approximate representation of random response functions in terms of finite-dimensional interpolation bases.

The stochastic collocation (SC) method is very similar to [polynomial_chaos](#), with the key difference that the orthogonal polynomial basis functions are replaced with interpolation polynomial bases. The interpolation polynomials may be either local or global and either value-based or gradient-enhanced. In the local case, valued-based are piecewise linear splines and gradient-enhanced are piecewise cubic splines, and in the global case, valued-based are Lagrange interpolants and gradient-enhanced are Hermite interpolants. A value-based expansion takes the form

$$R = \sum_{i=1}^{N_p} r_i L_i(\xi)$$

where N_p is the total number of collocation points, r_i is a response value at the i^{th} collocation point, L_i is the i^{th} multidimensional interpolation polynomial, and ξ is a vector of standardized random variables.

Thus, in PCE, one forms coefficients for known orthogonal polynomial basis functions, whereas SC forms multidimensional interpolation functions for known coefficients.

Basis polynomial family (Group 2)

In addition to the [askey](#) and [wiener](#) basis types also supported by [polynomial_chaos](#), SC supports the option of `piecewise` local basis functions. These are piecewise linear splines, or in the case of gradient-enhanced interpolation via the `use_derivatives` specification, piecewise cubic Hermite splines. Both of these basis options provide local support only over the range from the interpolated point to its nearest 1D neighbors (within a tensor grid or within each of the tensor grids underlying a sparse grid), which exchanges the fast convergence of global bases for smooth functions for robustness in the representation of nonsmooth response functions (that can induce Gibbs oscillations when using high-order global basis functions). When local basis functions are used, the usage of nonequidistant collocation points (e.g., the Gauss point selections described above) is not well motivated, so equidistant Newton-Cotes points are employed in this case, and all random variable types are transformed to standard uniform probability space. The global gradient-enhanced interpolants (Hermite interpolation polynomials) are also restricted to uniform or transformed uniform random variables (due to the need to compute collocation weights by integration of the basis polynomials) and share the variable support shown in [variable_support](#) for Piecewise SE. Due to numerical instability in these high-order basis polynomials, they are deactivated by default but can be activated by developers using a compile-time switch.

Interpolation grid type (Group 3)

To form the multidimensional interpolants L_i of the expansion, two options are provided.

1. interpolation on a tensor-product of Gaussian quadrature points (specified with `quadrature_order` and, optionally, `dimension_preference` for anisotropic tensor grids). As for PCE, non-nested Gauss rules are employed by default, although the presence of `p_refinement` or `h_refinement` will result in default usage of nested rules for normal or uniform variables after any variable transformations have been applied (both defaults can be overridden using explicit `nested` or `non_nested` specifications).
2. interpolation on a Smolyak sparse grid (specified with `sparse_grid_level` and, optionally, `dimension_preference` for anisotropic sparse grids) defined from Gaussian rules. As for sparse PCE, nested rules are employed unless overridden with the `non_nested` option, and the growth rules are restricted unless overridden by the `unrestricted` keyword.

Another distinguishing characteristic of stochastic collocation relative to [polynomial.chaos](#) is the ability to reformulate the interpolation problem from a nodal interpolation approach into a hierarchical formulation in which each new level of interpolation defines a set of incremental refinements (known as hierarchical surpluses) layered on top of the interpolants from previous levels. This formulation lends itself naturally to uniform or adaptive refinement strategies, since the hierarchical surpluses can be interpreted as error estimates for the interpolant. Either global or local/piecewise interpolants in either value-based or gradient-enhanced approaches can be formulated using hierarchical interpolation. The primary restriction for the hierarchical case is that it currently requires a sparse grid approach using nested quadrature rules (Genz-Keister, Gauss-Patterson, or Newton-Cotes for standard normals and standard uniforms in a transformed space: Askey, Wiener, or Piecewise settings may be required), although this restriction can be relaxed in the future. A selection of hierarchical interpolation will provide greater precision in the increments to mean, standard deviation, covariance, and reliability-based level mappings induced by a grid change within uniform or goal-oriented adaptive refinement approaches (see following section).

