	Optional (<i>Choose One</i>)	Group 1	dimension_- preference nodal	A set of weights specifying the relative importance of each uncertain variable (dimension) Level to use in sparse grid integration or interpolation
			hierarchical	Level to use in sparse grid integration or interpolation

	Optional (<i>Choose One</i>)	Quadrature Rule Growth (Group 2)	restricted	Restrict the growth rates for nested and non-nested rules can be synchronized for consistency.
			unrestricted	Override the default restriction of growth rates for nested and non-nested rules that are by default synchronized for consistency.
	Optional (<i>Choose One</i>)	Quadrature Rule Nesting (Group 3)	nested	Enforce use of nested quadrature rules if available
			non_nested	Enforce use of non-nested quadrature rules

Description

Multi-dimensional integration by the Smolyak sparse grid method (specified with `sparse_grid_level` and, optionally, `dimension_preference`). The underlying one-dimensional integration rules are the same as for the tensor-product quadrature case; however, the default rule selection is nested for sparse grids (Genz-Keister for normals/transformed normals and Gauss-Patterson for uniforms/transformed uniforms). This default can be overridden with an explicit `non_nested` specification (resulting in Gauss-Hermite for normals/transformed normals and Gauss-Legendre for uniforms/transformed uniforms). As for tensor quadrature, the `dimension_preference` specification enables the use of anisotropic sparse grids (refer to the PCE description in the User's Manual for the anisotropic index set constraint definition). Similar to anisotropic tensor grids, the dimension with greatest preference will have resolution at the full `sparse_grid_level` and all other dimension resolutions will be reduced in proportion to their reduced preference. For PCE with either isotropic or anisotropic sparse grids, a summation of tensor-product expansions is used, where each anisotropic tensor-product quadrature rule underlying the sparse grid construction results in its own anisotropic tensor-product expansion as described in case 1. These anisotropic tensor-product expansions are summed into a sparse PCE using the standard Smolyak summation (again, refer to the User's Manual for additional details). As for `quadrature_order`, the `sparse_grid_level` specification admits an array input for enabling specification of multiple grid resolutions used by certain advanced solution methodologies.

Usage Tips

This keyword can be used when using sparse grid integration to calculate PCE coefficients or when generating samples for sparse grid collocation.

For most use cases, this keyword will specify a single integer level. In more advanced UQ studies with hierarchical models, the list of integers can apply to different models and/or model levels

- [restricted](#)

Restrict the growth rates for nested and non-nested rules can be synchronized for consistency.

Specification

Alias: none

Argument(s): none

Default: restricted (except for generalized sparse grids)

Description

In the quadrature and sparse grid cases, growth rates for nested and non-nested rules can be synchronized for consistency. For a non-nested Gauss rule used within a sparse grid, linear one-dimensional growth rules of $m = 2l + 1$ are used to enforce odd quadrature orders, where l is the grid level and m is the number of points in the rule. The precision of this Gauss rule is then $i = 2m - 1 = 4l + 1$. For nested rules, order growth with level is typically exponential; however, the default behavior is to restrict the number of points to be the lowest order rule that is available that meets the one-dimensional precision requirement implied by either a level l for a sparse grid ($i = 4l + 1$) or an order m for a tensor grid ($i = 2m - 1$). This behavior is known as "restricted growth" or "delayed sequences." To override this default behavior in the case of sparse grids, the `unrestricted` keyword can be used; it cannot be overridden for tensor grids using nested rules since it also provides a mapping to the available nested rule quadrature orders. An exception to the default usage of restricted growth is the `dimension_adaptive_p_refinement` generalized sparse grid case described previously, since the ability to evolve the index sets of a sparse grid in an unstructured manner eliminates the motivation for restricting the exponential growth of nested rules.

- [emulator](#)
- [mf_sc](#)
- [piecewise](#)

Use piecewise local basis functions

Specification

Alias: none

Argument(s): none

Default: extended (Askey + numerically-generated)

Description

SC also supports the option of piecewise local basis functions. These are piecewise linear splines, or in the case of gradient-enhanced interpolation via the `use_derivatives` specification, piecewise cubic Hermite splines. Both of these basis selections provide local support only over the range from the interpolated point to its nearest 1D neighbors (within a tensor grid or within each of the tensor grids underlying a sparse grid), which exchanges the fast convergence of global bases for smooth functions for robustness in the representation of nonsmooth response functions (that can induce Gibbs oscillations when using high-order global basis functions). When local basis functions are used, the usage of nonequidistant collocation points (e.g., the Gauss point selections described above) is not well motivated, so equidistant Newton-Cotes points are employed in this case, and all random variable types are transformed to standard uniform probability space.

askey

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [dream](#)
- [emulator](#)
- [mf_sc](#)

- [askey](#)

Select the standardized random variables (and associated basis polynomials) from the Askey family that best match the user-specified random variables.

Specification

Alias: none

Argument(s): none

Default: extended (Askey + numerically-generated)

Description

The Askey option employs standard normal, standard uniform, standard exponential, standard beta, and standard gamma random variables in a transformed probability space. These selections correspond to Hermite, Legendre, Laguerre, Jacobi, and generalized Laguerre orthogonal polynomials, respectively.

Specific mappings for the basis polynomials are based on a closest match criterion, and include Hermite for normal (optimal) as well as bounded normal, lognormal, bounded lognormal, gumbel, frechet, and weibull (sub-optimal); Legendre for uniform (optimal) as well as loguniform, triangular, and bin-based histogram (sub-optimal); Laguerre for exponential (optimal); Jacobi for beta (optimal); and generalized Laguerre for gamma (optimal).

- [use_derivatives](#)

Use derivative data to construct surrogate models

Specification

Alias: none

Argument(s): none

Default: use function values only

Description

The `use_derivatives` flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, its use with Surfpack Gaussian process is not recommended.

standardized_space

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [dream](#)
- [standardized_space](#)

Perform Bayesian inference in standardized probability space

Specification

Alias: none

Argument(s): none

Description

This option transforms the inference process (MCMC sampling and any emulator model management) into a standardized probability space.

The variable transformations performed are as described in [askey](#).

Default Behavior

The default for the Gaussian process and no emulator options is to perform inference in the original probability space (no transformation). Polynomial chaos and stochastic collocation emulators, on the other hand, are always formed in standardized probability space, such that the inference process is also performed in this standardized space.

Expected Output

The user will see the truth model evaluations performed in the original space, whereas any method diagnostics relating to the MCMC samples (e.g., QUESO data in the `outputData` directory) will report points and response data (response gradients and Hessians, if present, will differ but response values will not) that correspond to the transformed space.

Usage Tips

Selecting `standardized_space` generally has the effect of scaling the random variables to be of comparable magnitude, which can improve the efficiency of the Bayesian inference process.

Examples

```
method,
  bayes_calibration queso
  samples = 2000 seed = 348
  dram
  standardized_space
```

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		<code>header</code>	Enable header row in custom-annotated tabular file
	Optional		<code>eval_id</code>	Enable evaluation ID column in custom-annotated tabular file
	Optional		<code>interface_id</code>	Enable interface ID column in custom-annotated tabular file

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether `header` row, `eval_id` column, and `interface_id` column appear in the tabular file, thus bridging `freeform` and (fully) `annotated`.

Default Behavior

The `annotated` format is the default for tabular export/import. To control which header row and columns are in the input/output, specify `custom_annotated`, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to `annotated` format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only `header` and `eval_id` (no `interface_id`), and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id      x1          x2          obj_fn  nln_ineq_con_1  nln_ineq_con_2
1              0.9          1.1          0.0002          0.26          0.76

- [export_chain_points_file](#)
- [annotated](#)

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The `annotated` keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include `interface_id`, specify `custom_annotated` header `eval_id`
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export an annotated top-level tabular data file containing a header row, leading `eval_id` and `interface_id` columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated
```

Resulting tabular file:

```
%eval_id interface          x1          x2          obj_fn nln_ineq_con_1 nln_ineq_con_2
1          NO_ID            0.9          1.1          0.0002          0.26          0.76
2          NO_ID            0.90009      1.1 0.0001996404857 0.2601620081 0.759955

```

freeform

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [dream](#)
- [export_chain_points_file](#)
- [freeform](#)

Selects freeform file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The `annotated` format is the default for tabular export/import. To change this behavior, specify `freeform` in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to `annotated` format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- In `freeform`, the `num_rows` x `num_cols` total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

```

      0.9          1.1          0.0002          0.26          0.76

experimental_design

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [experimental_design](#)

(Experimental) Adaptively select experimental designs for iterative Bayesian updating

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Required	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required		initial_samples	Number of data points used during initial Bayesian calibration
	Optional		num_candidates	Number of candidate design points considered
	Optional		max_hifi- evaluations	Maximum number of high-fidelity model runs to be used
	Optional		batch_size	Number of optimal designs selected concurrently
	Optional		import_candidate_ points_file	Specify text file containing candidate design points

	Optional	<code>ksg2</code>	Use second Kraskov algorithm to compute mutual information
--	-----------------	-------------------	--

Description

This "experimental design" algorithm uses responses produced by a high-fidelity model as data to update the parameters of a low-fidelity model using Bayes' Rule. It is a capability that is under active development and is currently compatible only with `queso`. The user-specified high-fidelity model should depend only on configuration variables (i.e. design conditions), such as temperature or spatial location, while the user-specified low-fidelity model should depend on both configuration variables and its own model parameters to be calibrated.

The algorithm starts with a preliminary Bayesian calibration using the number of data points specified in `initial_samples`. These data points can be read in through the `calibration_data_file` command in the `responses` block. If `num_experiments` is less than `initial_samples` or if no such data file is provided, Latin Hypercube Samples of the design space (specified in the `variables` block) will be run through the user-specified high-fidelity code to supplement the initial data. Once this first calibration is complete, a set of possible experimental design conditions, specified using the configuration variables, is proposed. The user specifies the size of this set using `num_candidates`. The set of candidates itself may be explicitly given through the `import_candidate_points_file` command. If the number of candidates in this file is less than `num_candidates`, or if this file is omitted, the set of candidate designs will again be supplemented with a Latin Hypercube Sample of the design space.

For each candidate design ξ_i in the set of possible design conditions, the mutual information (MI) between the low-fidelity model parameters θ and the high-fidelity model response $\mathbf{y}(\xi_i)$,

$$MI = \iint f(\theta, \mathbf{y}(\xi_i)) \log \frac{f(\theta, \mathbf{y}(\xi_i))}{f(\theta)f(\mathbf{y}(\xi_i))} d\theta d\mathbf{y},$$

is approximated. The high-fidelity model is replaced by the low-fidelity model and a k -nearest neighbor approximation is used in the calculation. The design point ξ^* for which MI is the largest is selected and run through the high-fidelity model to yield a new observation $y(\xi^*)$. This new observation is added to the calibration data, and a subsequent Bayesian calibration is performed. A new MI for each remaining candidate design is computed, and the process repeats until one of three stopping criteria are met. Multiple optimal designs may be selected concurrently by specifying `batch_size`.

Of the three stopping criteria, two are automatically checked by Dakota. If the relative change in the MI from one iteration to the next is sufficiently small or if the set of candidate design conditions has been exhausted, the algorithm terminates. The user may specify the third stopping criteria using `max_hifi_evaluations`. This limits the number of high-fidelity model evaluations that will be performed during this algorithm. It therefore limits the number of iterations through the algorithm that will be performed. Any high-fidelity model runs needed to produce the data set for the initial calibration are not included in this allocation.

In the case that the high-fidelity model must be run independently of Dakota, the user may set `max_hifi_evaluations` to zero. The optimal experimental design point will be calculated and reported, but the high-fidelity model will not be run. For more details, see the User's Manual.

Expected Output

Information regarding the progress and termination condition of the experimental design algorithm is output to the screen with varying levels of verbosity. Further details can be found, regardless of verbosity, in the output file `experimental_design_output.txt`

Usage Tips

Due to the optional file read-ins and the supplemental sampling, it is important for the user to check consistency within the input file specifications. For example, if `num_experiments` is less than the number of

experiments in the `calibration_data_file`, only the first lines of the file will be used and the rest will be discarded. The same holds true for the `import_candidate_points_file` and `num_candidates`.

Examples

The input file below illustrates the use of `experimental_design` and its options

```

bayes_calibration
  queso
  dram
  chain_samples = 1000 seed = 348
experimental_design
  initial_samples = 5
  num_candidates = 10
  import_candidate_points_file = "bayes_experimental_design.cand.dat"
  freeform
  max_hifi_evaluations = 3

```

initial_samples

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [experimental_design](#)
- [initial_samples](#)

Number of data points used during initial Bayesian calibration

Specification

Alias: samples

Argument(s): INTEGER

Default: method-dependent

Description

The experimental design algorithm starts with a preliminary Bayesian calibration. The keyword `initial_samples` specifies the number of data points used during this initial calibration. These data points may come from external data sources through `calibration_data_file`, from an LHS sample of the design space, or both.

num_candidates

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [experimental_design](#)
- [num_candidates](#)

Number of candidate design points considered

Specification

Alias: none

Argument(s): INTEGER

Default: 1

Description

After the initial Bayesian calibration, a set of candidate design points is created, from which the optimal design(s) will be chosen. This set is of size `num_candidates`. These candidate points may be specified by the user through `import_candidate_points_file`, from an LHS sample of the design space, or both.

`max_hifi_evaluations`

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [experimental_design](#)
- [max_hifi_evaluations](#)

Maximum number of high-fidelity model runs to be used

Specification

Alias: none

Argument(s): INTEGER

Description

There are three stopping criteria by which the Bayesian experimental design algorithm will be terminated:

- The high-fidelity model has been run `max_hifi_evaluations` times
- The set of candidate design points have been exhausted
- The relative change in the mutual information from one iteration to the next is sufficiently small The first criterion is controlled by this keyword specification

Default Behavior

If no maximum number of high-fidelity model runs is specified, only the last two stopping criteria listed above will be evaluated.

Usage Tips

Be wary that `max_hifi_evaluations` does not include any high-fidelity model evaluations that need to be run to produce the data set for the initial Bayesian calibration. This number only includes those evaluations performed on the sequentially chosen optimal design points

If `max_hifi_evaluations` is set to zero, the a single optimal experimental design point will be selected, and Dakota will exit without running the high- fidelity model.

batch_size

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [experimental_design](#)
- [batch_size](#)

Number of optimal designs selected concurrently

Specification

Alias: none

Argument(s): INTEGER

Description

Each iteration of the `experimental_design` algorithm yields `batch_size` optimal designs. If `max_hifi` is set to zero, these values will merely be reported in Dakota output and the file `experimental_design_output.txt`. Otherwise, the high-fidelity model will be run at all optimal designs, and the responses will be added to the list of experiment data before the Bayesian calibration is performed in the next iteration of the algorithm.

Default Behavior

By default, optimal designs will be selected one at a time.

import_candidate_points_file

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [experimental_design](#)
- [import_candidate_points_file](#)

Specify text file containing candidate design points

Specification

Alias: none

Argument(s): STRING

Default: no point import from a file

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description

	Optional (<i>Choose One</i>)	Tabular Format (Group 1)	custom_annotated	Selects custom-annotated tabular file format
			annotated	Selects annotated tabular file format
			freeform	Selects freeform file format

Description

Enables text file import of user-specified design points (i.e. configuration variables). No model responses should be included. Each row should correspond to a single design or configuration.

Default Behavior

Be default, methods do not import points from a file.

Usage Tips

Dakota parses input files without regard to whitespace, but the `import_build_points_file` must be in one of three formats:

- `annotated` (default)
- `custom_annotated`
- `freeform`

`custom_annotated`

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [experimental_design](#)
- [import_candidate_points_file](#)
- [custom_annotated](#)

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		<code>header</code>	Enable header row in custom-annotated tabular file
	Optional		<code>eval_id</code>	Enable evaluation ID column in custom-annotated tabular file
	Optional		<code>interface_id</code>	Enable interface ID column in custom-annotated tabular file

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, `eval_id` column, and `interface_id` column appear in the tabular file, thus bridging `freeform` and (fully) annotated.

Default Behavior

The `annotated` format is the default for tabular export/import. To control which header row and columns are in the input/output, specify `custom_annotated`, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to `annotated` format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and `eval_id` (no `interface_id`), and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id      x1          x2          obj_fn  nln_ineq_con_1  nln_ineq_con_2
1              0.9          1.1          0.0002          0.26           0.76
2              0.90009      1.1 0.0001996404857  0.2601620081    0.759955

- [annotated](#)

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The `annotated` keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include `interface_id`, specify `custom_annotated` header `eval_id`
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export an annotated top-level tabular data file containing a header row, leading `eval_id` and `interface_id` columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated
```

Resulting tabular file:

```
%eval_id interface          x1          x2          obj_fn nln_ineq_con_1 nln_ineq_con_2
1          NO_ID            0.9          1.1          0.0002          0.26          0.76
2          NO_ID            0.90009      1.1 0.0001996404857 0.2601620081 0.759955

...
```

freeform

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [experimental_design](#)
- [import_candidate_points_file](#)
- [freeform](#)

Selects freeform file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The `annotated` format is the default for tabular export/import. To change this behavior, specify `freeform` in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to `annotated` format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- In `freeform`, the `num_rows` x `num_cols` total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

```
      0.9      1.1      0.0002      0.26      0.76
0.90009      1.1 0.0001996404857 0.2601620081 0.759955
0.89991      1.1 0.0002003604863 0.2598380081 0.760045

```

ksg2

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)

- [experimental_design](#)
- [ksg2](#)

Use second Kraskov algorithm to compute mutual information

Specification

Alias: none

Argument(s): none

Description

This algorithm is derived in[57]. The mutual information between m random variables is approximated by

$$I_2(X_1, X_2, \dots, X_m) = \psi(k) + (m-1)\psi(N) - (m-1)/k - \langle \psi(n_{x_1}) + \psi(n_{x_2}) + \dots + \psi(n_{x_m}) \rangle,$$

where ψ is the digamma function, k is the number of nearest neighbors being used, and N is the number of samples available for the joint distribution of the random variables. For each point $z_i = (x_{1,i}, x_{2,i}, \dots, x_{m,i})$ in the joint distribution, z_i and its k nearest neighbors are projected into each marginal subspace. For each subspace $j = 1, \dots, m$, $\epsilon_{j,i}$ is defined as the radius of the l_∞ -ball containing all $k+1$ points. Then, $n_{x_{j,i}}$ is the number of points in the j -th subspace within a distance of $\epsilon_{j,i}$ from the point $x_{j,i}$. The angular brackets denote that the average of $\psi(n_{x_{j,i}})$ is taken over all points $i = 1, \dots, N$.

Examples

```
method
  bayes_calibration queso
  dram

calibrate_error_multipliers

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [calibrate_error_multipliers](#)

Calibrate hyper-parameter multipliers on the observation error covariance

Specification

Alias: none

Argument(s): none

Default: none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Calibrate Error Multipliers (Group 1)	one	Calibrate one hyper-parameter multiplier across all re-sponses/experiments
			per_experiment	Calibrate one hyper-parameter multiplier per experiment
			per_response	Calibrate one hyper-parameter multiplier per response
			both	Calibrate one hyper-parameter multiplier for each re-sponse/experiment pair
	Optional		hyperprior_alphas	Shape (alpha) of the inverse gamma hyper-parameter prior

Description

Calibrate one or more multipliers on the user-provided observation error covariance ([experiment_variance_type](#)). Options include [one](#) multiplier on the whole block-diagonal covariance structure, one multiplier [per_experiment](#) covariance block, one multiplier [per_response](#) covariance block, or separate multipliers for each response/experiment pair (for a total of number experiments X number response groups).

Default Behavior: No hyper-parameter calibration. When hyper-parameter calibration is enabled, the default prior on the multiplier is a diffuse inverse gamma, with mean and mode approximately 1.0.

Expected Output: Final calibration results will include both inference parameters and one or more calibrated hyper-parameters.

Usage Tips: The [per_response](#) option can be useful when each response has its own measurement error process, but all experiments were gathered with the same equipment and conditions. The [per_experiment](#) option might be used when working with data from multiple independent laboratories.

Examples

Perform Bayesian calibration with 2 calibration variables and two hyper-parameter multipliers, one per each of two responses. The multipliers are assumed the same across the 10 experiments. The priors on the multipliers are specified using the [hyperprior_alphas](#) and [hyperprior_betas](#) keywords.

```

bayes_calibration queso

Scale (beta) of the inverse gamma hyper-parameter prior

Specification

Alias: none

Argument(s): REALLIST

Description

Scale of the prior distribution for calibrated error multipliers. Either a single value or number of hyper-parameters values may be specified.

Defaults to 103.0 (with alpha = 102.0) so mean and mode are approximately 1.0 and standard deviation is about 0.1.

burn_in_samples

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [burn_in_samples](#)

Manually specify the burn in period for the MCMC chain.

Specification

Alias: none

Argument(s): INTEGER

Default: 0

Description

The burn in period is the number of samples at the beginning of the MCMC chain that are discarded. The resulting chain is less dependent on the starting point of the chain.

Default Behavior

If not specified, no MCMC samples are discarded

Expected Output

If `burn_in_samples` is specified, an additional tabular output file containing the final MCMC chain is generated.

Examples

Generate a chain of length 1000 and discard the first 100 points, resulting in a chain of length 900.

```
method,
  bayes_calibration queso
  chain_samples = 1000 seed = 348
  dram
  proposal_covariance
  diagonal values 1.0e6 1.0e-1

posterior_stats

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [posterior_stats](#)

Compute information-theoretic metrics on posterior parameter distribution

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			kl_divergence	Calculate the Kullback-Leibler Divergence between prior and posterior
	Optional		mutual_info	Calculate the mutual information between prior and posterior
	Optional		kde	Calculate the Kernel Density Estimate of the posterior distribution

Description

Information theory allows for the calculation and quantification of the information contained within a distribution. It is particularly useful for distributions which are not Gaussian, such as those which are bimodal or highly skewed. The `posterior_stats` command calculates information metrics relating to the posterior distribution of the model parameters. These metrics are approximated by making use of the MCMC chain produced during the Bayesian update. This capability can be used with any Bayesian method.

kl_divergence

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)

- [posterior_stats](#)
- [kl_divergence](#)

Calculate the Kullback-Leibler Divergence between prior and posterior

Specification

Alias: none

Argument(s): none

Description

The Kullback-Leibler (KL) Divergence, also called the relative entropy, provides a measure of the difference between two probability distributions. By specifying `kl_divergence`, the KL Divergence between the posterior $f(\boldsymbol{\theta}|\mathbf{y}^{Data})$ and the prior $f(\boldsymbol{\theta})$ parameter distributions is calculated such that

$$D_{KL} = \int f(\boldsymbol{\theta}|\mathbf{y}^{Data}) \log \frac{f(\boldsymbol{\theta}|\mathbf{y}^{Data})}{f(\boldsymbol{\theta})} d\boldsymbol{\theta}$$

This quantity can be interpreted as the amount of information gained about the parameters during the Bayesian update.

Expected Output

If `kl_divergence` is specified, the calculated value will be reported to the screen at the end of the calibration, following the sample statistics of the response functions. Example output is given below.

Additional Discussion

The quantity calculated is a k -nearest neighbor approximation of the possibly multi-dimensional integral given above. Therefore, some applications whose true KL Divergence is quite close to zero may report a negative KL Divergence.

Examples

Below is a `method` block of a Dakota input file that indicates the calculation of the KL Divergence

```
method,
  bayes_calibration queso
  dram
  seed = 34785
  chain_samples = 1000
  posterior_stats kl_divergence
```

The calculated KL approximation is indicated in the screen output by "Information gained from prior to posterior" as shown below

```
Sample moment statistics for each response function:
              Mean          Std Dev          Skewness          Kurtosis
least_sq_term_1  3.9982462078e-01  4.7683816550e-04  -2.3448518080e+00  7.7381497770e+00

Information gained from prior to posterior = 1.0066819600e+01

<<<<< Iterator bayes_calibration completed.
<<<<< Environment execution completed.
```

mutual_info

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [posterior_stats](#)
- [mutual_info](#)

Calculate the mutual information between prior and posterior

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			ksg2	Use second Kraskov algorithm to compute mutual information

Description

The mutual information quantifies how much information two random variables contain about each other. It is a measure of the mutual dependence of two random variables. The mutual information is a non-negative measure, with zero representing complete independence of the two random variables. For continuous random variables X and Y , the mutual information is

$$I(X, Y) = \int \int p(x, y) \log \frac{p(x, y)}{p(x)p(y)} dx dy.$$

The mutual information can also be interpreted as the reduction in uncertainty of one random variable due to the knowledge of another. By specifying, `mutual_info`, the mutual information between the posterior parameters and the prior parameters is calculated.

The mutual information is calculated using a k -nearest neighbor approximation algorithm. As of Dakota 6.6, there are two such algorithms available, both of which are derived in [57]. By default, Dakota uses the first such algorithm; the second may be selected by specifying the keyword `ksg2`. Further details can be found in the Dakota Theory Manual [6].

Expected Output

If `mutual_information` is specified, the calculated value will be reported to the screen at the end of the calibration.

Additional Discussion

Due to the necessary approximation of the multidimensional integral above, a negative mutual information may be reported for applications whose true value is close to or equal to zero. As of Dakota 6.6, mutual information calculations are primarily used in the implementation of the `experimental_design` algorithm.

Examples

```
method
  bayes_calibration queso
  dram
  seed = 34785
  chain_samples = 1000
  posterior_stats mutual_info
```

Argument(s): none

Description

A kernel density estimate (KDE) is a non-parametric, smooth approximation of the probability density function of a random variable. It is calculated using a set of samples of the random variable. If X is a univariate random variable with unknown density f and independent and identically distributed samples x_1, x_2, \dots, x_n , the KDE is given by

$$\hat{f} = \frac{1}{nh} \sum_{i=1}^n K\left(\frac{x - x_i}{h}\right).$$

The kernel K is a non-negative function which integrates to one. Although the kernel can take many forms, such as uniform or triangular, Dakota uses a normal kernel. The bandwidth h is a smoothing parameter that should be optimized. Choosing a large value of h yields a wide KDE with large variance, while choosing a small value of h yields a choppy KDE with large bias. Dakota approximates the bandwidth using Silverman's rule of thumb,

$$h = \hat{\sigma} \left(\frac{4}{3n}\right)^{1/5},$$

where $\hat{\sigma}$ is the standard deviation of the sample set $\{x_i\}$.

For multivariate cases, the random variables are treated as independent, and a separate KDE is calculated for each.

Expected Output

If `kde` is specified, calculated values of \hat{f} will be output to the file `kde_posterior.dat`. Example output is given below.

Examples

Below is a `method` block of a Dakota input file that indicates the calculation of the KDE

```
method,
  bayes_calibration queso
  dram
  seed = 34785
  chain_samples = 1000
  posterior_stats kde
```

The calculated KDE values are output to the file `kde_posterior.dat`, as shown below

```

- [chain_diagnostics](#)

Compute diagnostic metrics for Markov chain

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			confidence_ intervals	Calculate the confidence intervals on estimates of first and second moments

Description

While a Markov chain produced via Monte Carlo sampling eventually converges to a set of samples representative of an underlying probability distribution, the first set of samples may not accurately capture the target distribution. Chain diagnostic metrics provide measures of this convergence, and are intended to help users decide whether samples should be increased in Bayesian calibration exercises.

confidence_intervals

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [chain_diagnostics](#)
- [confidence_intervals](#)

Calculate the confidence intervals on estimates of first and second moments

Specification

Alias: none

Argument(s): none

Description

During Bayesian calibration, a chain of samples is produced, which represents the underlying posterior distribution of model parameters. For each parameter sample, the corresponding model response is computed. The `confidence_intervals` keyword indicates the calculation of a 95% confidence interval on the estimated mean and variance of each parameter and each response.

As of Dakota 6.10, these confidence intervals are calculated using the asymptotically valid interval estimator,

$$\bar{g}_n \pm t_* \frac{\hat{\sigma}_n}{\sqrt{n}},$$

where \bar{g}_n is the moment (i.e. mean or variance), t_* is the Student's t -value for the 95th quantile, n is the sample size, and $\hat{\sigma}_n$ is an estimate of the standard error whose square is obtained using batch means estimation. The Markov chain produced during calibration is broken up into "batches," the sample moment is calculated for each batch, and $\hat{\sigma}_n$ is an unbiased estimate of the standard deviation in these batch moment calculations.

Expected Output

If `confidence_intervals` is specified, the 95% confidence interval for the mean and variance for each parameter and for each response will be output to the screen. If `output` is set to `debug`, the mean of the moment calculated for each batch will also be output to the screen.

Additional Discussion

Confidence intervals may be used to indicate to the user whether `samples` needs to be increased during the Bayesian calibration. For example, if the width of the intervals (one, many, or all) is below some threshold value, that may indicate that enough samples have been drawn.

Examples

Below is a `method` block of a Dakota input file that indicates the calculation of confidence intervals

```
method,
  bayes_calibration queso
  dram
  seed = 34785
  chain_samples = 1000
  chain_diagnostics
  confidence_intervals
```

The calculated confidence intervals are output to the screen under "Chain diagnostics":

model_evidence

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [model_evidence](#)

Calculate model evidence (marginal likelihood of model) when using Bayesian methods

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		mc_approx	Calculate model evidence using a Monte Carlo sampling approach

	Optional	evidence_samples	The number of samples used in Monte Carlo approximation of the model evidence.
	Optional	laplace_approx	Calculate model evidence using the Laplace approximation

Description

Model evidence is used in Bayesian model selection and model averaging. It is defined as the probability of the data given the model, and is calculated by averaging the likelihood of the model parameters over all values of the model parameters according to their prior distributions. In Dakota, one must calculate the model evidence separately for each model and perform the normalization to obtain the posterior model plausibility for each model.

Default Behavior

When specifying `model_evidence`, there are two methods of calculating it. One or both may be specified. They include the Monte Carlo approximation, given by `mc_approx` and the Laplace approximation, given by `laplace_approx`. `mc_approx` is the default approach.

Expected Output Currently, the model evidence will be printed in the screen output with prefacing text indicating if it is calculated by Monte Carlo sampling or the Laplace approximation.

Usage Tips

`mc_approx`

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [model_evidence](#)
- [mc_approx](#)

Calculate model evidence using a Monte Carlo sampling approach

Specification

Alias: none

Argument(s): none

Description

The `mc_approx` keyword for model evidence indicates that sample values will be generated from the prior distribution, and then the simulation model will be evaluated at these sample values to obtain corresponding likelihood values. The average of the likelihood weighted by the prior is the model evidence. The accuracy of

this approximation depends on the number of samples taken, which is specified by the `evidence_samples` keyword.

Default Behavior

If `evidence_samples` is not specified with `mc_approx`, Dakota uses the number of chain samples from the MCMC (`chain_samples`) as the number of samples to use for calculating the model evidence.

Expected Output Currently, the model evidence will be printed in the screen output with prefacing text indicating if it is calculated by Monte Carlo sampling.

Usage Tips

evidence_samples

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [model_evidence](#)
- [evidence_samples](#)

The number of samples used in Monte Carlo approximation of the model evidence.

Specification

Alias: none

Argument(s): INTEGER

Description

The `mc_approx` keyword for model evidence indicates that sample values will be generated from the prior distribution, and then the simulation model will be evaluated at these sample values to obtain corresponding likelihood values. The average of the likelihood weighted by the prior is the model evidence. The accuracy of this approximation depends on the number of samples taken, which is specified by the `evidence_samples` keyword. Note that each sample specified by the `evidence_samples` keyword will require an evaluation of the simulation model to compute the corresponding likelihood. So, this may become costly for expensive simulations. Additionally, many prior samples will have very low (near zero) likelihood, so millions of samples may be required for accurate computation of the integral which defines model evidence.

Default Behavior

If `evidence_samples` is not specified with `mc_approx`, Dakota uses the number of chain samples from the MCMC (`chain_samples`) as the number of samples to use for calculating the model evidence.

Expected Output Currently, the model evidence will be printed in the screen output with prefacing text indicating if it is calculated by Monte Carlo sampling.

Usage Tips

laplace_approx

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)

- [model_evidence](#)
- [laplace_approx](#)

Calculate model evidence using the Laplace approximation

Specification

Alias: none

Argument(s): none

Description

The `laplace_approx` keyword for model evidence indicates that a pre-solve will be used prior to the Bayesian MCMC sampling to estimate the Maximum A Posteriori (MAP) point. The Laplace approximation assumes the posterior density is nearly Gaussian and is given by a formula which involves the likelihood at the MAP point, the prior density at the MAP point, and the Hessian of the log-posterior at the MAP point. The formula is given in the Dakota User's manual. This method is efficient at estimating the model evidence for posterior densities with weak non-Gaussian characteristics but it does require a MAP solve (so `pre-solve` should be specified) and it does require gradient and Hessians of the response to be on.

Default Behavior

Expected Output Currently, the model evidence will be printed in the screen output with prefacing text indicating if it is calculated by the Laplace approximation.

(Experimental) Post-calibration calculation of model discrepancy correction

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			discrepancy_type	Specify the type of model discrepancy

	Optional	num_prediction_-configs	Specify number of prediction locations for model discrepancy
	Optional	prediction_configs	List prediction locations for model discrepancy
	Optional	import_prediction_-configs	Specify text file containing prediction configurations for model discrepancy
	Optional	export_-discrepancy_file	Output file for prediction discrepancy calculations
	Optional	export_corrected_-model_file	Output file for corrected model prediction calculations
	Optional	export_corrected_-variance_file	Output file for prediction variance calculations

Description

The goal of parameter calibration is to minimize the difference between experimental data, $d(x)$, and model observations, $M(\theta, x)$, where θ are the model parameters and x is a configuration variable, such as temperature or pressure. However, it is not uncommon that, at the conclusion of parameter calibration, the agreement between experimental data and the calibrated model is not "close enough." This is often due to model form or structural error. In this case, the canonical equation

$$d(x) = M(\theta, x) + \varepsilon$$

is replaced by one that also includes model discrepancy $\delta(x)$,

$$d(x) = M(\theta, x) + \delta(x) + \varepsilon.$$

In the Dakota implementation, the calculation of $\delta(x)$ is performed after the model parameters θ are calibrated. For each observable d_i , the discrepancy

$$\delta_i(x_j) = d_i(x_j) - M_i(\theta^*, x_j)$$

is calculated for each value x_j of the configuration variable, where θ^* is the optimal parameter value obtained during the calibration. For scalar responses, the model discrepancy is only a function of the configuration

variables, and there is one discrepancy regression model for each observable d_i . This set of discrepancy models may be specified to be either Gaussian process or polynomial regression models of constant, linear, or quadratic order, and each model is fit to the calculated discrepancy values. See the [discrepancy_type](#) command for more details regarding these options. For field responses, the model discrepancy is a function of the configuration variables as well as the independent field coordinates (such as time or space), and there is one discrepancy regression model for each field. In this case, the discrepancy models are Gaussian process models. The calculation of model discrepancy has not been tested for cases in which responses are mixed scalar and field responses.

The user may then specify new or "prediction" configurations at which the corrected model $M(\theta^*, x_{new}) + \delta(x_{new})$ should be calculated, using one of the `num_prediction_configs`, `prediction_configs`, or `import_prediction_configs` keywords. If none of these keywords is specified, the number of prediction configurations is set to 10 for scalar responses. The corresponding prediction variances are also calculated, according to

$$\Sigma_{total}(x) = \Sigma_{\delta}(x) + \sigma_{exp}^2 I.$$

Here, $\Sigma_{\delta}(x)$ is the (co)variance calculated from the Gaussian process or polynomial regression model, and σ_{exp}^2 is the maximum variance, taken over all configuration variables for that observation. In the case of field responses, the default prediction configurations are set equal to the input configurations, and the variance information contains only the variance calculated from the Gaussian process correction model. Further details can be found in the Dakota User's and Theory Manuals.

Usage Tips

For field responses, the keyword [read_field_coordinates](#) *must* be specified when computing the model discrepancy. See [field_calibration_terms](#) for more information regarding options for calibration with field responses.

Expected Output

The resulting values of $\delta(x_{new})$ will be exported to the file specified using `export_discrepancy_file` or to the default file `dakota_discrepancy_tabular.dat`. The values of the corrected model at the specified prediction configurations will be exported to the file specified using `export_corrected_model_file` or to the default file `dakota_corrected_model_tabular.dat`, and the corresponding prediction variances will be exported to `dakota_discrepancy_variance_tabular.dat` or the file specified with `export_corrected_variance_file`.

Examples

Extensive examples can be found in the Dakota User's and Theory Manuals. The input files below illustrate the options available to `model_discrepancy`

```
model_discrepancy
  discrepancy_type gaussian_process
  num_prediction_configs 11

- [model_discrepancy](#)
- [discrepancy_type](#)

Specify the type of model discrepancy

Specification

Alias: none

Argument(s): none

Default: gaussian process

Child Keywords:

	Required/ Optional Required (<i>Choose One</i>)	Description of Group Discrepancy Model (Group 1)	Dakota Keyword	Dakota Keyword Description
			gaussian_process	Use the Surpack version of Gaussain process as the discrepancy model
			polynomial	Use a polynomial surrogate as the discrepancy model
	Optional		correction_order	Trend function order of the model discrepancy

Description

After the model parameters are calibrated, the difference between the data and the calibrated model, i.e. the model discrepancy, is calculated

$$\delta_i(x_j) = d_i(x_j) - M_i(\theta^*, x_j).$$

Each δ_i corresponds to a different regression model. These regression models must all be either Gaussian process or polynomial models, and they are functions of the configuration variable x . The order of the trend function may be selected using the `correction_order` command by specifying `constant`, `linear`, or `quadratic`.

Note that for Dakota 6.9 and earlier, this keyword only applies to discrepancy calculations for scalar responses. For field responses, a Gaussian process model with a quadratic function is used by default.

gaussian_process

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [model_discrepancy](#)
- [discrepancy_type](#)
- [gaussian_process](#)

Use the Surfpack version of Gaussain process as the discrepancy model

Specification

Alias: kriging

Argument(s): none

Description

This keyword specifies a generic version of the Gaussian process implemented in the surface-fitting library called Surfpack. With the exception of the `correction_order` specification, all default options are used in the approximation of the model discrepancy function. That is, DIRECT is used as the optimization method for finding the maximum likelihood estimates of the hyper-parameters that govern the trend and correlation functions, the correlation lengths are optimized by Surfpack, and ill-conditioning is handled internally; gradient-enhanced kriging is not provided as an option in this application.

By selecting this option, each discrepancy function will take the form of a Gaussian process

polynomial

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [model_discrepancy](#)
- [discrepancy_type](#)
- [polynomial](#)

Use a polynomial surrogate as the discrepancy model

Specification

Alias: none

Argument(s): none

Description

For the purposes of model discrepancy, constant, linear, and quadratic polynomial surrogate models are available. These models are less expensive to calculate than Gaussian process models but are consequently less flexible to discrepancy trends that are not constant, linear, or quadratic in nature. For more information, see the Dakota User's and Theory Manuals.

By specifying this command, each discrepancy function will take the form of a polynomial regression. They will all have the same order.

- [import_prediction_configs](#)
- [custom_annotated](#)

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			header	Enable header row in custom-annotated tabular file

	Optional	eval_id	Enable evaluation ID column in custom-annotated tabular file
	Optional	interface_id	Enable interface ID column in custom-annotated tabular file

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, `eval_id` column, and `interface_id` column appear in the tabular file, thus bridging `freeform` and (fully) annotated.