It is important to note that, while `quadrature_order` and `sparse_grid_level` are array inputs, only one scalar from these arrays is active at a time for a particular expansion estimation. These scalars can be augmented with a `dimension_preference` to support anisotropy across the random dimension set. The array inputs are present to support advanced use cases such as multifidelity UQ, where multiple grid resolutions can be employed.

Automated refinement type (Group 1)

Automated expansion refinement can be selected as either `p_refinement` or `h_refinement`, and either refinement specification can be either `uniform` or `dimension_adaptive`. The `dimension_adaptive` case can be further specified as either `sobol` or `generalized` (decay not supported). Each of these automated refinement approaches makes use of the `max_iterations` and `convergence_tolerance` iteration controls. The `h_refinement` specification involves use of the same piecewise interpolants (linear or cubic Hermite splines) described above for the `piecewise` specification option (it is not necessary to redundantly specify `piecewise` in the case of `h_refinement`). In future releases, the hierarchical interpolation approach will enable local refinement in addition to the current `uniform` and `dimension_adaptive` options.

Covariance type (Group 5)

These two keywords are used to specify how this method computes, stores, and outputs the covariance of the responses. In particular, the diagonal covariance option is provided for reducing post-processing overhead and output volume in high dimensional applications.

Active Variables

The default behavior is to form expansions over aleatory uncertain continuous variables. To form expansions over a broader set of variables, one needs to specify `active` followed by `state`, `epistemic`, `design`, or `all` in the variables specification block.

For continuous design, continuous state, and continuous epistemic uncertain variables included in the expansion, interpolation points for these dimensions are based on Gauss-Legendre rules if non-nested, Gauss-Patterson rules if nested, and Newton-Cotes points in the case of piecewise bases. Again, when probability integrals are

evaluated, only the aleatory random variable domain is integrated, leaving behind a polynomial relationship between the statistics and the remaining design/state/epistemic variables.

Optional Keywords regarding method outputs

Each of these sampling specifications refer to sampling on the SC approximation for the purposes of generating approximate statistics.

- `sample_type`
- `samples`
- `seed`
- `fixed_seed`
- `rng`
- `probability_refinement`
- `distribution`
- `reliability_levels`
- `response_levels`
- `probability_levels`
- `gen_reliability_levels`

Since SC approximations are formed on structured grids, there should be no ambiguity with simulation sampling for generating the SC expansion.

When using the `probability_refinement` control, the number of refinement samples is not under the user's control (these evaluations are approximation-based, so management of this expense is less critical). This option allows for refinement of probability and generalized reliability results using importance sampling.

Multi-fidelity UQ

When using multifidelity UQ, the high fidelity expansion generated from combining the low fidelity and discrepancy expansions retains the polynomial form of the low fidelity expansion (only the coefficients are updated). Refer to [polynomial_chaos](#) for information on the multifidelity interpretation of array inputs for `quadrature_order` and `sparse_grid_level`.

Usage Tips

If n is small, then tensor-product Gaussian quadrature is again the preferred choice. For larger n , tensor-product quadrature quickly becomes too expensive and the sparse grid approach is preferred. For self-consistency in growth rates, nested rules employ restricted exponential growth (with the exception of the `dimension_adaptive_p_refinement_generalized` case) for consistency with the linear growth used for non-nested Gauss rules (integrand precision $i = 4l + 1$ for sparse grid level l and $i = 2m - 1$ for tensor grid order m).