Default Behavior

The `annotated` format is the default for tabular export/import. To control which header row and columns are in the input/output, specify `custom_annotated`, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and `eval_id` (no `interface_id`), and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id      x1          x2          obj_fn  nln_ineq_con_1  nln_ineq_con_2
1              0.9          1.1          0.0002         0.26           0.76

- [import_prediction_configs](#)
- [annotated](#)

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The `annotated` keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include `interface_id`, specify `custom_annotated` header `eval_id`
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export an annotated top-level tabular data file containing a header row, leading `eval_id` and `interface_id` columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated
```

Resulting tabular file:

```
%eval_id interface          x1          x2          obj_fn nln_ineq_con_1 nln_ineq_con_2

Selects freeform file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The `annotated` format is the default for tabular export/import. To change this behavior, specify `freeform` in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to `annotated` format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- In `freeform`, the `num_rows` x `num_cols` total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    freeform
```

Resulting tabular file:

```
      0.9      1.1      0.0002      0.26      0.76
0.90009      1.1 0.0001996404857 0.2601620081 0.759955

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The `annotated` keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include `interface_id`, specify `custom_annotated_header eval_id`
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export an annotated top-level tabular data file containing a header row, leading `eval_id` and `interface_id` columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated
```

			annotated	Selects annotated tabular file format
			freeform	Selects freeform file format

Description

Enables the user to specify the name and format of the file to which corrected model variance information is output. The file will contain the values of the variances computed at those points specified with `num_predictions`, `prediction_configs`, or `import_prediction_configs`.

For scalar responses, the prediction variance for each observable d_i is calculated according to

$$\Sigma_{total}(x) = \Sigma_{\delta}(x) + \sigma_{exp}^2 I.$$

Here, $\Sigma_{\delta}(x)$ is the (co)variance calculated from the Gaussian process or polynomial regression model, details of which can be found in the Dakota User's and Theory Manuals. If experimental variance information is provided for the calibration, the maximum variance found for the observable d_i is used as σ_{exp}^2 . For more details, see the Dakota User's and Theory Manuals. For field responses, the variance of the discrepancy model alone is output to this file.

Default Behavior

If `export_corrected_variance_file` is not specified, information will be automatically output to `dakota_discrepancy_variance_tabular.dat`.

Usage Tips

Dakota exports tabular data in one of three formats:

- `annotated` (default)
- `custom_annotated`
- `freeform`

- [model_discrepancy](#)
- [export_corrected_variance_file](#)
- [annotated](#)

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The `annotated` keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include `interface_id`, specify `custom_annotated` header `eval_id`
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export an annotated top-level tabular data file containing a header row, leading `eval_id` and `interface_id` columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
  annotated
```

Resulting tabular file:

```
%eval_id interface          x1          x2          obj_fn nln_ineq_con_1 nln_ineq_con_2
1          NO_ID            0.9          1.1          0.0002          0.26          0.76
2          NO_ID            0.90009      1.1 0.0001996404857 0.2601620081 0.759955
3          NO_ID            0.89991      1.1 0.0002003604863 0.2598380081 0.760045
...
```

freeform

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [model_discrepancy](#)
- [export_corrected_variance_file](#)
- [freeform](#)

Selects freeform file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The `annotated` format is the default for tabular export/import. To change this behavior, specify `freeform` in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to `annotated` format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- In `freeform`, the `num_rows` x `num_cols` total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

```

      0.9          1.1          0.0002          0.26          0.76
0.90009          1.1 0.0001996404857  0.2601620081  0.759955
0.89991          1.1 0.0002003604863  0.2598380081  0.760045
...

```

sub_sampling_period

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [sub_sampling_period](#)

Specify a sub-sampling of the MCMC chain

Specification

Alias: none

Argument(s): INTEGER

Default: 0

Description

If a `sub_sampling_period` is specified, the MCMC chain is filtered such that only the sample at the beginning of each period is in the final MCMC chain. The `sub_sampling_period` should therefore be greater than or equal to the correlation length of the samples.

Default Behavior

If not specified, all MCMC samples are included in the final chain.

Expected Output

If specified, an additional tabular output file containing the final (sub- sampled) MCMC chain is generated.

Examples

Generate and then filter a 1000 sample MCMC chain, retainining the first accepted sample and every 100th sample thereafter.

An example method block of a Dakota input file is given below

```
method,
  bayes_calibration queso
    chain_samples = 1000 seed = 348
    dram
  proposal_covariance
    diagonal values 1.0e6 1.0e-1
  sub_sampling_period 100
```

probability_levels

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [probability_levels](#)

Specify probability levels at which to compute credible and prediction intervals

Specification

Alias: none

Argument(s): REALLIST

Default: No CDF/CCDF response levels to compute

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		<code>num_probability_- levels</code>	This capability is currently inactive

Description

Credible and prediction intervals of model responses are computed for specified probabilities. Credible intervals are calculated from the response function values corresponding to the final MCMC chain. Calculation of prediction intervals consider these response values as well as the experimental uncertainty, which is specified by the user via the `experiment_variance_type` command.

Expected Output

If `probability_levels` is specified, Dakota will create a table containing the credible intervals for each response function. The corresponding table containing the prediction intervals will also be created if a `experiment_variance_type` has been specified. This information is output to the screen and to a file. In addition, the output file contains the means and standard deviations of each response function and Gaussian approximations of the 5/95 credible and prediction intervals, in which the lower bound is two standard deviations below the mean and the upper bound is two standard deviations above the mean.

Usage Tips

Only one probability level needs to be specified for each desired interval. Both corresponding end points of the intervals are automatically calculated. For example, if 0.05 is specified, both the 0.05 and 0.95 probability levels are output to the screen and output file.

Additional Discussion

Credible intervals propagate uncertainties in parameter density information to the quantity of interest and quantify how well the model fits the provided data. Prediction intervals propagate both parameter and experimental measurement uncertainties and contain the next experimental or simulated observation with the specified probability.

Examples

Below is a Dakota input file specifying the calculation of credible and prediction intervals

```
method,
  bayes_calibration queso
    chain_samples = 1000 seed = 348
  dram
  proposal_covariance
    diagonal values 1.0e6 1.0e-1
  probability_levels 0.05 0.1
    0.075 0.1

variables,
  uniform_uncertain 2
    upper_bounds 1.e8 10.0
    lower_bounds 1.e6 0.1
    initial_point 2.85e7 2.5
    descriptors 'E' 'w'
  continuous_state 4
```

```

initial_state 3 40000 500 1000
descriptors 't' 'R' 'X' 'Y'

interface,
  direct
  analysis_driver = 'mod_cantilever'

responses,
  calibration_terms = 2
  calibration_data_file = 'dakota_cantilever_queso.withsigma.dat'
  freeform
  num_experiments = 10
  experiment_variance_type = 'scalar'
  descriptors = 'stress' 'displacement'
  no_gradients
  no_hessians

```

The resulting screen output below shows the table of credible and prediction intervals.

```

num_probability_levels

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [probability_levels](#)
- [num_probability_levels](#)

This capability is currently inactive

Specification

Alias: none

Argument(s): INTEGERLIST

Default: probability_levels evenly distributed among response functions

convergence_tolerance

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

max_iterations

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [max_iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: fsu_cvt , local_reliability: 25; global_{reliability , interval_est , evidence} / efficient-global: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

model_pointer

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                    0.1 0.2 0.6
                    0.1 0.2 0.6

    sample_type lhs
    distribution cumulative

model
  id_model = 'SURR'
  surrogate global,
  dace_method_pointer = 'DACE'
  polynomial quadratic

method
  id_method = 'DACE'
  model_pointer = 'DACE_M'
  sampling sample_type lhs
  samples = 121 seed = 5034 rng rnum2

model
  id_model = 'DACE_M'
  single
  interface_pointer = 'I1'

variables
  uniform_uncertain = 2
  lower_bounds = 0. 0.
  upper_bounds = 1. 1.
  descriptors = 'x1' 'x2'
```

```

interface
  id_interface = 'I1'
  system async evaluation_concurrency = 5
  analysis_driver = 'text_book'

responses
  response_functions = 3
  no_gradients
  no_hessians

```

scaling

- [Keywords Area](#)
- [method](#)
- [bayes_calibration](#)
- [scaling](#)

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some of the optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated by providing the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords which are found in the [method](#), [variables](#), and [responses](#) blocks. When the `scaling` keyword is omitted, all `_scale_types` and `*_scales` specifications are ignored in the method, variables, and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities to be scaled. These quantities can be constraint equations, variables, or responses.

- a `*scales` keyword, which gives characteristic values
- a `*scale_type` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can either be zero, one, or equal to the number of quantities to be scaled. If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are four scale types:

1. `none` (default) - no scaling, value of `*scales` keyword is ignored
2. `value` - multiplicative scaling
3. `auto` - automatic scaling

First the quantity is scaled by the characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

4. `log` - logarithmic scaling

First, any characteristic values from the optional `*_scales` specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*_scale_type`, as described above.

Depending on the scale type, the characteristic values may be required or optional.

- `none`, `auto`, `log` - optional
- `value` - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 * \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100

responses
objective_functions 3
sense "maximize"
primary_scale_types = "value" "value" "value"
primary_scales = 1 1 100
```

7.2.63 dace

- [Keywords Area](#)
- [method](#)
- [dace](#)

Design and Analysis of Computer Experiments

Topics

This keyword is related to the topics:

- [package_ddace](#)
- [design_and_analysis_of_computer_experiments](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

			oa_lhs	Orthogonal Array Latin Hypercube Sampling
			box_behnken	Box-Behnken Design
			central_composite	Central Composite Design

	Optional	samples	Number of samples for sampling-based methods
	Optional	seed	Seed of the random number generator
	Optional	fixed_seed	Reuses the same seed value for multiple random sampling sets
	Optional Optional	main_effects quality_metrics	ANOVA Calculate metrics to assess the quality of quasi-Monte Carlo samples
	Optional	variance_based_- decomp	Activates global sensitivity analysis based on decomposition of response variance into contributions from variables
	Optional	symbols	Number of replications in the sample set
	Optional	model_pointer	Identifier for model block to be used by a method

Description

The Distributed Design and Analysis of Computer Experiments (DDACE) library provides the following DACE techniques:

1. grid sampling ([grid](#))
2. pure random sampling ([random](#))
3. orthogonal array sampling ([oas](#))
4. latin hypercube sampling ([lhs](#))
5. orthogonal array latin hypercube sampling ([oa_lhs](#))
6. Box-Behnken ([box_behnken](#))
7. central composite design ([central_composite](#))

These methods all generate point sets that may be used to drive a set of computer experiments. Note that all of the DACE methods generated randomized designs, except for Box-Behnken and Central composite which are classical designs. That is, the grid sampling will generate a randomized grid, not what one typically thinks of as a grid of uniformly spaced points over a rectangular grid. Similar, the orthogonal array is a randomized version of an orthogonal array: it does not generate discrete, fixed levels.

In addition to the selection of the method, there are keywords that affect the method outputs:

1. [main_effects](#)
2. [quality_metrics](#)
3. [variance_based_decomp](#)

And keywords that affect the sampling:

1. [fixed_seed](#)
2. [symbols](#)
3. [samples](#)
4. [seed](#)

Grid Sampling

Specification

Alias: none

Argument(s): none

Description

The grid option in DACE will produce a randomized grid of points. If you are interested in a regular grid of points, use the multidimensional parameter study (under Parameter Studies) instead. Grid Sampling

random

- [Keywords Area](#)
- [method](#)
- [dace](#)
- [random](#)

Uses purely random Monte Carlo sampling to sample variables

Specification

Alias: none

Argument(s): none

Description

The `random` keyword invokes Monte Carlo sampling as the means of drawing samples of uncertain variables according to their probability distributions.

Default Behavior

In most contexts, Monte Carlo sampling is not the default sampling mode (exception: `multilevel_sampling`). To change this behavior, the `random` keyword must be specified in conjunction with the `sample_type` keyword.

Usage Tips

Monte Carlo sampling is more computationally expensive than Latin Hypercube Sampling as it requires a larger number of samples to accurately estimate statistics.

Examples

```
method
  sampling
    sample_type random
    samples = 200
```

oas

- [Keywords Area](#)
- [method](#)
- [dace](#)
- [oas](#)

Orthogonal Array Sampling

Specification

Alias: none

Argument(s): none

Description

Orthogonal array sampling (OAS) is a widely used technique for running experiments and systematically testing factor effects. An orthogonal array sample can be described as a 4-tuple $(m; n; s; r)$, where m is the number of sample points, n is the number of input variables, s is the number of symbols, and r is the strength of the orthogonal array. The number of sample points, m , must be a multiple of the number of symbols, s . The number of symbols refers to the number of levels per input variable. The strength refers to the number of columns where we are guaranteed to see all the possibilities an equal number of times. Note that the DACE OAS capability produces a randomized orthogonal array: the samples for a particular level are randomized within that level.

If one examines the sample sets in an orthogonal array by looking at the rows as individual samples and columns as the variables sampled, one sees that the columns are orthogonal to each other in an orthogonal array. This feature is important in main effects analysis, which is a sensitivity analysis technique that identifies which variables have the most influence on the output.

lhs

- [Keywords Area](#)
- [method](#)
- [dace](#)
- [lhs](#)

Uses Latin Hypercube Sampling (LHS) to sample variables

Specification

Alias: none

Argument(s): none

Description

The `lhs` keyword invokes Latin Hypercube Sampling as the means of drawing samples of uncertain variables according to their probability distributions. This is a stratified, space-filling approach that selects variable values from a set of equi-probable bins.

Default Behavior

Latin Hypercube Sampling is the default sampling mode in most contexts (exception: `multilevel_sampling`). To explicitly specify LHS in the Dakota input file, the `lhs` keyword must appear in conjunction with the `sample_type` keyword.

Usage Tips

Latin Hypercube Sampling is very robust and can be applied to any problem. It is fairly effective at estimating the mean of model responses and linear correlations with a reasonably small number of samples relative to the number of variables.

Examples

```
method
  sampling
    sample_type lhs
    samples = 20
```

oa_lhs

- [Keywords Area](#)
- [method](#)
- [dace](#)
- [oa_lhs](#)

Orthogonal Array Latin Hypercube Sampling

Specification

Alias: none

Argument(s): none

Description

The Orthogonal Array Latin Hypercube Sampling option in DACE produces a "latinized" version of an orthogonal array. That is, after the orthogonal array is generated, the samples go through a stratification process to produce samples that have been both orthogonalized and stratified.

These keywords may also be of interest:

- [oas](#)

box_behnken

- [Keywords Area](#)
- [method](#)
- [dace](#)
- [box_behnken](#)

Box-Behnken Design

Specification

Alias: none

Argument(s): none

Description

The Box-Behnken design is similar to a Central Composite design, with some differences. The Box-Behnken design is a quadratic design in that it does not contain an embedded factorial or fractional factorial design. In this design the treatment combinations are at the midpoints of edges of the process space and at the center, as compared with CCD designs where the extra points are placed at star points on a circle outside of the process space. Box- Behken designs are rotatable (or near rotatable) and require 3 levels of each factor.

central_composite

- [Keywords Area](#)
- [method](#)
- [dace](#)
- [central_composite](#)

Central Composite Design

Specification

Alias: none

Argument(s): none

Description

A central composite design (CCD), contains an embedded factorial or fractional factorial design with a center points that is augmented with a group of "star points" that allow estimation of curvature.

Examples

See the User's Manual for an example.

samples

- [Keywords Area](#)
- [method](#)
- [dace](#)
- [samples](#)

Number of samples for sampling-based methods

Specification

Alias: none

Argument(s): INTEGER

Default: 0

Description

The `samples` keyword is used to define the number of samples (i.e., randomly chosen sets of variable values) at which to execute a model.

Default Behavior

By default, Dakota will use the minimum number of samples required by the chosen method.

Usage Tips

To obtain linear sensitivities or to construct a linear response surface, at least $\text{dim}+1$ samples should be used, where "dim" is the number of variables. For sensitivities to quadratic terms or quadratic response surfaces, at least

$(\text{dim}+1)(\text{dim}+2)/2$ samples are needed. For uncertainty quantification, we recommend at least $10 \cdot \text{dim}$ samples. For `variance_based_decomp`, we recommend hundreds to thousands of samples. Note that for `variance_based_decomp`, the number of simulations performed will be $N \cdot (\text{dim}+2)$.

Examples

```
method
  sampling
    sample_type lhs
    samples = 20
```

seed

- [Keywords Area](#)
- [method](#)
- [dace](#)
- [seed](#)

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)

Description

The random `seed` control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

fixed_seed

- [Keywords Area](#)
- [method](#)
- [dace](#)
- [fixed_seed](#)

Reuses the same seed value for multiple random sampling sets

Specification

Alias: none

Argument(s): none

Default: not fixed; pattern varies run-to-run

Description

The `fixed_seed` flag is relevant if multiple sampling sets will be generated over the course of a Dakota analysis. This occurs when using advance methods (e.g., surrogate-based optimization, optimization under uncertainty). The same seed value is reused for each of these multiple sampling sets, which can be important for reducing variability in the sampling results.

Default Behavior

The default behavior is to not use a fixed seed, as the repetition of the same sampling pattern can result in a modeling weakness that an optimizer could potentially exploit (resulting in actual reliabilities that are lower than the estimated reliabilities). For repeatable studies, the `seed` must also be specified.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    fixed_seed
```

main_effects

- [Keywords Area](#)
- [method](#)
- [dace](#)
- [main_effects](#)

ANOVA

Specification

Alias: none

Argument(s): none

Default: No main_effects

Description

The `main_effects` control prints Analysis-of-Variance main effects results (e.g. ANOVA tables with p-values per variable). The `main_effects` control is only operational with the orthogonal arrays or Latin Hypercube designs, not for Box Behnken or Central Composite designs.

Main effects is a sensitivity analysis method which identifies the input variables that have the most influence on the output. In main effects, the idea is to look at the mean of the response function when variable A (for example) is at level 1 vs. when variable A is at level 2 or level 3. If these mean responses of the output are statistically significantly different at different levels of variable A, this is an indication that variable A has a significant effect on the response. The orthogonality of the columns is critical in performing main effects analysis, since the column orthogonality means that the effects of the other variables "cancel out" when looking at the overall effect from one variable at its different levels.

quality_metrics

- [Keywords Area](#)
- [method](#)
- [dace](#)
- [quality_metrics](#)

Calculate metrics to assess the quality of quasi-Monte Carlo samples

Topics

This keyword is related to the topics:

- [package_fsudace](#)

Specification

Alias: none

Argument(s): none

Default: No `quality_metrics`

Description

`quality_metrics` calculates four quality metrics relating to the volumetric spacing of the samples. The four quality metrics measure different aspects relating to the uniformity of point samples in hypercubes. Desirable properties of such point samples are:

- are the points equally spaced
- do the points cover the region
- and are they isotropically distributed
- with no directional bias in the spacing

The four quality metrics we report are:

- `h`: the point distribution norm, which is a measure of uniformity of the point distribution

- chi: a regularity measure, and provides a measure of local uniformity of a set of points
- tau: the second moment trace measure
- d: the second moment determinant measure

All of these values are scaled so that smaller is better (the smaller the metric, the better the uniformity of the point distribution).

Examples

Complete explanation of these measures can be found in [38].

variance_based_decomp

- [Keywords Area](#)
- [method](#)
- [dace](#)
- [variance_based_decomp](#)

Activates global sensitivity analysis based on decomposition of response variance into contributions from variables

Specification

Alias: none

Argument(s): none

Default: no variance-based decomposition

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			drop_tolerance	Suppresses output of sensitivity indices with values lower than this tolerance

Description

Dakota can calculate sensitivity indices through variance based decomposition using the keyword `variance_based_decomp`. These indicate how important the uncertainty in each input variable is in contributing to the output variance.

Default Behavior

Because of the computational cost, `variance_based_decomp` is turned off as a default.

If the user specified a number of samples, N , and a number of nondeterministic variables, M , variance-based decomposition requires the evaluation of $N*(M+2)$ samples. **Note that specifying this keyword will increase the number of function evaluations above the number requested with the `samples` keyword since replicated sets of sample values are evaluated.**

Expected Outputs

When `variance_based_decomp` is specified, sensitivity indices for main effects and total effects will be reported. Main effects (roughly) represent the percent contribution of each individual variable to the variance in the model response. Total effects represent the percent contribution of each individual variable in combination with all other variables to the variance in the model response

Usage Tips

To obtain sensitivity indices that are reasonably accurate, we recommend that N , the number of samples, be at least one hundred and preferably several hundred or thousands.

Examples

```
method,
  sampling
  sample_type lhs
  samples = 100
  variance_based_decomp
```

Theory

In this context, we take sensitivity analysis to be global, not local as when calculating derivatives of output variables with respect to input variables. Our definition is similar to that of [75]: "The study of how uncertainty in the output of a model can be apportioned to different sources of uncertainty in the model input."

Variance based decomposition is a way of using sets of samples to understand how the variance of the output behaves, with respect to each input variable. A larger value of the sensitivity index, S_i , means that the uncertainty in the input variable i has a larger effect on the variance of the output. More details on the calculations and interpretation of the sensitivity indices can be found in [75] and [89].

drop_tolerance

- [Keywords Area](#)
- [method](#)
- [dace](#)
- [variance_based_decomp](#)
- [drop_tolerance](#)

Suppresses output of sensitivity indices with values lower than this tolerance

Specification

Alias: none

Argument(s): REAL

Default: All VBD indices displayed

Description

The `drop_tolerance` keyword allows the user to specify a value below which sensitivity indices generated by `variance_based_decomp` are not displayed.

Default Behavior

By default, all sensitivity indices generated by `variance_based_decomp` are displayed.

Usage Tips

For `polynomial_chaos`, which outputs main, interaction, and total effects by default, the `univariate_effects` may be a more appropriate option. It allows suppression of the interaction effects since the output volume of these results can be prohibitive for high dimensional problems. Similar to suppression of these interactions is the covariance control, which can be selected to be `diagonal_covariance` or `full_covariance`, with the former supporting suppression of the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

Examples

```
method,
  sampling
    sample_type lhs
    samples = 100
    variance_based_decomp
    drop_tolerance = 0.001
```

symbols

- [Keywords Area](#)
- [method](#)
- [dace](#)
- [symbols](#)

Number of replications in the sample set

Specification

Alias: none

Argument(s): INTEGER

Default: default for sampling algorithm

Description

`symbols` is related to the number of levels per variable in the sample set (a larger number of symbols equates to more stratification and fewer replications). For example, if `symbols = 7`, each variable would be divided into seven levels.

model_pointer

- [Keywords Area](#)
- [method](#)
- [dace](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which [model](#) block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a [model](#) block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                    0.1 0.2 0.6
                    0.1 0.2 0.6

    sample_type lhs
    distribution cumulative

```

```

interface_pointer = 'I1'

variables
  uniform_uncertain = 2
  lower_bounds = 0.  0.
  upper_bounds = 1.  1.
  descriptors = 'x1' 'x2'

interface
  id_interface = 'I1'
  system async evaluation_concurrency = 5
  analysis_driver = 'text_book'

responses
  response_functions = 3
  no_gradients
  no_hessians

```

7.2.64 fsu_cvt

- [Keywords Area](#)
- [method](#)
- [fsu_cvt](#)

Design of Computer Experiments - Centroidal Voronoi Tessellation

Topics

This keyword is related to the topics:

- [package_fsudace](#)
- [design_and_analysis_of_computer_experiments](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			samples	Number of samples for sampling-based methods

	Optional	seed	Seed of the random number generator
	Optional	fixed_seed	Reuses the same seed value for multiple random sampling sets
	Optional	latinize	Adjust samples to improve the discrepancy of the marginal distributions
	Optional	quality_metrics	Calculate metrics to assess the quality of quasi-Monte Carlo samples
	Optional	variance_based_-decomp	Activates global sensitivity analysis based on decomposition of response variance into contributions from variables
	Optional	trial_type	Specify how the trial samples are generated
	Optional	num_trials	The number of secondary sample points generated to adjust the location of the primary sample points
	Optional	max_iterations	Number of iterations allowed for optimizers and adaptive UQ methods

	Optional	model_pointer	Identifier for model block to be used by a method
--	-----------------	-------------------------------	---

Description

The FSU Centroidal Voronoi Tessellation method (`fsu_cvt`) produces a set of sample points that are (approximately) a Centroidal Voronoi Tessellation. The primary feature of such a set of points is that they have good volumetric spacing; the points tend to arrange themselves in a pattern of cells that are roughly the same shape.

To produce this set of points, an almost arbitrary set of initial points is chosen, and then an internal set of iterations is carried out. These iterations repeatedly replace the current set of sample points by an estimate of the centroids of the corresponding Voronoi subregions. [18].

The user may generally ignore the details of this internal iteration. If control is desired, however, there are a few variables with which the user can influence the iteration. The user may specify:

- [max_iterations](#), the number of iterations carried out
- [num_trials](#), the number of secondary sample points generated to adjust the location of the primary sample points
- [trial_type](#), which controls how these secondary sample points are generated

This method generates sets of uniform random variables on the interval [0,1]. If the user specifies lower and upper bounds for a variable, the [0,1] samples are mapped to the [lower, upper] interval.

Theory

This method is designed to generate samples with the goal of low discrepancy. Discrepancy refers to the nonuniformity of the sample points within the hypercube.

Discrepancy is defined as the difference between the actual number and the expected number of points one would expect in a particular set B (such as a hyper-rectangle within the unit hypercube), maximized over all such sets. Low discrepancy sequences tend to cover the unit hypercube reasonably uniformly.

Centroidal Voronoi Tessellation does very well volumetrically: it spaces the points fairly equally throughout the space, so that the points cover the region and are isotropically distributed with no directional bias in the point placement. There are various measures of volumetric uniformity which take into account the distances between pairs of points, regularity measures, etc. Note that Centroidal Voronoi Tessellation does not produce low-discrepancy sequences in lower dimensions. The lower-dimension (such as 1-D) projections of Centroidal Voronoi Tessellation can have high discrepancy.

samples

- [Keywords Area](#)
- [method](#)
- [fsu_cvt](#)
- [samples](#)

Number of samples for sampling-based methods

Specification

Alias: none

Argument(s): INTEGER

Default: 0

Description

The `samples` keyword is used to define the number of samples (i.e., randomly chosen sets of variable values) at which to execute a model.

Default Behavior

By default, Dakota will use the minimum number of samples required by the chosen method.

Usage Tips

To obtain linear sensitivities or to construct a linear response surface, at least $\text{dim}+1$ samples should be used, where "dim" is the number of variables. For sensitivities to quadratic terms or quadratic response surfaces, at least $(\text{dim}+1)(\text{dim}+2)/2$ samples are needed. For uncertainty quantification, we recommend at least $10*\text{dim}$ samples. For `variance_based_decomp`, we recommend hundreds to thousands of samples. Note that for `variance_based_decomp`, the number of simulations performed will be $N*(\text{dim}+2)$.

Examples

```
method
  sampling
    sample_type lhs
    samples = 20
```

seed

- [Keywords Area](#)
- [method](#)
- [fsu_cvt](#)
- [seed](#)

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)

Description

The random `seed` control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

fixed_seed

- [Keywords Area](#)
- [method](#)
- [fsu_cvt](#)
- [fixed_seed](#)

Reuses the same seed value for multiple random sampling sets

Specification

Alias: none

Argument(s): none

Default: not fixed; pattern varies run-to-run

Description

The `fixed_seed` flag is relevant if multiple sampling sets will be generated over the course of a Dakota analysis. This occurs when using advance methods (e.g., surrogate-based optimization, optimization under uncertainty). The same seed value is reused for each of these multiple sampling sets, which can be important for reducing variability in the sampling results.

Default Behavior

The default behavior is to not use a fixed seed, as the repetition of the same sampling pattern can result in a modeling weakness that an optimizer could potentially exploit (resulting in actual reliabilities that are lower than the estimated reliabilities). For repeatable studies, the `seed` must also be specified.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    fixed_seed
```

latinize

- [Keywords Area](#)
- [method](#)
- [fsu_cvt](#)
- [latinize](#)

Adjust samples to improve the discrepancy of the marginal distributions

Specification

Alias: none

Argument(s): none

Default: No latinization

Description

The `latinize` control takes the samples and "latinizes" them, meaning that each original sample is moved so that it falls into one strata or bin in each dimension as in Latin Hypercube sampling. The default setting is NOT to latinize. However, one may be interested in doing this in situations where one wants better discrepancy of the 1-dimensional projections (the marginal distributions).

quality_metrics

- [Keywords Area](#)
- [method](#)
- [fsu_cvt](#)
- [quality_metrics](#)

Calculate metrics to assess the quality of quasi-Monte Carlo samples

Topics

This keyword is related to the topics:

- [package_fsudace](#)

Specification

Alias: none

Argument(s): none

Default: No quality_metrics

Description

`quality_metrics` calculates four quality metrics relating to the volumetric spacing of the samples. The four quality metrics measure different aspects relating to the uniformity of point samples in hypercubes. Desirable properties of such point samples are:

- are the points equally spaced
- do the points cover the region
- and are they isotropically distributed
- with no directional bias in the spacing

The four quality metrics we report are:

- `h`: the point distribution norm, which is a measure of uniformity of the point distribution
- `chi`: a regularity measure, and provides a measure of local uniformity of a set of points
- `tau`: the second moment trace measure
- `d`: the second moment determinant measure

All of these values are scaled so that smaller is better (the smaller the metric, the better the uniformity of the point distribution).

Examples

Complete explanation of these measures can be found in [38].

`variance_based_decomp`

- [Keywords Area](#)
- [method](#)
- [fsu_cvt](#)
- [variance_based_decomp](#)

Activates global sensitivity analysis based on decomposition of response variance into contributions from variables

Specification

Alias: none

Argument(s): none

Default: no variance-based decomposition

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description

	Optional	drop_tolerance	Suppresses output of sensitivity indices with values lower than this tolerance
--	-----------------	--------------------------------	--

Description

Dakota can calculate sensitivity indices through variance based decomposition using the keyword `variance_based_decomp`. These indicate how important the uncertainty in each input variable is in contributing to the output variance.

Default Behavior

Because of the computational cost, `variance_based_decomp` is turned off as a default.

If the user specified a number of samples, N, and a number of nondeterministic variables, M, variance-based decomposition requires the evaluation of $N*(M+2)$ samples. **Note that specifying this keyword will increase the number of function evaluations above the number requested with the `samples` keyword since replicated sets of sample values are evaluated.**

Expected Outputs

When `variance_based_decomp` is specified, sensitivity indices for main effects and total effects will be reported. Main effects (roughly) represent the percent contribution of each individual variable to the variance in the model response. Total effects represent the percent contribution of each individual variable in combination with all other variables to the variance in the model response

Usage Tips

To obtain sensitivity indices that are reasonably accurate, we recommend that N, the number of samples, be at least one hundred and preferably several hundred or thousands.

Examples

```
method,
  sampling
  sample_type lhs
  samples = 100
  variance_based_decomp
```

Theory

In this context, we take sensitivity analysis to be global, not local as when calculating derivatives of output variables with respect to input variables. Our definition is similar to that of [75]: "The study of how uncertainty in the output of a model can be apportioned to different sources of uncertainty in the model input."

Variance based decomposition is a way of using sets of samples to understand how the variance of the output behaves, with respect to each input variable. A larger value of the sensitivity index, S_i , means that the uncertainty in the input variable i has a larger effect on the variance of the output. More details on the calculations and interpretation of the sensitivity indices can be found in [75] and [89].

drop_tolerance

- [Keywords Area](#)
- [method](#)
- [fsu_cvt](#)

- [variance_based_decomp](#)
- [drop_tolerance](#)

Suppresses output of sensitivity indices with values lower than this tolerance

Specification

Alias: none

Argument(s): REAL

Default: All VBD indices displayed

Description

The `drop_tolerance` keyword allows the user to specify a value below which sensitivity indices generated by `variance_based_decomp` are not displayed.

Default Behavior

By default, all sensitivity indices generated by `variance_based_decomp` are displayed.

Usage Tips

For `polynomial_chaos`, which outputs main, interaction, and total effects by default, the `univariate_effects` may be a more appropriate option. It allows suppression of the interaction effects since the output volume of these results can be prohibitive for high dimensional problems. Similar to suppression of these interactions is the covariance control, which can be selected to be `diagonal_covariance` or `full_covariance`, with the former supporting suppression of the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

Examples

```
method,
  sampling
    sample_type lhs
    samples = 100

    drop_tolerance = 0.001
```

trial_type

- [Keywords Area](#)
- [method](#)
- [fsu_cvt](#)
- [trial_type](#)

Specify how the trial samples are generated

Specification

Alias: none

Argument(s): none

Default: random

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Trial Type (Group 1)	grid	Samples on a regular grid
			halton	Generate samples from a Halton sequence
			random	Uses purely random Monte Carlo sampling to sample variables

Description

The user has the option to specify the method by which the trials are created to adjust the centroids. The `trial_type` can be one of three types:

- `random`, where points are generated randomly
- `halton`, where points are generated according to the Halton sequence
- `grid`, where points are placed on a regular grid over the hyperspace.

grid

- [Keywords Area](#)
- [method](#)
- [fsu_cvt](#)
- [trial_type](#)
- [grid](#)

Samples on a regular grid

Specification

Alias: none

Argument(s): none

Description

Points are placed on a regular grid over the hyperspace.

These keywords may also be of interest:

- [trial_type](#)

halton

- [Keywords Area](#)
- [method](#)
- [fsu_cvt](#)
- [trial_type](#)
- [halton](#)

Generate samples from a Halton sequence

Topics

This keyword is related to the topics:

- [package_fsudace](#)

Specification

Alias: none

Argument(s): none

Description

The quasi-Monte Carlo sequences of Halton are deterministic sequences determined by a set of prime bases. These sequences generate random numbers with the goal of filling a unit hypercube uniformly.

Generally, we recommend that the user leave the default setting for the bases, which are the lowest primes. Thus, if one wants to generate a sample set for 3 random variables, the default bases used are 2, 3, and 5 in the Halton sequence. To give an example of how these sequences look, the Halton sequence in base 2 starts with points 0.5, 0.25, 0.75, 0.125, 0.625, etc. The first few points in a Halton base 3 sequence are 0.33333, 0.66667, 0.11111, 0.44444, 0.77777, etc. Notice that the Halton sequence tends to alternate back and forth, generating a point closer to zero then a point closer to one. An individual sequence is based on a radix inverse function defined on a prime base. The prime base determines how quickly the [0,1] interval is filled in.

Theory

For more information about these sequences, see [\[43\]](#), [\[44\]](#), and [\[1\]](#).

random

- [Keywords Area](#)
- [method](#)
- [fsu_cvt](#)
- [trial_type](#)
- [random](#)

Uses purely random Monte Carlo sampling to sample variables

Specification

Alias: none

Argument(s): none

Description

The `random` keyword invokes Monte Carlo sampling as the means of drawing samples of uncertain variables according to their probability distributions.

Default Behavior

In most contexts, Monte Carlo sampling is not the default sampling mode (exception: `multilevel_sampling`). To change this behavior, the `random` keyword must be specified in conjunction with the `sample_type` keyword.

Usage Tips

Monte Carlo sampling is more computationally expensive than Latin Hypercube Sampling as it requires a larger number of samples to accurately estimate statistics.

Examples

```
method
  sampling
    sample_type random
    samples = 200
```

num_trials

- [Keywords Area](#)
- [method](#)
- [fsu_cvt](#)
- [num_trials](#)

The number of secondary sample points generated to adjust the location of the primary sample points

Specification

Alias: none

Argument(s): INTEGER

Default: 10000

Description

In general, the variable with the most influence on the quality of the final sample set is `num_trials`, which determines how well the Voronoi subregions are sampled.

Generally, `num_trials` should be "large", certainly much bigger than the number of sample points being requested; a reasonable value might be 10,000, but values of 100,000 or 1 million are not unusual.

max_iterations

- [Keywords Area](#)
- [method](#)
- [fsu_cvt](#)
- [max_iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: fsu_cvt , local_reliability: 25; global_{reliability , interval_est , evidence} / efficient-global: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

model_pointer

- [Keywords Area](#)
- [method](#)
- [fsu_cvt](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method

	Optional	<code>model_pointer</code>	Identifier for model block to be used by a method

Description

The Morris One-At-A-Time (MOAT) method, originally proposed by Morris [63], is a screening method, designed to explore a computational model to distinguish between input variables that have negligible, linear and additive, or nonlinear or interaction effects on the output. The computer experiments performed consist of individually randomized designs which vary one input factor at a time to create a sample of its elementary effects.

The number of samples (`samples`) must be a positive integer multiple of (number of continuous design variable + 1) and will be automatically adjusted if misspecified.

The number of partitions (`partitions`) applies to each variable being studied and must be odd (the number of MOAT levels per variable is `partitions + 1`). This will also be adjusted at runtime as necessary.

For information on practical use of this method, see [75].

Theory

With MOAT, each dimension of a k -dimensional input space is uniformly partitioned into p levels, creating a grid of p^k points $\mathbf{x} \in \mathbf{R}^k$ at which evaluations of the model $y(\mathbf{x})$ might take place. An elementary effect corresponding to input i is computed by a forward difference

$$d_i(\mathbf{x}) = \frac{y(\mathbf{x} + \Delta \mathbf{e}_i) - y(\mathbf{x})}{\Delta},$$

where \mathbf{e}_i is the i^{th} coordinate vector, and the step Δ is typically taken to be large (this is not intended to be a local derivative approximation). In the present implementation of MOAT, for an input variable scaled to $[0, 1]$, $\Delta = \frac{p}{2(p-1)}$, so the step used to find elementary effects is slightly larger than half the input range.

The distribution of elementary effects d_i over the input space characterizes the effect of input i on the output of interest. After generating r samples from this distribution, their mean,

$$\mu_i = \frac{1}{r} \sum_{j=1}^r d_i^{(j)}$$

modified mean

$$\mu_i^* = \frac{1}{r} \sum_{j=1}^r |d_i^{(j)}|,$$

(using absolute value) and standard deviation

$$\sigma_i = \sqrt{\frac{1}{r} \sum_{j=1}^r (d_i^{(j)} - \mu_i)^2}$$

are computed for each input i . The mean and modified mean give an indication of the overall effect of an input on the output. Standard deviation indicates nonlinear effects or interactions, since it is an indicator of elementary effects varying throughout the input space.

partitions

- [Keywords Area](#)
- [method](#)
- [psuade_moat](#)
- [partitions](#)

Number of partitions of each variable

Specification

Alias: none

Argument(s): INTEGERLIST

Default: 3

Description

Described on the parent page, [psuade_moat](#)

samples

- [Keywords Area](#)
- [method](#)
- [psuade_moat](#)
- [samples](#)

Number of samples for sampling-based methods

Specification

Alias: none

Argument(s): INTEGER

Default: 0

Description

The `samples` keyword is used to define the number of samples (i.e., randomly chosen sets of variable values) at which to execute a model.

Default Behavior

By default, Dakota will use the minimum number of samples required by the chosen method.

Usage Tips

To obtain linear sensitivities or to construct a linear response surface, at least $\text{dim}+1$ samples should be used, where "dim" is the number of variables. For sensitivities to quadratic terms or quadratic response surfaces, at least $(\text{dim}+1)(\text{dim}+2)/2$ samples are needed. For uncertainty quantification, we recommend at least $10*\text{dim}$ samples. For `variance_based_decomp`, we recommend hundreds to thousands of samples. Note that for `variance_based_decomp`, the number of simulations performed will be $N*(\text{dim}+2)$.

Examples

```
method
  sampling
    sample_type lhs
    samples = 20
```

seed

- [Keywords Area](#)
- [method](#)
- [psuade.moat](#)
- [seed](#)

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)

Description

The random `seed` control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

model_pointer

- [Keywords Area](#)
- [method](#)
- [psuade.moat](#)

- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which [model](#) block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a [model](#) block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                    0.1 0.2 0.6
                    0.1 0.2 0.6

    sample_type lhs
    distribution cumulative

model
  id_model = 'SURR'
  surrogate global,
  dace_method_pointer = 'DACE'
  polynomial quadratic

method
  id_method = 'DACE'
  model_pointer = 'DACE_M'
  sampling sample_type lhs
```

```

    samples = 121 seed = 5034 rng rnum2

model
  id_model = 'DACE_M'
  single
  interface_pointer = 'I1'

variables
  uniform_uncertain = 2
  lower_bounds = 0. 0.
  upper_bounds = 1. 1.
  descriptors = 'x1' 'x2'

interface
  id_interface = 'I1'
  system asynch evaluation_concurrency = 5
  analysis_driver = 'text_book'

responses
  response_functions = 3
  no_gradients
  no_hessians

```

7.2.66 local_evidence

- [Keywords Area](#)
- [method](#)
- [local_evidence](#)

Evidence theory with evidence measures computed with local optimization methods

Topics

This keyword is related to the topics:

- [epistemic_uncertainty_quantification_methods](#)
- [evidence_theory](#)

Specification

Alias: nond.local.evidence

Argument(s): none

Child Keywords:

	Required/- Optional Optional (<i>Choose One</i>)	Description of Group Optimization Solver (Group 1)	Dakota Keyword	Dakota Keyword Description
			sqp	Uses a sequential quadratic programming method for underlying optimization
			nip	Uses a nonlinear interior point method for underlying optimization
	Optional		response_levels	Values at which to estimate desired statistics for each response
	Optional		probability_levels	Specify probability levels at which to estimate the corresponding response value
	Optional		gen_reliability_levels	Specify generalized reliability levels at which to estimate the corresponding response value
	Optional		distribution	Selection of cumulative or complementary cumulative functions
	Optional		model_pointer	Identifier for model block to be used by a method

Description

Two local optimization methods are available: [sqp](#) (sequential quadratic programming or [nip](#) (nonlinear interior point method)).

Additional Resources

See the topic page [evidence.theory](#) for important background information and usage notes.

Refer to [variable.support](#) for information on supported variable types.

See Also

These keywords may also be of interest:

- [global_evidence](#)
- [global_interval_est](#)
- [local_interval_est](#)

sqp

- [Keywords Area](#)
- [method](#)
- [local_evidence](#)
- [sqp](#)

Uses a sequential quadratic programming method for underlying optimization

Specification

Alias: none

Argument(s): none

Description

Many uncertainty quantification methods solve a constrained optimization problem under the hood. The `sqp` keyword directs Dakota to use a sequential quadratic programming method to solve that problem. A sequential quadratic programming solves a sequence of linearly constrained quadratic optimization problems to arrive at the solution to the optimization problem.

nip

- [Keywords Area](#)
- [method](#)
- [local_evidence](#)
- [nip](#)

Uses a nonlinear interior point method for underlying optimization

Specification

Alias: none

Argument(s): none

Description

Many uncertainty quantification methods solve a constrained optimization problem under the hood. The `nip` keyword directs Dakota to use a nonlinear interior point to solve that problem. A nonlinear interior point method traverses the interior of the feasible region to arrive at the solution to the optimization problem.

response_levels

- [Keywords Area](#)
- [method](#)
- [local_evidence](#)
- [response_levels](#)

Values at which to estimate desired statistics for each response

Specification

Alias: none

Argument(s): REALLIST

Default: No CDF/CCDF probabilities/reliabilities to compute

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			num_response_ levels	Number of values at which to estimate desired statistics for each response
	Optional		compute	Selection of statistics to compute at each response level

Description

The `response_levels` specification provides the target response values for which to compute probabilities, reliabilities, or generalized reliabilities (forward mapping).

Default Behavior

If `response_levels` are not specified, no statistics will be computed. If they are, probabilities will be computed by default.

Expected Outputs

If `response_levels` are specified, Dakota will create two tables in the standard output: a Probability Density function (PDF) histogram and a Cumulative Distribution Function (CDF) table. The PDF histogram has the lower and upper endpoints of each bin and the corresponding density of that bin. Note that the PDF histogram has bins defined by the `probability_levels` and/or `response_levels` in the Dakota input file. If there are not very many levels, the histogram will be coarse. Dakota does not do anything to optimize the bin size or spacing. The CDF table has the list of response levels and the corresponding probability that the response value is less than or equal to each response level threshold.

Usage Tips

The `num_response_levels` is used to specify which arguments of the `response_level` correspond to which response.

Examples

For example, specifying a `response_level` of 52.3 followed with `compute probabilities` will result in the calculation of the probability that the response value is less than or equal to 52.3, given the uncertain distributions on the inputs.

For an example with multiple responses, the following specification

```
response_levels = 1. 2. .1 .2 .3 .4 10. 20. 30.
num_response_levels = 2 4 3
```

would assign the first two response levels (1., 2.) to response function 1, the next four response levels (.1, .2, .3, .4) to response function 2, and the final three response levels (10., 20., 30.) to response function 3. If the `num_response_levels` key were omitted from this example, then the response levels would be evenly distributed among the response functions (three levels each in this case).

The Dakota input file below specifies a sampling method with response levels of interest.