Additional Resources

Dakota provides access to SC methods through the `NonDStochCollocation` class. Refer to the Uncertainty Quantification Capabilities chapter of the Users Manual[4] and the Stochastic Expansion Methods chapter of the Theory Manual[6] for additional information on the SC algorithm.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the `hdf5` keyword, this method writes the following results to HDF5:

- [Integration and Expansion Moments](#)
- [Probability Density](#)

- [Level Mappings](#)
- [Variance-Based Decomposition \(Sobol' Indices\)](#)

Examples

```
method,
  stoch_collocation
  sparse_grid_level = 2
  samples = 10000 seed = 12347 rng rnum2
  response_levels = .1 1. 50. 100. 500. 1000.
  variance_based_decomp
```

Theory

As mentioned above, a value-based expansion takes the form

$$R = \sum_{i=1}^{N_p} r_i L_i(\xi)$$

The i^{th} interpolation polynomial assumes the value of 1 at the i^{th} collocation point and 0 at all other collocation points, involving either a global Lagrange polynomial basis or local piecewise splines. It is easy to see that the approximation reproduces the response values at the collocation points and interpolates between these values at other points. A gradient-enhanced expansion (selected via the `use_derivatives` keyword) involves both type 1 and type 2 basis functions as follows:

$$R = \sum_{i=1}^{N_p} [r_i H_i^{(1)}(\xi) + \sum_{j=1}^n \frac{dr_i}{d\xi_j} H_{ij}^{(2)}(\xi)]$$

where the i^{th} type 1 interpolant produces 1 for the value at the i^{th} collocation point, 0 for values at all other collocation points, and 0 for derivatives (when differentiated) at all collocation points, and the ij^{th} type 2 interpolant produces 0 for values at all collocation points, 1 for the j^{th} derivative component at the i^{th} collocation point, and 0 for the j^{th} derivative component at all other collocation points. Again, this expansion reproduces the response values at each of the collocation points, and when differentiated, also reproduces each component of the gradient at each of the collocation points. Since this technique includes the derivative interpolation explicitly, it eliminates issues with matrix ill-conditioning that can occur in the gradient-enhanced PCE approach based on regression. However, the calculation of high-order global polynomials with the desired interpolation properties can be similarly numerically challenging such that the use of local cubic splines is recommended due to numerical stability.

Automatic polynomial order refinement

Specification

Alias: none

Argument(s): none

Default: no refinement

Child Keywords:

	Required/- Optional Required(<i>Choose One</i>)	Description of Group p-refinement Type (Group 1)	Dakota Keyword uniform	Dakota Keyword Description Refine an expansion uniformly in all dimensions.
			dimension_- adaptive	Perform anisotropic expansion refinement by preferentially adapting in dimensions that are detected to have higher 'importance'.

Description

The `p_refinement` keyword specifies the usage of automated polynomial order refinement, which can be either `uniform` or `dimension_adaptive`.

The `dimension_adaptive` option is supported for the tensor-product quadrature and Smolyak sparse grid options and `uniform` is supported for tensor and sparse grids as well as regression approaches (`collocation_points` or `collocation_ratio`).

Each of these refinement cases makes use of the `max_iterations` and `convergence_tolerance` method independent controls. The former control limits the number of refinement iterations, and the latter control terminates refinement when the two-norm of the change in the response covariance matrix (or, in goal-oriented approaches, the two-norm of change in the statistical quantities of interest (QOI)) falls below the tolerance.

The `dimension_adaptive` case can be further specified to utilize `sobol`, `decay`, or generalized refinement controls. The former two cases employ anisotropic tensor/sparse grids in which the anisotropic dimension preference (leading to anisotropic integrations/expansions with differing refinement levels for different random dimensions) is determined using either total Sobol' indices from variance-based decomposition (`sobol` case: high indices result in high dimension preference) or using spectral coefficient decay rates from a rate estimation technique similar to Richardson extrapolation (`decay` case: low decay rates result in high dimension preference). In these two cases as well as the `uniform` refinement case, the `quadrature_order` or `sparse_grid_level` are ramped by one on each refinement iteration until either of the two convergence controls is satisfied. For the `uniform` refinement case with regression approaches, the `expansion_order` is ramped by one on each iteration while the oversampling ratio (either defined by `collocation_ratio` or inferred from `collocation_points` based on the initial expansion) is held fixed. Finally, the generalized `dimension_adaptive` case is the default adaptive approach; it refers to the generalized sparse grid algorithm, a greedy approach in which candidate index sets are evaluated for their impact on the statistical QOI, the most influential sets are selected and used to generate additional candidates, and the index set frontier of a sparse grid is evolved in an unstructured and goal-oriented manner (refer to User's Manual PCE descriptions for additional specifics).

For the case of `p_refinement` or the case of an explicit nested override, Gauss-Hermite rules are replaced with Genz-Keister nested rules and Gauss-Legendre rules are replaced with Gauss-Patterson nested rules, both of which exchange lower integrand precision for greater point reuse.

	Required(<i>Choose One</i>)	h-refinement Type (Group 1)	uniform	Refine an expansion uniformly in all dimensions.
			dimension_- adaptive	Perform anisotropic expansion refinement by preferentially adapting in dimensions that are detected to have higher 'importance'.

			local_adaptive	Planned future capability for local pointwise refinement within a generalized sparse grid.
--	--	--	--------------------------------	--

Description

Automated expansion refinement can be selected as either `p_refinement` or `h_refinement`, and either refinement specification can be either uniform or `dimension_adaptive`. The `dimension_adaptive` case can be further specified as either `sobol` or `generalized` (decay not supported). Each of these automated refinement approaches makes use of the `max_iterations` and `convergence_tolerance` iteration controls. The `h_refinement` specification involves use of the same piecewise interpolants (linear or cubic Hermite splines) described above for the piecewise specification option (it is not necessary to redundantly specify piecewise in the case of `h_refinement`). In future releases, the hierarchical interpolation approach will enable local refinement in addition to the current uniform and `dimension_adaptive` options.

- [stoch_collocation](#)
- [quadrature_order](#)

Order for tensor-products of Gaussian quadrature rules

Specification

Alias: none

Argument(s): INTEGER

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional (<i>Choose One</i>)	Quadrature Rule Nesting (Group 1)	nested	A set of weights specifying the relative importance of each uncertain variable (dimension) Enforce use of nested quadrature rules if available
			non_nested	Enforce use of non-nested quadrature rules

Description

Multidimensional integration by a tensor-product of Gaussian quadrature rules (specified with `quadrature_order`, and, optionally, `dimension_preference`). The default rule selection is to employ `non_nested` Gauss rules including Gauss-Hermite (for normals or transformed normals), Gauss-Legendre (for uniforms or transformed uniforms), Gauss-Jacobi (for betas), Gauss-Laguerre (for exponentials), generalized Gauss-Laguerre (for gammas), and numerically-generated Gauss rules (for other distributions when using an Extended basis). For the case of `p_refinement` or the case of an explicit `nested` override, Gauss-Hermite rules are replaced with Genz-Keister nested rules and Gauss-Legendre rules are replaced with Gauss-Patterson nested rules, both of which exchange lower integrand precision for greater point reuse. By specifying a `dimension_preference`, where higher preference leads to higher order polynomial resolution, the tensor grid may be rendered anisotropic.

The dimension specified to have highest preference will be set to the specified `quadrature_order` and all other dimensions will be reduced in proportion to their reduced preference; any non-integral portion is truncated. To synchronize with tensor-product integration, a tensor-product expansion is used, where the order p_i of the expansion in each dimension is selected to be half of the integrand precision available from the rule in use, rounded down. In the case of non-nested Gauss rules with integrand precision $2m_i - 1$, p_i is one less than the quadrature order m_i in each dimension (a one-dimensional expansion contains the same number of terms, $p + 1$, as the number of Gauss points). The total number of terms, N , in a tensor-product expansion involving n uncertain input variables is

$$N = 1 + P = \prod_{i=1}^n (p_i + 1)$$

In some advanced use cases (e.g., multifidelity UQ), multiple grid resolutions can be employed; for this reason, the `quadrature_order` specification supports an array input.