```
method,
  sampling,
  samples = 100 seed = 1
  complementary distribution
  response_levels = 3.6e+11 4.0e+11 4.4e+11
                   6.0e+04 6.5e+04 7.0e+04

4.0000000000e+05	4.5000000000e+05	1.8000000000e-06

Level mappings for each response function:

Complementary Cumulative Distribution Function (CCDF) for response_fn_1:

Response Level	Probability Level	Reliability Index	General Rel Index
3.6000000000e+11	5.5000000000e-01		
4.0000000000e+11	3.8000000000e-01		
4.4000000000e+11	2.3000000000e-01		

Complementary Cumulative Distribution Function (CCDF) for response_fn_2:

Response Level	Probability Level	Reliability Index	General Rel Index
6.0000000000e+04	6.1000000000e-01		
6.5000000000e+04	2.9000000000e-01		
7.0000000000e+04	9.0000000000e-02		

Complementary Cumulative Distribution Function (CCDF) for response_fn_3:

Response Level	Probability Level	Reliability Index	General Rel Index
3.5000000000e+05	5.2000000000e-01		
4.0000000000e+05	9.0000000000e-02		
4.5000000000e+05	0.0000000000e+00		

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

A forward mapping involves computing the belief and plausibility probability level for a specified response level.

num_response_levels

- [Keywords Area](#)
- [method](#)
- [local_evidence](#)

- [response_levels](#)
- [num_response_levels](#)

Number of values at which to estimate desired statistics for each response

Specification

Alias: none

Argument(s): INTEGERLIST

Default: response_levels evenly distributed among response functions

Description

The `num_response_levels` keyword allows the user to specify the number of response values, for each response, at which estimated statistics are of interest. Statistics that can be computed are probabilities and reliabilities, both according to either a cumulative distribution function or a complementary cumulative distribution function.

Default Behavior

If `num_response_levels` is not specified, the `response_levels` will be evenly distributed among the responses.

Expected Outputs

The specific output will be determined by the type of statistics that are specified. In a general sense, the output will be a list of response level-statistic pairs that show the estimated value of the desired statistic for each response level specified.

Examples

```
method
  sampling
    samples = 100
    seed = 34785
    num_response_levels = 1 1 1
    response_levels = 0.5 0.5 0.5
```

compute

- [Keywords Area](#)
- [method](#)
- [local_evidence](#)
- [response_levels](#)
- [compute](#)

Selection of statistics to compute at each response level

Specification

Alias: none

Argument(s): none

Default: probabilities

Child Keywords:

	Required/ Optional Required (<i>Choose One</i>)	Description of Group Statistics to Compute (Group 1)	Dakota Keyword	Dakota Keyword Description
			probabilities	Computes probabilities associated with response levels
			gen_reliabilities	Computes generalized reliabilities associated with response levels
	Optional		system	Compute system reliability (series or parallel)

Description

The `compute` keyword is used to select which forward stastical mapping is calculated at each response level.

Default Behavior

If `response_levels` is not specified, no statistics are computed. If `response_levels` is specified but `compute` is not, probabilities will be computed by default. If both `response_levels` and `compute` are specified, then on of the following must be specified: `probabilities`, `reliabilities`, or `gen_reliabilities`.

Expected Output

The type of statistics specified by `compute` will be reported for each response level.

Usage Tips

CDF/CCDF probabilities are calculated for specified response levels using a simple binning approach.

CDF/CCDF reliabilities are calculated for specified response levels by computing the number of sample standard deviations separating the sample mean from the response level.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                    6.0e+04 6.5e+04 7.0e+04
                    3.5e+05 4.0e+05 4.5e+05
    compute reliabilities
```

probabilities

- [Keywords Area](#)
- [method](#)
- [local_evidence](#)

- [response_levels](#)
- [compute](#)
- [probabilities](#)

Computes probabilities associated with response levels

Specification

Alias: none

Argument(s): none

Description

The `probabilities` keyword directs Dakota to compute the probability that the model response will be below (cumulative) or above (complementary cumulative) a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the probabilities are computed by default. To explicitly specify it in the Dakota input file, though, the `probabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-probability pairs that give the probability that the model response will be below or above the corresponding response level, depending on the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                    6.0e+04 6.5e+04 7.0e+04
                    3.5e+05 4.0e+05 4.5e+05
    compute probabilities
```

gen_reliabilities

- [Keywords Area](#)
- [method](#)
- [local_evidence](#)
- [response_levels](#)
- [compute](#)
- [gen_reliabilities](#)

Computes generalized reliabilities associated with response levels

Specification

Alias: none

Argument(s): none

Description

The `gen_reliabilities` keyword directs Dakota to compute generalized reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the generalized reliabilities are not computed by default. To change this behavior, the `gen_reliabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-generalized reliability pairs according to the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                    6.0e+04 6.5e+04 7.0e+04
                    3.5e+05 4.0e+05 4.5e+05
    compute gen_reliabilities
```

system

- [Keywords Area](#)
- [method](#)

- [compute](#)
- [system](#)

Compute system reliability (series or parallel)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Required (<i>Choose One</i>)	Description of Group System Reliability Mode (Group 1)	Dakota Keyword	Dakota Keyword Description
			series	Aggregate response statistics assuming a series system
			parallel	Aggregate response statistics assuming a parallel system

Description

With the system probability/reliability option, statistics for specified `response_levels` are calculated and reported assuming the response functions combine either in series or parallel to produce a total system response.

For a series system, the system fails when any one component (response) fails. The probability of failure is the complement of the product of the individual response success probabilities.

For a parallel system, the system fails only when all components (responses) fail. The probability of failure is the product of the individual response failure probabilities.

series

probability_levels

- [Keywords Area](#)
- [method](#)
- [local_evidence](#)
- [probability_levels](#)

Specify probability levels at which to estimate the corresponding response value

Specification

Alias: none

Argument(s): REALLIST

Default: No CDF/CCDF response levels to compute

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			num_probability_- levels	Specify which probability_- levels correspond to which response

Description

Response levels are calculated for specified CDF/CCDF probabilities by indexing into a sorted samples array (the response levels computed are not interpolated and will correspond to one of the sampled values).

Expected Output

If `probability_levels` are specified, Dakota will create two tables in the standard output: a Probability Density function (PDF) histogram and a Cumulative Distribution Function (CDF) table. The PDF histogram has the lower and upper endpoints of each bin and the corresponding density of that bin. Note that the PDF histogram has bins defined by the `probability_levels` and/or `response_levels` in the Dakota input file. If there are not very many levels, the histogram will be coarse. Dakota does not do anything to optimize the bin size or spacing. The CDF table has the list of response levels and the corresponding probability that the response value is less than or equal to each response level threshold.

Examples

The Dakota input file below specifies a sampling method with probability levels of interest.

```
method,
  sampling,
  samples = 100 seed = 1
  complementary distribution
  probability_levels = 1. .66 .33 0.
    1. .8 .5 0.
    1. .3 .2 0.

variables,
  normal_uncertain = 2
  means = 248.89, 593.33
  std_deviations = 12.4, 29.7
  descriptors = 'TF1n' 'TF2n'
  uniform_uncertain = 2
  lower_bounds = 199.3, 474.63
  upper_bounds = 298.5, 712.
  descriptors = 'TF1u' 'TF2u'

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).

num_probability_levels

- [Keywords Area](#)
- [method](#)
- [local_evidence](#)

distribution

- [Keywords Area](#)
- [method](#)
- [local_evidence](#)
- [distribution](#)

Selection of cumulative or complementary cumulative functions

Specification

Alias: none

Argument(s): none

Default: cumulative (CDF)

Child Keywords:

	Required/- Optional Required (<i>Choose One</i>)	Description of Group Distribution Type (CDF/CCDF) (Group 1)	Dakota Keyword cumulative	Dakota Keyword Description Computes statistics according to cumulative functions
			complementary	Computes statistics according to complementary cumulative functions

Description

The `distribution` keyword allows the user to select between a cumulative distribution/belief/plausibility function and a complementary cumulative distribution/belief/plausibility function. This choice affects how probabilities and reliability indices are reported.

Default Behavior

If the `distribution` keyword is present, it must be accompanied by either `cumulative` or `complementary`. Otherwise, a cumulative distribution will be used by default.

Expected Outputs

Output will be a set of model response-probability pairs determined according to the choice of distribution. The choice of distribution also defines the sign of the reliability or generalized reliability indices.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

cumulative

- [Keywords Area](#)
- [method](#)
- [local_evidence](#)
- [distribution](#)
- [cumulative](#)

Computes statistics according to cumulative functions

Specification

Alias: none

Argument(s): none

Description

Statistics on model responses will be computed according to a cumulative distribution/belief/plausibility function.

Default Behavior

By default, a cumulative distribution/belief/plausibility function will be used. To explicitly specify it in the Dakota input file, however, the `cumulative` keyword must be appear in conjunction with the `distribution` keyword.

Expected Outputs

Output will be a set of model response-probability pairs determined according to a cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls below given response thresholds.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

complementary

- [Keywords Area](#)
- [method](#)
- [local_evidence](#)
- [distribution](#)
- [complementary](#)

Computes statistics according to complementary cumulative functions

Specification

Alias: none

Argument(s): none

Description

Statistics on model responses will be computed according to a complementary cumulative distribution/belief/plausibility function.

Default Behavior

By default, a complementary cumulative distribution/belief/plausibility function will not be used. To change that behavior, the `complementary` keyword must be appear in conjunction with the `distribution` keyword.

Expected Outputs

Output will be a set of model response-probability pairs determined according to a complementary cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls above given response thresholds.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    distribution complementary
```

model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
  samples = 10
```

```

seed = 98765 rng rnum2
response_levels = 0.1 0.2 0.6
                 0.1 0.2 0.6

Interval analysis using local optimization

Topics

This keyword is related to the topics:

- [uncertainty_quantification](#)
- [epistemic_uncertainty_quantification_methods](#)
- [interval_estimation](#)

Specification

Alias: nond_local_interval_est

Argument(s): none

Child Keywords:

	Required/ Optional Optional(<i>Choose One</i>)	Description of Group Optimization Solver (Group 1)	Dakota Keyword	Dakota Keyword Description
			sqp	Uses a sequential quadratic programming method for underlying optimization
			nip	Uses a nonlinear interior point method for underlying optimization
	Optional		convergence_ tolerance	Stopping criterion based on objective function or statistics convergence
	Optional		model_pointer	Identifier for model block to be used by a method

Description

Interval analysis using local methods (`local_interval_est`). If the problem is amenable to local optimization methods (e.g. can provide derivatives or use finite difference method to calculate derivatives), then one can use one of two local methods to calculate these bounds.

- sqp
- nip

Additional Resources

Refer to [variable.support](#) for information on supported variable types.

Theory

In interval analysis, one assumes that nothing is known about an epistemic uncertain variable except that its value lies somewhere within an interval. In this situation, it is NOT assumed that the value has a uniform probability of occurring within the interval. Instead, the interpretation is that any value within the interval is a possible value or a potential realization of that variable. In interval analysis, the uncertainty quantification problem is one of determining the resulting bounds on the output (defining the output interval) given interval bounds on the inputs.

Again, any output response that falls within the output interval is a possible output with no frequency information assigned to it.

sqp

- [Keywords Area](#)
- [method](#)
- [local_interval_est](#)
- [sqp](#)

Uses a sequential quadratic programming method for underlying optimization

Specification

Alias: none

Argument(s): none

Description

Many uncertainty quantification methods solve a constrained optimization problem under the hood. The `sqp` keyword directs Dakota to use a sequential quadratic programming method to solve that problem. A sequential quadratic programming solves a sequence of linearly constrained quadratic optimization problems to arrive at the solution to the optimization problem.

nip

- [Keywords Area](#)
- [method](#)
- [local_interval_est](#)
- [nip](#)

Uses a nonlinear interior point method for underlying optimization

Specification

Alias: none

Argument(s): none

Description

Many uncertainty quantification methods solve a constrained optimization problem under the hood. The `nip` keyword directs Dakota to use a nonlinear interior point to solve that problem. A nonlinear interior point method traverses the interior of the feasible region to arrive at the solution to the optimization problem.

convergence_tolerance

- [Keywords Area](#)
- [method](#)
- [local_interval_est](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

7.2.68 local_reliability

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)

Local reliability method

Topics

This keyword is related to the topics:

- [uncertainty_quantification](#)
- [reliability_methods](#)

Specification

Alias: nond_local_reliability

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		mpp_search	Specify which MPP search option to use
	Optional		response_levels	Values at which to estimate desired statistics for each response
	Optional		probability_levels	Specify probability levels at which to estimate the corresponding response value
	Optional		reliability_levels	Specify reliability levels at which the response values will be estimated
	Optional		gen_reliability_levels	Specify generalized reliability levels at which to estimate the corresponding response value
	Optional		distribution	Selection of cumulative or complementary cumulative functions
	Optional		max_iterations	Number of iterations allowed for optimizers and adaptive UQ methods

	Optional	convergence_tolerance	Stopping criterion based on objective function or statistics convergence
	Optional	final_moments	Output moments of the specified type and include them within the set of final statistics.
	Optional	model_pointer	Identifier for model block to be used by a method

Description

Local reliability methods compute approximate response function distribution statistics based on specified uncertain variable probability distributions. Each of the local reliability methods can compute forward and inverse mappings involving response, probability, reliability, and generalized reliability levels.

The forward reliability analysis algorithm of computing reliabilities/probabilities for specified response levels is called the Reliability Index Approach (RIA), and the inverse reliability analysis algorithm of computing response levels for specified probability levels is called the Performance Measure Approach (PMA).

The different RIA/PMA algorithm options are specified using the `mpp_search` specification which selects among different limit state approximations that can be used to reduce computational expense during the MPP searches.

Theory

The Mean Value method (MV, also known as MVFOSM in [42]) is the simplest, least-expensive method in that it estimates the response means, response standard deviations, and all CDF/CCDF forward/inverse mappings from a single evaluation of response functions and gradients at the uncertain variable means. This approximation can have acceptable accuracy when the response functions are nearly linear and their distributions are approximately Gaussian, but can have poor accuracy in other situations.

All other reliability methods perform an internal nonlinear optimization to compute a most probable point (MPP) of failure. A sign convention and the distance of the MPP from the origin in the transformed standard normal space ("u-space") define the reliability index, as explained in the section on Reliability Methods in the Uncertainty Quantification chapter of the Users Manual [4]. Also refer to [variable.support](#) for additional information on supported variable types for transformations to standard normal space. The reliability can then be converted to a probability using either first- or second-order integration, may then be refined using importance sampling, and finally may be converted to a generalized reliability index.

Description

The `x_taylor_mean` MPP search option performs a single Taylor series approximation in the space of the original uncertain variables (“x-space”) centered at the uncertain variable means, searches for the MPP for each response/probability level using this approximation, and performs a validation response evaluation at each predicted MPP. This option is commonly known as the Advanced Mean Value (AMV) method. The `u_taylor_mean` option is identical to the `x_taylor_mean` option, except that the approximation is performed in u-space. The `x_taylor_mpp` approach starts with an x-space Taylor series at the uncertain variable means, but iteratively updates the Taylor series approximation at each MPP prediction until the MPP converges. This option is commonly known as the AMV+ method. The `u_taylor_mpp` option is identical to the `x_taylor_mpp` option, except that all approximations are performed in u-space. The order of the Taylor-series approximation is determined by the corresponding `responses` specification and may be first or second-order. If second-order (methods named AMV^2 and AMV^2+ in [22]), the series may employ analytic, finite difference, or quasi Hessians (BFGS or S-R1). The `x_two_point` MPP search option uses an x-space Taylor series approximation at the uncertain variable means for the initial MPP prediction, then utilizes the Two-point Adaptive Nonlinear Approximation (TANA) outlined in [94] for all subsequent MPP predictions. The `u_two_point` approach is identical to `x_two_point`, but all the approximations are performed in u-space. The `x_taylor_mpp` and `u_taylor_mpp`, `x_two_point` and `u_two_point` approaches utilize the `max_iterations` and `convergence_tolerance` method independent controls to control the convergence of the MPP iterations (the maximum number of MPP iterations per level is limited by `max_iterations`, and the MPP iterations are considered converged when $\| \mathbf{u}^{(k+1)} - \mathbf{u}^{(k)} \|_2 < \text{convergence_tolerance}$). And, finally, the `no_approx` option performs the MPP search on the original response functions without the use of any approximations. The optimization algorithm used to perform these MPP searches can be selected to be either sequential quadratic programming (uses the `npsol_sqp` optimizer) or nonlinear interior point (uses the `optpp_q_newton` optimizer) algorithms using the `sqp` or `nip` keywords.

In addition to the MPP search specifications, one may select among different integration approaches for computing probabilities at the MPP by using the `integration` keyword followed by either `first_order` or `second_order`. Second-order integration employs the formulation of [50] (the approach of [13] and the correction of [51] are also implemented, but are not active). Combining the `no_approx` option of the MPP search with first- and second-order integrations results in the traditional first- and second-order reliability methods (FORM and SORM). These integration approximations may be subsequently refined using importance sampling. The `refinement` specification allows the selection of basic importance sampling (`import`), adaptive importance sampling (`adapt_import`), or multimodal adaptive importance sampling (`mm_adapt_import`), along with the specification of number of samples (`samples`) and random seed (`seed`). Additional details on these methods are available in [24] and [22] and in the Uncertainty Quantification Capabilities chapter of the Users Manual

[4].

- [mpp_search](#)
- [u_multi_point](#)

MPP search for local reliability based on QMEA multi-point approximation in x-space

Specification

Alias: none

Argument(s): none

Description

Local reliability methods that search for the most probable point of failure (MPP) may use a surrogate-based optimization procedure. The `u_multi_point` surrogate option creates a QMEA approximation in the transformed probability space ("u-space") from accumulating data from multiple expansion points.

This capability is **experimental**.

no_approx

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [mpp_search](#)
- [no_approx](#)

Perform MPP search on original response functions (use no approximation)

Topics

This keyword is related to the topics:

- [reliability_methods](#)

Specification

Alias: none

Argument(s): none

Description

This `mpp_search` option performs the MPP search on the original response functions without the use of any approximations. Note that the use of the `no_approx` MPP search with first-order probability integration results in the traditional reliability method called FORM (First-Order Reliability Method). Similarly, the use of `no_approx` with second-order probability integration results in SORM (Second-Order Reliability Method).

sqp

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [mpp_search](#)
- [sqp](#)

Uses a sequential quadratic programming method for underlying optimization

Specification

Alias: none

Argument(s): none

Default: sqp

Description

Many uncertainty quantification methods solve a constrained optimization problem under the hood. The `sqp` keyword directs Dakota to use a sequential quadratic programming method to solve that problem. A sequential quadratic programming solves a sequence of linearly constrained quadratic optimization problems to arrive at the solution to the optimization problem.

nip

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [mpp_search](#)
- [nip](#)

Uses a nonlinear interior point method for underlying optimization

Specification

Alias: none

Argument(s): none

Default: sqp

Description

Many uncertainty quantification methods solve a constrained optimization problem under the hood. The `nip` keyword directs Dakota to use a nonlinear interior point to solve that problem. A nonlinear interior point method traverses the interior of the feasible region to arrive at the solution to the optimization problem.

integration

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [mpp_search](#)
- [integration](#)

Integration approach

Topics

This keyword is related to the topics:

- [reliability_methods](#)

Specification

Alias: none

Argument(s): none

Default: First-order integration

Child Keywords:

	Required/ Optional Required(<i>Choose One</i>)	Description of Group Integration Order (Group 1)	Dakota Keyword	Dakota Keyword Description
			first_order	First-order integration scheme
			second_order	Second-order integration scheme
	Optional		probability_ refinement	Allow refinement of probability and generalized reliability results using importance sampling

Description

This keyword controls how the probabilities at the MPP are computed: integration is followed by either `first_order` or `second_order`, indicating the order of the probability integration.

first_order

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [mpp_search](#)
- [integration](#)
- [first_order](#)

First-order integration scheme

Topics

This keyword is related to the topics:

- [reliability_methods](#)

Specification

Alias: none

Argument(s): none

Description

First-order integration in local reliability methods uses the minimum Euclidean distance from the origin to the most probable point (MPP) in transformed space to compute the probability of failure. This distance, commonly called the reliability index Beta, is used to calculate the probability of failure by calculating the standard normal cumulative distribution function at $-\text{Beta}$.

second_order

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [mpp_search](#)
- [integration](#)
- [second_order](#)

Second-order integration scheme

Topics

This keyword is related to the topics:

- [reliability_methods](#)

Specification

Alias: none

Argument(s): none

Description

Second-order integration in local reliability methods modifies the first-order integration approach to apply a curvature correction. This correction is based on the formulation of [Hoh88 "Hohenbichler and Rackwitz, 1988"].

probability_refinement

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [mpp_search](#)
- [integration](#)
- [probability_refinement](#)

Allow refinement of probability and generalized reliability results using importance sampling

Topics

This keyword is related to the topics:

- [reliability_methods](#)

Specification

Alias: sample_refinement

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
		Importance	import	Sampling option
	Required (<i>Choose One</i>)	Sampling Approach (Group 1)	adapt_import	Importance sampling option
			mm_adapt_import	Sampling option
	Optional		refinement_-samples	Number of samples used to refine a probability estimate or sampling design.

	Optional	seed	Seed of the random number generator
--	-----------------	----------------------	-------------------------------------

Description

The `probability_refinement` allows refinement of probability and generalized reliability results using importance sampling. If one specifies `probability_refinement`, there are some additional options. One can specify which type of importance sampling to use (`import`, `adapt_import`, or `mm_adapt_import`). Additionally, one can specify the number of refinement samples to use with `refinement_samples` and the seed to use with `seed`.

The `probability_refinement` density reweighting accounts originally was developed based on Gaussian distributions. It now accounts for additional non-Gaussian cases.

import

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [mpp_search](#)
- [integration](#)
- [probability_refinement](#)
- [import](#)

Sampling option

Specification

Alias: none

Argument(s): none

Description

`import` centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level).

adapt_import

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [mpp_search](#)
- [integration](#)

- [probability_refinement](#)
- [adapt_import](#)

Importance sampling option

Specification

Alias: none

Argument(s): none

Description

`adapt_import` centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level). This continues iteratively until the failure probability estimate converges.

mm_adapt_import

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [mpp_search](#)
- [integration](#)
- [probability_refinement](#)
- [mm_adapt_import](#)

Sampling option

Specification

Alias: none

Argument(s): none

Description

`mm_adapt_import` starts with all of the samples located in the failure region to build a multimodal sampling density. First, it uses a small number of samples around each of the initial samples in the failure region. Note that these samples are allocated to the different points based on their relative probabilities of occurrence: more probable points get more samples. This early part of the approach is done to search for "representative" points. Once these are located, the multimodal sampling density is set and then `mm_adapt_import` proceeds similarly to `adapt_import` (sample until convergence).

refinement_samples

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [mpp_search](#)
- [integration](#)
- [probability_refinement](#)
- [refinement_samples](#)

Number of samples used to refine a probability estimate or sampling design.

Specification

Alias: none

Argument(s): INTEGERLIST

Description

Probability estimate: Specify the (scalar) number of samples used to improve a probability estimate. If using uni-modal sampling all samples are assigned to the sampling center. If using multi-modal sampling the samples are split between multiple samples according to some internally computed weights.

Sampling design: Specify one or a sequence of refinement samples to augment the initial_samples in a sampling design.

seed

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [mpp_search](#)
- [integration](#)
- [probability_refinement](#)
- [seed](#)

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)

Description

The random `seed` control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

response_levels

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [response_levels](#)

Values at which to estimate desired statistics for each response

Specification

Alias: none

Argument(s): REALLIST

Default: No CDF/CCDF probabilities/reliabilities to compute

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		num_response_ levels	Number of values at which to estimate desired statistics for each response

	Optional	<code>compute</code>	Selection of statistics to compute at each response level
--	-----------------	----------------------	---

Description

The `response_levels` specification provides the target response values for which to compute probabilities, reliabilities, or generalized reliabilities (forward mapping).

Default Behavior

If `response_levels` are not specified, no statistics will be computed. If they are, probabilities will be computed by default.

Expected Outputs

If `response_levels` are specified, Dakota will create two tables in the standard output: a Probability Density function (PDF) histogram and a Cumulative Distribution Function (CDF) table. The PDF histogram has the lower and upper endpoints of each bin and the corresponding density of that bin. Note that the PDF histogram has bins defined by the `probability_levels` and/or `response_levels` in the Dakota input file. If there are not very many levels, the histogram will be coarse. Dakota does not do anything to optimize the bin size or spacing. The CDF table has the list of response levels and the corresponding probability that the response value is less than or equal to each response level threshold.

Usage Tips

The `num_response_levels` is used to specify which arguments of the `response_level` correspond to which response.

Examples

For example, specifying a `response_level` of 52.3 followed with `compute probabilities` will result in the calculation of the probability that the response value is less than or equal to 52.3, given the uncertain distributions on the inputs.

For an example with multiple responses, the following specification

```
response_levels = 1. 2. .1 .2 .3 .4 10. 20. 30.
num_response_levels = 2 4 3
```

would assign the first two response levels (1., 2.) to response function 1, the next four response levels (.1, .2, .3, .4) to response function 2, and the final three response levels (10., 20., 30.) to response function 3. If the `num_response_levels` key were omitted from this example, then the response levels would be evenly distributed among the response functions (three levels each in this case).

The Dakota input file below specifies a sampling method with response levels of interest.

```
method,
  sampling,
  samples = 100 seed = 1
  complementary distribution
  response_levels = 3.6e+11 4.0e+11 4.4e+11
                   6.0e+04 6.5e+04 7.0e+04
                   3.5e+05 4.0e+05 4.5e+05

variables,
  normal_uncertain = 2
  means             = 248.89, 593.33
  std_deviations    = 12.4, 29.7
  descriptors       = 'TF1n' 'TF2n'
```

```

uniform_uncertain = 2
  lower_bounds      = 199.3, 474.63
  upper_bounds      = 298.5, 712.
  descriptors        = 'TF1u' 'TF2u'
weibull_uncertain = 2
  alphas             = 12., 30.
  betas              = 250., 590.
  descriptors        = 'TF1w' 'TF2w'
histogram_bin_uncertain = 2
  num_pairs          = 3      4
  abscissas          = 5 8 10 .1 .2 .3 .4
  counts             = 17 21 0 12 24 12 0
  descriptors        = 'TF1h' 'TF2h'
histogram_point_uncertain
  real = 1
  num_pairs          = 2
  abscissas          = 3 4
  counts             = 1 1
  descriptors        = 'TF3h'

interface,
  system_async_evaluation_concurrency = 5
  analysis_driver = 'text_book'

responses,
  response_functions = 3
  no_gradients
  no_hessians

```

Given the above Dakota input file, the following excerpt from the output shows the PDF and CCDF generated. Note that the bounds on the bins of the PDF are the response values specified in the input file. The probability levels corresponding to those response values are shown in the CCDF.

Probability Density Function (PDF) histograms for each response function:

PDF for response_fn_1:

  4.5000000000e+05  0.0000000000e+00

```

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

A forward mapping involves computing the belief and plausibility probability level for a specified response level.

num_response_levels

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [response_levels](#)
- [num_response_levels](#)

Number of values at which to estimate desired statistics for each response

Specification

Alias: none

Argument(s): INTEGERLIST

Default: response_levels evenly distributed among response functions

Description

The `num_response_levels` keyword allows the user to specify the number of response values, for each response, at which estimated statistics are of interest. Statistics that can be computed are probabilities and reliabilities, both according to either a cumulative distribution function or a complementary cumulative distribution function.

Default Behavior

If `num_response_levels` is not specified, the `response_levels` will be evenly distributed among the responses.

Expected Outputs

The specific output will be determined by the type of statistics that are specified. In a general sense, the output will be a list of response level-statistic pairs that show the estimated value of the desired statistic for each response level specified.

Examples

```
method
  sampling
    samples = 100
    seed = 34785
    num_response_levels = 1 1 1
    response_levels = 0.5 0.5 0.5
```

compute

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [response_levels](#)
- [compute](#)

Selection of statistics to compute at each response level

Specification

Alias: none

Argument(s): none

Default: probabilities

Child Keywords:

	Required/- Optional <i>Required(Choose One)</i>	Description of Group Statistics to Compute (Group 1)	Dakota Keyword probabilities	Dakota Keyword Description Computes probabilities associated with response levels
			reliabilities	Computes reliabilities associated with response levels

		gen_reliabilities	Computes generalized reliabilities associated with response levels
	Optional	system	Compute system reliability (series or parallel)

Description

The `compute` keyword is used to select which forward stastical mapping is calculated at each response level.

Default Behavior

If `response_levels` is not specified, no statistics are computed. If `response_levels` is specified but `compute` is not, probabilities will be computed by default. If both `response_levels` and `compute` are specified, then one of the following must be specified: `probabilities`, `reliabilities`, or `gen_reliabilities`.

Expected Output

The type of statistics specified by `compute` will be reported for each response level.

Usage Tips

CDF/CCDF probabilities are calculated for specified response levels using a simple binning approach.

CDF/CCDF reliabilities are calculated for specified response levels by computing the number of sample standard deviations separating the sample mean from the response level.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                     6.0e+04 6.5e+04 7.0e+04
                     3.5e+05 4.0e+05 4.5e+05
    compute reliabilities
```

probabilities

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [response_levels](#)
- [compute](#)
- [probabilities](#)

Computes probabilities associated with response levels

Specification

Alias: none

Argument(s): none

Description

The `probabilities` keyword directs Dakota to compute the probability that the model response will be below (cumulative) or above (complementary cumulative) a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the probabilities are computed by default. To explicitly specify it in the Dakota input file, though, the `probabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-probability pairs that give the probability that the model response will be below or above the corresponding response level, depending on the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                    6.0e+04 6.5e+04 7.0e+04
                    3.5e+05 4.0e+05 4.5e+05
    compute probabilities
```

reliabilities

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [response_levels](#)
- [compute](#)
- [reliabilities](#)

Computes reliabilities associated with response levels

Specification

Alias: none

Argument(s): none

Description

The `reliabilities` keyword directs Dakota to compute reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the reliabilities are not computed by default. To change this behavior, the `reliabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-reliability pairs according to the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                    6.0e+04 6.5e+04 7.0e+04
                    3.5e+05 4.0e+05 4.5e+05
    compute reliabilities
```

gen_reliabilities

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [response_levels](#)
- [compute](#)
- [gen_reliabilities](#)

Computes generalized reliabilities associated with response levels

Specification

Alias: none

Argument(s): none

Description

The `gen_reliabilities` keyword directs Dakota to compute generalized reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the generalized reliabilities are not computed by default. To change this behavior, the `gen_reliabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-generalized reliability pairs according to the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                    6.0e+04 6.5e+04 7.0e+04
                    3.5e+05 4.0e+05 4.5e+05
    compute gen_reliabilities
```

system

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [response_levels](#)
- [compute](#)
- [system](#)

Compute system reliability (series or parallel)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Required(<i>Choose One</i>)	Description of Group System Reliability Mode (Group 1)	Dakota Keyword	Dakota Keyword Description
			series	Aggregate response statistics assuming a series system
			parallel	Aggregate response statistics assuming a parallel system

Description

With the system probability/reliability option, statistics for specified `response_levels` are calculated and reported assuming the response functions combine either in series or parallel to produce a total system response.

For a series system, the system fails when any one component (response) fails. The probability of failure is the complement of the product of the individual response success probabilities.

For a parallel system, the system fails only when all components (responses) fail. The probability of failure is the product of the individual response failure probabilities.

series

probability_levels

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [probability_levels](#)

Specify probability levels at which to estimate the corresponding response value

Specification

Alias: none

Argument(s): REALLIST

Default: No CDF/CCDF response levels to compute

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			num_probability_- levels	Specify which probability_- levels correspond to which response

Description

Response levels are calculated for specified CDF/CCDF probabilities by indexing into a sorted samples array (the response levels computed are not interpolated and will correspond to one of the sampled values).

Expected Output

If `probability_levels` are specified, Dakota will create two tables in the standard output: a Probability Density function (PDF) histogram and a Cumulative Distribution Function (CDF) table. The PDF histogram has the lower and upper endpoints of each bin and the corresponding density of that bin. Note that the PDF histogram has bins defined by the `probability_levels` and/or `response_levels` in the Dakota input file. If there are not very many levels, the histogram will be coarse. Dakota does not do anything to optimize the bin size or spacing. The CDF table has the list of response levels and the corresponding probability that the response value is less than or equal to each response level threshold.

Examples

The Dakota input file below specifies a sampling method with probability levels of interest.

```
method,
  sampling,
  samples = 100 seed = 1
  complementary distribution
  probability_levels = 1. .66 .33 0.
                    1. .8 .5 0.
                    1. .3 .2 0.

variables,
  normal_uncertain = 2
  means             = 248.89, 593.33
```

```

std_deviations = 12.4, 29.7
descriptors = 'TF1n' 'TF2n'

```

Given the above Dakota input file, the following excerpt from the output shows the PDF and CCDF generated. Note that the bounds on the bins of the PDF are the response values that correspond the probability levels specified in the input file. Those response values are also shown in the CCDF.

Probability Density Function (PDF) histograms for each response function:

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).

num_probability_levels

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [probability_levels](#)
- [num_probability_levels](#)

Specify which `probability_levels` correspond to which response

Specification

distribution

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [distribution](#)

Selection of cumulative or complementary cumulative functions

Specification

Alias: none

Argument(s): none

Default: cumulative (CDF)

Child Keywords:

	Required/- Optional Required <i>(Choose One)</i>	Description of Group Distribution Type (CDF/CCDF) (Group 1)	Dakota Keyword	Dakota Keyword Description
			cumulative	Computes statistics according to cumulative functions

			complementary	Computes statistics according to complementary cumulative functions
--	--	--	-------------------------------	---

Description

The `distribution` keyword allows the user to select between a cumulative distribution/belief/plausibility function and a complementary cumulative distribution/belief/plausibility function. This choice affects how probabilities and reliability indices are reported.

Default Behavior

If the `distribution` keyword is present, it must be accompanied by either `cumulative` or `complementary`. Otherwise, a cumulative distribution will be used by default.

Expected Outputs

Output will be a set of model response-probability pairs determined according to the choice of distribution. The choice of distribution also defines the sign of the reliability or generalized reliability indices.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

cumulative

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [distribution](#)
- [cumulative](#)

Computes statistics according to cumulative functions

Specification

Alias: none

Argument(s): none

Description

Statistics on model responses will be computed according to a cumulative distribution/belief/plausibility function.

Default Behavior

By default, a cumulative distribution/belief/plausibility function will be used. To explicitly specify it in the Dakota input file, however, the `cumulative` keyword must appear in conjunction with the `distribution` keyword.

Expected Outputs

Output will be a set of model response-probability pairs determined according to a cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls below given response thresholds.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

complementary

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [distribution](#)
- [complementary](#)

Computes statistics according to complementary cumulative functions

Specification

Alias: none

Argument(s): none

Description

Statistics on model responses will be computed according to a complementary cumulative distribution/belief/plausibility function.

Default Behavior

By default, a complementary cumulative distribution/belief/plausibility function will not be used. To change that behavior, the `complementary` keyword must be appear in conjunction with the `distribution` keyword.

Expected Outputs

Output will be a set of model response-probability pairs determined according to a complementary cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls above given response thresholds.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    distribution complementary
```

max_iterations

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [max_iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: `fsu_cvt`, `local_reliability`: 25; `global_{reliability, interval_est, evidence}` / `efficient-global`: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

convergence_tolerance

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

final_moments

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [final_moments](#)

Output moments of the specified type and include them within the set of final statistics.

Specification

Alias: none

Argument(s): none

Default: standard

Child Keywords:

	Required/ Optional Required (<i>Choose One</i>)	Description of Group Objective Formulation (Group 1)	Dakota Keyword <i>none</i>	Dakota Keyword Description Omit moments from the set of final statistics.
			<i>standard</i>	Output standardized moments and include them within the set of final statistics.
			<i>central</i>	Output central moments and include them within the set of final statistics.

Description

When performing a nested study that may employ moment statistics on the inner loop, it can be desirable to control the type of these moments. The `final_moments` specification supports options of `none`, `standard` (default), or `central`, corresponding to omission of moments, standardized moments (mean, standard deviation, skewness, and excess kurtosis), or central moments (mean, variance, 3rd central, and 4th central).

The presence or omission of moment results in the final statistics influences the outer level mappings in the case of a nested study. For example, `final_moments none` can allow for a more compact specification of primary and/or secondary response mappings.

Examples

The following method specification overrides the default to print `central` moments and include them in the set of final statistics.

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments central
```

Overriding the default to `none` as follows:

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments none
```

allows associated nested model mappings to be simplified from:

```
model
  nested
    sub_method_pointer = 'UQ'
    primary_response_mapping = 0. 0. 1. 0. 0. 1. 0. 0. 0.
    secondary_response_mapping = 0. 0. 0. 0. 0. 0. 0. 0. 1.
```

to a more compact version focused only on the response level mappings (two leading zeros per response function for moment mappings have been removed):

```
model
  nested
    sub_method_pointer = 'UQ'
    primary_response_mapping = 1. 1. 0.
    secondary_response_mapping = 0. 0. 1.
```

none

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [final_moments](#)
- [none](#)

Omit moments from the set of final statistics.

Specification

Alias: none

Argument(s): none

Description

The omission of moment results from the final statistics can allow for a more compact definition of primary and/or secondary response mappings within a nested model specification.

Examples

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments none
```

standard

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [final_moments](#)
- [standard](#)

Output standardized moments and include them within the set of final statistics.

Specification

Alias: none

Argument(s): none

Description

Output standardized moments (mean, standard deviation, skewness, and excess kurtosis) and include the first two within the set of final statistics to be used at a higher level (e.g., optimization under uncertainty, mixed aleatory-epistemic UQ). This inclusion of moment results affects the primary and/or secondary response mappings in a nested model specification.

Examples

The following method specification overrides the default to print `central` moments and include them in the set of final statistics.