Usage Tips

For most use cases, this keyword will specify a single integer order. In more advanced UQ studies with hierarchical models, the list of integers can apply to different models and/or model levels

sparse_grid_level

- [Keywords Area](#)
- [method](#)
- [stoch_collocation](#)
- [sparse_grid_level](#)

Level to use in sparse grid integration or interpolation

Specification

Alias: none

Argument(s): INTEGER

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			dimension_- preference	A set of weights specifying the relative importance of each uncertain variable (dimension)
	Optional (<i>Choose One</i>)	Group 1	nodal	Level to use in sparse grid integration or interpolation
			hierarchical	Level to use in sparse grid integration or interpolation
	Optional (<i>Choose One</i>)	Quadrature Rule Growth (Group 2)	restricted	Restrict the growth rates for nested and non-nested rules can be synchronized for consistency.

			unrestricted	Level to use in sparse grid integration or interpolation
	Optional (<i>Choose One</i>)	Quadrature Rule Nesting (Group 3)	nested	Level to use in sparse grid integration or interpolation
			non_nested	Level to use in sparse grid integration or interpolation

Description

Multi-dimensional integration by the Smolyak sparse grid method (specified with `sparse_grid_level` and, optionally, `dimension_preference`). The underlying one-dimensional integration rules are the same as for the tensor-product quadrature case; however, the default rule selection is nested for sparse grids (Genz-Keister for normals/transformed normals and Gauss-Patterson for uniforms/transformed uniforms). This default can be overridden with an explicit `non_nested` specification (resulting in Gauss-Hermite for normals/transformed normals and Gauss-Legendre for uniforms/transformed uniforms). As for tensor quadrature, the `dimension_preference` specification enables the use of anisotropic sparse grids (refer to the PCE description in the User's Manual for the anisotropic index set constraint definition). Similar to anisotropic tensor grids, the dimension with greatest preference will have resolution at the full `sparse_grid_level` and all other dimension resolutions will be reduced in proportion to their reduced preference. For PCE with either isotropic or anisotropic sparse grids, a summation of tensor-product expansions is used, where each anisotropic tensor-product quadrature rule underlying the sparse grid construction results in its own anisotropic tensor-product expansion as described in case 1. These anisotropic tensor-product expansions are summed into a sparse PCE using the standard Smolyak summation (again, refer to the User's Manual for additional details). As for `quadrature_order`, the `sparse_grid_level` specification admits an array input for enabling specification of multiple grid resolutions used by certain advanced solution methodologies.

Usage Tips

This keyword can be used when using sparse grid integration to calculate PCE coefficients or when generating samples for sparse grid collocation.

For most use cases, this keyword will specify a single integer level. In more advanced UQ studies with hierarchical models, the list of integers can apply to different models and/or model levels

restricted

- [Keywords Area](#)
- [method](#)
- [stoch_collocation](#)
- [sparse_grid_level](#)
- [restricted](#)

Restrict the growth rates for nested and non-nested rules can be synchronized for consistency.

Specification

Alias: none

Argument(s): none

Default: restricted (except for generalized sparse grids)

Description

In the quadrature and sparse grid cases, growth rates for nested and non-nested rules can be synchronized for consistency. For a non-nested Gauss rule used within a sparse grid, linear one-dimensional growth rules of $m = 2l + 1$ are used to enforce odd quadrature orders, where l is the grid level and m is the number of points in the rule. The precision of this Gauss rule is then $i = 2m - 1 = 4l + 1$. For nested rules, order growth with level is typically exponential; however, the default behavior is to restrict the number of points to be the lowest order rule that is available that meets the one-dimensional precision requirement implied by either a level l for a sparse grid ($i = 4l + 1$) or an order m for a tensor grid ($i = 2m - 1$). This behavior is known as "restricted growth" or "delayed sequences." To override this default behavior in the case of sparse grids, the unrestricted keyword can be used; it cannot be overridden for tensor grids using nested rules since it also provides a mapping to the available nested rule quadrature orders. An exception to the default usage of restricted growth is the `dimension_adaptive_p_refinement` generalized sparse grid case described previously, since the ability to evolve the index sets of a sparse grid in an unstructured manner eliminates the motivation for restricting the exponential growth of nested rules.