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments standard
```

central

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [final_moments](#)
- [central](#)

Output central moments and include them within the set of final statistics.

Specification

Alias: none

Argument(s): none

Description

Output central moments (mean, variance, 3rd central, and 4th central) and include the first two within the set of final statistics to be used at a higher level (e.g., optimization under uncertainty, mixed aleatory-epistemic UQ). This inclusion of moment results affects the primary and/or secondary response mappings in a nested model specification.

Examples

The following method specification overrides the default to print `central` moments and include them in the set of final statistics.

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments central
```

model_pointer

- [Keywords Area](#)
- [method](#)
- [local_reliability](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which [model](#) block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a [model](#) block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'
```

```
method
  id_method = 'UQ'
```

```

model_pointer = 'SURR'
sampling,
  samples = 10
  seed = 98765 rng rnum2
  response_levels = 0.1 0.2 0.6
                    0.1 0.2 0.6
                    0.1 0.2 0.6
  sample_type lhs
  distribution cumulative

model
  id_model = 'SURR'
  surrogate global,
  dace_method_pointer = 'DACE'
  polynomial quadratic

method
  id_method = 'DACE'
  model_pointer = 'DACE_M'
  sampling sample_type lhs
  samples = 121 seed = 5034 rng rnum2

model
  id_model = 'DACE_M'
  single
  interface_pointer = 'I1'

variables
  uniform_uncertain = 2
  lower_bounds = 0.  0.
  upper_bounds = 1.  1.
  descriptors = 'x1' 'x2'

interface
  id_interface = 'I1'
  system asynch evaluation_concurrency = 5
  analysis_driver = 'text_book'

responses
  response_functions = 3
  no_gradients
  no_hessians

```

7.2.69 `global_reliability`

- [Keywords Area](#)
- [method](#)
- [global_reliability](#)

Global reliability methods

Topics

This keyword is related to the topics:

- [uncertainty_quantification](#)
- [reliability_methods](#)

Specification

Alias: nond_global_reliability

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		initial_samples	Initial number of samples for sampling-based methods
	Required(<i>Choose One</i>)	Approximation (Group 1)	x_gaussian_process	Create GP surrogate in x-space
			u_gaussian_process	Create GP surrogate in u-space
	Optional(<i>Choose One</i>)	GP Implementation (Group 2)	surfpack	Use the Surfpack version of Gaussian Process surrogates
			dakota	Select the built in Gaussian Process surrogate
	Optional		import_build_points_file	File containing points you wish to use to build a surrogate
	Optional		export_approx_points_file	Output file for evaluations of a surrogate model
	Optional		use_derivatives	Use derivative data to construct surrogate models
	Optional		seed	Seed of the random number generator
	Optional		rng	Selection of a random number generator

	Optional	response_levels	Values at which to estimate desired statistics for each response
	Optional	probability_levels	Specify probability levels at which to estimate the corresponding response value
	Optional	gen_reliability_levels	Specify generalized reliability levels at which to estimate the corresponding response value
	Optional	distribution	Selection of cumulative or complementary cumulative functions
	Optional	max_iterations	Number of iterations allowed for optimizers and adaptive UQ methods
	Optional	convergence_tolerance	Stopping criterion based on objective function or statistics convergence
	Optional	model_pointer	Identifier for model block to be used by a method

Description

These methods do not support forward/inverse mappings involving `reliability_levels`, since they never form a reliability index based on distance in *u*-space. Rather they use a Gaussian process model to form an approximation to the limit state (based either in *x*-space via the `x_gaussian_process` specification or in *u*-space via the `u_gaussian_process` specification), followed by probability estimation based on multimodal adaptive importance sampling (see [11]) and [12]). These probability estimates may then be transformed into generalized reliability levels if desired. At this time, inverse reliability analysis (mapping probability or generalized reliability levels into response levels) is not implemented.

The Gaussian process model approximation to the limit state is formed over the aleatory uncertain variables by default, but may be extended to also capture the effect of design, epistemic uncertain, and state variables. If

this is desired, one must use the appropriate controls to specify the active variables in the variables specification block. Refer to [variable_support](#) for additional information on supported variable types.

initial_samples

- [Keywords Area](#)
- [method](#)
- [global_reliability](#)
- [initial_samples](#)

Initial number of samples for sampling-based methods

Specification

Alias: none

Argument(s): INTEGER

Default: $(d+1)(d+2)/2$

Description

The `initial_samples` keyword is used to define the number of initial samples (i.e., randomly chosen sets of variable values) at which to execute a model. The initial samples may later be augmented in an iterative process.

Default Behavior

By default, Dakota will use the minimum number of samples required by the chosen method.

Usage Tips

To obtain linear sensitivities or to construct a linear response surface, at least $\text{dim}+1$ samples should be used, where "dim" is the number of variables. For sensitivities to quadratic terms or quadratic response surfaces, at least $(\text{dim}+1)(\text{dim}+2)/2$ samples are needed. For uncertainty quantification, we recommend at least $10 \cdot \text{dim}$ samples. For `variance_based_decomp`, we recommend hundreds to thousands of samples. Note that for `variance_based_decomp`, the number of simulations performed will be $N \cdot (\text{dim}+2)$.

Examples

```
method
  sampling
    sample_type random
    initial_samples = 20
    refinement_samples = 5
```

surfpack

- [Keywords Area](#)
- [method](#)
- [global_reliability](#)
- [surfpack](#)

Use the Surfpack version of Gaussian Process surrogates

Specification

Alias: none

Argument(s): none

Description

This keyword specifies the use of the Gaussian process that is incorporated in our surface fitting library called Surfpack.

Several user options are available:

1. Optimization methods:

Maximum Likelihood Estimation (MLE) is used to find the optimal values of the hyper-parameters governing the trend and correlation functions. By default the global optimization method DIRECT is used for MLE, but other options for the optimization method are available. See [optimization.method](#).

The total number of evaluations of the likelihood function can be controlled using the `max_trials` keyword followed by a positive integer. Note that the likelihood function does not require running the "truth" model, and is relatively inexpensive to compute.

2. Trend Function:

The GP models incorporate a parametric trend function whose purpose is to capture large-scale variations. See [trend](#).

3. Correlation Lengths:

Correlation lengths are usually optimized by Surfpack, however, the user can specify the lengths manually. See [correlation.lengths](#).

4. Ill-conditioning

One of the major problems in determining the governing values for a Gaussian process or Kriging model is the fact that the correlation matrix can easily become ill-conditioned when there are too many input points close together. Since the predictions from the Gaussian process model involve inverting the correlation matrix, ill-conditioning can lead to poor predictive capability and should be avoided.

Note that a sufficiently bad sample design could require correlation lengths to be so short that any interpolatory GP model would become inept at extrapolation and interpolation.

The `surfpack` model handles ill-conditioning internally by default, but behavior can be modified using

5. Gradient Enhanced Kriging (GEK).

The `use_derivatives` keyword will cause the Surfpack GP to be constructed from a combination of function value and gradient information (if available).

See notes in the Theory section.

Theory

Gradient Enhanced Kriging

Incorporating gradient information will only be beneficial if accurate and inexpensive derivative information is available, and the derivatives are not infinite or nearly so. Here "inexpensive" means that the cost of evaluating a function value plus gradient is comparable to the cost of evaluating only the function value, for example gradients computed by analytical, automatic differentiation, or continuous adjoint techniques. It is not cost effective to use derivatives computed by finite differences. In tests, GEK models built from finite difference derivatives were also significantly less accurate than those built from analytical derivatives. Note that GEK's correlation matrix tends to have a significantly worse condition number than Kriging for the same sample design.

This issue was addressed by using a pivoted Cholesky factorization of Kriging's correlation matrix (which is a small sub-matrix within GEK's correlation matrix) to rank points by how much unique information they contain. This reordering is then applied to whole points (the function value at a point immediately followed by gradient information at the same point) in GEK's correlation matrix. A standard non-pivoted Cholesky is then applied to the reordered GEK correlation matrix and a bisection search is used to find the last equation that meets the constraint on the (estimate of) condition number. The cost of performing pivoted Cholesky on Kriging's correlation matrix is usually negligible compared to the cost of the non-pivoted Cholesky factorization of GEK's correlation matrix. In tests, it also resulted in more accurate GEK models than when pivoted Cholesky or whole-point-block pivoted Cholesky was performed on GEK's correlation matrix.

dakota

Select the built in Gaussian Process surrogate

Specification

Alias: none

Argument(s): none

Description

A second version of GP surrogates was available in prior versions of Dakota. **For now, both versions are supported but the dakota version is deprecated and intended to be removed in a future release.**

Historically these models were drastically different, but in Dakota 5.1, they became quite similar. They now differ in that the Surfpack GP has a richer set of features/options and tends to be more accurate than the Dakota version. Due to how the Surfpack GP handles ill-conditioned correlation matrices (which significantly contributes to its greater accuracy), the Surfpack GP can be a factor of two or three slower than Dakota's. As of Dakota 5.2, the Surfpack implementation is the default in all contexts except Bayesian calibration.

More details on the `gaussian_process` dakota model can be found in[59].

Dakota's GP deals with ill-conditioning in two ways. First, when it encounters a non-invertible correlation matrix it iteratively increases the size of a "nugget," but in such cases the resulting approximation smooths rather than interpolates the data. Second, it has a `point_selection` option (default off) that uses a greedy algorithm to select a well-spaced subset of points prior to the construction of the GP. In this case, the GP will only interpolate the selected subset. Typically, one should not need point selection in trust-region methods because a small

number of points are used to develop a surrogate within each trust region. Point selection is most beneficial when constructing with a large number of points, typically more than order one hundred, though this depends on the number of variables and spacing of the sample points.

This differs from the `point_selection` option of the Dakota GP which initially chooses a well-spaced subset of points and finds the correlation parameters that are most likely for that one subset.

import_build_points_file

- [Keywords Area](#)
- [method](#)
- [global_reliability](#)
- [import_build_points_file](#)

File containing points you wish to use to build a surrogate

Specification

Alias: `import_points_file`

Argument(s): STRING

Default: no point import from a file

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional(<i>Choose One</i>)	Tabular Format (Group 1)	custom_annotated	Selects custom-annotated tabular file format
			annotated	Selects annotated tabular file format
			freeform	Selects freeform file format
	Optional		active_only	Import only active variables from tabular data file

Description

The `import_build_points_file` allows the user to specify a file that contains a list of points and truth model responses used to construct a surrogate model. These can be used by all methods that (explicitly, e.g. surrogate-based optimization, or implicitly, e.g. efficient global optimization) operate on a surrogate. In particular, these points and responses are used in place of truth model evaluations to construct the initial surrogate. When used to construct surrogate models or emulators these are often called build points or training data.

Default Behavior

By default, methods do not import points from a file.

Usage Tips

Dakota parses input files without regard to whitespace, but the `import_build_points_file` must be in one of three formats:

- `annotated` (default)
- `custom_annotated`
- `freeform`

Examples

```
method
  polynomial_chaos
    expansion_order = 4
    import_build_points_file = 'dakota_uq_rosenbrock_pce_import.annot.pts.dat'
```

custom_annotated

- [Keywords Area](#)
- [method](#)
- [global_reliability](#)
- [import_build_points_file](#)
- [custom_annotated](#)

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			header	Enable header row in custom-annotated tabular file

	Optional	eval_id	Enable evaluation ID column in custom-annotated tabular file
	Optional	interface_id	Enable interface ID column in custom-annotated tabular file

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, `eval_id` column, and `interface_id` column appear in the tabular file, thus bridging `freeform` and (fully) annotated.

Default Behavior

The `annotated` format is the default for tabular export/import. To control which header row and columns are in the input/output, specify `custom_annotated`, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and `eval_id` (no `interface_id`), and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id      x1          x2          obj_fn  nln_ineq_con_1  nln_ineq_con_2
1              0.9          1.1          0.0002         0.26           0.76

- [annotated](#)

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The `annotated` keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include `interface_id`, specify `custom_annotated` header `eval_id`
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export an annotated top-level tabular data file containing a header row, leading `eval_id` and `interface_id` columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated
```

Resulting tabular file:

```
%eval_id interface          x1          x2          obj_fn nln_ineq_con_1 nln_ineq_con_2
1          NO_ID            0.9          1.1          0.0002          0.26          0.76
2          NO_ID            0.90009      1.1 0.0001996404857 0.2601620081 0.759955
3          NO_ID            0.89991      1.1 0.0002003604863 0.2598380081 0.760045

```

freeform

- [Keywords Area](#)
- [method](#)
- [global_reliability](#)
- [import_build_points_file](#)
- [freeform](#)

Selects freeform file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The `annotated` format is the default for tabular export/import. To change this behavior, specify `freeform` in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to `annotated` format, though `freeform` remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- In `freeform`, the `num_rows` x `num_cols` total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

```
      0.9          1.1          0.0002          0.26          0.76
0.90009      1.1 0.0001996404857  0.2601620081  0.759955

...
```

active_only

- [Keywords Area](#)
- [method](#)
- [global_reliability](#)
- [import_build_points_file](#)
- [active_only](#)

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

export_approx_points_file

- [Keywords Area](#)
- [method](#)
- [global_reliability](#)
- [export_approx_points_file](#)

Output file for evaluations of a surrogate model

Specification

Alias: export_points_file

Argument(s): STRING

Default: no point export to a file

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional(<i>Choose One</i>)	Tabular Format (Group 1)	custom_annotated	Selects custom-annotated tabular file format
			annotated	Selects annotated tabular file format
			freeform	Selects freeform file format

Description

The `export_approx_points_file` keyword allows the user to specify a file in which the points (input variable values) at which the surrogate model is evaluated and corresponding response values computed by the surrogate model will be written. The response values are the surrogate's predicted approximation to the truth model responses at those points.

Usage Tips

Dakota exports tabular data in one of three formats:

- `annotated` (default)
- `custom_annotated`
- `freeform`

custom_annotated

- [Keywords Area](#)
- [method](#)
- [global_reliability](#)

use_derivatives

- [Keywords Area](#)
- [method](#)
- [global_reliability](#)
- [use_derivatives](#)

Use derivative data to construct surrogate models

Specification

Alias: none

Argument(s): none

Default: use function values only

Description

The `use_derivatives` flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, its use with Surfpack Gaussian process is not recommended.

seed

- [Keywords Area](#)
- [method](#)
- [global_reliability](#)
- [seed](#)

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)

Description

The random `seed` control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

rng

- [Keywords Area](#)
- [method](#)
- [global_reliability](#)
- [rng](#)

Selection of a random number generator

Specification

Alias: none

Argument(s): none

Default: Mersenne twister (`mt19937`)

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	RNG Algorithm (Group 1)	mt19937	Generates random numbers using the Mersenne twister
			rnum2	Generates pseudo-random numbers using the Pecos package

Description

The `rng` keyword is used to indicate a choice of random number generator.

Default Behavior

If specified, the `rng` keyword must be accompanied by either `rnum2` (pseudo-random numbers) or `mt19937` (random numbers generated by the Mersenne twister). Otherwise, `mt19937`, the Mersenne twister is used by default.

Usage Tips

The default is recommended, as the Mersenne twister is a higher quality random number generator.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2
```

mt19937

- [Keywords Area](#)
- [method](#)
- [global_reliability](#)
- [rng](#)
- [mt19937](#)

Generates random numbers using the Mersenne twister

Specification

Alias: none

Argument(s): none

Description

The `mt19937` keyword directs Dakota to use the Mersenne twister to generate random numbers. Additional information can be found on wikipedia: http://en.wikipedia.org/wiki/Mersenne_twister.

Default Behavior

`mt19937` is the default random number generator. To specify it explicitly in the Dakota input file, however, it must be specified in conjunction with the `rng` keyword.

Usage Tips

Use of the Mersenne twister random number generator (`mt19937`) is recommended.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng mt19937
```

rnum2

- [Keywords Area](#)
- [method](#)
- [global_reliability](#)
- [rng](#)

- [rnum2](#)

Generates pseudo-random numbers using the Pecos package

Specification

Alias: none

Argument(s): none

Description

The `rnum2` keyword directs Dakota to use pseudo-random numbers generated by the Pecos package.

Default Behavior

`rnum2` is not used by default. To change this behavior, it must be specified in conjunction with the `rng` keyword.

Usage Tips

Use of the Mersenne twister random number generator (`mt19937`) is recommended over `rnum2`.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2
```

response_levels

- [Keywords Area](#)
- [method](#)
- [global_reliability](#)
- [response_levels](#)

Values at which to estimate desired statistics for each response

Specification

Alias: none

Argument(s): REALLIST

Default: No CDF/CCDF probabilities/reliabilities to compute

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		<code>num_response_ levels</code>	Number of values at which to estimate desired statistics for each response
	Optional		<code>compute</code>	Selection of statistics to compute at each response level

Description

The `response_levels` specification provides the target response values for which to compute probabilities, reliabilities, or generalized reliabilities (forward mapping).

Default Behavior

If `response_levels` are not specified, no statistics will be computed. If they are, probabilities will be computed by default.

Expected Outputs

If `response_levels` are specified, Dakota will create two tables in the standard output: a Probability Density function (PDF) histogram and a Cumulative Distribution Function (CDF) table. The PDF histogram has the lower and upper endpoints of each bin and the corresponding density of that bin. Note that the PDF histogram has bins defined by the `probability_levels` and/or `response_levels` in the Dakota input file. If there are not very many levels, the histogram will be coarse. Dakota does not do anything to optimize the bin size or spacing. The CDF table has the list of response levels and the corresponding probability that the response value is less than or equal to each response level threshold.

Usage Tips

The `num_response_levels` is used to specify which arguments of the `response_level` correspond to which response.

Examples

For example, specifying a `response_level` of 52.3 followed with `compute probabilities` will result in the calculation of the probability that the response value is less than or equal to 52.3, given the uncertain distributions on the inputs.

For an example with multiple responses, the following specification

```
response_levels = 1. 2. .1 .2 .3 .4 10. 20. 30.
num_response_levels = 2 4 3
```

would assign the first two response levels (1., 2.) to response function 1, the next four response levels (.1, .2, .3, .4) to response function 2, and the final three response levels (10., 20., 30.) to response function 3. If the `num_response_levels` key were omitted from this example, then the response levels would be evenly distributed among the response functions (three levels each in this case).

The Dakota input file below specifies a sampling method with response levels of interest.

```
method,
    sampling,
    samples = 100 seed = 1
```

```

complementary distribution
response_levels = 3.6e+11 4.0e+11 4.4e+11
                 6.0e+04 6.5e+04 7.0e+04

4.5000000000e+05  0.0000000000e+00

```

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

A forward mapping involves computing the belief and plausibility probability level for a specified response level.

num_response_levels

- [Keywords Area](#)
- [method](#)
- [global_reliability](#)
- [response_levels](#)
- [num_response_levels](#)

Number of values at which to estimate desired statistics for each response

Specification

Alias: none

Argument(s): INTEGERLIST

Default: response_levels evenly distributed among response functions

Description

The `num_response_levels` keyword allows the user to specify the number of response values, for each response, at which estimated statistics are of interest. Statistics that can be computed are probabilities and reliabilities, both according to either a cumulative distribution function or a complementary cumulative distribution function.

Default Behavior

If `num_response_levels` is not specified, the `response_levels` will be evenly distributed among the responses.

Expected Outputs

The specific output will be determined by the type of statistics that are specified. In a general sense, the output will be a list of response level-statistic pairs that show the estimated value of the desired statistic for each response level specified.

Examples

```
method
  sampling
    samples = 100
    seed = 34785
    num_response_levels = 1 1 1
    response_levels = 0.5 0.5 0.5
```

compute

- [Keywords Area](#)
- [method](#)
- [global_reliability](#)
- [response_levels](#)
- [compute](#)

Selection of statistics to compute at each response level

Specification

Alias: none

Argument(s): none

Default: probabilities

Child Keywords:

	Required/- Optional Required(<i>Choose One</i>)	Description of Group Statistics to Compute (Group 1)	Dakota Keyword probabilities	Dakota Keyword Description Computes probabilities associated with response levels

		gen_reliabilities	Computes generalized reliabilities associated with response levels
	Optional	system	Compute system reliability (series or parallel)

Description

The `compute` keyword is used to select which forward stastical mapping is calculated at each response level.

Default Behavior

If `response_levels` is not specified, no statistics are computed. If `response_levels` is specified but `compute` is not, probabilities will be computed by default. If both `response_levels` and `compute` are specified, then on of the following must be specified: `probabilities`, `reliabilities`, or `gen_reliabilities`.

Expected Output

The type of statistics specified by `compute` will be reported for each response level.

Usage Tips

CDF/CCDF probabilities are calculated for specified response levels using a simple binning approach.

CDF/CCDF reliabilities are calculated for specified response levels by computing the number of sample standard deviations separating the sample mean from the response level.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                    6.0e+04 6.5e+04 7.0e+04
                    3.5e+05 4.0e+05 4.5e+05
    compute reliabilities
```

probabilities

- [Keywords Area](#)
- [method](#)
- [global_reliability](#)
- [response_levels](#)
- [compute](#)
- [probabilities](#)

Computes probabilities associated with response levels

Specification

Alias: none

Argument(s): none

Description

The `probabilities` keyword directs Dakota to compute the probability that the model response will be below (cumulative) or above (complementary cumulative) a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the probabilities are computed by default. To explicitly specify it in the Dakota input file, though, the `probabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-probability pairs that give the probability that the model response will be below or above the corresponding response level, depending on the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                    6.0e+04 6.5e+04 7.0e+04
                    3.5e+05 4.0e+05 4.5e+05
    compute probabilities
```

gen_reliabilities

- [Keywords Area](#)
- [method](#)
- [global_reliability](#)
- [response_levels](#)
- [compute](#)
- [gen_reliabilities](#)

Computes generalized reliabilities associated with response levels

Specification

Alias: none

Argument(s): none

Description

The `gen_reliabilities` keyword directs Dakota to compute generalized reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the generalized reliabilities are not computed by default. To change this behavior, the `gen_reliabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-generalized reliability pairs according to the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                    6.0e+04 6.5e+04 7.0e+04
                    3.5e+05 4.0e+05 4.5e+05
    compute gen_reliabilities
```

system

- [system](#)

Compute system reliability (series or parallel)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required(<i>Choose One</i>)	System Reliability Mode (Group 1)	series	Aggregate response statistics assuming a series system

			parallel	Aggregate response statistics assuming a parallel system
--	--	--	--------------------------	--

Description

With the system probability/reliability option, statistics for specified `response_levels` are calculated and reported assuming the response functions combine either in series or parallel to produce a total system response.

For a series system, the system fails when any one component (response) fails. The probability of failure is the complement of the product of the individual response success probabilities.

For a parallel system, the system fails only when all components (responses) fail. The probability of failure is the product of the individual response failure probabilities.

probability_levels

- [Keywords Area](#)
- [method](#)
- [global_reliability](#)
- [probability_levels](#)

Specify probability levels at which to estimate the corresponding response value

Specification

Alias: none

Argument(s): REALLIST

Default: No CDF/CCDF response levels to compute

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		num_probability_levels	Specify which probability_levels correspond to which response

Description

Response levels are calculated for specified CDF/CCDF probabilities by indexing into a sorted samples array (the response levels computed are not interpolated and will correspond to one of the sampled values).

Expected Output

If `probability_levels` are specified, Dakota will create two tables in the standard output: a Probability Density function (PDF) histogram and a Cumulative Distribution Function (CDF) table. The PDF histogram has the lower and upper endpoints of each bin and the corresponding density of that bin. Note that the PDF histogram has bins defined by the `probability_levels` and/or `response_levels` in the Dakota input file. If there are not very many levels, the histogram will be coarse. Dakota does not do anything to optimize the bin size or spacing. The CDF table has the list of response levels and the corresponding probability that the response value is less than or equal to each response level threshold.

Examples

The Dakota input file below specifies a sampling method with probability levels of interest.

```
method,
  sampling,
  samples = 100 seed = 1
  complementary distribution
  probability_levels = 1. .66 .33 0.
    1. .8 .5 0.
    1. .3 .2 0.

variables,
  normal_uncertain = 2
  means           = 248.89, 593.33

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).

distribution

- [Keywords Area](#)
- [method](#)
- [global_reliability](#)
- [distribution](#)

Selection of cumulative or complementary cumulative functions

Specification

Alias: none

Argument(s): none

Default: cumulative (CDF)

Child Keywords:

	Required/ Optional Required(<i>Choose One</i>)	Description of Group Distribution Type (CDF/CCDF) (Group 1)	Dakota Keyword	Dakota Keyword Description
			cumulative	Computes statistics according to cumulative functions

			complementary	Computes statistics according to complementary cumulative functions
--	--	--	-------------------------------	---

Description

The `distribution` keyword allows the user to select between a cumulative distribution/belief/plausibility function and a complementary cumulative distribution/belief/plausibility function. This choice affects how probabilities and reliability indices are reported.

Default Behavior

If the `distribution` keyword is present, it must be accompanied by either `cumulative` or `complementary`. Otherwise, a cumulative distribution will be used by default.

Expected Outputs

Output will be a set of model response-probability pairs determined according to the choice of distribution. The choice of distribution also defines the sign of the reliability or generalized reliability indices.

Examples

```
method
  sampling
  sample_type lhs
  samples = 10
  distribution cumulative
```

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: fsu_cvt, local_reliability: 25; global_{reliability, interval_est, evidence} / efficient-global: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

convergence_tolerance

- [Keywords Area](#)
- [method](#)
- [global_reliability](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

model_pointer

- [Keywords Area](#)
- [method](#)
- [global_reliability](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last `model` block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                    0.1 0.2 0.6
                    0.1 0.2 0.6
    sample_type lhs
    distribution cumulative

model
  id_model = 'SURR'
  surrogate global,

7.2.70 fsu_quasi_mc

- [Keywords Area](#)
- [method](#)
- [fsu_quasi_mc](#)

Design of Computer Experiments - Quasi-Monte Carlo sampling

Topics

This keyword is related to the topics:

- [package_fsudace](#)
- [design_and_analysis_of_computer_experiments](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Required (<i>Choose One</i>)	Description of Group Sequence Type (Group 1)	Dakota Keyword	Dakota Keyword Description
			halton	Generate samples from a Halton sequence
			hammersley	Use Hammersley sequences
	Optional		latinize	Adjust samples to improve the discrepancy of the marginal distributions
	Optional		quality_metrics	Calculate metrics to assess the quality of quasi-Monte Carlo samples

	Optional	variance_based_-decomp	Activates global sensitivity analysis based on decomposition of response variance into contributions from variables
	Optional	samples	Number of samples for sampling-based methods
	Optional	fixed_sequence	Reuse the same sequence and samples for multiple sampling sets
	Optional	sequence_start	Choose where to start sampling the sequence
	Optional	sequence_leap	Specify how often the sequence is sampled
	Optional	prime_base	The prime numbers used to generate the sequence
	Optional	max_iterations	Number of iterations allowed for optimizers and adaptive UQ methods
	Optional	model_pointer	Identifier for model block to be used by a method

Description

Quasi-Monte Carlo methods produce low discrepancy sequences, especially if one is interested in the uniformity of projections of the point sets onto lower dimensional faces of the hypercube (usually 1-D: how well do the marginal distributions approximate a uniform?)

This method generates sets of uniform random variables on the interval [0,1]. If the user specifies lower and upper bounds for a variable, the [0,1] samples are mapped to the [lower, upper] interval.

The user must first choose the sequence type:

- halton or
- hammersley

Then three keywords are used to define the sequence and how it is sampled:

- `prime_base`
- `sequence_start`
- `sequence_leap`

Each of these has defaults, so specification is optional.

Theory

The quasi-Monte Carlo sequences of Halton and Hammersley are deterministic sequences determined by a set of prime bases. Generally, we recommend that the user leave the default setting for the bases, which are the lowest primes. Thus, if one wants to generate a sample set for 3 random variables, the default bases used are 2, 3, and 5 in the Halton sequence. To give an example of how these sequences look, the Halton sequence in base 2 starts with points 0.5, 0.25, 0.75, 0.125, 0.625, etc. The first few points in a Halton base 3 sequence are 0.33333, 0.66667, 0.11111, 0.44444, 0.77777, etc. Notice that the Halton sequence tends to alternate back and forth, generating a point closer to zero then a point closer to one. An individual sequence is based on a radix inverse function defined on a prime base. The prime base determines how quickly the [0,1] interval is filled in. Generally, the lowest primes are recommended.

The Hammersley sequence is the same as the Halton sequence, except the values for the first random variable are equal to $1/N$, where N is the number of samples. Thus, if one wants to generate a sample set of 100 samples for 3 random variables, the first random variable has values $1/100$, $2/100$, $3/100$, etc. and the second and third variables are generated according to a Halton sequence with bases 2 and 3, respectively.

For more information about these sequences, see [\[43\]](#), [\[44\]](#), and [\[1\]](#).

halton

- [Keywords Area](#)
- [method](#)
- [fsu_quasi_mc](#)
- [halton](#)

Generate samples from a Halton sequence

Topics

This keyword is related to the topics:

- [package_fsudace](#)

Specification

Alias: none

Argument(s): none

Description

The quasi-Monte Carlo sequences of Halton are deterministic sequences determined by a set of prime bases. These sequences generate random numbers with the goal of filling a unit hypercube uniformly.

Generally, we recommend that the user leave the default setting for the bases, which are the lowest primes. Thus, if one wants to generate a sample set for 3 random variables, the default bases used are 2, 3, and 5 in the Halton sequence. To give an example of how these sequences look, the Halton sequence in base 2 starts with points 0.5, 0.25, 0.75, 0.125, 0.625, etc. The first few points in a Halton base 3 sequence are 0.33333, 0.66667, 0.11111, 0.44444, 0.77777, etc. Notice that the Halton sequence tends to alternate back and forth, generating a point closer to zero then a point closer to one. An individual sequence is based on a radix inverse function defined on a prime base. The prime base determines how quickly the [0,1] interval is filled in.

Theory

For more information about these sequences, see[\[43\]](#), [\[44\]](#), and [\[1\]](#).

hammersley

- [Keywords Area](#)
- [method](#)
- [fsu_quasi_mc](#)
- [hammersley](#)

Use Hammersley sequences

Topics

This keyword is related to the topics:

- [package_fsudace](#)
- [design_and_analysis_of_computer_experiments](#)

Specification

Alias: none

Argument(s): none

Description

The Hammersley sequence is the same as the Halton sequence, except the values for the first random variable are equal to $1/N$, where N is the number of samples. Thus, if one wants to generate a sample set of 100 samples for 3 random variables, the first random variable has values $1/100$, $2/100$, $3/100$, etc. and the second and third variables are generated according to a Halton sequence with bases 2 and 3, respectively.

These keywords may also be of interest:

- [fsu_quasi_mc](#)

latinize

- [Keywords Area](#)
- [method](#)
- [fsu_quasi_mc](#)
- [latinize](#)

Adjust samples to improve the discrepancy of the marginal distributions

Specification

Alias: none

Argument(s): none

Default: No latinization

Description

The `latinize` control takes the samples and "latinizes" them, meaning that each original sample is moved so that it falls into one strata or bin in each dimension as in Latin Hypercube sampling. The default setting is NOT to latinize. However, one may be interested in doing this in situations where one wants better discrepancy of the 1-dimensional projections (the marginal distributions).

quality_metrics

- [Keywords Area](#)
- [method](#)
- [fsu_quasi_mc](#)
- [quality_metrics](#)

Calculate metrics to assess the quality of quasi-Monte Carlo samples

Topics

This keyword is related to the topics:

- [package_fsudace](#)

Specification

Alias: none

Argument(s): none

Default: No quality_metrics

Description

`quality_metrics` calculates four quality metrics relating to the volumetric spacing of the samples. The four quality metrics measure different aspects relating to the uniformity of point samples in hypercubes. Desirable properties of such point samples are:

- are the points equally spaced
- do the points cover the region
- and are they isotropically distributed
- with no directional bias in the spacing

The four quality metrics we report are:

- `h`: the point distribution norm, which is a measure of uniformity of the point distribution
- `chi`: a regularity measure, and provides a measure of local uniformity of a set of points
- `tau`: the second moment trace measure
- `d`: the second moment determinant measure

All of these values are scaled so that smaller is better (the smaller the metric, the better the uniformity of the point distribution).

Examples

Complete explanation of these measures can be found in [38].

`variance_based_decomp`

- [Keywords Area](#)
- [method](#)
- [fsu_quasi_mc](#)
- [variance_based_decomp](#)

Activates global sensitivity analysis based on decomposition of response variance into contributions from variables

Specification

Alias: none

Argument(s): none

Default: no variance-based decomposition

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description

	Optional	drop_tolerance	Suppresses output of sensitivity indices with values lower than this tolerance
--	-----------------	--------------------------------	--

Description

Dakota can calculate sensitivity indices through variance based decomposition using the keyword `variance_based_decomp`. These indicate how important the uncertainty in each input variable is in contributing to the output variance.

Default Behavior

Because of the computational cost, `variance_based_decomp` is turned off as a default.

If the user specified a number of samples, N, and a number of nondeterministic variables, M, variance-based decomposition requires the evaluation of $N*(M+2)$ samples. **Note that specifying this keyword will increase the number of function evaluations above the number requested with the `samples` keyword since replicated sets of sample values are evaluated.**

Expected Outputs

When `variance_based_decomp` is specified, sensitivity indices for main effects and total effects will be reported. Main effects (roughly) represent the percent contribution of each individual variable to the variance in the model response. Total effects represent the percent contribution of each individual variable in combination with all other variables to the variance in the model response

Usage Tips

To obtain sensitivity indices that are reasonably accurate, we recommend that N, the number of samples, be at least one hundred and preferably several hundred or thousands.

Examples

```
method,
  sampling
  sample_type lhs
  samples = 100
  variance_based_decomp
```

Theory

In this context, we take sensitivity analysis to be global, not local as when calculating derivatives of output variables with respect to input variables. Our definition is similar to that of [75]: "The study of how uncertainty in the output of a model can be apportioned to different sources of uncertainty in the model input."

Variance based decomposition is a way of using sets of samples to understand how the variance of the output behaves, with respect to each input variable. A larger value of the sensitivity index, S_i , means that the uncertainty in the input variable i has a larger effect on the variance of the output. More details on the calculations and interpretation of the sensitivity indices can be found in [75] and [89].

drop_tolerance

- [Keywords Area](#)
- [method](#)
- [fsu_quasi_mc](#)

- [variance_based_decomp](#)
- [drop_tolerance](#)

Suppresses output of sensitivity indices with values lower than this tolerance

Specification

Alias: none

Argument(s): REAL

Default: All VBD indices displayed

Description

The `drop_tolerance` keyword allows the user to specify a value below which sensitivity indices generated by `variance_based_decomp` are not displayed.

Default Behavior

By default, all sensitivity indices generated by `variance_based_decomp` are displayed.

Usage Tips

For `polynomial_chaos`, which outputs main, interaction, and total effects by default, the `univariate_effects` may be a more appropriate option. It allows suppression of the interaction effects since the output volume of these results can be prohibitive for high dimensional problems. Similar to suppression of these interactions is the covariance control, which can be selected to be `diagonal_covariance` or `full_covariance`, with the former supporting suppression of the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

Examples

```
method,
  sampling
  sample_type lhs
  samples = 100
  variance_based_decomp
  drop_tolerance = 0.001
```

samples

- [Keywords Area](#)
- [method](#)
- [fsu_quasi_mc](#)
- [samples](#)

Number of samples for sampling-based methods

Specification

Alias: none

Argument(s): INTEGER

Default: 0

Description

The `samples` keyword is used to define the number of samples (i.e., randomly chosen sets of variable values) at which to execute a model.

Default Behavior

By default, Dakota will use the minimum number of samples required by the chosen method.

Usage Tips

To obtain linear sensitivities or to construct a linear response surface, at least $\text{dim}+1$ samples should be used, where "dim" is the number of variables. For sensitivities to quadratic terms or quadratic response surfaces, at least $(\text{dim}+1)(\text{dim}+2)/2$ samples are needed. For uncertainty quantification, we recommend at least $10*\text{dim}$ samples. For `variance_based_decomp`, we recommend hundreds to thousands of samples. Note that for `variance_based_decomp`, the number of simulations performed will be $N*(\text{dim}+2)$.

Examples

```
method
  sampling
    sample_type lhs
    samples = 20
```

fixed_sequence

- [Keywords Area](#)
- [method](#)
- [fsu_quasi_mc](#)
- [fixed_sequence](#)

Reuse the same sequence and samples for multiple sampling sets

Specification

Alias: none

Argument(s): none

Default: sequence not fixed: sampling patterns are variable among multiple QMC runs

Description

The `fixed_sequence` control is similar to `fixed_seed` for other sampling methods. If `fixed_sequence` is specified, the user will get the same sequence (meaning the same set of samples) for subsequent calls of the QMC sampling method (for example, this might be used in a surrogate based optimization method or a parameter study where one wants to fix the uncertain variables).

sequence_start

- [Keywords Area](#)
- [method](#)
- [fsu_quasi_mc](#)
- [sequence_start](#)

Choose where to start sampling the sequence

Specification

Alias: none

Argument(s): INTEGERLIST

Default: Vector of zeroes

Description

`sequence_start` determines where in the sequence the samples will start.

The default `sequence_start` is a vector with 0 for each variable, specifying that each sequence start with the first term.

Examples

For example, for the Halton sequence in base 2, if the user specifies `sequence_start = 2`, the sequence would not include 0.5 and 0.25, but instead would start at 0.75.

`sequence_leap`

- [Keywords Area](#)
- [method](#)
- [fsu_quasi_mc](#)
- [sequence_leap](#)

Specify how often the sequence is sampled

Specification

Alias: none

Argument(s): INTEGERLIST

Default: Vector of ones

Description

`sequence_leap` controls the "leaping" of terms in the sequence. The default is 1 for each variable, meaning that each term in the sequence be returned.

Examples

If the user specifies a `sequence_leap` of 2 for a variable, the points returned would be every other term from the QMC sequence.

Theory

The advantage to using a leap value greater than one is mainly for high-dimensional sets of random deviates. In this case, setting a leap value to the next prime number larger than the largest prime base can help maintain uniformity when generating sample sets for high dimensions. For more information about the efficacy of leaped Halton sequences, see [\[73\]](#).

prime_base

- [Keywords Area](#)
- [method](#)
- [fsu_quasi_mc](#)
- [prime_base](#)

The prime numbers used to generate the sequence

Specification

Alias: none

Argument(s): INTEGERLIST

Default: Vector of the first s primes for s-dimensions in Halton, First (s-1) primes for Hammersley

Description

It is recommended that the user not specify this and use the default values.

- For the Halton sequence, the default bases are primes in increasing order, starting with 2, 3, 5, etc.
- For the Hammersley sequence, the user specifies (s-1) primes if one is generating an s-dimensional set of random variables.

max_iterations

- [Keywords Area](#)
- [method](#)
- [fsu_quasi_mc](#)
- [max_iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: fsu_cvt, local_reliability: 25; global_{reliability, interval_est, evidence} / efficient-global: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_`
`iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

model_pointer

- [Keywords Area](#)
- [method](#)
- [fsu_quasi_mc](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_`
`pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
```

```

samples = 10
seed = 98765 rng rnum2
response_levels = 0.1 0.2 0.6
                 0.1 0.2 0.6
                 0.1 0.2 0.6

  no_hessians

```

7.2.71 vector_parameter_study

- [Keywords Area](#)
- [method](#)
- [vector_parameter_study](#)

Samples variables along a user-defined vector

Topics

This keyword is related to the topics:

- [parameter_studies](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Step Control (Group 1)	final_point	Final variable values defining vector in vector parameter study
			step_vector	Size of step for each variable
	Required		num_steps	Number of sampling steps along the vector in a vector parameter study
	Optional		model_pointer	Identifier for model block to be used by a method

Description

Dakota's vector parameter study computes response data sets at selected intervals along a vector in parameter space. It is often used for single-coordinate parameter studies (to study the effect of a single variable on a response set), but it can be used more generally for multiple coordinate vector studies (to investigate the response variations along some n-dimensional vector such as an optimizer search direction).

Default Behavior

By default, the vector parameter study operates over all types of variables.

Expected Outputs

A vector parameter study produces a set of responses for each parameter set that is generated.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the [hdf5](#) keyword, this method writes the following results to HDF5:

- [Parameter Sets](#)

Usage Tips

Group 1 is used to define the vector along which the parameters are varied. Both cases also rely on the variables specification of an initial value, through:

- the [initial_point](#) keyword
- the [initial_state](#) keyword
- relying on the default initial value, based on the rest of the variables specification

From the initial value, the vector can be defined using one of the two keyword choices.

Once the vector is defined, the samples are then fully specified by [num_steps](#).

Examples

The following example is a good comparison to the examples on [multidim_parameter_study](#) and [centered_parameter_study](#).

```
# tested on Dakota 6.0 on 140501
environment
  tabular_data
    tabular_data_file = 'rosen_vector.dat'

method
  vector_parameter_study
    num_steps = 10
    final_point = 2.0 2.0
model
  single

variables
  continuous_design = 2
  initial_point = -2.0 -2.0
  descriptors = 'x1' "x2"

interface
  analysis_driver = 'rosenbrock'
  fork

responses
  response_functions = 1
  no_gradients
  no_hessians
```

See Also

These keywords may also be of interest:

- [centered_parameter_study](#)
- [multidim_parameter_study](#)
- [list_parameter_study](#)

final_point

- [Keywords Area](#)
- [method](#)
- [vector_parameter_study](#)
- [final_point](#)

Final variable values defining vector in vector parameter study

Specification

Alias: none

Argument(s): REALLIST

Description

The `final_point` keyword is used to define the final values for each variable on the vector to be used in the vector parameter study. The vector's direction and magnitude are determined by the initial value from the variables specification, and the `final_point`.

Default Behavior

The user is required to specify either `final_point` or `step_vector`. There is no default definition for the vector.

Usage Tips

The actual points are determined based on this vector and the number of points chosen is given in `num_points`.

Examples

```
method
  vector_parameter_study
    num_steps = 10
    final_point = 2.0 2.0
```

step_vector

- [Keywords Area](#)
- [method](#)
- [vector_parameter_study](#)
- [step_vector](#)

Size of step for each variable

Specification

Alias: none

Argument(s): REALLIST

Description

The `step_vector` keyword specifies how much each variable will be incremented in a single step.

`step_vector` works in conjunction with `num_steps`, which determines the number of steps taken during the `vector_parameter_study`. If instead of `step_vector`, `final_point` is specified with `num_steps`, Dakota will infer the step sizes.

Entries in the `step_vector` are the actual amounts by which continuous and range variables are incremented. For set variables, `step_vector` entries are interpreted as indexes into the underlying set.

Default Behavior

The user is required to specify either `final_point` or `step_vector`. There is no default definition for the vector.

Examples

```

variables
  continuous_design 1
    initial_point 1.0
    descriptors 'x1'
  discrete_design_set
    string 1
    elements 'bar' 'baz' 'foo' 'fuzz'
    initial_point 'bar'
    descriptors 's1'

method
  vector_parameter_study
    num_steps = 3
    # Add 2.0 to x1 and increment s1 by 1 element in each step
    step_vector = 2.0 1

```

num_steps

- [Keywords Area](#)
- [method](#)
- [vector_parameter_study](#)
- [num_steps](#)

Number of sampling steps along the vector in a vector parameter study

Specification

Alias: none

Argument(s): INTEGER

Description

`num_steps` defines the number of steps that are taken in the direction of the vector. The magnitude of each step is determined in conjunction with the rest of the method specification.

Default Behavior

The user is required to specify `num_steps` for a vector parameter study. There is no default value.

This study performs function evaluations at both ends, making the total number of evaluations equal to `num_steps+1`.

Usage Tips

The study has stringent requirements on performing appropriate steps with any discrete range and discrete set variables. A `num_steps` specification must result in discrete range and set index steps that are integers: no remainder is currently permitted in the integer step calculation and no rounding to integer steps will occur.

Examples

```

method
  vector_parameter_study
    num_steps = 10
    final_point = 2.0 2.0

```

model_pointer

- [Keywords Area](#)
- [method](#)
- [vector_parameter_study](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2

7.2.72 list_parameter_study

- [Keywords Area](#)
- [method](#)
- [list_parameter_study](#)

Samples variables as a specified values

Topics

This keyword is related to the topics:

- [parameter_studies](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description

	Required (<i>Choose One</i>)	Points Source (Group 1)	list_of_points	List of variable values to evaluate in a list parameter study
			import_points_file	File containing list of variable values to evaluate in a list parameter study
	Optional		model_pointer	Identifier for model block to be used by a method

Description

Dakota's list parameter study allows for evaluations at user selected points of interest.

Default Behavior

By default, the list parameter study operates over all types of variables.

The number of real values in the `list_of_points` specification or file referenced by `import_points_file` must be a multiple of the total number of variables (including continuous and discrete types) contained in the variables specification.

Expected Outputs

A list parameter study produces a set of responses for each parameter set that is specified.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the `hdf5` keyword, this method writes the following results to HDF5:

- [Parameter Sets](#)

Usage Tips

- This parameter study simply performs simulations for the first parameter set (the first n entries in the list), followed by the next parameter set (the next n entries), and so on, until the list of points has been exhausted.
- Since the initial values from the variables specification will not be used, they need not be specified.
- When the points are specified in the Dakota input file using the `list_of_points` keyword, discrete set values must be referred to using 0-based indexes, and not the values themselves. However, when using `import_points_file`, refer to discrete set values directly, not by index.
- For both `list_of_points` and `import_points_file`, Dakota expects the values for each evaluation to be ordered by type. The type ordering matches that of the [variables](#) section of this Reference Manual and of the listing in the Parameters file format section of the Dakota User's Manual[4]. When multiple variables are present for a single type, the ordering within that type must match the order specified by the user in the variables section of her input file.

Examples

This shows the method and variables block of a Dakota input file that runs a `list_parameter_study`.

```

method
  list_parameter_study
    list_of_points =
      3.1e6    0.0029    0.31
      3.2e6    0.0028    0.32
      3.3e6    0.0027    0.34
      3.3e6    0.0026    0.36

variables
  continuous_design = 3
  descriptors = 'E'   'MASS'   'DENSITY'

```

Note that because of the way Dakota treats whitespace, the above example is equivalent to:

```

method
  list_parameter_study
    list_of_points =
3.1e6    0.0029    0.31  3.2e6    0.0028
0.32    3.3e6    0.0027
0.34    3.3e6    0.0026    0.36

variables
  continuous_design = 3
  descriptors = 'E'   'MASS'   'DENSITY'

```

Although the first example is much more readable.

And here's a full input file:

```

# tested on Dakota 6.0 on 140501
environment
  tabular_data
    tabular_data_file 'List_param_study.dat'

method
  list_parameter_study
    list_of_points =      0.1    0.1
                        0.2    0.1
                        0.3    0.0
                        0.3    1.0

model
  single

variables
  active design
  continuous_design = 2
  descriptors      'x1' 'x2'
  continuous_state = 1
  descriptors      'constant1'
  initial_state = 100

interface
  analysis_drivers 'text_book'
  fork
  asynchronous
  evaluation_concurrency 2

responses
  response_functions = 1
  no_gradients
  no_hessians

```

This example illustrates the `list_parameter_study`.

- The function evaluations are independent, so any level of `evaluation_concurrency` can be used
- Default behavior for parameter studies is to iterate on all variables. However, because `active design` is specified, this study will only iterate on the `continuous_design` variables.

list_of_points

- [Keywords Area](#)
- [method](#)
- [list_parameter_study](#)
- [list_of_points](#)

List of variable values to evaluate in a list parameter study

Specification

Alias: none

Argument(s): REALLIST

Description

The `list_of_points` keyword allows the user to specify, in a freeform format, a list of variable values at which to compute a model response.

Default Behavior

The user is required to provide a list of points for a list parameter study either by specifying it with `list_of_points` or by providing a file from which such a list can be read via `import_points_file`. There is no default list of points.

Usage Tips

The number of values in the list must be an integer multiple of the number of variables. Dakota will verify that this condition is met.

Examples

```
method
  list_parameter_study
    list_of_points =
      3.1e6    0.0029    0.31
      3.2e6    0.0028    0.32
      3.3e6    0.0027    0.34
      3.3e6    0.0026    0.36
```

import_points_file

- [Keywords Area](#)
- [method](#)
- [list_parameter_study](#)
- [import_points_file](#)

File containing list of variable values to evaluate in a list parameter study

Specification

Alias: none

Argument(s): STRING

Default: no point import from a file

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional(<i>Choose One</i>)	Tabular Format (Group 1)	custom_annotated	Selects custom-annotated tabular file format
			annotated	Selects annotated tabular file format
			freeform	Selects freeform file format
	Optional		active_only	Import only active variables from tabular data file

Description

The `import_points_file` specifies a file containing a list of variable values at which to compute a model response.

Default Behavior

By default, methods do not import points from a file.

Usage Tips

Dakota parses input files without regard to whitespace, but the `import_points_file` must be in one of three formats:

- `annotated` (default)
- `custom_annotated`
- `freeform`

Examples

```
method
  list_parameter_study
  import_points_file = 'dakota_pstudy.3.dat'
```

custom_annotated

- [Keywords Area](#)
- [method](#)
- [list_parameter_study](#)
- [import_points_file](#)
- [custom_annotated](#)

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		header	Enable header row in custom-annotated tabular file
	Optional		eval_id	Enable evaluation ID column in custom-annotated tabular file
	Optional		interface_id	Enable interface ID column in custom-annotated tabular file

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, `eval_id` column, and `interface_id` column appear in the tabular file, thus bridging `freeform` and (fully) annotated.

Default Behavior

The `annotated` format is the default for tabular export/import. To control which header row and columns are in the input/output, specify `custom_annotated`, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and `eval_id` (no `interface_id`), and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id      x1          x2          obj_fn  nln_ineq_con_1  nln_ineq_con_2
1             0.9          1.1          0.0002          0.26           0.76
2             0.90009      1.1 0.0001996404857  0.2601620081    0.759955
3             0.89991      1.1 0.0002003604863  0.2598380081    0.760045
...
```

annotated

- [Keywords Area](#)
- [method](#)
- [list_parameter_study](#)
- [import_points_file](#)
- [annotated](#)

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The `annotated` keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include `interface_id`, specify `custom_annotated_header eval_id`
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export an annotated top-level tabular data file containing a header row, leading `eval_id` and `interface_id` columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated
```

Resulting tabular file:

```
%eval_id interface          x1          x2          obj_fn nln_ineq_con_1 nln_ineq_con_2
1          NO_ID           0.9          1.1          0.0002      0.26          0.76
2          NO_ID           0.90009      1.1 0.0001996404857 0.2601620081 0.759955

...
```

freeform

- [Keywords Area](#)
- [method](#)
- [list_parameter_study](#)
- [import_points_file](#)
- [freeform](#)

Selects freeform file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The `annotated` format is the default for tabular export/import. To change this behavior, specify `freeform` in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to `annotated` format, though `freeform` remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- In `freeform`, the `num_rows` x `num_cols` total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

```

      0.9          1.1          0.0002          0.26          0.76
0.90009          1.1 0.0001996404857  0.2601620081  0.759955
0.89991          1.1 0.0002003604863  0.2598380081  0.760045
...

```

active_only

- [Keywords Area](#)
- [method](#)
- [list_parameter_study](#)
- [import_points_file](#)
- [active_only](#)

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

model_pointer

- [Keywords Area](#)
- [method](#)
- [list_parameter_study](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                    0.1 0.2 0.6
                    0.1 0.2 0.6

```

7.2.73 centered_parameter_study

- [Keywords Area](#)
- [method](#)
- [centered_parameter_study](#)

Samples variables along points moving out from a center point

Topics

This keyword is related to the topics:

- [parameter_studies](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description

	Required	step_vector	Size of steps to be taken in each dimension of a centered parameter study
	Required	steps_per_variable	Number of steps to take in each dimension of a centered parameter study
	Optional	model_pointer	Identifier for model block to be used by a method

Description

Dakota's centered parameter study computes response data sets along multiple coordinate-based vectors, one per parameter, centered about the initial values from the variables specification. This is useful for investigation of function contours with respect to each parameter individually in the vicinity of a specific point (e.g., post-optimality analysis for verification of a minimum), thereby avoiding the cost associated with a multidimensional grid.

Default Behavior

By default, the centered parameter study operates over all types of variables.

The `centered_parameter_study` takes steps along each orthogonal dimension. Each dimension is treated independently. The number of steps are taken in each direction, so that the total number of points in the parameter study is $1 + 2 \sum n$.

Expected Outputs

A centered parameter study produces a set of responses for each parameter set that is generated.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the `hdf5` keyword, this method writes the following results to HDF5:

- [Parameter Sets](#)
- [Variable Slices](#)

Examples

The following example is a good comparison to the examples on [multidim_parameter_study](#) and [vector_parameter_study](#).

```
# tested on Dakota 6.0 on 140501
environment
  tabular_data
    tabular_data_file = 'rosen_centered.dat'

method
  centered_parameter_study
    steps_per_variable = 5 4
    step_vector = 0.4 0.5
```

```
model
  single

variables
  continuous_design = 2
  initial_point = 0      0
  descriptors = 'x1'    "x2"

interface
  analysis_driver = 'rosenbrock'
  fork

responses
  response_functions = 1
  no_gradients
  no_hessians
```

step_vector

- [Keywords Area](#)
- [method](#)
- [centered_parameter_study](#)
- [step_vector](#)

Size of steps to be taken in each dimension of a centered parameter study

Specification

Alias: none

Argument(s): REALLIST

Description

The `step_vector` keyword defines the individual step size in each dimension, treated separately.

Default Behavior

The user is required to define the number of step sizes for a centered parameter study. There are no default values.

Steps are taken in the plus and minus directions, and are defined in either actual values (continuous and discrete range) or index offsets (discrete set).

Examples

```
method
  centered_parameter_study
    steps_per_variable = 5 4
    step_vector = 0.4 0.5
```

steps_per_variable

- [Keywords Area](#)
- [method](#)
- [centered_parameter_study](#)
- [steps_per_variable](#)

Number of steps to take in each dimension of a centered parameter study

Specification

Alias: deltas_per_variable

Argument(s): INTEGERLIST

Description

The `steps_per_variable` keyword allows the user to define the number of steps in each dimension of a centered parameter study. Because they are taken independently, the number of steps can be specified for each.

Default Behavior

The user is required to define the number of steps per variable for a centered parameter study. There are no default values.

Steps are taken in the plus and minus directions, and are defined in either actual values (continuous and discrete range) or index offsets (discrete set).

Examples

```
method
  centered_parameter_study
    steps_per_variable = 5 4
    step_vector = 0.4 0.5
```

7.2.74 multidim_parameter_study

- [Keywords Area](#)
- [method](#)
- [multidim_parameter_study](#)

Samples variables on full factorial grid of study points

Topics

This keyword is related to the topics:

- [parameter_studies](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Required	Description of Group	Dakota Keyword	Dakota Keyword Description
			partitions	Samples variables on full factorial grid of study points
	Optional		model_pointer	Identifier for model block to be used by a method

Description

Dakota's multidimensional parameter study computes response data sets for an n-dimensional grid of points. Each continuous and discrete range variable is partitioned into equally spaced intervals between its upper and lower

bounds, each discrete set variable is partitioned into equally spaced index intervals. The partition boundaries in n-dimensional space define a grid of points, and every point is evaluated.

Default Behavior

By default, the multidimensional parameter study operates over all types of variables.

Expected Outputs

A multidimensional parameter study produces a set of responses for each parameter set that is generated.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the [hdf5](#) keyword, this method writes the following results to HDF5:

- [Parameter Sets](#)
- [Correlations](#)

Usage Tips

Since the initial values from the variables specification will not be used, they need not be specified.

Examples

This example is taken from the Users Manual and is a good comparison to the examples on [centered_parameter_study](#) and [vector_parameter_study](#).

```
# tested on Dakota 6.0 on 140501
environment
  tabular_data
    tabular_data_file = 'rosen_multidim.dat'

method
  multidim_parameter_study
    partitions = 10 8

model
  single

variables
  continuous_design = 2

Samples variables on full factorial grid of study points

Topics

This keyword is related to the topics:

- [parameter_studies](#)

Specification

Alias: none

Argument(s): INTEGERLIST

Description

Dakota's multidimensional parameter study computes response data sets for an n-dimensional grid of points. Each continuous and discrete range variable is partitioned into equally spaced intervals between its upper and lower bounds, each discrete set variable is partitioned into equally spaced index intervals. The partition boundaries in n-dimensional space define a grid of points, and every point is evaluated.

Default Behavior

By default, the multidimensional parameter study operates over all types of variables.

Expected Outputs

A multidimensional parameter study produces a set of responses for each parameter set that is generated.

Usage Tips

Since the initial values from the variables specification will not be used, they need not be specified.

Examples

This example is taken from the Users Manual and is a good comparison to the examples on [centered_parameter_study](#) and [vector_parameter_study](#).

```
# tested on Dakota 6.0 on 140501
environment
  tabular_data
    tabular_data_file = 'rosen_multidim.dat'

method
  multidim_parameter_study
    partitions = 10 8

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last `model` block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```

Estimate order of convergence of a response as model fidelity increases

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Required (<i>Choose One</i>)	Description of Group Verification Mode (Group 1)	Dakota Keyword	Dakota Keyword Description
			estimate_order	Compute the best estimate of the convergence order from three points
			converge_order	Refine until the estimated convergence order converges
			converge_qoi	Refine until the response converges
	Optional		refinement_rate	Rate at which the state variables are refined
	Optional		convergence_tolerance	Stopping criterion based on objective function or statistics convergence

	Optional	max_iterations	Number of iterations allowed for optimizers and adaptive UQ methods
	Optional	model_pointer	Identifier for model block to be used by a method

Description

Solution verification procedures estimate the order of convergence of the simulation response data during the course of a refinement study. This branch of methods is new and currently only contains one algorithm: Richardson extrapolation.

Refinement of the model

The model fidelity must be parameterized by one or more continuous state variable(s).

The refinement path is determined from the `initial_state` of the `continuous_state` variables specification in combination with the `refinement_rate`, where each of the state variables is treated as an independent refinement factor and each of the initial state values is repeatedly divided by the refinement rate value to define new discretization states.

Results

Three algorithm options are currently provided:

1. `estimate_order`
2. `converge_order`
3. `converge_qoi`

Stopping Criteria

The method employs the `max_iterations` and `convergence_tolerance` method independent controls as stopping criteria.

Theory

In each of these cases, convergence order for a response quantity of interest (QoI) is estimated from

$$p = \ln \left(\frac{QoI_3 - QoI_2}{QoI_2 - QoI_1} \right) / \ln(r)$$

where r is the uniform refinement rate specified by `refinement_rate`.

estimate_order

- [Keywords Area](#)
- [method](#)
- [richardson_extrap](#)
- [estimate_order](#)

Compute the best estimate of the convergence order from three points

Specification

Alias: none

Argument(s): none

Description

The `estimate_order` option is the simplest option. For each of the refinement factors, it evaluates three points along the refinement path and uses these results to perform an estimate of the convergence order for each response function.

`converge_order`

- [Keywords Area](#)
- [method](#)
- [richardson_extrap](#)
- [converge_order](#)

Refine until the estimated convergence order converges

Specification

Alias: none

Argument(s): none

Description

The `converge_order` option is initialized using the `estimate_order` approach, and additional refinements are performed along the refinement path until the convergence order estimates converge (two-norm of the change in response orders is less than the convergence tolerance).

`converge_qoi`

- [Keywords Area](#)
- [method](#)
- [richardson_extrap](#)
- [converge_qoi](#)

Refine until the response converges

Specification

Alias: none

Argument(s): none

Description

The `converge_qoi` option is similar to the `converge_order` option, except that the convergence criterion is that the two-norm of the response discretization errors (computed from extrapolation) must be less than the convergence tolerance.

refinement_rate

- [Keywords Area](#)
- [method](#)
- [richardson_extrap](#)
- [refinement_rate](#)

Rate at which the state variables are refined

Specification

Alias: none

Argument(s): REAL

Default: 2.

Description

Described on parent page

convergence_tolerance

- [Keywords Area](#)
- [method](#)
- [richardson_extrap](#)
- [convergence_tolerance](#)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See [nl2sol](#)
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

max.iterations

- [Keywords Area](#)
- [method](#)
- [richardson_extrap](#)
- [max.iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: `fsu_cvt`, `local_reliability`: 25; `global_{reliability, interval_est, evidence}` / `efficient-global`: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_`
`iterations` iterations. See also `max_function_evaluations`.

Default Behavior

Default value is 100.

model_pointer

- [Keywords Area](#)
- [method](#)
- [richardson_extrap](#)
- [model_pointer](#)

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_`
`pointer` for each method is imperative.

See [block_pointer](#) for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
```

```

samples = 10

  descriptors = 'x1' 'x2'

interface
  id_interface = 'I1'
  system asynch evaluation_concurrency = 5
  analysis_driver = 'text_book'

responses
  response_functions = 3
  no_gradients
  no_hessians

```

7.3 model

- [Keywords Area](#)
- [model](#)

Specifies how variables are mapped into a set of responses

Topics

This keyword is related to the topics:

- [block](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required(<i>Choose One</i>)	Model Type (Group 1)		
			id_model	Give the model block an identifying name, in case of multiple model blocks
			single	A model with one of each block: variable, interface, and response
			surrogate	An empirical model that is created from data or the results of a submodel
			nested	A model whose responses are computed through the use of a sub-iterator
			active_subspace	Active (variable) subspace model
			adapted_basis	Unused (reserved for future Adapted Basis Model)
			random_field	Experimental capability to generate a random field representation. from data, from simulation runs, or from a covariance matrix. The representation may then be sampled for use as a random field input to another simulation. THIS IS AN EXPERIMENTAL CAPABILITY.
	Optional		variables_pointer	Specify which variables block will be included with this model block

	Optional	responses_pointer	Specify which responses block will be used by this model block
	Optional	hierarchical_tagging	Enables hierarchical evaluation tagging

Description

A model is comprised of a mapping from variables, through an interface, to responses.

Model Group 1 The type of model can be:

1. `single` (default)
2. `surrogate`
3. `nested`
4. `subspace`
5. `random_field`

The input file must specify one of these types. If the type is not specified, Dakota will assume a single model.

Block Pointers and ID

Each of these model types supports `variables_pointer` and `responses_pointer` strings for identifying the variables and responses specifications used in constructing the model by cross-referencing with `id_variables` and `id_responses` strings from particular variables and responses keyword specifications.

These pointers are valid for each model type since each model contains a set of variables that is mapped into a set of responses – only the specifics of the mapping differ.

Additional pointers are used for each model type for constructing the components of the variable to response mapping. As an environment specification identifies a top-level method and a method specification identifies a model, a model specification identifies variables, responses, and (for some types) interface specifications. This top-down flow specifies all of the object interrelationships.

Examples

The first example shows a minimal specification for a `single` model, which is the default model when no models are explicitly specified by the user.

```
model
  single
```

The next example displays a surrogate model specification which selects a quadratic polynomial from among the global approximation methods. It uses a pointer to a design of experiments method for generating the data needed for building the global approximation, reuses any old data available for the current approximation region, and employs the first-order multiplicative approach to correcting the approximation each time correction is requested.

```
model,
  id_model = 'M1'
  variables_pointer = 'V1'
  responses_pointer = 'R1'
  surrogate
```

```

global
  polynomial quadratic
  dace_method_pointer = 'DACE'
  reuse_samples region
  correction multiplicative first_order

```

This example demonstrates the use of identifiers and pointers. It provides the optional model independent specifications for model identifier, variables pointer, and responses pointer as well as model dependent specifications for global surrogates (see [global](#)).

Finally, an advanced nested model example would be

```

model
  id_model = 'M1'
  variables_pointer = 'V1'
  responses_pointer = 'R1'
  nested
    optional_interface_pointer = 'O11'
    optional_interface_responses_pointer = 'OIR1'
    sub_method_pointer = 'SM1'
    primary_variable_mapping = '' '' 'X' 'Y'
    secondary_variable_mapping = '' '' 'mean' 'mean'
    primary_response_mapping = 1. 0. 0. 0. 0. 0. 0. 0. 0. 0.
    secondary_response_mapping = 0. 0. 0. 1. 3. 0. 0. 0. 0. 0.
                                0. 0. 0. 0. 0. 0. 1. 3. 0.

```

This example illustrates controls for model identifier, variables pointer, and responses pointer and for specifying details of the nested mapping.

7.3.1 id_model

- [Keywords Area](#)
- [model](#)
- [id_model](#)

Give the model block an identifying name, in case of multiple model blocks

Topics

This keyword is related to the topics:

- [block_identifier](#)

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed

Description

The model identifier string is supplied with `id_model` and is used to provide a unique identifier string for use within method specifications (refer to the keyword `model_pointer` in any of the methods in the [method](#) block, for example: [model_pointer](#))

This is used to determine which model the method will run.

See Also

These keywords may also be of interest:

- [model_pointer](#)

7.3.2 single

- [Keywords Area](#)
- [model](#)
- [single](#)

A model with one of each block: variable, interface, and response

Specification

Alias: simulation

Argument(s): none

Default: N/A (single if no model specification)

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			interface_pointer	Interface block pointer for the single model type
	Optional		solution_level_cost	Cost estimates associated with a set of solution control values.

Description

The single model is the simplest model type. It uses a single [interface](#) instance to map [variables](#) into [responses](#). There is no recursion in this case.

The optional [interface_pointer](#) specification identifies the interface block by cross-referencing with the `id_interface` string input from a particular interface keyword specification. This is only necessary when the input file has multiple interface blocks, and you wish to explicitly point to the desired block. The same logic follows for responses and variables blocks and pointers.

Examples

The example shows a minimal specification for a single model, which is the default model when no models are specified by the user.

```
model
  single
```

This example does not provide any pointer strings and therefore relies on the default behavior of constructing the model with the last variables, interface, and responses specifications parsed.

See Also

These keywords may also be of interest:

- [surrogate](#)
- [nested](#)

interface_pointer

- [Keywords Area](#)
- [model](#)
- [single](#)
- [interface_pointer](#)

Interface block pointer for the single model type

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: model use of last interface parsed

Description

In the `single` model case, a single interface is used to map the variables into responses. The optional `interface_pointer` specification identifies this interface by cross-referencing with the `id_interface` string input from a particular interface keyword specification.

See [block_pointer](#) for details about pointers.

When an interface pointer is not specified, the model will use the last interface block parsed from the input file.

solution_level_cost

- [Keywords Area](#)
- [model](#)
- [single](#)
- [solution_level_cost](#)

Cost estimates associated with a set of solution control values.

Specification

Alias: none

Argument(s): REALLIST

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			solution_level_ control	Cost estimates associated with a set of solution control values.

Description

Simulation-based models may have an associated `solution_level_control`, which identifies a hierarchy of solution states, such as a set of mesh discretizations from coarse to fine, a set of solver tolerances from loose to tight, etc. In algorithms that manage such a hierarchy and perform optimal resource allocation among the solution states (e.g., multilevel Monte Carlo), it is important to estimate a set of costs associated with each state. These cost estimates can be relative, such as in the example below (lowest cost normalized to 1.)

Note: a scalar solution cost can be specified without an associated solution level control. This is useful when employing a hierarchy of model forms (each model has a scalar solution cost and no solution level control) instead of a hierarchy of discretization levels (one model has a vector-valued solution cost associated with multiple solution levels).

Examples

```
model,
  simulation
    solution_level_control = 'mesh_size'
    solution_level_cost = 1. 8. 64. 512. 4096.

variables,
  uniform_uncertain = 9
    lower_bounds      = 9*-1.
    upper_bounds      = 9* 1.
  discrete_state_set
    integer = 1
    set_values = 4 8 16 32 64
    descriptors = 'mesh_size'
```

`solution_level_control`

- [Keywords Area](#)
- [model](#)
- [single](#)
- [solution_level_cost](#)
- [solution_level_control](#)

Cost estimates associated with a set of solution control values.

Specification

Alias: none

Argument(s): STRING

Default: use of single default solution level

Description

Simulation-based models may have an associated `solution_level_control`, which identifies a hierarchy of solution states, such as a set of mesh discretizations from coarse to fine, a set of solver tolerances from loose to tight, etc. The string specified as the `solution_level_control` identifies a discrete variable label that parameterizes the hierarchy of solution states.

Note: If the discrete variable identified is a discrete set variable, then it is important to note that the variable's set values will be ordered (lexicographically in the case of string variables), and the ordering of values provided in `solution_level_cost` should correspond to this set ordering. A common error is to provide a listing of set values that is out of order and then providing a set of costs corresponding to this misordered list – in this case, the solution level costs will be associated with the re-ordered set values.

Examples

In this example, integer solution control values and solution costs are naturally well ordered.

```
model,
  simulation
    solution_level_control = 'mesh_size'
    solution_level_cost = 1. 8. 64. 512. 4096.

variables,
  uniform_uncertain = 9
  lower_bounds      = 9*-1.
  upper_bounds      = 9* 1.
  discrete_state_set
    integer = 1
    set_values = 4 8 16 32 64
    descriptors = 'mesh_size'
```

In this example, string solution control values are lexicographically ordered, and care must be taken to align the solution cost estimates.

```
model,
  simulation
    solution_level_control = 'mesh_size'
    solution_level_cost = 1. 64. 8. # match set ordering

variables,
  uniform_uncertain = 9
  lower_bounds      = 9*-1.
  upper_bounds      = 9* 1.
  discrete_state_set
    string = 1
    set_values = 'COARSE' 'FINE' 'MEDIUM' # lexicographical ordering
    descriptors = 'mesh_size'
```

7.3.3 surrogate

- [Keywords Area](#)
- [model](#)
- [surrogate](#)

An empirical model that is created from data or the results of a submodel

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Surrogate Category (Group 1)	id_surrogates global	Identifies the subset of the response functions by number that are to be approximated (the default is all functions). Select a surrogate model with global support
			multipoint	Construct a surrogate from multiple existing training points
			local	Build a locally accurate surrogate from data at a single point
			hierarchical	Hierarchical approximations use corrected results from a low fidelity model as an approximation to the results of a high fidelity "truth" model.

Description

Surrogate models are inexpensive approximate models that are intended to capture the salient features of an expensive high-fidelity model. They can be used to explore the variations in response quantities over regions of the parameter space, or they can serve as inexpensive stand-ins for optimization or uncertainty quantification studies (see, for example, the surrogate-based optimization methods, [surrogate_based_global](#) and [surrogate_based_local](#)).

Surrogate models supported in Dakota are categorized as Data Fitting or Hierarchical, as shown below. Each of these surrogate types provides an approximate representation of a "truth" model which is used to perform the parameter to response mappings. This approximation is built and updated using results from the truth model, called the "training data".

- Data fits:

Known Issue: When using discrete variables, there have been sometimes significant differences in surrogate behavior observed across computing platforms in some cases. The cause has not yet been fully diagnosed

and is currently under investigation. In addition, guidance on appropriate construction and use of surrogates with discrete variables is under development. In the meantime, users should therefore be aware that there is a risk of inaccurate results when using surrogates with discrete variables.

Data fitting methods involve construction of an approximation or surrogate model using data (response values, gradients, and Hessians) generated from the original truth model. Data fit methods can be further categorized as local, multipoint, and global approximation techniques, based on the number of points used in generating the data fit.

1. Local: built from response data from a single point in parameter space
 - Taylor series expansion: [taylor_series](#)
Training data consists of a single point, plus gradient and Hessian information.
2. Multipoint: built from two or more points in parameter space, often involving the current and previous iterates of a minimization algorithm.
 - TANA-3: [tana](#)
Training Data comes from a few previously evaluated points
3. Global full space response surface methods:
 - Polynomial regression: [polynomial](#)
 - Gaussian process (Kriging): [gaussian_process](#)
 - Artificial neural network: [neural_network](#)
 - MARS: [mars](#)
 - Radial Basis Functions: [radial_basis](#)
 - Orthogonal polynomials (only supported in PCE/SC for now): [polynomial_chaos](#) and [stoch_collocation](#)

Training data is generated using either a design of experiments method applied to the truth model (specified by [dace_method_pointer](#)), or from saved data (specified by [reuse_points](#)) in a restart database, or an import file.

- Multifidelity/hierarchical:

Multifidelity modeling involves the use of a low-fidelity physics-based model as a surrogate for the original high-fidelity model. The low-fidelity model typically involves a coarser mesh, looser convergence tolerances, reduced element order, or omitted physics.

See [hierarchical](#).

The global and hierarchal surrogates have a correction feature in order to improve the local accuracy of the surrogate models. The correction factors force the surrogate models to match the true function values and possibly true function derivatives at the center point of each trust region. Details can be found on global [correction](#) or hierarchical [correction](#).

Theory

Surrogate models are used extensively in the surrogate-based optimization and least squares methods, in which the goals are to reduce expense by minimizing the number of truth function evaluations and to smooth out noisy data with a global data fit. However, the use of surrogate models is not restricted to optimization techniques; uncertainty quantification and optimization under uncertainty methods are other primary users.

Data Fit Surrogate Models

A surrogate of the $\{data\ fit\}$ type is a non-physics-based approximation typically involving interpolation or regression of a set of data generated from the original model. Data fit surrogates can be further characterized by

the number of data points used in the fit, where a local approximation (e.g., first or second-order Taylor series) uses data from a single point, a multipoint approximation (e.g., two-point exponential approximations (TPEA) or two-point adaptive nonlinearity approximations (TANA)) uses a small number of data points often drawn from the previous iterates of a particular algorithm, and a global approximation (e.g., polynomial response surfaces, kriging/gaussian_process, neural networks, radial basis functions, splines) uses a set of data points distributed over the domain of interest, often generated using a design of computer experiments.

Dakota contains several types of surface fitting methods that can be used with optimization and uncertainty quantification methods and strategies such as surrogate-based optimization and optimization under uncertainty. These are: polynomial models (linear, quadratic, and cubic), first-order Taylor series expansion, kriging spatial interpolation, artificial neural networks, multivariate adaptive regression splines, radial basis functions, and moving least squares. With the exception of Taylor series methods, all of the above methods listed in the previous sentence are accessed in Dakota through the Surfpack library. All of these surface fitting methods can be applied to problems having an arbitrary number of design parameters. However, surface fitting methods usually are practical only for problems where there are a small number of parameters (e.g., a maximum of somewhere in the range of 30-50 design parameters). The mathematical models created by surface fitting methods have a variety of names in the engineering community. These include surrogate models, meta-models, approximation models, and response surfaces. For this manual, the terms surface fit model and surrogate model are used.

The data fitting methods in Dakota include software developed by Sandia researchers and by various researchers in the academic community.

Multifidelity Surrogate Models

A second type of surrogate is the $\{model\}$ hierarchy type (also called multifidelity, variable fidelity, variable complexity, etc.). In this case, a model that is still physics-based but is of lower fidelity (e.g., coarser discretization, reduced element order, looser convergence tolerances, omitted physics) is used as the surrogate in place of the high-fidelity model. For example, an inviscid, incompressible Euler CFD model on a coarse discretization could be used as a low-fidelity surrogate for a high-fidelity Navier-Stokes model on a fine discretization.

Surrogate Model Selection

This section offers some guidance on choosing from among the available surrogate model types.

- For Surrogate Based Local Optimization, using the [surrogate_based_local](#) method with a trust region: using the keywords:

1. [surrogate local taylor_series](#) or
2. [surrogate multipoint tana](#)

will probably work best.

If for some reason you wish or need to use a global surrogate (not recommended) then the best of these options is likely to be either:

1. [surrogate global gaussian_process surfpack](#) or
2. [surrogate global moving_least_squares](#).

- For Efficient Global Optimization (EGO), the [efficient_global](#) method:

the default surrogate is: [gaussian_process surfpack](#) which is likely to find a more optimal value and/or require fewer true function evaluations than the alternative, [gaussian_process dakota](#). However, the [surfpack](#) will likely take more time to build than the [dakota](#) version. Note that currently the [use_derivatives](#) keyword is not recommended for use with EGO based methods.

- For EGO based global interval estimation, the [global_interval_est ego](#) method:

the default [gaussian_process surfpack](#) will likely work better than the alternative [gaussian_process dakota](#).

- For Efficient Global Reliability Analysis (EGRA), the [global_reliability](#) method:
 - the [surfpack](#) and `dakota` versions of the gaussian process tend to give similar answers with the `dakota` version tending to use fewer true function evaluations. Since this is based on EGO, it is likely that the default [surfpack](#) is more accurate, although this has not been rigorously demonstrated.
- For EGO based Dempster-Shafer Theory of Evidence, i.e. the [global_evidence_ego](#) method, the default [gaussian_process_surfpack](#) often use significantly fewer true function evaluations than the alternative [gaussian-process_dakota](#).
- When using a global surrogate to extrapolate, any of the surrogates:
 - [gaussian_process_surfpack](#)
 - [polynomial_quadratic](#)
 - [polynomial_cubic](#)

are recommended.

- When there is over roughly two or three thousand data points and you wish to interpolate (or approximately interpolate) then a Taylor series, Radial Basis Function Network, or Moving Least Squares fit is recommended. The only reason that the [gaussian_process_surfpack](#) is not recommended is that it can take a considerable amount of time to construct when the number of data points is very large. Use of the third party MARS package included in Dakota is generally discouraged.
- In other situations that call for a global surrogate, the [gaussian_process_surfpack](#) is generally recommended. The `use_derivatives` keyword will only be useful if accurate and inexpensive derivatives are available. Finite difference derivatives are disqualified on both counts. However, derivatives generated by analytical, automatic differentiation, or continuous adjoint techniques can be appropriate. Currently, first order derivatives, i.e. gradients, are the highest order derivatives that can be used to construct the [gaussian_process_surfpack](#) model; Hessians will not be used even if they are available.

These keywords may also be of interest:

- [single](#)
- [nested](#)

id_surrogates

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [id_surrogates](#)

Identifies the subset of the response functions by number that are to be approximated (the default is all functions).

Specification

Alias: none

Argument(s): INTEGERLIST

Default: All response functions are approximated

Description

In the `surrogate` model case, the specification first allows a mixture of surrogate and actual response mappings through the use of the optional `id_surrogates` specification. This identifies the subset of the response functions by number that are to be approximated (the default is all functions). The valid response function identifiers range from 1 through the total number of response functions (see [response_functions](#)).

global

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)

Select a surrogate model with global support

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			gaussian_process	Gaussian Process surrogate model
	Required (<i>Choose One</i>)	Global Surrogate Type (Group 1)	mars	Multivariate Adaptive Regression Spline (MARS)
			moving_least_squares	Moving Least Squares surrogate models

			function_train	Global surrogate model based on functional tensor train decomposition
			neural_network	Artificial neural network model
			radial_basis	Radial basis function (RBF) model
			polynomial	Polynomial surrogate model
	Optional		domain_-decomposition	Piecewise Domain Decomposition for Global Surrogate Models
	Optional(Choose One)	Number of Build Points (Group 2)	total_points	Specified number of training points
			minimum_points	Construct surrogate with minimum number of points
			recommended_-points	Construct surrogate with recommended number of points
	Optional(Choose One)	Build Data Source (Group 3)	dace_method_-pointer	Specify a method to gather training data
			actual_model_-pointer	A surrogate model pointer that guides a method to whether it should use a surrogate model or compute truth function evaluations

	Optional	reuse_points	Surrogate model training data reuse control
	Optional	import_build_points_file	File containing points you wish to use to build a surrogate
	Optional	export_approx_points_file	Output file for evaluations of a surrogate model
	Optional	use_derivatives	Use derivative data to construct surrogate models
	Optional	correction	Correction approaches for surrogate models
	Optional	metrics	Compute surrogate quality metrics
	Optional	import_challenge_points_file	Datafile of points to assess surrogate quality

Description

The global surrogate model requires specification of one of the following approximation types:

1. Polynomial
2. Gaussian process (Kriging interpolation)
3. Layered perceptron artificial neural network approximation
4. MARS
5. Moving least squares
6. Radial basis function
7. Voronoi Piecewise Surrogate (VPS)

All these approximations are implemented in SurfPack[36], except for VPS. In addition, a second version of Gaussian process is implemented directly in Dakota.

Training Data

Training data can be taken from prior runs, stored in a datafile, or by running a Design of Experiments method. The keywords listed below are used to determine how to collect training data:

- `dace_method_pointer`

- `reuse_points`
- `import_points_file`
- `use_derivatives` The source of training data is determined by the contents of a provided `import_points_file`, whether `reuse_points` and `use_derivatives` are specified, and the contents of the method block specified by `dace_method_pointer`. `use_derivatives` is a special case, the other keywords are discussed below.

The number of training data points used in building a global approximation is determined by specifying one of three point counts:

1. `minimum_points`: minimum required or minimum "reasonable" amount of training data. Defaults to $d+1$ for d input dimensions for most models, e.g., polynomials override to the number of coefficients required to estimate the requested order.
2. `recommended_points`: recommended number of training data, (this is the default option, if none of the keywords is specified). Defaults to $5*d$, except for polynomials where it's equal to the minimum.
3. `total_points`: specify the number of training data points. However, if the `total_points` value is less than the default `minimum_points` value, the `minimum_points` value is used.

The sources of training data depend on the number of training points, N_{tp} , the number of points in the import file, N_{if} , and the value of `reuse_points`.

- If there is no import file, all training data come from the DACE method
- If there is an import file, all N_{if} points from the file are used, and the remaining $N_{tp} - N_{if}$ points come from the DACE method
- If there is an import file and `reuse_points` is:
 - `none` - all N_{tp} points from DACE method
 - `region` - only the points within a trust region are taken from the import file, and all remaining points are from the DACE method.
 - `all` - (Default) all N_{if} points from the file are used, and the remaining $N_{tp} - N_{if}$ points come from the DACE method

Surrogate Correction

A `correction` model can be added to the constructed surrogate in order to better match the training data. The specified correction method will be applied to the surrogate, and then the corrected surrogate model is used by the method.

Finally, the quality of the surrogate can be tested using the `metrics` and `challenge_points_file` keywords.

Theory

Global methods, also referred to as response surface methods, involve many points spread over the parameter ranges of interest. These surface fitting methods work in conjunction with the sampling methods and design of experiments methods.

Procedures for Surface Fitting

The surface fitting process consists of three steps:

1. selection of a set of design points

2. evaluation of the true response quantities (e.g., from a user-supplied simulation code) at these design points,
3. using the response data to solve for the unknown coefficients (e.g., polynomial coefficients, neural network weights, kriging correlation factors) in the surface fit model.

In cases where there is more than one response quantity (e.g., an objective function plus one or more constraints), then a separate surface is built for each response quantity. Currently, the surface fit models are built using only 0th-order information (function values only), although extensions to using higher-order information (gradients and Hessians) are possible.

Each surface fitting method employs a different numerical method for computing its internal coefficients. For example, the polynomial surface uses a least-squares approach that employs a singular value decomposition to compute the polynomial coefficients, whereas the kriging surface uses Maximum Likelihood Estimation to compute its correlation coefficients. More information on the numerical methods used in the surface fitting codes is provided in the Dakota Developers Manual.

- [gaussian_process](#)

Gaussian Process surrogate model

Specification

Alias: kriging

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required(<i>Choose One</i>)	GP Implementation (Group 1)	dakota	Select the built in Gaussian Process surrogate

			surfpack	Use the Surfpack version of Gaussian Process surrogates
--	--	--	--------------------------	---

Description

Use the Gaussian process (GP) surrogate from Surfpack, which is specified using the [surfpack](#) keyword.

An alternate version of GP surrogates was available in prior versions of Dakota. **For now, both versions are supported but the dakota version is deprecated and intended to be removed in a future release.**

Known Issue: When using discrete variables, there have been sometimes significant differences in surrogate behavior observed across computing platforms in some cases. The cause has not yet been fully diagnosed and is currently under investigation. In addition, guidance on appropriate construction and use of surrogates with discrete variables is under development. In the meantime, users should therefore be aware that there is a risk of inaccurate results when using surrogates with discrete variables.

dakota

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			point_selection	Enable greedy selection of well-spaced build points

	Optional	trend	Choose a trend function for a Gaussian process surrogate
--	-----------------	-----------------------	--

Description

A second version of GP surrogates was available in prior versions of Dakota. **For now, both versions are supported but the dakota version is deprecated and intended to be removed in a future release.**

Historically these models were drastically different, but in Dakota 5.1, they became quite similar. They now differ in that the Surfpack GP has a richer set of features/options and tends to be more accurate than the Dakota version. Due to how the Surfpack GP handles ill-conditioned correlation matrices (which significantly contributes to its greater accuracy), the Surfpack GP can be a factor of two or three slower than Dakota's. As of Dakota 5.2, the Surfpack implementation is the default in all contexts except Bayesian calibration.

More details on the `gaussian_process` dakota model can be found in[59].

Dakota's GP deals with ill-conditioning in two ways. First, when it encounters a non-invertible correlation matrix it iteratively increases the size of a "nugget," but in such cases the resulting approximation smooths rather than interpolates the data. Second, it has a `point_selection` option (default off) that uses a greedy algorithm to select a well-spaced subset of points prior to the construction of the GP. In this case, the GP will only interpolate the selected subset. Typically, one should not need point selection in trust-region methods because a small number of points are used to develop a surrogate within each trust region. Point selection is most beneficial when constructing with a large number of points, typically more than order one hundred, though this depends on the number of variables and spacing of the sample points.

This differs from the `point_selection` option of the Dakota GP which initially chooses a well-spaced subset of points and finds the correlation parameters that are most likely for that one subset.

`point_selection`

- [surfpack](#)

Use the Surfpack version of Gaussian Process surrogates

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			trend	Choose a trend function for a Gaussian process surrogate
	Optional		optimization_ - method	Change the optimization method used to compute hyperparameters
	Optional		max_trials	Max number of likelihood function evaluations
	Optional (<i>Choose One</i>)	Nugget (Group 1)	nugget	Specify a nugget to handle ill-conditioning
			find_nugget	Have Surfpack compute a nugget to handle ill-conditioning
	Optional		correlation_lengths	Specify the correlation lengths for the Gaussian process
	Optional		export_model	Exports surrogate model in user-selected format

Description

This keyword specifies the use of the Gaussian process that is incorporated in our surface fitting library called Surfpack.

Several user options are available:

1. Optimization methods:

Maximum Likelihood Estimation (MLE) is used to find the optimal values of the hyper-parameters governing the trend and correlation functions. By default the global optimization method DIRECT is used for MLE, but other options for the optimization method are available. See [optimization.method](#).

The total number of evaluations of the likelihood function can be controlled using the `max_trials` keyword followed by a positive integer. Note that the likelihood function does not require running the "truth" model, and is relatively inexpensive to compute.

2. Trend Function:

The GP models incorporate a parametric trend function whose purpose is to capture large-scale variations. See [trend](#).

3. Correlation Lengths:

Correlation lengths are usually optimized by Surfpack, however, the user can specify the lengths manually. See [correlation_lengths](#).

4. Ill-conditioning

One of the major problems in determining the governing values for a Gaussian process or Kriging model is the fact that the correlation matrix can easily become ill-conditioned when there are too many input points close together. Since the predictions from the Gaussian process model involve inverting the correlation matrix, ill-conditioning can lead to poor predictive capability and should be avoided.

Note that a sufficiently bad sample design could require correlation lengths to be so short that any interpolatory GP model would become inept at extrapolation and interpolation.

The `surfpack` model handles ill-conditioning internally by default, but behavior can be modified using

5. Gradient Enhanced Kriging (GEK).

The `use_derivatives` keyword will cause the Surfpack GP to be constructed from a combination of function value and gradient information (if available).

See notes in the Theory section.

Theory

Gradient Enhanced Kriging

Incorporating gradient information will only be beneficial if accurate and inexpensive derivative information is available, and the derivatives are not infinite or nearly so. Here "inexpensive" means that the cost of evaluating a function value plus gradient is comparable to the cost of evaluating only the function value, for example gradients computed by analytical, automatic differentiation, or continuous adjoint techniques. It is not cost effective to use derivatives computed by finite differences. In tests, GEK models built from finite difference derivatives were also significantly less accurate than those built from analytical derivatives. Note that GEK's correlation matrix tends to have a significantly worse condition number than Kriging for the same sample design.

This issue was addressed by using a pivoted Cholesky factorization of Kriging's correlation matrix (which is a small sub-matrix within GEK's correlation matrix) to rank points by how much unique information they contain. This reordering is then applied to whole points (the function value at a point immediately followed by gradient information at the same point) in GEK's correlation matrix. A standard non-pivoted Cholesky is then applied to the reordered GEK correlation matrix and a bisection search is used to find the last equation that meets the constraint on the (estimate of) condition number. The cost of performing pivoted Cholesky on Kriging's correlation matrix is usually negligible compared to the cost of the non-pivoted Cholesky factorization of GEK's correlation matrix. In tests, it also resulted in more accurate GEK models than when pivoted Cholesky or whole-point-block pivoted Cholesky was performed on GEK's correlation matrix.

trend

- [optimization_method](#)

Change the optimization method used to compute hyperparameters

Specification

Alias: none

Argument(s): STRING

Default: global

Description

Select the optimization method to compute hyperparameters of the Gaussian Process by specifying one of these arguments:

- `global` (default) - DIRECT method
- `local` - CONMIN method
- `sampling` - generates several random guesses and picks the candidate with greatest likelihood
- `none` - no optimization, pick the center of the feasible region

The `none` option, and the starting location of the `local` optimization, default to the center, in $\log(\text{correlation length})$ scale, of the of feasible region.

Surfpack picks a small feasible region of correlation parameters.

Note that we have found the `global` optimization method to be the most robust.

- [global](#)
- [gaussian_process](#)
- [surfpack](#)
- [nugget](#)

Specify a nugget to handle ill-conditioning

Specification

Alias: none

Argument(s): REAL

Default: None

Description

By default, the Surfpack GP handles ill-conditioning and does not use a nugget. If the user wishes to specify a nugget, there are two approaches.

- The user can specify the value of a nugget with [nugget](#).
- Have Surfpack find the optimal value of the nugget. This is specified by [find_nugget](#). There are two options for `find_nugget`.
 - `find_nugget = 1`: assume that the reciprocal condition number of the correlation matrix R , `rcondR`, is zero and calculate the nugget needed to make the worst case of R not ill-conditioned.
 - `find_nugget = 2`: calculate `rcondR`, which requires a Cholesky factorization. If `rcondR` indicates that R is not ill-conditioned, then kriging uses the Cholesky factorization. Otherwise, if `rcondR` says R is ill conditioned, then kriging will calculate the nugget needed to make the worst case of R not ill conditioned.

`find_nugget = 1` and `2` are similar, the second option just takes more computation (the initial Cholesky factorization) for larger problems.

find_nugget

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [gaussian_process](#)
- [surfpack](#)

- [model](#)
- [surrogate](#)
- [global](#)
- [gaussian_process](#)
- [surfpack](#)
- [export_model](#)

Exports surrogate model in user-selected format

Topics

This keyword is related to the topics:

- [surrogate_models](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			filename_prefix	User-customizable portion of exported model filenames
	Required		formats	Formats for surrogate model export

Description

Export the surrogate for later evaluation using the `surfpack` executable (`bin/surfpack`) or a user-developed tool. Export format is controlled using the `formats` specification. Four formats are available in Dakota; however, not all have been enabled for all surrogates.

The four formats are:

- `text_archive` - Plain-text, machine-readable archive for use with the `surfpack` executable
- `binary_archive` - Binary, machine-readable archive for use with the `surfpack` executable
- `algebraic_file` - Plain-text, human-readable file intended for use with user-created tools; not compatible with the `surfpack` executable
- `algebraic_console` - Print the model in algebraic format to the screen; not compatible with the `surfpack` executable

Most global surrogates can be exported in all four formats. These include:

- Gaussian process (keyword `gaussian_process` `surfpack`)
- Artificial neural network (keyword `neural_network`)
- Radial basis Functions (keyword `radial_basis`)
- Polynomial (keyword `polynomial`)

However, for Multivariate Adaptive Regression Spline (keyword `mars`) and moving least squares (keyword `moving_least_squares`) models, only `text_archive` and `binary_archive` formats may be used.

Currently, no other surrogate models can be exported. In addition, Dakota cannot import models that have been exported. They are strictly for use with external tools.

Default Behavior

No export.

Expected Output

Output depends on selected format; see the `formats` specification.

Additional Discussion

The Dakota examples folder includes a demonstration of using the `surfpack` executable with an exported model file.

filename_prefix

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [gaussian_process](#)
- [surfpack](#)
- [export_model](#)
- [filename_prefix](#)

User-customizable portion of exported model filenames

Topics

This keyword is related to the topics:

- [surrogate_models](#)

Specification

Alias: none

Argument(s): STRING

Default: exported_surrogate

Description

When a file-based export of a surrogate model is specified, Dakota writes one file per response, per requested format. The files are named using the pattern `{prefix}.{response_descriptor}.{extension}`.

The `response_descriptor` portion of the pattern is filled in using the response [descriptors](#) provided by the user (or, if none are specified, descriptors automatically generated by Dakota). Extension is a three or four letter string that depends on the format. The `filename_prefix` keyword is used to supply the prefix portion of the pattern.

Examples

This input snippet directs Dakota to write one algebraic format file and one binary archive file for each response. The names of the files will follow the patterns `my_surrogate.{response_descriptor}.alg` (for the algebraic files) and `my_surrogate.{response_descriptor}.bsps` (for the binary files).

```
surrogate global gaussian_process surfpack
export_model
  filename_prefix = 'my_surrogate'
  formats
    algebraic_file

Formats for surrogate model export

Topics

This keyword is related to the topics:

- [surrogate_models](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		text_archive	Export surrogate model to a plain-text archive file
	Optional		binary_archive	Export surrogate model to a binary archive file
	Optional		algebraic_file	Export surrogate model in algebraic format to a file
	Optional		algebraic_console	Export surrogate model in algebraic format to the console

Description

Select from among the 2-4 available export formats available for this surrogate. Multiple selections are permitted.

See `export_model` and the entries for the format selection keywords for further information.

text_archive

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [gaussian_process](#)
- [surfpack](#)
- [export_model](#)
- [formats](#)
- [text_archive](#)

Export surrogate model to a plain-text archive file

Topics

This keyword is related to the topics:

- [surrogate_models](#)

Specification

Alias: none

Argument(s): none

Description

After the surrogate model has been built, Dakota will export it to a plain-text archival file suitable only for use with the surfpack executable (`bin/surfpack`). The file is named using the pattern `{prefix}.{response-descriptor}.sps`, in which 'sps' stands for Surfpack Surrogate. See `filename_prefix` for further information about exported surrogate file naming.

The Dakota examples folder includes a demonstration of using the surfpack executable with an exported model file.

binary_archive

- [model](#)
- [surrogate](#)
- [global](#)
- [gaussian_process](#)
- [surfpack](#)
- [export_model](#)
- [formats](#)
- [algebraic_file](#)

Export surrogate model in algebraic format to a file

Topics

This keyword is related to the topics:

- [surrogate_models](#)

Specification

Alias: none

Argument(s): none

Description

After the surrogate model has been built, Dakota will export it to a file in a human-readable "algebraic" format. The file is named using the pattern `{prefix}.{response_descriptor}.alg`. See `filename_prefix` for further information about exported surrogate file naming. The file contains sufficient information for the user to (re)construct and evaluate the model outside of Dakota.

Expected Output

The format depends on the type of surrogate model, but in general will include a LaTeX-like representation of the analytic form of the model to aid tool development, all needed model hyperparameters, and headers describing the shape or dimension of the provided data.

The output written to the file matches exactly the output written to the console when `algebraic_console` is specified.

algebraic_console

- [global](#)
- [gaussian_process](#)
- [surfpack](#)
- [export_model](#)
- [formats](#)
- [algebraic_console](#)

Export surrogate model in algebraic format to the console

Topics

This keyword is related to the topics:

- [surrogate_models](#)

Specification

Alias: none

Argument(s): none

Description

After the surrogate model has been built, Dakota will export it to the console (screen, or output file if Dakota was run using the -o option) in a human-readable "algebraic" format. The output contains sufficient information for the user to (re)construct and evaluate the model outside of Dakota.

Expected Output

The format depends on the type of surrogate model, but in general will include a LaTeX-like representation of the analytic form of the model to aid tool development, all needed model hyperparameters, and headers describing the shape or dimension of the provided data.

The output written to the screen for the exported model matches exactly the output written to file when `algebraic_file` is specified. Use of `algebraic_file` is preferred over `algebraic_console`, which exists largely to provide a measure of backward compatibility.

mars

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [mars](#)

Multivariate Adaptive Regression Spline (MARS)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			<code>max_bases</code>	Maximum number of MARS bases
	Optional		<code>interpolation</code>	MARS model interpolation type
	Optional		<code>export_model</code>	Exports surrogate model in user-selected format

Description

This surface fitting method uses multivariate adaptive regression splines from the MARS3.5 package[27] developed at Stanford University.

The MARS reference material does not indicate the minimum number of data points that are needed to create a MARS surface model. However, in practice it has been found that at least $n_{c_{quad}}$, and sometimes as many as 2 to 4 times $n_{c_{quad}}$, data points are needed to keep the MARS software from terminating. Provided that sufficient data samples can be obtained, MARS surface models can be useful in SBO and OUU applications, as well as in the prediction of global trends throughout the parameter space.

Known Issue: When using discrete variables, there have been sometimes significant differences in surrogate behavior observed across computing platforms in some cases. The cause has not yet been fully diagnosed and is currently under investigation. In addition, guidance on appropriate construction and use of surrogates with discrete variables is under development. In the meantime, users should therefore be aware that there is a risk of inaccurate results when using surrogates with discrete variables.

Theory

The form of the MARS model is based on the following expression:

$$\hat{f}(\mathbf{x}) = \sum_{m=1}^M a_m B_m(\mathbf{x})$$

where the a_m are the coefficients of the truncated power basis functions B_m , and M is the number of basis functions. The MARS software partitions the parameter space into subregions, and then applies forward and backward regression methods to create a local surface model in each subregion. The result is that each subregion contains its own basis functions and coefficients, and the subregions are joined together to produce a smooth, C^2 -continuous surface model.

MARS is a nonparametric surface fitting method and can represent complex multimodal data trends. The regression component of MARS generates a surface model that is not guaranteed to pass through all of the response data values. Thus, like the quadratic polynomial model, it provides some smoothing of the data.

max_bases

- [mars](#)
- [export_model](#)

Exports surrogate model in user-selected format

Topics

This keyword is related to the topics:

- [surrogate_models](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required		filename_prefix	User-customizable portion of exported model filenames
			formats	Formats for surrogate model export

Description

Export the surrogate for later evaluation using the `surfpack` executable (`bin/surfpack`) or a user-developed tool. Export format is controlled using the `formats` specification. Four formats are available in Dakota; however, not all have been enabled for all surrogates.

The four formats are:

- `text_archive` - Plain-text, machine-readable archive for use with the `surfpack` executable
- `binary_archive` - Binary, machine-readable archive for use with the `surfpack` executable
- `algebraic_file` - Plain-text, human-readable file intended for use with user-created tools; not compatible with the `surfpack` executable

- `algebraic_console` - Print the model in algebraic format to the screen; not compatible with the `surfpack` executable

Most global surrogates can be exported in all four formats. These include:

- Gaussian process (keyword `gaussian_process` `surfpack`)
- Artificial neural network (keyword `neural_network`)
- Radial basis Functions (keyword `radial_basis`)
- Polynomial (keyword `polynomial`)

However, for Multivariate Adaptive Regression Spline (keyword `mars`) and moving least squares (keyword `moving_least_squares`) models, only `text_archive` and `binary_archive` formats may be used.

Currently, no other surrogate models can be exported. In addition, Dakota cannot import models that have been exported. They are strictly for use with external tools.

Default Behavior

No export.

Expected Output

Output depends on selected format; see the `formats` specification.

Additional Discussion

The Dakota examples folder includes a demonstration of using the `surfpack` executable with an exported model file.

filename_prefix

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [mars](#)
- [export_model](#)
- [filename_prefix](#)

User-customizable portion of exported model filenames

Topics

This keyword is related to the topics:

- [surrogate_models](#)

Specification

Alias: none

Argument(s): STRING

Default: `exported_surrogate`

Description

When a file-based export of a surrogate model is specified, Dakota writes one file per response, per requested format. The files are named using the pattern `{prefix}.{response_descriptor}.{extension}`.

The `response_descriptor` portion of the pattern is filled in using the response [descriptors](#) provided by the user (or, if none are specified, descriptors automatically generated by Dakota). Extension is a three or four letter string that depends on the format. The `filename_prefix` keyword is used to supply the prefix portion of the pattern.

Examples

This input snippet directs Dakota to write one algebraic format file and one binary archive file for each response. The names of the files will follow the patterns `my_surrogate.{response_descriptor}.alg` (for the algebraic files) and `my_surrogate.{response_descriptor}.bsps` (for the binary files).

```
surrogate global gaussian_process surfpack
  export_model
    filename_prefix = 'my_surrogate'
    formats
      algebraic_file
      binary_archive
```

moving_least_squares

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [moving_least_squares](#)

Moving Least Squares surrogate models

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		basis_order	Polynomial order for the MLS bases
	Optional		weight_function	Selects the weight function for the MLS model
	Optional		export_model	Exports surrogate model in user-selected format

Description

Moving least squares is a further generalization of weighted least squares where the weighting is "moved" or recalculated for every new point where a prediction is desired[65].

The implementation of moving least squares is still under development. It tends to work well in trust region optimization methods where the surrogate model is constructed in a constrained region over a few points. The present implementation may not work as well globally.

Known Issue: When using discrete variables, there have been sometimes significant differences in surrogate behavior observed across computing platforms in some cases. The cause has not yet been fully diagnosed and is currently under investigation. In addition, guidance on appropriate construction and use of surrogates with discrete variables is under development. In the meantime, users should therefore be aware that there is a risk of inaccurate results when using surrogates with discrete variables.

Theory

Moving Least Squares can be considered a more specialized version of linear regression models. In linear regression, one usually attempts to minimize the sum of the squared residuals, where the residual is defined as the difference between the surrogate model and the true model at a fixed number of points.

In weighted least squares, the residual terms are weighted so the determination of the optimal coefficients governing the polynomial regression function, denoted by $\hat{f}(\mathbf{x})$, are obtained by minimizing the weighted sum of squares at N data points:

$$\sum_{n=1}^N w_n (\| \hat{f}(\mathbf{x}_n) - f(\mathbf{x}_n) \|)$$

basis_order

function_train

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [function_train](#)

Global surrogate model based on functional tensor train decomposition

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			max_solver_ iterations	Placeholder keyword for limiting maximum number of iterations used by internal optimizer
	Optional		solver_tolerance	Convergence tolerance for the optimizer used during the regression solve.
	Optional		rounding_tolerance	An accuracy parameter that is used to guide rounding during rank adaptation.
	Optional		start_order	Placeholder keyword
	Optional		max_order	Polynomial order of each univariate function within the functional tensor train.
	Optional		start_rank	The initial rank used for the starting point during a rank adaptation.
	Optional		kick_rank	The increment in rank employed during each iteration of the rank adaptation.

	Optional	max_rank	Limits the maximum rank that is explored during a rank adaptation.
	Optional	adapt_rank	Activate adaptive procedure for determining best rank representation
	Optional	max_cross-iterations	Maximum number of iterations for cross-approximation during a rank adaptation.

Description

Tensor train decompositions are approximations that exploit low rank structure in an input-output mapping. In the current implementation, orthogonal polynomial basis functions are employed as the basis functions, although the C3 library will enable additional options in the future.

Usage Tips

This new capability is under active development. It is not included in the Dakota build by default, as some C3 library dependencies can induce small differences in our regression suite.

This capability is also being used as a prototype to explore model-based versus method-based specification of stochastic expansions. While the model specification is stand-alone, it currently requires a corresponding method specification to exercise the model, which can be either a `function.train_uq` method specification or more generic UQ strategy such as a `sampling` method. The intent is to migrate `function.train`, polynomial chaos, and stochastic collocation toward model-only specifications that can then be employed in any surrogate/emulator context.

Examples

```
model,
  id_model = 'FT'
  surrogate global function_train
  max_order = 5
  start_rank = 2  kick_rank = 2  max_rank = 10
  adapt_rank
  dace_method_pointer = 'SAMPLING'
```

- [function.train_uq](#)

max_solver_iterations

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [function_train](#)
- [max_solver_iterations](#)

Placeholder keyword for limiting maximum number of iterations used by internal optimizer

Specification

Alias: none

Argument(s): INTEGER

Default: 100

Description

This general control is not currently implemented in `function_train`.

solver_tolerance

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [function_train](#)
- [solver_tolerance](#)

Convergence tolerance for the optimizer used during the regression solve.

Specification

Alias: none

Argument(s): REAL

Default: 1.0e-10

Description

Defines the function value and function gradient tolerance for optimizer used solving the regression problem for the functional tensor train coefficients.

rounding_tolerance

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [function_train](#)
- [rounding_tolerance](#)

An accuracy parameter that is used to guide rounding during rank adaptation.

Specification

Alias: none

Argument(s): REAL

Default: 1.0e-10

Description

The rounding tolerance is used to measure how closely one can approximate a functional tensor train representation at a step of the optimization procedure using one of lower ranks. If this tolerance is small, then less compression is achieved but greater accuracy is obtained. If this tolerance is big, greater compression is achieved at the expense of accuracy.

- [adapt_rank](#)

start_order

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [function_train](#)
- [start_order](#)

Placeholder keyword

Specification

Alias: none

Argument(s): INTEGER

Default: 2

Description

In future adaptation options, this will specify the initial polynomial order of each univariate function that makes up the functional tensor train decomposition. Adaptation of polynomial order starts from this value and is limited by `max_order`. Within current regression procedures it is not used, but will become active in future cross-approximation adaptation options.

See Also

These keywords may also be of interest:

- [max_order](#)

max_order

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [function_train](#)
- [max_order](#)

Polynomial order of each univariate function within the functional tensor train.

Specification

Alias: none

Argument(s): INTEGER

Default: 4

Description

This specification relates to the polynomial order of each univariate function that makes up the functional tensor train decomposition.

In future adaptation options (i.e., cross-approximation adaptation), this will specify the maximum order that can be obtained during adaptation, where polynomial order will start from `start_order` and be limited by `max_order`.

Within current regression procedures, however, order adaptation is not supported and `max_order` is instead used to provide the fixed order of the basis (either with or without rank adaptation).

Activate adaptive procedure for determining best rank representation

Specification

Alias: none

Argument(s): none

Default: false

Description

The adaptive algorithm proceeds as follows:

1. Start from rank `start_rank` and form an approximation
2. Adapt the current approximation by searching for a solution with lower rank that achieves L2 accuracy within epsilon accuracy of the reference.
3. If a lower rank solution is found with comparable accuracy, then stop. If not, increase the rank by an amount specified by `kick_rank`.
4. Return to step 2 and continue until either `max_rank` is reached or a converged rank (rank less than current reference with comparable accuracy) is found.

Examples

This example shows specification of a rank adaptation starting at rank 2, incrementing by 2, and limited at rank 10.

```
model,
  id_model = 'FT'
  surrogate global function_train
  max_order = 5
  adapt_rank start_rank = 2 kick_rank = 2 max_rank = 10
  solver_tolerance = 1e-12
  rounding_tolerance = 1e-12
  dace_method_pointer = 'SAMPLING'
```

Artificial neural network model

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		max_nodes	Maximum number of hidden layer nodes
	Optional		range	Range for neural network random weights

	Optional	random_weight	(Inactive) Random weight control
	Optional	export_model	Exports surrogate model in user-selected format

Description

Dakota's artificial neural network surrogate is a stochastic layered perceptron network, with a single hidden layer. Weights for the input layer are chosen randomly, while those in the hidden layer are estimated from data using a variant of the Zimmerman direct training approach[95].

This typically yields lower training cost than traditional neural networks, yet good out-of-sample performance. This is helpful in surrogate-based optimization and optimization under uncertainty, where multiple surrogates may be repeatedly constructed during the optimization process, e.g., a surrogate per response function, and a new surrogate for each optimization iteration.

The neural network is a non parametric surface fitting method. Thus, along with Kriging (Gaussian Process) and MARS, it can be used to model data trends that have slope discontinuities as well as multiple maxima and minima. However, unlike Kriging, the neural network surrogate is not guaranteed to interpolate the data from which it was constructed.

This surrogate can be constructed from fewer than $n_{c_{quad}}$ data points, however, it is a good rule of thumb to use at least $n_{c_{quad}}$ data points when possible.

Known Issue: When using discrete variables, there have been sometimes significant differences in surrogate behavior observed across computing platforms in some cases. The cause has not yet been fully diagnosed and is currently under investigation. In addition, guidance on appropriate construction and use of surrogates with discrete variables is under development. In the meantime, users should therefore be aware that there is a risk of inaccurate results when using surrogates with discrete variables.

Theory

The form of the neural network model is

$$\hat{f}(\mathbf{x}) \approx \tanh \{ \mathbf{A}_1 \tanh (\mathbf{A}_0^T \mathbf{x} + \theta_0^T) + \theta_1 \}$$

where \mathbf{x} is the evaluation point in n -dimensional parameter space; the terms \mathbf{A}_0, θ_0 are the random input layer weight matrix and bias vector, respectively; and \mathbf{A}_1, θ_1 are a weight vector and bias scalar, respectively, estimated from training data. These coefficients are analogous to the polynomial coefficients obtained from regression to training data. The neural network uses a cross validation-based orthogonal matching pursuit solver to determine the optimal number of nodes and to solve for the weights and offsets.

max_nodes

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)

- [neural_network](#)
- [max_nodes](#)

Maximum number of hidden layer nodes

Topics

This keyword is related to the topics:

- [surrogate_models](#)

Specification

Alias: nodes

Argument(s): INTEGER

Default: numTrainingData - 1

Description

Limits the maximum number of hidden layer nodes in the neural network model. The default is to use one less node than the number of available training data points yielding a fully-determined linear least squares problem. However, reducing the number of nodes can help reduce overfitting and more importantly, can drastically reduce surrogate construction time when building from a large data set. (Historically, Dakota limited the number of nodes to 100.)

The keyword `max_nodes` provides an upper bound. Dakota's orthogonal matching pursuit algorithm may further reduce the effective number of nodes in the final model to achieve better generalization to unseen points.

range

Exports surrogate model in user-selected format

Topics

This keyword is related to the topics:

- [surrogate_models](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			<code>filename_prefix</code>	User-customizable portion of exported model filenames
	Required		<code>formats</code>	Formats for surrogate model export

Description

Export the surrogate for later evaluation using the `surfpack` executable (`bin/surfpack`) or a user-developed tool. Export format is controlled using the `formats` specification. Four formats are available in Dakota; however, not all have been enabled for all surrogates.

The four formats are:

- `text_archive` - Plain-text, machine-readable archive for use with the `surfpack` executable
- `binary_archive` - Binary, machine-readable archive for use with the `surfpack` executable
- `algebraic_file` - Plain-text, human-readable file intended for use with user-created tools; not compatible with the `surfpack` executable
- `algebraic_console` - Print the model in algebraic format to the screen; not compatible with the `surfpack` executable

Most global surrogates can be exported in all four formats. These include:

- Gaussian process (keyword `gaussian_process` `surfpack`)
- Artificial neural network (keyword `neural_network`)
- Radial basis Functions (keyword `radial_basis`)
- Polynomial (keyword `polynomial`)

However, for Multivariate Adaptive Regression Spline (keyword `mars`) and moving least squares (keyword `moving_least_squares`) models, only `text_archive` and `binary_archive` formats may be used.

Currently, no other surrogate models can be exported. In addition, Dakota cannot import models that have been exported. They are strictly for use with external tools.

Default Behavior

No export.

Expected Output

Output depends on selected format; see the `formats` specification.

Additional Discussion

The Dakota examples folder includes a demonstration of using the `surfpack` executable with an exported model file.

filename_prefix

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [neural_network](#)
- [export_model](#)
- [filename_prefix](#)

User-customizable portion of exported model filenames

Topics

This keyword is related to the topics:

- [surrogate_models](#)

Specification

Alias: none

Argument(s): STRING

Default: exported_surrogate

Description

When a file-based export of a surrogate model is specified, Dakota writes one file per response, per requested format. The files are named using the pattern `{prefix}.{response_descriptor}.{extension}`.

The `response_descriptor` portion of the pattern is filled in using the response [descriptors](#) provided by the user (or, if none are specified, descriptors automatically generated by Dakota). Extension is a three or four letter string that depends on the format. The `filename_prefix` keyword is used to supply the prefix portion of the pattern.

Examples

This input snippet directs Dakota to write one algebraic format file and one binary archive file for each response. The names of the files will follow the patterns `my_surrogate.{response_descriptor}.alg` (for the algebraic files) and `my_surrogate.{response_descriptor}.bsps` (for the binary files).

```
surrogate global gaussian_process surfpack
  export_model
    filename_prefix = 'my_surrogate'
    formats
      algebraic_file
      binary_archive
```

			bases	Initial number of radial basis functions
	Optional		max_pts	Maximum number of RBF CVT points
	Optional		min_partition	(Inactive) Minimum RBF partition
	Optional		max_subsets	Number of trial RBF subsets
	Optional		export_model	Exports surrogate model in user-selected format

Description

Radial basis functions ϕ are functions whose value typically depends on the distance from a center point, called the centroid, \mathbf{c} .

The surrogate model approximation comprises a sum of K weighted radial basis functions:

$$\hat{f}(\mathbf{x}) = \sum_{k=1}^K w_k \phi(\|\mathbf{x} - \mathbf{c}_k\|)$$

These basis functions take many forms, but Gaussian kernels or splines are most common. The Dakota implementation uses a Gaussian radial basis function. The weights are determined via a linear least squares solution approach. See[69] for more details.

Known Issue: When using discrete variables, there have been sometimes significant differences in surrogate behavior observed across computing platforms in some cases. The cause has not yet been fully diagnosed and is currently under investigation. In addition, guidance on appropriate construction and use of surrogates with discrete variables is under development. In the meantime, users should therefore be aware that there is a risk of inaccurate results when using surrogates with discrete variables.

Polynomial surrogate model

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Polynomial Order (Group 1)	basis_order	Polynomial order
			linear	Use a linear polynomial or trend function
			quadratic	Use a quadratic polynomial or trend function
			cubic	Use a cubic polynomial
	Optional		export_model	Exports surrogate model in user-selected format

Description

Linear, quadratic, and cubic polynomial surrogate models are available in Dakota. The utility of the simple polynomial models stems from two sources:

- over a small portion of the parameter space, a low-order polynomial model is often an accurate approximation to the true data trends
- the least-squares procedure provides a surface fit that smooths out noise in the data.

Local surrogate-based optimization methods ([surrogate_based_local](#)) are often successful when using polynomial models, particularly quadratic models. However, a polynomial surface fit may not be the best choice for modeling data trends globally over the entire parameter space, unless it is known a priori that the true data trends are close to linear, quadratic, or cubic. See[64] for more information on polynomial models.

Known Issue: When using discrete variables, there have been sometimes significant differences in surrogate behavior observed across computing platforms in some cases. The cause has not yet been fully diagnosed and is currently under investigation. In addition, guidance on appropriate construction and use of surrogates with discrete variables is under development. In the meantime, users should therefore be aware that there is a risk of inaccurate results when using surrogates with discrete variables.

Theory

The form of the linear polynomial model is

$$\hat{f}(\mathbf{x}) \approx c_0 + \sum_{i=1}^n c_i x_i$$

the form of the quadratic polynomial model is:

$$\hat{f}(\mathbf{x}) \approx c_0 + \sum_{i=1}^n c_i x_i + \sum_{i=1}^n \sum_{j \geq i}^n c_{ij} x_i x_j$$

and the form of the cubic polynomial model is:

$$\hat{f}(\mathbf{x}) \approx c_0 + \sum_{i=1}^n c_i x_i + \sum_{i=1}^n \sum_{j \geq i}^n c_{ij} x_i x_j + \sum_{i=1}^n \sum_{j \geq i}^n \sum_{k \geq j}^n c_{ijk} x_i x_j x_k$$

In all of the polynomial models, $\hat{f}(\mathbf{x})$ is the response of the polynomial model; the x_i, x_j, x_k terms are the components of the n -dimensional design parameter values; the $c_0, c_i, c_{ij}, c_{ijk}$ terms are the polynomial coefficients, and n is the number of design parameters. The number of coefficients, n_c , depends on the order of polynomial model and the number of design parameters. For the linear polynomial:

$$n_{c_{linear}} = n + 1$$

for the quadratic polynomial:

$$n_{c_{quad}} = \frac{(n+1)(n+2)}{2}$$

and for the cubic polynomial:

$$n_{c_{cubic}} = \frac{(n^3 + 6n^2 + 11n + 6)}{6}$$

There must be at least n_c data samples in order to form a fully determined linear system and solve for the polynomial coefficients. In Dakota, a least-squares approach involving a singular value decomposition numerical method is applied to solve the linear system.

- [polynomial](#)
- [export_model](#)

Exports surrogate model in user-selected format

Topics

This keyword is related to the topics:

- [surrogate_models](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			<code>filename_prefix</code>	User-customizable portion of exported model filenames
	Required		<code>formats</code>	Formats for surrogate model export

Description

Export the surrogate for later evaluation using the `surfpack` executable (`bin/surfpack`) or a user-developed tool. Export format is controlled using the `formats` specification. Four formats are available in Dakota; however, not all have been enabled for all surrogates.

The four formats are:

- `text_archive` - Plain-text, machine-readable archive for use with the `surfpack` executable
- `binary_archive` - Binary, machine-readable archive for use with the `surfpack` executable
- `algebraic_file` - Plain-text, human-readable file intended for use with user-created tools; not compatible with the `surfpack` executable
- `algebraic_console` - Print the model in algebraic format to the screen; not compatible with the `surfpack` executable

Most global surrogates can be exported in all four formats. These include:

- Gaussian process (keyword `gaussian_process surfpack`)
- Artificial neural network (keyword `neural_network`)
- Radial basis Functions (keyword `radial_basis`)
- Polynomial (keyword `polynomial`)

However, for Multivariate Adaptive Regression Spline (keyword `mars`) and moving least squares (keyword `moving_least_squares`) models, only `text_archive` and `binary_archive` formats may be used.

Currently, no other surrogate models can be exported. In addition, Dakota cannot import models that have been exported. They are strictly for use with external tools.

Default Behavior

No export.

Expected Output

Output depends on selected format; see the `formats` specification.

Additional Discussion

The Dakota examples folder includes a demonstration of using the `surfpack` executable with an exported model file.

filename_prefix

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [polynomial](#)
- [export_model](#)
- [filename_prefix](#)

User-customizable portion of exported model filenames

Topics

This keyword is related to the topics:

- [surrogate_models](#)

Specification

Alias: none

Argument(s): STRING

Default: exported_surrogate

Description

When a file-based export of a surrogate model is specified, Dakota writes one file per response, per requested format. The files are named using the pattern `{prefix}.{response_descriptor}.{extension}`.

The `response_descriptor` portion of the pattern is filled in using the response [descriptors](#) provided by the user (or, if none are specified, descriptors automatically generated by Dakota). Extension is a three or four letter string that depends on the format. The `filename_prefix` keyword is used to supply the prefix portion of the pattern.

Examples

This input snippet directs Dakota to write one algebraic format file and one binary archive file for each response. The names of the files will follow the patterns `my_surrogate.{response_descriptor}.alg` (for the algebraic files) and `my_surrogate.{response_descriptor}.bsps` (for the binary files).

```
surrogate global gaussian_process surfpack
export_model
  filename_prefix = 'my_surrogate'
  formats
    algebraic_file
    binary_archive
```

- [model](#)
- [surrogate](#)
- [global](#)
- [polynomial](#)
- [export_model](#)
- [formats](#)
- [algebraic_file](#)

Export surrogate model in algebraic format to a file

Topics

This keyword is related to the topics:

- [surrogate_models](#)

Specification

Alias: none

Argument(s): none

Description

After the surrogate model has been built, Dakota will export it to a file in a human-readable "algebraic" format. The file is named using the pattern `{prefix}.{response_descriptor}.alg`. See `filename_prefix` for further information about exported surrogate file naming. The file contains sufficient information for the user to (re)construct and evaluate the model outside of Dakota.

Expected Output

The format depends on the type of surrogate model, but in general will include a LaTeX-like representation of the analytic form of the model to aid tool development, all needed model hyperparameters, and headers describing the shape or dimension of the provided data.

The output written to the file matches exactly the output written to the console when `algebraic_console` is specified.

`algebraic_console`

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [polynomial](#)
- [export_model](#)
- [formats](#)
- [algebraic_console](#)

Export surrogate model in algebraic format to the console

Topics

This keyword is related to the topics:

- [surrogate_models](#)

Specification

Alias: none

Argument(s): none

Description

After the surrogate model has been built, Dakota will export it to the console (screen, or output file if Dakota was run using the `-o` option) in a human-readable "algebraic" format. The output contains sufficient information for the user to (re)construct and evaluate the model outside of Dakota.

Expected Output

The format depends on the type of surrogate model, but in general will include a LaTeX-like representation of the analytic form of the model to aid tool development, all needed model hyperparameters, and headers describing the shape or dimension of the provided data.

The output written to the screen for the exported model matches exactly the output written to file when `algebraic_file` is specified. Use of `algebraic_file` is preferred over `algebraic_console`, which exists largely to provide a measure of backward compatibility.

domain_decomposition

- [Keywords Area](#)
- [model](#)
- [surrogate](#)

- [domain_decomposition](#)

Piecewise Domain Decomposition for Global Surrogate Models

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		cell_type	Type of the Geometric Cells Used for the Piecewise Decomposition Option of Global Surrogates
	Optional		support_layers	Optional Number of Support Layers for the Piecewise Decomposition Option of Global Surrogates
	Optional		discontinuity_- detection	Optional Discontinuity Detection Capability for the Piecewise Decomposition Option of Global Surrogates

Description

Typical regression techniques use all available sample points to build continuous approximations the underlying function.

An alternative option is to use piecewise decomposition to locally approximate the function at some point using a few sample points from its neighborhood only. This option currently supports Polynomial Regression,

Gaussian Process (GP) Interpolation, and Radial Basis Functions (RBF) Regression. It requires a decomposition cell type (currently set to be Voronoi cells). Optional parameters are: the number of layers of neighbors used to solve the regression problem (default is one layer), and an optional discontinuity detection capability (identified by a user-input jump or gradient threshold).

The method can also make use of the gradient and Hessian information, if available. The user needs to specify the keyword `user_derivatives`.

cell_type

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [domain_decomposition](#)
- [cell_type](#)

Type of the Geometric Cells Used for the Piecewise Decomposition Option of Global Surrogates

Specification

Alias: none

Argument(s): STRING

Description

The piecewise decomposition option for global surrogates is used to locally approximate a function at some point using a few sample points from its neighborhood.

This option requires a decomposition cell type that can vary from structured grid boxes, to polygonal Voronoi cells. Currently, this option only supports Voronoi cells.

support_layers

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [domain_decomposition](#)
- [support_layers](#)

Optional Number of Support Layers for the Piecewise Decomposition Option of Global Surrogates

Specification

Alias: none

Argument(s): INTEGER

Description

The piecewise decomposition option for global surrogates is used to locally approximate a function at some point using a few sample points from its neighborhood.

The neighborhood of a cell is parameterized via a number of (support layers). The default value is set to one layer of neighbors (cells that share direct edges with the cell under study). One more support layer would include the neighbors of that cells neighbors, and so on.

discontinuity_detection

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [domain_decomposition](#)
- [discontinuity_detection](#)

Optional Discontinuity Detection Capability for the Piecewise Decomposition Option of Global Surrogates

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/- Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Threshold Mode (Group 1)	jump_threshold	Gradient Threshold Parameter of the Optional Discontinuity Detection Capability for the Piecewise Decomposition Option of Global Surrogates

			gradient_threshold	Gradient Threshold Parameter of the Optional Discontinuity Detection Capability for the Piecewise Decomposition Option of Global Surrogates
--	--	--	------------------------------------	--

Description

The piecewise decomposition option for global surrogates is used to locally approximate a function at some point using a few sample points from its neighborhood.

The domain decomposition algorithm supports an optional discontinuity detection capability where seeds across a user-input discontinuity threshold are not considered neighbors when building the approximate connectivity Delaunay graph. Alternatively, the domain is split into patches that trap discontinuities between them. This capability is specified by either jump or gradient threshold values in the input spec.

jump_threshold

- [Keywords Area](#)

Argument(s): INTEGER

Default: recommended_points

Description

See parent page.

minimum_points

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [minimum_points](#)

Construct surrogate with minimum number of points

Specification

Alias: none

Argument(s): none

Description

The minimum is $d+1$, for d input dimensions, except for polynomials. See parent page.

recommended_points

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [recommended_points](#)

Construct surrogate with recommended number of points

Specification

Alias: none

Argument(s): none

Description

This is the default option. It requires $5*d$ build points for d input dimensions, except for polynomial models. See parent page.

dace_method_pointer

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [dace_method_pointer](#)

Specify a method to gather training data

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: no design of experiments data

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			auto_refinement	Experimental auto-refinement of surrogate model

Description

The number of training points and the sources are specified on [global](#), as well as the number of new training points required.

New training points are gathered by running the "truth" model using the method specified by `dace_method_pointer`. The DACE method will only be invoked if it has new samples to perform, and if new samples are required and no DACE iterator has been provided, an error will result.

The `dace_method_pointer` points to design of experiments method block used to generate truth model data.

Permissible methods include: Monte Carlo (random) sampling, Latin hypercube sampling, orthogonal array sampling, central composite design sampling, and Box-Behnken sampling.

Note that the number of samples specified in the method block may be overwritten, if the requested number of samples is less than [minimum_points](#).

auto_refinement

- [Keywords Area](#)
- [model](#)

- [surrogate](#)
- [global](#)
- [dace_method_pointer](#)
- [auto_refinement](#)

Experimental auto-refinement of surrogate model

Topics

This keyword is related to the topics:

- [surrogate_models](#)

Specification

Alias: none

Argument(s): none

Default: no refinement

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			max_iterations	Number of iterations allowed for optimizers and adaptive UQ methods
	Optional		max_function_ evaluations	Number of function evaluations allowed for optimizers
	Optional		convergence_ tolerance	Cross-validation threshold for surrogate convergence
	Optional		soft_convergence_ limit	Maximum number of iterations without improvement in cross-validation

	Optional	cross_validation_metric	Choice of error metric to satisfy
--	-----------------	---	-----------------------------------

Description

(Experimental option) Automatically refine the surrogate model until desired cross-validation quality is achieved. Refinement is accomplished by iteratively adding more data to the training set until the cross-validation convergence_tolerance is achieved, or max_function_evaluations or max_iterations is exceeded.

The amount of new training data that is incorporated each iteration is specified in the DACE method that is referred to by the model's dace_method_pointer. See [refinement_samples](#) for more information.

max_iterations

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [dace_method_pointer](#)
- [auto_refinement](#)
- [max_iterations](#)

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 100

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed max_iterations iterations. See also max_function_evaluations.

Default Behavior

Default value is 100.

max_function_evaluations

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [dace_method_pointer](#)
- [auto_refinement](#)
- [max_function_evaluations](#)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- [method_independent_controls](#)

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

Default Behavior

Default value is 1000.

convergence_tolerance

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [dace_method_pointer](#)
- [auto_refinement](#)
- [convergence_tolerance](#)

Cross-validation threshold for surrogate convergence

Specification

Alias: none

Argument(s): REAL

Default: 1.0e-4

Description

The surrogate model will be refined until the selected `cross_validation_metric` falls below this convergence tolerance.

Default Behavior The default is 1e-4.

`soft_convergence_limit`

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [dace_method_pointer](#)
- [auto_refinement](#)
- [soft_convergence_limit](#)

Maximum number of iterations without improvement in cross-validation

Specification

Alias: none

Argument(s): INTEGER

Default: 0

Description

The purpose of this control is to cease auto-refinement when improvement in the cross-validation score appears to have stalled or occurs too slowly.

A rolling average of improvement in the cross-validation score is computed over `soft_convergence_limit` iterations. Auto-refinement is halted if the average becomes smaller than the `convergence_tolerance`. The average is computed but ignored until the number of iterations has exceeded `soft_convergence_limit`.

The default setting of 0 disables soft convergence.

`cross_validation_metric`

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)

- [dace_method_pointer](#)
- [auto_refinement](#)
- [cross_validation_metric](#)

Choice of error metric to satisfy

Specification

Alias: none

Argument(s): STRING

Default: root-mean-squared error

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			folds	Number of cross validation folds

Description

The cross-validation score that the auto-refinement routine seeks to satisfy is based on an error metric. Any of the surrogate diagnostic [metrics](#) may be used. These include:

- [root_mean_squared](#)
- [mean_abs](#)
- [rsquared](#)
- [sum_squared](#)
- [mean_squared](#)
- [sum_abs](#)
- [max_abs](#)

Default Behavior The default metric is the the root mean squared error ('root_mean_squared').

folds

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [dace_method_pointer](#)
- [auto_refinement](#)
- [cross_validation_metric](#)
- [folds](#)

Number of cross validation folds

Specification

Alias: none

Argument(s): INTEGER

Default: 10

Description

Number of folds (partitions) of the training data to use in cross validation (default 10).

actual_model_pointer

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [actual_model_pointer](#)

A surrogate model pointer that guides a method to whether it should use a surrogate model or compute truth function evaluations

Specification

Alias: none

Argument(s): STRING

Description

Dakota methods use global surrogate models to compute surrogate function approximations. They also need to know the true function evaluations. A global surrogate model now must have an `actual_model_pointer` keyword to decide for the method whether to evaluate the global surrogate model, or compute the true function evaluations if `actual_model_pointer = TRUTH`.

reuse_points

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [reuse_points](#)

Surrogate model training data reuse control

Topics

This keyword is related to the topics:

- [surrogate_models](#)

Specification

Alias: reuse_samples

Argument(s): none

Default: all for import; none otherwise

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Reuse Domain (Group 1)	all	Option for reuse_points
			region	Option for reuse_points
			none	Option for reuse_points

Description

Dakota's global surrogate methods rely on training data, which can either come from evaluation of a "truth" model, which is generated by the method specified with [dace_method_pointer](#), from a file of existing training data, identified by [import_build_points_file](#), or both.

The `reuse_points` keyword controls the amount of training data used in building a surrogate model, either initially, or during iterative rebuild, as in surrogate-based optimization. If [import_build_points_file](#) is specified, `reuse_points` controls how the file contents are used. If used during iterative rebuild, it controls what data from previous surrogate builds is reused in building the current model.

- all (default for file import) - use all points in the file or available from previous builds
- region - use only the points falling in the current trust region (see [surrogate_based_local](#))
- none (default when no import) - ignore the contents of the file or previous build points, and gather new training data using the specified DACE method

all

Description

This is described on the parent page.

import_build_points_file

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [import_build_points_file](#)

File containing points you wish to use to build a surrogate

Specification

Alias: import_points_file samples_file

Argument(s): STRING

Default: no point import from a file

Child Keywords:

	Required/ Optional Optional(<i>Choose One</i>)	Description of Group Tabular Format (Group 1)	Dakota Keyword custom_annotated	Dakota Keyword Description Selects custom-annotated tabular file format
			annotated	Selects annotated tabular file format
			freeform	Selects freeform file format
	Optional		active_only	Import only active variables from tabular data file

Description

The `import_build_points_file` allows the user to specify a file that contains a list of points and truth model responses used to construct a surrogate model. These can be used by all methods that (explicitly, e.g. surrogate-based optimization, or implicitly, e.g. efficient global optimization) operate on a surrogate. In particular, these points and responses are used in place of truth model evaluations to construct the initial surrogate. When used to construct surrogate models or emulators these are often called build points or training data.

Default Behavior

By default, methods do not import points from a file.

Usage Tips

Dakota parses input files without regard to whitespace, but the `import_build_points_file` must be in one of three formats:

- `annotated` (default)
- `custom_annotated`
- `freeform`

Examples

```
method
  polynomial_chaos
    expansion_order = 4
    import_build_points_file = 'dakota_uq_rosenbrock_pce_import.annot.pts.dat'
```

custom_annotated

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [import_build_points_file](#)
- [custom_annotated](#)

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			header	Enable header row in custom-annotated tabular file
	Optional		eval_id	Enable evaluation ID column in custom-annotated tabular file

	Optional	interface_id	Enable interface ID column in custom-annotated tabular file
--	-----------------	------------------------------	---

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, `eval_id` column, and `interface_id` column appear in the tabular file, thus bridging `freeform` and (fully) annotated.

Default Behavior

The `annotated` format is the default for tabular export/import. To control which header row and columns are in the input/output, specify `custom_annotated`, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and `eval_id` (no `interface_id`), and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id      x1          x2          obj_fn  nln_ineq_con_1  nln_ineq_con_2
1             0.9          1.1          0.0002          0.26          0.76
2             0.90009      1.1 0.0001996404857  0.2601620081  0.759955
3             0.89991      1.1 0.0002003604863  0.2598380081  0.760045
...
```

header

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [import_build_points_file](#)
- [custom_annotated](#)
- [header](#)

Enable header row in custom-annotated tabular file

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		use_variable_labels	Validate/use variable labels from tabular file header

Description

See description of parent `custom_annotated`

use_variable_labels

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [import_build_points_file](#)
- [custom_annotated](#)
- [header](#)
- [use_variable_labels](#)

Validate/use variable labels from tabular file header

Specification

Alias: none

Argument(s): none

Description

When importing global surrogate training data (or challenge evaluation points) from a tabular data file containing a header (annotated or `custom_annotated` header), this keyword toggles validation of variable labels present in the header row.

The labels are validated against the descriptors of the variables being imported to. If the tabular file labels can be rearranged to match the expected labels, the columns in the data file will be reordered on read to match the Dakota variable order. If the read labels are not a permutation of, nor equal to, the expected labels, an error will result.

Default Behavior

When not specified, variable labels will be read, but not strictly enforced or reordered. A warning will be issued if the variable labels are not as expected, and guidance offered if they can be permuted to match expectations.

Expected Output

Console output will be generated for any warnings, as well as to indicate whether any variable reordering is taking place.

Usage Tips

The use of this keyword is recommended when importing header-annotated tabular data files where the variables are appropriately labeled. Tabular files do not always contain response labels, so no attempt is made to disambiguate variable from response labels. The variable labels must appear contiguously in the header after any leading column IDs such as 'eval_id' or 'interface'.

Examples

This example enforces variable labels for both build and challenge points

```
model
  id_model = 'SURR'
  surrogate global
    polynomial quadratic
    import_build_points_file = 'dakota_surrogate_import.unc_fixedothers.dat'
      annotated use_variable_labels
    challenge_points_file = 'dakota_surrogate_import.dat'
      annotated use_variable_labels
```

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword use_variable_labels	Dakota Keyword Description Validate/use variable labels from tabular file header

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The `annotated` keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include `interface_id`, specify `custom_annotated` header `eval_id`
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export an annotated top-level tabular data file containing a header row, leading `eval_id` and `interface_id` columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated
```

Resulting tabular file:

```
%eval_id interface          x1          x2          obj_fn nln_ineq_con_1 nln_ineq_con_2
1          NO_ID            0.9         1.1         0.0002          0.26          0.76

- [freeform](#)

Selects freeform file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The `annotated` format is the default for tabular export/import. To change this behavior, specify `freeform` in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to `annotated` format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- In `freeform`, the `num_rows` x `num_cols` total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

```
    0.9          1.1          0.0002          0.26          0.76

- [global](#)
- [import_build_points_file](#)
- [active_only](#)

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

export_approx_points_file

- [Keywords Area](#)

- `export_approx_points_file`
- `custom_annotated`

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		<code>header</code>	Enable header row in custom-annotated tabular file
	Optional		<code>eval_id</code>	Enable evaluation ID column in custom-annotated tabular file
	Optional		<code>interface_id</code>	Enable interface ID column in custom-annotated tabular file

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether `header` row, `eval_id` column, and `interface_id` column appear in the tabular file, thus bridging `freeform` and (fully) annotated.

Default Behavior

The `annotated` format is the default for tabular export/import. To control which header row and columns are in the input/output, specify `custom_annotated`, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to `annotated` format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only `header` and `eval_id` (no `interface_id`), and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id      x1          x2          obj_fn  nln_ineq_con_1  nln_ineq_con_2
1              0.9          1.1          0.0002          0.26           0.76

Correction approaches for surrogate models

Specification

Alias: none

Argument(s): none

Default: no surrogate correction

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description

	Required (<i>Choose One</i>)	Correction Order (Group 1)	<code>zeroth_order</code>	Specify that truth values must be matched.
			<code>first_order</code>	Specify that truth values and gradients must be matched.
			<code>second_order</code>	Specify that truth values, gradients and Hessians must be matched.
	Required (<i>Choose One</i>)	Correction Type (Group 2)	<code>additive</code>	Additive correction factor for local surrogate accuracy
			<code>multiplicative</code>	Multiplicative correction factor for local surrogate accuracy.
			<code>combined</code>	Multipoint correction for a hierarchical surrogate

Description

Some of the surrogate model types support the use of correction factors that improve the local accuracy of the surrogate models.

The `correction` specification specifies that the approximation will be corrected to match truth data, either matching truth values in the case of `zeroth_order` matching, matching truth values and gradients in the case of `first_order` matching, or matching truth values, gradients, and Hessians in the case of `second_order` matching. For `additive` and `multiplicative` corrections, the correction is local in that the truth data is matched at a single point, typically the center of the approximation region. The `additive` correction adds a scalar offset (`zeroth_order`), a linear function (`first_order`), or a quadratic function (`second_order`) to the approximation to match the truth data at the point, and the `multiplicative` correction multiplies the approximation by a scalar (`zeroth_order`), a linear function (`first_order`), or a quadratic function (`second_order`) to match the truth data at the point. The `additive first_order` case is due to[58] and the `multiplicative first_order` case is commonly known as `beta correction`[40]. For the `combined` correction, the use of both `additive` and `multiplicative` corrections allows the satisfaction of an additional matching condition, typically the truth function values at the previous correction point (e.g., the center of the previous trust region). The `combined` correction is then a multipoint correction, as opposed to the local `additive` and `multiplicative` corrections. Each of these correction capabilities is described in detail in[24].

The correction factors force the surrogate models to match the true function values and possibly true function derivatives at the center point of each trust region. Currently, Dakota supports either `zeroth`-, `first`-, or `second`-order accurate correction methods, each of which can be applied using either an `additive`, `multiplicative`, or `combined`

correction function. For each of these correction approaches, the correction is applied to the surrogate model and the corrected model is then interfaced with whatever algorithm is being employed. The default behavior is that no correction factor is applied.

The simplest correction approaches are those that enforce consistency in function values between the surrogate and original models at a single point in parameter space through use of a simple scalar offset or scaling applied to the surrogate model. First-order corrections such as the first-order multiplicative correction (also known as beta correction[15]) and the first-order additive correction[58] also enforce consistency in the gradients and provide a much more substantial correction capability that is sufficient for ensuring provable convergence in SBO algorithms. SBO convergence rates can be further accelerated through the use of second-order corrections which also enforce consistency in the Hessians[24], where the second-order information may involve analytic, finite-difference, or quasi-Newton Hessians.

Correcting surrogate models with additive corrections involves

$$\hat{f}_{hi_\alpha}(\mathbf{x}) = f_{lo}(\mathbf{x}) + \alpha(\mathbf{x}) \quad (7.1)$$

where multifidelity notation has been adopted for clarity. For multiplicative approaches, corrections take the form

$$\hat{f}_{hi_\beta}(\mathbf{x}) = f_{lo}(\mathbf{x})\beta(\mathbf{x}) \quad (7.2)$$

where, for local corrections, $\alpha(\mathbf{x})$ and $\beta(\mathbf{x})$ are first or second-order Taylor series approximations to the exact correction functions:

$$\alpha(\mathbf{x}) = A(\mathbf{x}_c) + \nabla A(\mathbf{x}_c)^T(\mathbf{x} - \mathbf{x}_c) + \frac{1}{2}(\mathbf{x} - \mathbf{x}_c)^T \nabla^2 A(\mathbf{x}_c)(\mathbf{x} - \mathbf{x}_c) \quad (7.3)$$

$$\beta(\mathbf{x}) = B(\mathbf{x}_c) + \nabla B(\mathbf{x}_c)^T(\mathbf{x} - \mathbf{x}_c) + \frac{1}{2}(\mathbf{x} - \mathbf{x}_c)^T \nabla^2 B(\mathbf{x}_c)(\mathbf{x} - \mathbf{x}_c) \quad (7.4)$$

where the exact correction functions are

$$A(\mathbf{x}) = f_{hi}(\mathbf{x}) - f_{lo}(\mathbf{x}) \quad (7.5)$$

$$B(\mathbf{x}) = \frac{f_{hi}(\mathbf{x})}{f_{lo}(\mathbf{x})} \quad (7.6)$$

Refer to[24] for additional details on the derivations.

A combination of additive and multiplicative corrections can provide for additional flexibility in minimizing the impact of the correction away from the trust region center. In other words, both additive and multiplicative corrections can satisfy local consistency, but through the combination, global accuracy can be addressed as well. This involves a convex combination of the additive and multiplicative corrections:

$$\hat{f}_{hi_\gamma}(\mathbf{x}) = \gamma \hat{f}_{hi_\alpha}(\mathbf{x}) + (1 - \gamma) \hat{f}_{hi_\beta}(\mathbf{x})$$

where γ is calculated to satisfy an additional matching condition, such as matching values at the previous design iterate.

It should be noted that in both first order correction methods, the function $\hat{f}(x)$ matches the function value and gradients of $f_t(x)$ at $x = x_c$. This property is necessary in proving that the first order-corrected SBO algorithms are provably convergent to a local minimum of $f_t(x)$. However, the first order correction methods are significantly more expensive than the zeroth order correction methods, since the first order methods require computing both $\nabla f_t(x_c)$ and $\nabla f_s(x_c)$. When the SBO strategy is used with either of the zeroth order correction methods, or with no correction method, convergence is not guaranteed to a local minimum of $f_t(x)$. That is, the SBO strategy becomes a heuristic optimization algorithm. From a mathematical point of view this is undesirable, but as a practical matter, the heuristic variants of SBO are often effective in finding local minima.

Usage guidelines

- Both the `additive zeroth_order` and `multiplicative zeroth_order` correction methods are "free" since they use values of $f_t(x_c)$ that are normally computed by the SBO strategy.
- The use of either the `additive first_order` method or the `multiplicative first_order` method does not necessarily improve the rate of convergence of the SBO algorithm.
- When using the first order correction methods, the gradient-related response keywords must be modified to allow either analytic or numerical gradients to be computed. This provides the gradient data needed to compute the correction function.
- For many computationally expensive engineering optimization problems, gradients often are too expensive to obtain or are discontinuous (or may not exist at all). In such cases the heuristic SBO algorithm has been an effective approach at identifying optimal designs[35].

zeroth_order

- [Keywords Area](#)
- [model](#)

Use a multiplicative correction factor to improve the local accuracy of a surrogate.

combined

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [correction](#)
- [combined](#)

Multipoint correction for a hierarchical surrogate

Specification

Alias: none

Argument(s): none

Description

For the combined correction, the use of both additive and multiplicative corrections allows the satisfaction of an additional matching condition, typically the truth function values at the previous correction point (e.g., the center of the previous trust region). The combined correction is then a multipoint correction, as opposed to the local additive and multiplicative corrections.

metrics

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [metrics](#)

Compute surrogate quality metrics

Topics

This keyword is related to the topics:

- [surrogate_models](#)

Specification

Alias: diagnostics

Argument(s): STRINGLIST

Default: No diagnostics

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			cross_validation	Perform k-fold cross validation
	Optional		press	Leave-one-out cross validation

Description

Diagnostic metrics assess the goodness of fit of a global surrogate to its training data.

The default diagnostics are:

- `root_mean_squared`
- `mean_abs`
- `rsquared`

Additional available diagnostics include

- `sum_squared`
- `mean_squared`
- `sum_abs`
- `max_abs`

The keywords `press` and `cross_validation` further specify leave-one-out or k-fold cross validation, respectively, for all of the active metrics from above.

Usage Tips When specified, the `metrics` keyword must be followed by a list of quoted strings, each of which activates a metric.

Examples

This example input fragment constructs a quadratic polynomial surrogate and computes four metrics on the fit, both with and without 5-fold cross validation. (Also see `dakota/share/dakota/test/dakota_surrogate_import.in` for additional examples.)

```
model
  surrogate global
  polynomial quadratic
  metrics = "root_mean_squared" "sum_abs" "mean_abs" "max_abs"
  cross_validation folds = 5
```

Theory

Most of these diagnostics refer to some operation on the residuals (the difference between the surrogate model and the truth model at the data points upon which the surrogate is built).

For example, `sum_squared` refers to the sum of the squared residuals, and `mean_abs` refers to the mean of the absolute value of the residuals. `rsquared` refers to the R-squared value typically used in regression analysis (the proportion of the variability in the response that can be accounted for by the surrogate model). Care should be taken when interpreting metrics, for example, errors may be near zero for interpolatory models or `rsquared` may not be applicable for non-polynomial models.

cross_validation

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [metrics](#)
- [cross_validation](#)

Perform k-fold cross validation

Topics

This keyword is related to the topics:

- [surrogate_models](#)

Specification

Alias: none

Argument(s): none

Default: No cross validation

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional(<i>Choose One</i>)	Partition Control (Group 1)	folds	Number of cross validation folds
			percent	Percent data per cross validation fold

Description

General k-fold cross validation may be performed by specifying `cross_validation`. The cross-validation statistics will be calculated for all metrics.

Cross validation may further specify:

- `folds`, the number of folds into which to divide the build data (between 2 and number of data points) or
- `percent`, the fraction of data (between 0 and 0.5) to use in each fold.

These will be adjusted as needed based on the number of available training points. The default number of folds $k = 10$, or 0.1

`folds`

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [metrics](#)
- [cross_validation](#)
- [folds](#)

Number of cross validation folds

Specification

Alias: none

Argument(s): INTEGER

Default: 10

Description

Number of folds (partitions) of the training data to use in cross validation (default 10).

percent

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [metrics](#)
- [cross_validation](#)
- [percent](#)

Percent data per cross validation fold

Specification

Alias: none

Argument(s): REAL

Default: 0.1

Description

Percent of the training data to use in each cross validation fold (default 0.1).

press

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [metrics](#)
- [press](#)

Leave-one-out cross validation

Specification

Alias: none

Argument(s): none

Default: No PRESS cross validation

Description

Leave-one-out (PRESS) cross validation may be performed by specifying `press`. The cross-validation statistics will be calculated for all metrics.

import_challenge_points_file

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [import_challenge_points_file](#)

Datafile of points to assess surrogate quality

Specification

Alias: challenge_points_file

Argument(s): STRING

Default: no user challenge data

Child Keywords:

	Required/- Optional <i>Optional(Choose One)</i>	Description of Group Tabular Format (Group 1)	Dakota Keyword custom_annotated	Dakota Keyword Description Selects custom-annotated tabular file format
			annotated	Selects annotated tabular file format
			freeform	Selects freeform file format
	Optional		active_only	Import only active variables from tabular data file

Description

Specifies a data file containing variable and response (truth) values, in one of three formats:

- `annotated` (default)
- `custom_annotated`
- `freeform`

The surrogate is evaluated at the points in the file, and the surrogate (approximate) responses are compared against the truth results from the file. All metrics specified with [metrics](#) will be computed for the challenge data.

custom_annotated

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [import_challenge_points_file](#)
- [custom_annotated](#)

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			header	Enable header row in custom-annotated tabular file
	Optional		eval_id	Enable evaluation ID column in custom-annotated tabular file
	Optional		interface_id	Enable interface ID column in custom-annotated tabular file

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, `eval_id` column, and `interface_id` column appear in the tabular file, thus bridging `freeform` and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify `custom_annotated`, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and `eval_id` (no `interface_id`), and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id      x1          x2          obj_fn  nln_ineq_con_1  nln_ineq_con_2
1             0.9          1.1          0.0002         0.26           0.76
2             0.90009       1.1 0.0001996404857  0.2601620081   0.759955
3             0.89991       1.1 0.0002003604863  0.2598380081   0.760045
...
```

header

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [import_challenge_points_file](#)
- [custom_annotated](#)
- [header](#)

Enable header row in custom-annotated tabular file

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword use_variable_labels	Dakota Keyword Description Validate/use variable labels from tabular file header

Description

See description of parent `custom_annotated`

use_variable_labels

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [import_challenge_points_file](#)
- [custom_annotated](#)
- [header](#)
- [use_variable_labels](#)

Validate/use variable labels from tabular file header

Specification

Alias: none

Argument(s): none

Description

When importing global surrogate training data (or challenge evaluation points) from a tabular data file containing a header (annotated or `custom_annotated` header), this keyword toggles validation of variable labels present in the header row.

The labels are validated against the descriptors of the variables being imported to. If the tabular file labels can be rearranged to match the expected labels, the columns in the data file will be reordered on read to match the Dakota variable order. If the read labels are not a permutation of, nor equal to, the expected labels, an error will result.

Default Behavior

When not specified, variable labels will be read, but not strictly enforced or reordered. A warning will be issued if the variable labels are not as expected, and guidance offered if they can be permuted to match expectations.

Expected Output

Console output will be generated for any warnings, as well as to indicate whether any variable reordering is taking place.

Usage Tips

The use of this keyword is recommended when importing header-annotated tabular data files where the variables are appropriately labeled. Tabular files do not always contain response labels, so no attempt is made to disambiguate variable from response labels. The variable labels must appear contiguously in the header after any leading column IDs such as 'eval_id' or 'interface'.

Examples

This example enforces variable labels for both build and challenge points

```
model
  id_model = 'SURR'
  surrogate global
    polynomial quadratic
  import_build_points_file = 'dakota_surrogate_import_unc_fixedothers.dat'
    annotated use_variable_labels
  challenge_points_file = 'dakota_surrogate_import.dat'
    annotated use_variable_labels
```

- [annotated](#)

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			use_variable_labels	Validate/use variable labels from tabular file header

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The `annotated` keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include `interface_id`, specify `custom_annotated` header `eval_id`
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export an annotated top-level tabular data file containing a header row, leading `eval_id` and `interface_id` columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
  annotated
```

Resulting tabular file:

```
%eval_id interface          x1          x2          obj_fn nln_ineq_con_1 nln_ineq_con_2
1          NO_ID            0.9          1.1          0.0002          0.26          0.76
2          NO_ID            0.90009      1.1 0.0001996404857 0.2601620081 0.759955

...
```

use_variable_labels

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [import_challenge_points_file](#)
- [annotated](#)
- [use_variable_labels](#)

Validate/use variable labels from tabular file header

Specification

Alias: none

Argument(s): none

Description

When importing global surrogate training data (or challenge evaluation points) from a tabular data file containing a header (annotated or custom_annotated header), this keyword toggles validation of variable labels present in the header row.

The labels are validated against the descriptors of the variables being imported to. If the tabular file labels can be rearranged to match the expected labels, the columns in the data file will be reordered on read to match the Dakota variable order. If the read labels are not a permutation of, nor equal to, the expected labels, an error will result.

Default Behavior

When not specified, variable labels will be read, but not strictly enforced or reordered. A warning will be issued if the variable labels are not as expected, and guidance offered if they can be permuted to match expectations.

Expected Output

Console output will be generated for any warnings, as well as to indicate whether any variable reordering is taking place.

Usage Tips

The use of this keyword is recommended when importing header-annotated tabular data files where the variables are appropriately labeled. Tabular files do not always contain response labels, so no attempt is made to disambiguate variable from response labels. The variable labels must appear contiguously in the header after any leading column IDs such as 'eval.id' or 'interface'.

Examples

This example enforces variable labels for both build and challenge points

```
model
  id_model = 'SURR'
  surrogate global
    polynomial quadratic
    import_build_points_file = 'dakota_surrogate_import.unc_fixedothers.dat'
      annotated use_variable_labels
    challenge_points_file = 'dakota_surrogate_import.dat'
      annotated use_variable_labels
```

freeform

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [import_challenge_points_file](#)
- [freeform](#)

Selects freeform file format

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The `annotated` format is the default for tabular export/import. To change this behavior, specify `freeform` in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to `annotated` format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- In `freeform`, the `num_rows` x `num_cols` total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

```

      0.9          1.1          0.0002          0.26          0.76
0.90009          1.1 0.0001996404857 0.2601620081 0.759955
0.89991          1.1 0.0002003604863 0.2598380081 0.760045
...

```

active_only

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [global](#)
- [import_challenge_points_file](#)
- [active_only](#)

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

multipoint

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [multipoint](#)

Construct a surrogate from multiple existing training points

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Required (<i>Choose One</i>)	Description of Group Multipoint Surrogate (Group 1)	Dakota Keyword	Dakota Keyword Description
			tana	Local multi-point model via two-point nonlinear approximation
			qmea	Multi-point surrogate approximation based on QMEA algorithm
	Required		actual_model_pointer	Pointer to specify a "truth" model, from which to construct a surrogate

Description

Multipoint approximations use data from previous design points to improve the accuracy of local approximations. The data often comes from the current and previous iterates of a minimization algorithm.

Currently, only the Two-point Adaptive Nonlinearity Approximation (TANA-3) method of [94] is supported with the [tana](#) keyword.

The truth model to be used to generate the value/gradient data used in the approximation is identified through the required [actual_model_pointer](#) specification.

tana

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [multipoint](#)
- [tana](#)

Local multi-point model via two-point nonlinear approximation

Specification

Alias: none

Argument(s): none

Description

TANA stands for Two Point Adaptive Nonlinearity Approximation.

The TANA-3 method[94] is a multipoint approximation method based on the two point exponential approximation[25]. This approach involves a Taylor series approximation in intermediate variables where the powers used for the intermediate variables are selected to match information at the current and previous expansion points.

Known Issue: When using discrete variables, there have been sometimes significant differences in surrogate behavior observed across computing platforms in some cases. The cause has not yet been fully diagnosed and is currently under investigation. In addition, guidance on appropriate construction and use of surrogates with discrete variables is under development. In the meantime, users should therefore be aware that there is a risk of inaccurate results when using surrogates with discrete variables.

Theory

The form of the TANA model is:

$$\hat{f}(\mathbf{x}) \approx f(\mathbf{x}_2) + \sum_{i=1}^n \frac{\partial f}{\partial x_i}(\mathbf{x}_2) \frac{x_{i,2}^{1-p_i}}{p_i} (x_i^{p_i} - x_{i,2}^{p_i}) + \frac{1}{2} \epsilon(\mathbf{x}) \sum_{i=1}^n (x_i^{p_i} - x_{i,2}^{p_i})^2$$

where n is the number of variables and:

$$p_i = 1 + \ln \left[\frac{\frac{\partial f}{\partial x_i}(\mathbf{x}_1)}{\frac{\partial f}{\partial x_i}(\mathbf{x}_2)} \right] \bigg/ \ln \left[\frac{x_{i,1}}{x_{i,2}} \right] \quad \epsilon(\mathbf{x}) = \frac{H}{\sum_{i=1}^n (x_i^{p_i} - x_{i,1}^{p_i})^2 + \sum_{i=1}^n (x_i^{p_i} - x_{i,2}^{p_i})^2} H = 2 \left[f(\mathbf{x}_1) - f(\mathbf{x}_2) - \sum_{i=1}^n \frac{\partial f}{\partial x_i}(\mathbf{x}_2) \frac{x_{i,2}^{1-p_i}}{p_i} \right]$$

and \mathbf{x}_2 and \mathbf{x}_1 are the current and previous expansion points. Prior to the availability of two expansion points, a first-order Taylor series is used.

qmea

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [multipoint](#)
- [qmea](#)

Multi-point surrogate approximation based on QMEA algorithm

Specification

Alias: none

Argument(s): none

Description

The Quadratic Multipoint Exponential Approximation (QMEA) builds a multi-point approximation from values and gradients at multiple expansion points. It is a generalization of the two-point exponential approximation (TPEA).

This capability is **experimental**.

Pointer to specify a "truth" model, from which to construct a surrogate

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Description

This must point to a model block, identified by [id_model](#). That model will be run to generate training data, from which a surrogate model will be constructed.

See [block_pointer](#) for details about pointers.

local

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [local](#)

Build a locally accurate surrogate from data at a single point

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required		taylor_series	Construct a Taylor Series expansion around a point
	Required		actual_model_pointer	Pointer to specify a "truth" model, from which to construct a surrogate

Description

Local approximations use value, gradient, and possibly Hessian data from a single point to form a series expansion for approximating data in the vicinity of this point.

The currently available local approximation is the `taylor_series` selection.

The truth model to be used to generate the value/gradient/Hessian data used in the series expansion is identified through the required `actual_model_pointer` specification. The use of a model pointer (as opposed to an interface pointer) allows additional flexibility in defining the approximation. In particular, the derivative specification for the truth model may differ from the derivative specification for the approximation, and the truth model results being approximated may involve a model recursion (e.g., the values/gradients from a nested model).

See Also

These keywords may also be of interest:

- [global](#)
- [hierarchical](#)
- [multipoint](#)

`taylor_series`

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [local](#)
- [taylor_series](#)

Construct a Taylor Series expansion around a point

Specification

Alias: none

Argument(s): none

Description

The Taylor series model is purely a local approximation method. That is, it provides local trends in the vicinity of a single point in parameter space.

The order of the Taylor series may be either first-order or second-order, which is automatically determined from the gradient and Hessian specifications in the responses specification (see [responses](#) for info on how to specify gradients and Hessians) for the truth model

Known Issue: When using discrete variables, there have been sometimes significant differences in surrogate behavior observed across computing platforms in some cases. The cause has not yet been fully diagnosed and is currently under investigation. In addition, guidance on appropriate construction and use of surrogates with discrete variables is under development. In the meantime, users should therefore be aware that there is a risk of inaccurate results when using surrogates with discrete variables.

Theory

The first-order Taylor series expansion is:

$$\hat{f}(\mathbf{x}) \approx f(\mathbf{x}_0) + \nabla_{\mathbf{x}} f(\mathbf{x}_0)^T (\mathbf{x} - \mathbf{x}_0) \quad (7.7)$$

and the second-order expansion is:

$$\hat{f}(\mathbf{x}) \approx f(\mathbf{x}_0) + \nabla_{\mathbf{x}} f(\mathbf{x}_0)^T (\mathbf{x} - \mathbf{x}_0) + \frac{1}{2} (\mathbf{x} - \mathbf{x}_0)^T \nabla_{\mathbf{x}}^2 f(\mathbf{x}_0) (\mathbf{x} - \mathbf{x}_0) \quad (7.8)$$

where \mathbf{x}_0 is the expansion point in n -dimensional parameter space and $f(\mathbf{x}_0)$, $\nabla_{\mathbf{x}} f(\mathbf{x}_0)$, and $\nabla_{\mathbf{x}}^2 f(\mathbf{x}_0)$ are the computed response value, gradient, and Hessian at the expansion point, respectively.

As dictated by the responses specification used in building the local surrogate, the gradient may be analytic or numerical and the Hessian may be analytic, numerical, or based on quasi-Newton secant updates.

In general, the Taylor series model is accurate only in the region of parameter space that is close to \mathbf{x}_0 . While the accuracy is limited, the first-order Taylor series model reproduces the correct value and gradient at the point \mathbf{x}_0 , and the second-order Taylor series model reproduces the correct value, gradient, and Hessian. This consistency is useful in provably-convergent surrogate-based optimization. The other surface fitting methods do not use gradient information directly in their models, and these methods rely on an external correction procedure in order to satisfy the consistency requirements of provably-convergent SBO.

actual_model_pointer

Pointer to specify a "truth" model, from which to construct a surrogate

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Description

This must point to a model block, identified by `id_model`. That model will be run to generate training data, from which a surrogate model will be constructed.

See [block_pointer](#) for details about pointers.

hierarchical

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [hierarchical](#)

Hierarchical approximations use corrected results from a low fidelity model as an approximation to the results of a high fidelity "truth" model.

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Required	Description of Group	Dakota Keyword	Dakota Keyword Description
			ordered_model_- fidelities	Specification of an hierarchy of model fidelities, ordered from low to high.
	Optional		correction	Correction approaches for surrogate models

Description

Hierarchical approximations use corrected results from a low fidelity model as an approximation to the results of a high fidelity "truth" model. These approximations are also known as model hierarchy, multifidelity, variable fidelity, and variable complexity approximations. The required `ordered_model_fidelities` specification points to a sequence of model specifications of varying fidelity, ordered from lowest to highest fidelity. The highest fidelity model provides the truth model, and each of the lower fidelity alternatives provides different levels of approximation at different levels of cost.

In multifidelity optimization, the search algorithm relies primarily on the lower fidelity models, which are corrected for consistency with higher fidelity models. The higher fidelity models are used primarily for verifying

candidate steps based on solution of low fidelity approximate subproblems and updating for low fidelity corrections. In multifidelity uncertainty quantification, resolution levels are tailored across the ordered model hierarchy with fine resolution of the lowest fidelity and then decreasing resolution for each level of model discrepancy.

The `correction` specification specifies which correction technique will be applied to the low fidelity results in order to match the high fidelity results at one or more points. In the hierarchical case (as compared to the global case), the `correction` specification is required, since the omission of a correction technique would effectively eliminate the purpose of the high fidelity model. If it is desired to use a low fidelity model without corrections, then a hierarchical approximation is not needed and a `single` model should be used. Refer to [global](#) for additional information on available correction approaches.

Theory

Multifidelity Surrogates : Multifidelity modeling involves the use of a low-fidelity physics-based model as a surrogate for the original high-fidelity model. The low-fidelity model typically involves a coarser mesh, looser convergence tolerances, reduced element order, or omitted physics. It is a separate model in its own right and does not require data from the high-fidelity model for construction. Rather, the primary need for high-fidelity evaluations is for defining correction functions that are applied to the low-fidelity results.

Multifidelity Surrogate Models

A second type of surrogate is the `{model hierarchy}` type (also called multifidelity, variable fidelity, variable complexity, etc.). In this case, a model that is still physics-based but is of lower fidelity (e.g., coarser discretization, reduced element order, looser convergence tolerances, omitted physics) is used as the surrogate in place of the high-fidelity model. For example, an inviscid, incompressible Euler CFD model on a coarse discretization could be used as a low-fidelity surrogate for a high-fidelity Navier-Stokes model on a fine discretization.

ordered_model_fidelities

- [Keywords Area](#)
- [model](#)
- [surrogate](#)
- [hierarchical](#)
- [ordered_model_fidelities](#)

Specification of an hierarchy of model fidelities, ordered from low to high.

Specification

Alias: `model_fidelity_sequence`

Argument(s): STRINGLIST

Description

A hierarchical surrogate model manages an ordered set of model fidelities, each of which may in turn involve multiple discretization levels (in the case of a simulation model) or additional model recursions.

The ordering is assumed to be from lowest fidelity to highest fidelity, as dictated by an accuracy versus cost trade-off. Corresponding sequence specifications within methods (e.g., `quadrature_order_sequence`, `sparse_grid_level_sequence`, `expansion_order_sequence`, etc. within stochastic expansion methods) should be synchronized with this model order.

Additional Discussion

Internal to the model, only one low fidelity model instance and one high fidelity model instance are active at any given time, although various optimization and UQ algorithms can be used to traverse deep multilevel and multifidelity hierarchies by activating different model combinations and different response modes within the hierarchical model infrastructure.

Examples

```
model,
  id_model = 'HIERARCH'
  surrogate hierarchical
  ordered_model_fidelities = 'LF' 'MF' 'HF'
  correction additive zeroth_order
```

```
model,
  id_model = 'LF'

	Required(Choose One)	Correction Type (Group 2)	additive	Additive correction factor for local surrogate accuracy
			multiplicative	Multiplicative correction factor for local surrogate accuracy.

			<code>combined</code>	Multipoint correction for a hierarchical surrogate
--	--	--	-----------------------	--

Description

Some of the surrogate model types support the use of correction factors that improve the local accuracy of the surrogate models.

The `correction` specification specifies that the approximation will be corrected to match truth data, either matching truth values in the case of `zeroth_order` matching, matching truth values and gradients in the case of `first_order` matching, or matching truth values, gradients, and Hessians in the case of `second_order` matching. For additive and multiplicative corrections, the correction is local in that the truth data is matched at a single point, typically the center of the approximation region. The additive correction adds a scalar offset (`zeroth_order`), a linear function (`first_order`), or a quadratic function (`second_order`) to the approximation to match the truth data at the point, and the multiplicative correction multiplies the approximation by a scalar (`zeroth_order`), a linear function (`first_order`), or a quadratic function (`second_order`) to match the truth data at the point. The additive `first_order` case is due to [58] and the multiplicative `first_order` case is commonly known as beta correction [40]. For the `combined` correction, the use of both additive and multiplicative corrections allows the satisfaction of an additional matching condition, typically the truth function values at the previous correction point (e.g., the center of the previous trust region). The `combined` correction is then a multipoint correction, as opposed to the local additive and multiplicative corrections. Each of these correction capabilities is described in detail in [24].

The correction factors force the surrogate models to match the true function values and possibly true function derivatives at the center point of each trust region. Currently, Dakota supports either zeroth-, first-, or second-order accurate correction methods, each of which can be applied using either an additive, multiplicative, or combined correction function. For each of these correction approaches, the correction is applied to the surrogate model and the corrected model is then interfaced with whatever algorithm is being employed. The default behavior is that no correction factor is applied.

The simplest correction approaches are those that enforce consistency in function values between the surrogate and original models at a single point in parameter space through use of a simple scalar offset or scaling applied to the surrogate model. First-order corrections such as the first-order multiplicative correction (also known as beta correction [15]) and the first-order additive correction [58] also enforce consistency in the gradients and provide a much more substantial correction capability that is sufficient for ensuring provable convergence in SBO algorithms. SBO convergence rates can be further accelerated through the use of second-order corrections which also enforce consistency in the Hessians [24], where the second-order information may involve analytic, finite-difference, or quasi-Newton Hessians.

Correcting surrogate models with additive corrections involves

$$\hat{f}_{hi_\alpha}(\mathbf{x}) = f_{lo}(\mathbf{x}) + \alpha(\mathbf{x}) \quad (7.9)$$

where multifidelity notation has been adopted for clarity. For multiplicative approaches, corrections take the form

$$\hat{f}_{hi_\beta}(\mathbf{x}) = f_{lo}(\mathbf{x})\beta(\mathbf{x}) \quad (7.10)$$

where, for local corrections, $\alpha(\mathbf{x})$ and $\beta(\mathbf{x})$ are first or second-order Taylor series approximations to the exact correction functions:

$$\alpha(\mathbf{x}) = A(\mathbf{x}_c) + \nabla A(\mathbf{x}_c)^T(\mathbf{x} - \mathbf{x}_c) + \frac{1}{2}(\mathbf{x} - \mathbf{x}_c)^T \nabla^2 A(\mathbf{x}_c)(\mathbf{x} - \mathbf{x}_c) \quad (7.11)$$

$$\beta(\mathbf{x}) = B(\mathbf{x}_c) + \nabla B(\mathbf{x}_c)^T(\mathbf{x} - \mathbf{x}_c) + \frac{1}{2}(\mathbf{x} - \mathbf{x}_c)^T \nabla^2 B(\mathbf{x}_c)(\mathbf{x} - \mathbf{x}_c) \quad (7.12)$$

where the exact correction functions are

$$A(\mathbf{x}) = f_{hi}(\mathbf{x}) - f_{lo}(\mathbf{x}) \quad (7.13)$$

$$B(\mathbf{x}) = \frac{f_{hi}(\mathbf{x})}{f_{lo}(\mathbf{x})} \quad (7.14)$$

Refer to [24] for additional details on the derivations.

A combination of additive and multiplicative corrections can provide for additional flexibility in minimizing the impact of the correction away from the trust region center. In other words, both additive and multiplicative corrections can satisfy local consistency, but through the combination, global accuracy can be addressed as well. This involves a convex combination of the additive and multiplicative corrections:

$$f_{hi_\gamma}(\mathbf{x}) = \gamma f_{hi_\alpha}(\mathbf{x}) + (1 - \gamma) f_{hi_\beta}(\mathbf{x})$$

where γ is calculated to satisfy an additional matching condition, such as matching values at the previous design iterate.

It should be noted that in both first order correction methods, the function $\hat{f}(x)$ matches the function value and gradients of $f_t(x)$ at $x = x_c$. This property is necessary in proving that the first order-corrected SBO algorithms are provably convergent to a local minimum of $f_t(x)$. However, the first order correction methods are significantly more expensive than the zeroth order correction methods, since the first order methods require computing both $\nabla f_t(x_c)$ and $\nabla f_s(x_c)$. When the SBO strategy is used with either of the zeroth order correction methods, or with no correction method, convergence is not guaranteed to a local minimum of $f_t(x)$. That is, the SBO strategy becomes a heuristic optimization algorithm. From a mathematical point of view this is undesirable, but as a practical matter, the heuristic variants of SBO are often effective in finding local minima.

Usage guidelines

- Both the `additive zeroth_order` and `multiplicative zeroth_order` correction methods are "free" since they use values of $f_t(x_c)$ that are normally computed by the SBO strategy.
- The use of either the `additive first_order` method or the `multiplicative first_order` method does not necessarily improve the rate of convergence of the SBO algorithm.
- When using the first order correction methods, the gradient-related response keywords must be modified to allow either analytic or numerical gradients to be computed. This provides the gradient data needed to compute the correction function.
- For many computationally expensive engineering optimization problems, gradients often are too expensive to obtain or are discontinuous (or may not exist at all). In such cases the heuristic SBO algorithm has been an effective approach at identifying optimal designs [35].

zeroth_order

- [Keywords Area](#)
- `model`

- [surrogate](#)
- [hierarchical](#)
- [correction](#)
- [zeroth_order](#)

Specify that truth values must be matched.

Specification

Alias: none

Argument(s): none

Description

The correction specification specifies that the approximation will be corrected to match truth data. The keyword `zeroth_order` matching ensures that truth values are matched.

first_order

- [Keywords Area](#)

- [model](#)
- [surrogate](#)
- [hierarchical](#)
- [correction](#)
- [combined](#)

Multipoint correction for a hierarchical surrogate

Specification

Alias: none

Argument(s): none

Description

For the combined correction, the use of both additive and multiplicative corrections allows the satisfaction of an additional matching condition, typically the truth function values at the previous correction point (e.g., the center of the previous trust region). The combined correction is then a multipoint correction, as opposed to the local additive and multiplicative corrections.

7.3.4 nested

- [Keywords Area](#)
- [model](#)
- [nested](#)

A model whose responses are computed through the use of a sub-iterator

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		optional_interface_pointer	Pointer to interface that provides non-nested responses
	Required		sub_method_pointer	The <code>sub_method_pointer</code> specifies the method block for the sub-iterator

Description

Instead of appealing directly to a primary interface, a nested model maps variables to responses by executing a secondary iterator, or a "sub-iterator". In other words, a function evaluation of the primary study consists of a solution of an entire secondary study - potentially many secondary function evaluations.

The sub-iterator in turn operates on a sub-model. The sub-iterator responses may be combined with non-nested contributions from an optional interface specification.

A **sub_method_pointer** must be provided in order to specify the method block describing the sub-iterator. The remainder of the model is specified under that keyword.

A **optional_interface_pointer** points to the interface specification and `optional_interface_responses_pointer` points to a responses specification describing the data to be returned by this interface. This interface is used to provide non-nested data, which is then combined with data from the nested iterator using the `primary_response_mapping`. (See the discussions for the `sub_method_pointer` and `optional_interface_pointer` keywords.)

Pointer to interface that provides non-nested responses

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: no optional interface

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			optional_interface- responses_pointer	Pointer to responses block that defines non-nested responses

Description

`optional_interface_pointer` is used to specify an optional interface (using that interface block's `id-interface` label) to provide non-nested responses to the nested model.

To generate the complete set of primary responses (response functions, objective functions, and calibration terms) expected by the nested model, primary responses from the optional interface may be combined (by addition) with responses derived from sub-iterator results, or they may be presented unchanged to the nested model. The way that Dakota treats primary responses from these two sources depends on the number of rows of and entries in the `primary_response_mapping` matrix.

To understand how, it is helpful to consider the following expression. Nested model primary responses r are computed from the column vector of optional interface responses f , the `primary_response_mapping` matrix W , and the column vector of results from the sub-iterator s .

$$\{r\} = \left\{ \begin{array}{c} f \\ 0 \end{array} \right\} + \left\{ \begin{array}{c} [W]\{s\} \\ 0 \end{array} \right\}$$

The number of rows in f is equal to the number of primary responses returned by the optional interface, and in r , the number of primary responses expected by the nested model. In this expression, 0 represents "padding" that may be needed by either the optional interface vector or the sub-iterator vector to make them the same dimension as r . One or the other of these quantities may be padded, but not both. In terms of the Dakota input, this means

that the number of nested model primary responses must equal the larger of these two quantities: the number of optional interface responses or the number of rows in the `primary_response_mapping`.

The nested model's secondary responses (nonlinear constraints) are the secondary responses from the optional interface augmented by the secondary responses constructed from sub-iterator results. Unlike primary responses from these two sources, which may be combined by adding, it is not possible presently to combine secondary responses. For this reason, the number of nested model's secondary responses must equal the number of secondary responses provided by the optional interface, plus the number provided by the sub-iterator (i.e. the number of rows in the `secondary_response_mapping`). Secondary responses from the optional interface are inserted first into the nested model's nonlinear constraints; those from the sub-iterator come after. If the nested model has secondary responses and an optional interface is used, it is necessary to specify a separate response block for the optional interface using the `optional_interface_response_pointer`. Targets and upper and lower bounds for the nonlinear constraints are taken from the nested model's response block.

Examples

The first example illustrates the use of an optional interface and primary response mapping. No secondary responses are present. Assume that the inner method returns two results (suppose its the mean and standard deviation of a single response), so that the dimensions of `primary_response_mapping` will be interpreted by Dakota as 1x2, just as they are written here.

The nested model (`nested`) expects two primary responses (`outer_resp` block), and the optional interface returns two (`opt_resp` block).

```
model
  id_model 'nested'
  nested
    optional_interface_pointer 'opt_intf'
    optional_interface_response_pointer 'opt_resp'
    sub_method_pointer 'inner_method'
    primary_response_mapping 1.0 2.0

    responses_pointer 'outer_resp'
    variables_pointer 'outer_vars'

responses
  id_responses 'opt_resp'
  response_functions 2
  descriptors 'opt1' 'opt2'
  no_gradients
  no_hessians

responses
  id_responses 'outer_resp'
  response_functions 2
  descriptors 'out1' 'out2'
  no_gradients
  no_hessians
```

The first nested model response, `out1` will be computed $out1 = opt1 + 1.0 * mean + 2.0 * stddev$, and the second response `out2` will be equal to simply `opt2`. In the matrix form introduced above, including the implicit padding:

$$\begin{Bmatrix} out1 \\ out2 \end{Bmatrix} = \begin{Bmatrix} opt1 \\ opt2 \end{Bmatrix} + \begin{Bmatrix} 1.0 \cdot mean + 2.0 \cdot stddev \\ 0 \end{Bmatrix}$$

The `optional_interface_response_pointer` was not strictly needed. Because the number of responses returned by the optional interface and expected by the nested model is the same (and no secondary responses are present), the nested model's response specification alone would have sufficed.

If it were desired to combine *opt2* with the sub-iterator's results and set *out1* to *opt1* with no combination, then the `primary_response_mapping` matrix could be changed to:

```
primary_response_mapping  0.0 0.0
                        1.0 2.0
```

Secondary responses will be demonstrated in the second example.

```
model
  id_model 'nested'
  nested
    optional_interface_pointer 'opt_intf'
    optional_interface_response_pointer 'opt_resp'
    sub_method_pointer 'inner_method'
    primary_response_mapping  1.0 2.0
    secondary_response_mapping 1.0 0.0
    responses_pointer 'outer_resp'
    variables_pointer 'outer_vars'

responses
  id_responses 'opt_resp'
  objective_functions 2
    descriptors 'opt1' 'opt2'
  nonlinear_inequality_constraints 1
    descriptors 'optc'
  no_gradients
  no_hessians

responses
  id_responses 'outer_resp'
  objective_functions 2
    descriptors 'out1' 'out2'
  nonlinear_inequality_constraints 2
    descriptors 'outc1' 'outc2'
  no_gradients
  no_hessians
```

The nested model expects a total of two constraints. Because the `secondary_response_mapping` has one row, one of these constraints will be supplied from the sub-iterator. The other is provided by the optional interface. Secondary responses from the optional iterator come first, and so `optc` is placed in `outc1`. `outc2` takes the value computed from the sub-iterator results.

optional_interface_responses_pointer

- [Keywords Area](#)

	Optional	secondary_response_mapping	Mapping of sub-method results to top-level secondary responses
	Optional	identity_response_mapping	Identity mapping of sub-method results to top-level responses

Description

The `sub_method_pointer` specifies the method block for the sub-iterator.

See [block_pointer](#) for details about pointers.

A nested model performs an evaluation (variables-to-responses mapping) by running a complete sub-iterator (i.e. method) to completion. The sub-iterator, which is specified using the `sub_method_pointer`, has its own model. This model, referred to here as the sub-model, possesses its own variables and responses. Prior to every execution of the sub-iterator, information about the nested model's variables is injected into the sub-model's variables. After the sub-iterator has completed, its results are passed back up to the nested model as responses.

Communication of variables information from a nested model to its sub-iterator, and in the opposite direction of sub-iterator results to nested model responses, is called mapping. (This mapping must not be confused with the variables-to-responses mapping that constitutes an evaluation.) Dakota allows considerable power and flexi-

bility in how nested model mappings are performed. They are specified using four keywords: for the variables, `primary_variable_mapping` and `secondary_variable_mapping`; and for the responses, `primary_response_mapping` and `secondary_response_mapping`. They are described below.

Variable Mappings

In the variable mapping case, primary and secondary variable mapping specifications are used to map from the top-level variables into the sub-model variables. These mappings support three possibilities in any combination: (1) insertion of an active top-level variable value into an identified sub-model distribution parameter for an identified active sub-model variable, (2) insertion of an active top-level variable value into an identified active sub-model variable value, and (3) addition of an active top-level variable value as an inactive sub-model variable, augmenting the active sub-model variables.

For the variable mappings, the primary and secondary specifications are lists of strings that are used to target specific sub-model variables and their sub-parameters, respectively. The primary strings are matched to sub-model variable descriptors such as `'cdv.1'` (either user-supplied or default labels). The secondary strings are matched to random variable distribution parameters such as `'mean'` or `'num.trials'` or design/state variable sub-parameters such as `'lower_bound'` or `'upper_bound'`.

An important limitation is that real-valued top-level variables must map to real-valued sub-model variables or real-valued sub-parameters, and integer-valued top-level variables must map to either integer-valued sub-model variables or integer-valued sub-parameters. However, as long as these real versus integer constraints are satisfied, mappings are free to cross variable types (design, aleatory uncertain, epistemic uncertain, state) and domain types (continuous, discrete).

Both `primary_variable_mapping` and `secondary_variable_mapping` specifications are optional, which is designed to support the following three possibilities:

1. If both primary and secondary variable mappings are specified, then an active top-level variable value will be inserted into the identified sub-parameter (the secondary mapping) for the identified sub-model variable (the primary mapping).
2. If a primary mapping is specified but a secondary mapping is not, then an active top-level variable value will be inserted into the identified sub-model variable value (the primary mapping).
3. If a primary mapping is not specified (corresponding secondary mappings, if specified, are ignored), then an active top-level variable value will be inserted into a corresponding sub-model variable, based on matching of variable types (e.g., top-level and sub-model variable specifications both allocate a set of `'continuous_design'` variables which are active at the top level). Multiple sub-model variable types may be updated in this manner, provided that they are all active in the top-level variables. Since there is a direct variable correspondence for these default insertions, sub-model bounds and descriptors are also updated from the top-level bounds and labels in order to eliminate the need for redundant input file specifications. Thus, it is typical for the sub-model variables specification to only contain the minimal required information, such as the number of variables of each type, for these insertion targets. The sub-model must allocate enough space for each of the types that will accept default insertions, and the leading set of matching sub-model variables are updated (i.e., the sub-model may allocate more than needed and the trailing set will be unmodified).

These different variable mapping possibilities may be used in any combination by employing empty strings (") for particular omitted mappings (the number of strings in user-supplied primary and secondary variable mapping specifications must equal the total number of active top-level variables, including both continuous and discrete types). The ordering of the active variables is the same as shown in `dakota.input.summary` on [Input Spec Summary](#) and as presented in the [variables](#) section of this manual.

Inactive nested model variables are treated differently from those in the active view. If inactive variables are present at the outer level, then the default type 3 mapping is used for these variables; that is, outer loop inactive variables are inserted into inner loop variables (active or inactive) based on matching of variable types, top-level bounds and labels are also propagated, the inner loop must allocate sufficient space to receive the outer

loop values, and the leading subset within this inner loop allocation is updated. This capability is important for allowing nesting beyond two levels, since an active variable at the outer-most loop may become inactive at the next lower level, but still needs to be further propagated down to lower levels in the recursion.

Response Mappings

For the response mappings, the primary and secondary specifications determine how results from the completed sub-iterator are mapped into nested model responses. The response mapping defines a matrix which scales and combines the results from the inner loop into outer loop responses. Each row of the mapping corresponds to one outer loop response, and each column of the mapping corresponds to a result from the inner loop. The results returned from the sub-model are best thought of as forming a column vector; the nested model responses are then the dot-product of the mapping matrix and results vector. The number and type of results that are available and must be accounted for in the response mapping depends on the sub-iterator type:

optimization: the final objective function(s) and nonlinear constraints

nonlinear least squares: the final least squares terms and nonlinear constraints

aleatory uncertainty quantification (UQ): for each response function, a mean statistic, a standard deviation statistic, and all probability/reliability/generalized reliability/response level results for any user-specified `response_levels`, `probability_levels`, `reliability_levels`, and/or `gen_reliability_levels`, in that order.

epistemic and mixed aleatory/epistemic UQ using interval estimation methods: lower and upper interval bounds for each response function.

epistemic and mixed aleatory/epistemic UQ using evidence methods: for each response function, lower and upper interval bounds (belief and plausibility) for all probability/reliability/generalized reliability/response level results computed from any user-specified `response_levels`, `probability_levels`, `reliability_levels`, and/or `gen_reliability_levels`, in that order. parameter studies and design of experiments: for optimization and least squares response data sets, the best solution found (lowest constraint violation if infeasible, lowest composite objective function if feasible). For generic response data sets, a best solution metric is not defined, so the sub-iterator response vector is empty in this case.

The `primary_response_mapping` matrix maps sub-iterator results into top-level objective functions, least squares terms, or generic response functions, depending on the declared top-level response set. The `secondary_response_mapping` matrix maps sub-iterator results into top-level nonlinear inequality and equality constraints. Alternately, if all the responses of the sub-iterator are to be mapped one-to-one to the top-level nested model responses `identity_response_mapping` may be specified instead.

Summary

The nested model constructs admit a wide variety of multi-iterator, multi-model solution approaches. For example, optimization within optimization (for hierarchical multidisciplinary optimization), uncertainty quantification within uncertainty quantification (for second-order probability), uncertainty quantification within optimization (for optimization under uncertainty), and optimization within uncertainty quantification (for uncertainty of optima) are all supported, with and without surrogate model indirection. Several examples of nested model usage are provided in the Users Manual, most notably mixed epistemic-aleatory UQ, optimization under uncertainty (OUU), and surrogate-based UQ.

Examples

Two examples are provided to illustrate nested models. The first is a relatively simple case. Although it is somewhat contrived, it demonstrates several features of nested models. A step-by-step explanation is provided below.

```
environment
  method_pointer 'opt'

method
  id_method 'opt'
```

```

asynch_pattern_search
model_pointer 'outer_model'
output verbose

model
  id_model 'outer_model'
  variables_pointer 'outer_vars'
  responses_pointer 'outer_resps'
  nested
    sub_method_pointer 'UQ_method'
    primary_variable_mapping 'x1' 'x2'
    secondary_variable_mapping 'mean' 'mean'
    primary_response_mapping 0 0 0.3 0 0 0.7

variables
  id_variables 'outer_vars'
  continuous_design 2
  descriptors 'x1_mean' 'x2_mean'
  lower_bounds -2.0 -2.0
  upper_bounds 2.0 2.0

responses
  id_responses 'outer_resps'
  objective_functions 1
  descriptors 'sum_p'
  no_gradients
  no_hessians

method
  id_method 'UQ_method'
  sampling samples 30
  seed 1234
  model_pointer 'UQ_model'
  probability_levels 0.9 0.9

model
  id_model 'UQ_model'
  single
  variables_pointer 'inner_vars'
  responses_pointer 'inner_resps'
  interface_pointer 'inf'

variables
  id_variables 'inner_vars'
  normal_uncertain 2
  descriptors 'x1' 'x2'
  means 0.0 0.0
  std_deviations 1.0 1.0

responses
  id_responses 'inner_resps'
  response_functions 2
  descriptors 'f1' 'f2'
  no_gradients
  no_hessians

interface
  id_interface 'inf'
  direct
  analysis_drivers 'text_book'

```

The example input is an 'optimization under uncertainty' or OOU. In an OOU, some statistic of the simulation

response is optimized. In this case, a weighted sum of the 90th percentiles of two simulation responses from the `text_book` driver is being minimized. The uncertainty in these responses is driven by uncertainty in the input variables, which are normally distributed. The means of the uncertain variables are the design variables in the optimization.

In Dakota, this is accomplished by nesting an uncertainty quantification method (`sampling`), which computes the 90th percentiles, within an optimizer (`method-asynch_pattern_search`), which iteratively adjusts the variable means to minimize the objective. For every evaluation requested by the optimizer, the design variables (`x1_mean` and `x2_mean` in the example) are inserted into the means of the uncertain variables (`x1` and `x2`), then the `sampling` study is run to completion, and finally the resulting statistics for the responses `f1` and `f2` are mapped into the responses `sum_p`.

It may be helpful to sketch out the relationships between blocks as indicated by their various pointers in order to understand the nested structure of the study. The top-level or outer method, `'opt'`, has a model named `'outer_model'`. This model refers to variables and responses blocks (`'outer_vars'` and `'outer_resps'`) that are used by the optimizer. The `'outer_model'` block also refers to a sub-method, `'UQ-method'` which defines the UQ study and has its own model, which in turn possess variables, an interface, and responses.

Next, note the primary and secondary variable mappings in `'outer_model'`, which specify that the values of the active design variables `x1_mean` and `x2_mean` are to be inserted into the means of the uncertain variables `x1` and `x2`.

The response mapping in `'outer_model'` is a matrix with a single row and six columns. The single row corresponds to the number of responses in the outer method. As described above, for each of our two sub-model responses, the `sampling` method returns a mean, a standard deviation, and a single probability level in that order to the nested model. There are a total of six results and accordingly six columns in the mapping matrix. The coefficients 0.3 and 0.7 in the matrix result in a weighted sum of the 90th percentiles:

$$sum_p = 0.3 * (90th\ percentile\ of\ f1) + 0.7 * (90th\ percentile\ of\ f2)$$

The next example is a fragment of an input file, showing only the nested model itself. It illustrates more complex variable and response mappings.

```
primary_variable_mapping = ' ' 'X' 'Y'
secondary_variable_mapping = ' ' 'mean' 'mean'
primary_response_mapping = 1. 0. 0. 0. 0. 0. 0. 0. 0.
secondary_response_mapping = 0. 0. 0. 1. 3. 0. 0. 0. 0.
                             0. 0. 0. 0. 0. 0. 1. 3. 0.
```

The variable mappings correspond to 4 top-level variables, the first two of which employ the default mappings from active top-level variables to sub-model variables of the same type (option 3 above) and the latter two of which are inserted into the mean distribution parameters of sub-model variables `'X'` and `'Y'` (option 1 above).

The response mappings define a 3 by 9 matrix corresponding to 9 inner loop results and 3 outer loop response functions (one primary response function and 2 secondary functions, such as one objective and two constraints). Each row of the response mapping is a vector which is multiplied (i.e., with a dot-product) against the 9 sub-iterator results to determine the outer loop function.

Consider again a UQ example with 3 response functions, each providing a mean, a standard deviation, and one level mapping (if no level mappings are specified, the responses would only have a mean and standard deviation). The primary response mapping can be seen to extract the first result from the inner loop, which would correspond to the mean of the first response function. This mapped sub-iterator response becomes a single objective function, least squares term, or generic response function at the outer level, as dictated by the top-level response specification. The secondary response mapping maps the fourth sub-iterator result plus 3 times the fifth sub-iterator result (mean plus 3 standard deviations) into one top-level nonlinear constraint and the seventh sub-iterator result plus 3 times the eighth sub-iterator result (mean plus 3 standard deviations) into another top-level nonlinear constraint,

where these top-level nonlinear constraints may be inequality or equality, as dictated by the top-level response specification.

Note that a common case is for each sub-iterator result to be mapped to a unique outer loop response (for example, in the nested UQ case where one wants to determine an interval on each inner loop statistic). In these simple cases, the response mapping would define an identity matrix and [identity_response_mapping](#) may instead be specified.

iterator_servers

- [Keywords Area](#)
- [model](#)
- [nested](#)
- [sub_method_pointer](#)
- [iterator_servers](#)

Specify the number of iterator servers when Dakota is run in parallel

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): INTEGER

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional `iterator_servers` specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, `hybrid`, `multi_start`, and `pareto_set` component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [4] for additional information.

iterator_scheduling

- [Keywords Area](#)
- [model](#)
- [nested](#)
- [sub_method_pointer](#)
- [iterator_scheduling](#)

Specify the scheduling of concurrent iterators when Dakota is run in parallel

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Required(<i>Choose One</i>)	Description of Group Server Mode (Group 1)	Dakota Keyword	Dakota Keyword Description
			master	Specify a dedicated master partition for parallel iterator scheduling
			peer	Specify a peer partition for parallel iterator scheduling

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional `iterator_scheduling` specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, `hybrid`, `multi_start`, and `pareto_set` component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [4] for additional information.

master

- [Keywords Area](#)
- [model](#)
- [nested](#)
- [sub_method_pointer](#)
- [iterator_scheduling](#)
- [master](#)

Specify a dedicated master partition for parallel iterator scheduling

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): none

Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a dedicated master partition. In a dedicated master partition, one processor (the "master") dynamically schedules work on the iterator servers. This reduces the number of processors available to create servers by 1.

peer

- [Keywords Area](#)
- [model](#)
- [nested](#)
- [sub_method_pointer](#)
- [iterator_scheduling](#)
- [peer](#)

Specify a peer partition for parallel iterator scheduling

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): none

Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a peer partition. In a peer partition, all processors are available to be assigned to iterator servers. Note that unlike the case of `evaluation_scheduling`, it is not possible to specify `static` or `dynamic`.

processors_per_iterator

- [Keywords Area](#)
- [model](#)
- [nested](#)
- [sub_method_pointer](#)
- [processors_per_iterator](#)

Specify the number of processors per iterator server when Dakota is run in parallel

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): INTEGER

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional `processors_per_iterator` specification supports user override of the automatic parallel configuration for the number of processors in each iterator server. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired server size at the iterator parallelism level. Currently, `hybrid`, `multi_start`, and `pareto_set` component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual[4] for additional information.

primary_variable_mapping

- [Keywords Area](#)
- [model](#)
- [nested](#)
- [sub_method_pointer](#)
- [primary_variable_mapping](#)

Primary mapping of top-level variables to sub-model variables

Specification

Alias: none

Argument(s): STRINGLIST

Default: default variable insertions based on variable type

Description

The `primary_variable_mapping`, `secondary_variable_mapping`, `primary_response_mapping`, and `secondary_response_mapping` keywords control how top-level variables and responses are mapped to variables and responses in the sub-model. Their usage is explained on the parent keyword (`sub_method_pointer`) page.

secondary_variable_mapping

- [Keywords Area](#)
- [model](#)
- [nested](#)
- [sub_method_pointer](#)
- [secondary_variable_mapping](#)

Secondary mapping of top-level variables to sub-model variables

Specification

Alias: none

Argument(s): STRINGLIST

Default: primary mappings into sub-model variables are value-based

Description

The `primary_variable_mapping`, `secondary_variable_mapping`, `primary_response_mapping`, and `secondary_response_mapping` keywords control how top-level variables and responses are mapped to variables and responses in the sub-model. Their usage is explained on the parent keyword (`sub_method_pointer`) page.

primary_response_mapping

- [Keywords Area](#)
- [model](#)
- [nested](#)
- [sub_method_pointer](#)
- [primary_response_mapping](#)

Mapping of sub-method results to top-level primary responses

Specification

Alias: none

Argument(s): REALLIST

Default: no sub-iterator contribution to primary functions

Description

Matrix that specifies how sub-method results (statistics, best parameters, etc.) map to top-level nested model primary responses (objectives, calibration terms, or response functions). Its usage is explained in detail on the parent keyword (`sub_method_pointer`) page.

secondary_response_mapping

- [Keywords Area](#)
- [model](#)
- [nested](#)
- [sub_method_pointer](#)
- [secondary_response_mapping](#)

Mapping of sub-method results to top-level secondary responses

Specification

Alias: none

Argument(s): REALLIST

Default: no sub-iterator contribution to secondary functions

Description

Matrix that specifies how sub-method results (statistics, best parameters, etc.) map to top-level nested model secondary responses (nonlinear inequality or equality constraints). Its usage is explained in detail on the parent keyword ([sub_method_pointer](#)) page.

identity_response_mapping

- [Keywords Area](#)
- [model](#)
- [nested](#)
- [sub_method_pointer](#)
- [identity_response_mapping](#)

Identity mapping of sub-method results to top-level responses

Specification

Alias: none

Argument(s): none

Default: no sub-iterator contribution to nested model functions

Description

Specifies that the list of sub-method results (statistics, best parameters, etc.) should map one-to-one to the list of top-level nested model responses.

Usage Tips

To use an identity mapping, the number of top-level nested model responses (primary + secondary responses) must equal the number of sub-method results. If receiving an error about this, set `output verbose` and re-run the Dakota study to see a list of sub-method results responses.

The identity map may not be used in conjunction with [optional_interface_pointer](#), nor with an explicit `primary_response_mapping` or `secondary_response_mapping`.

Examples

```
model
  id_model 'nested'
  nested
  sub_method_pointer 'aleat'
  identity_response_mapping
```

Input Spec Summary This file is derived automatically from `dakota.xml`, which is used in the generation of parser system files that are compiled into the Dakota executable. Therefore, these files are the definitive source for input syntax, capability options, and associated data inputs. Refer to the Developers Manual information on how to modify the input specification and propagate the changes through the parsing system.

Key features of the input specification and the associated user input files include:

- In the input specification, required individual specifications simply appear, optional individual and group specifications are enclosed in `[]`, required group specifications are enclosed in `()`, and either-or relationships are denoted by the `|` symbol. These symbols only appear in `dakota.input.summary`; they must not appear in actual user input files.
- Keyword specifications (i.e., `environment`, `method`, `model`, `variables`, `interface`, and `responses`) begin with the keyword possibly preceded by white space (blanks, tabs, and newlines) both in the input specifications and in user input files. For readability, keyword specifications may be spread across several lines. Earlier versions of Dakota (prior to 4.1) required a backslash character (`\`) at the ends of intermediate lines of a keyword. While such backslashes are still accepted, they are no longer required.
- Some of the keyword components within the input specification indicate that the user must supply `INTEGER`, `REAL`, `STRING`, `INTEGERLIST`, `REALLIST`, or `STRINGLIST` data as part of the specification. In a user input file, the `"="` is optional, data in a `LIST` can be separated by commas or whitespace, and the `STRING` data are enclosed in single or double quotes (e.g., `'text_book'` or `"text_book"`).
- In user input files, input is largely order-independent (except for entries in lists of data), case insensitive, and white-space insensitive. Although the order of input shown in the [Sample Input Files](#) generally follows the order of options in the input specification, this is not required.
- In user input files, specifications may be abbreviated so long as the abbreviation is unique. For example, the `npsol_sqp` specification within the `method` keyword could be abbreviated as `npsol`, but `dot_sqp` should not be abbreviated as `dot` since this would be ambiguous with other `DOT` method specifications.
- In both the input specification and user input files, comments are preceded by `#`.
- `ALIAS` refers to synonymous keywords, which often exist for backwards compatibility. Users are encouraged to use the most current keyword.

7.3.5 active_subspace

- [Keywords Area](#)
- [model](#)
- [active_subspace](#)

Active (variable) subspace model

Specification

Alias: subspace

Argument(s): none

Child Keywords:

	Required/ Optional Required	Description of Group	Dakota Keyword	Dakota Keyword Description
			actual_model_ pointer	Pointer to specify a full-space model, from which to construct a lower dimensional surrogate

	Optional	initial_samples	Initial number of samples for sampling-based methods
	Optional	sample_type	Selection of sampling strategy
	Optional	truncation_method	Metric that estimates active subspace size
	Optional	dimension	Explicitly specify the desired subspace size
	Optional	bootstrap_samples	Number of bootstrap replicates used in truncation metrics
	Optional	build_surrogate	Construct moving least squares surrogate over active subspace
	Optional	normalization	Normalize gradient samples

Description

A model that transforms the original model (given by [actual_model_pointer](#)) to one with a reduced set of variables. This reduced model is identified by iteratively sampling the gradient of the original model and performing a singular value decomposition of the gradient matrix.

Expected Output

A subspace model will perform an initial sampling design to identify an active subspace using one of the truncation methods.

Usage Tips

If the desired subspace size is not identified, consider using the explicit [dimension](#) truncation option or one of the other truncation methods.

Examples

Perform an initial 100 gradient samples and use the [bing_li](#) truncation method to identify an active subspace. The truncation method uses 150 bootstrap samples to compute the Bing Li truncation metric.

```
model
  subspace
    id_model = 'SUBSPACE'
    actual_model_pointer = 'FULLSPACE'
```

```

initial_samples 100
truncation_method bing_li
bootstrap_samples 150

```

Theory

The idea behind active subspaces is to find directions in the input variable space in which the quantity of interest is nearly constant. After rotation of the input variables, this method can allow significant dimension reduction. Below is a brief summary of the process.

1. Compute the gradient of the quantity of interest, $q = f(\mathbf{x})$, at several locations sampled from the full input space,

$$\nabla_{\mathbf{x}} f_i = \nabla f(\mathbf{x}_i).$$

2. Compute the eigendecomposition of the matrix $\hat{\mathbf{C}}$,

$$\hat{\mathbf{C}} = \frac{1}{M} \sum_{i=1}^M \nabla_{\mathbf{x}} f_i \nabla_{\mathbf{x}} f_i^T = \hat{\mathbf{W}} \hat{\mathbf{\Lambda}} \hat{\mathbf{W}}^T,$$

where $\hat{\mathbf{W}}$ has eigenvectors as columns, $\hat{\mathbf{\Lambda}} = \text{diag}(\hat{\lambda}_1, \dots, \hat{\lambda}_N)$ contains eigenvalues, and N is the total number of parameters.

3. Using a [truncation_method](#) or specifying a [dimension](#) to estimate the active subspace size, split the eigenvectors into active and inactive directions,

$$\hat{\mathbf{W}} = \begin{bmatrix} \hat{\mathbf{W}}_1 & \hat{\mathbf{W}}_2 \end{bmatrix}.$$

These eigenvectors are used to rotate the input variables.

4. Next the input variables, \mathbf{x} , are expanded in terms of active and inactive variables,

$$\mathbf{x} = \hat{\mathbf{W}}_1 \mathbf{y} + \hat{\mathbf{W}}_2 \mathbf{z}.$$

5. A surrogate is then built as a function of the active variables,

$$g(\mathbf{y}) \approx f(\mathbf{x})$$

actual_model_pointer

- [Keywords Area](#)
- [model](#)
- [active_subspace](#)
- [actual_model_pointer](#)

Pointer to specify a full-space model, from which to construct a lower dimensional surrogate

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Description

This must point to a model block, identified by [id_model](#). That model will be run to generate gradient data, from which an active subspace model will be identified and built.

See [block_pointer](#) for details about pointers.

initial_samples

- [Keywords Area](#)
- [model](#)
- [active_subspace](#)
- [initial_samples](#)

Initial number of samples for sampling-based methods

Specification

Alias: none

Argument(s): INTEGER

Default: model-dependent

Description

The `initial_samples` keyword is used to define the number of initial samples (i.e., randomly chosen sets of variable values) at which to execute a model. The initial samples may later be augmented in an iterative process.

Default Behavior

By default, Dakota will use the minimum number of samples required by the chosen method.

Usage Tips

To obtain linear sensitivities or to construct a linear response surface, at least $\text{dim}+1$ samples should be used, where "dim" is the number of variables. For sensitivities to quadratic terms or quadratic response surfaces, at least $(\text{dim}+1)(\text{dim}+2)/2$ samples are needed. For uncertainty quantification, we recommend at least $10*\text{dim}$ samples. For `variance_based_decomp`, we recommend hundreds to thousands of samples. Note that for `variance_based_decomp`, the number of simulations performed will be $N*(\text{dim}+2)$.

Examples

```
method
  sampling
    sample_type random
    initial_samples = 20
    refinement_samples = 5
```

sample_type

- [Keywords Area](#)
- [model](#)
- [active_subspace](#)
- [sample_type](#)

Selection of sampling strategy

Specification

Alias: none

Argument(s): none

Default: random

Child Keywords:

	Required/ Optional Required(<i>Choose One</i>)	Description of Group Sample Type (Group 1)	Dakota Keyword	Dakota Keyword Description
			lhs	Uses Latin Hypercube Sampling (LHS) to sample variables
			random	Uses purely random Monte Carlo sampling to sample variables

Description

The `sample_type` keyword allows the user to select between two types of sampling: Monte Carlo (pure random) and Latin hypercube (stratified) sampling.

The incremental keywords are deprecated; instead use `samples` together with `refinement_samples`.

Default Behavior

If the `sample_type` keyword is present, it must be accompanied by `lhs` or `random`. In most contexts, `lhs` is the default (exception: `multilevel_sampling` uses Monte Carlo by default).

Examples

```
method
  sampling
    sample_type lhs
    samples = 20
    seed = 83921
```

lhs

- [Keywords Area](#)
- [model](#)
- [active_subspace](#)
- [sample_type](#)
- [lhs](#)

Uses Latin Hypercube Sampling (LHS) to sample variables

Specification

Alias: none

Argument(s): none

Description

The `lhs` keyword invokes Latin Hypercube Sampling as the means of drawing samples of uncertain variables according to their probability distributions. This is a stratified, space-filling approach that selects variable values from a set of equi-probable bins.

Default Behavior

Latin Hypercube Sampling is the default sampling mode in most contexts (exception: `multilevel_sampling`). To explicitly specify LHS in the Dakota input file, the `lhs` keyword must appear in conjunction with the `sample_type` keyword.

Usage Tips

Latin Hypercube Sampling is very robust and can be applied to any problem. It is fairly effective at estimating the mean of model responses and linear correlations with a reasonably small number of samples relative to the number of variables.

Examples

```
method
  sampling
    sample_type lhs
    samples = 20
```

random

- [Keywords Area](#)
- [model](#)
- [active_subspace](#)
- [sample_type](#)
- [random](#)

Uses purely random Monte Carlo sampling to sample variables

Specification

Alias: none

Argument(s): none

Description

The `random` keyword invokes Monte Carlo sampling as the means of drawing samples of uncertain variables according to their probability distributions.

Default Behavior

In most contexts, Monte Carlo sampling is not the default sampling mode (exception: `multilevel_sampling`). To change this behavior, the `random` keyword must be specified in conjunction with the `sample_type` keyword.

Usage Tips

Monte Carlo sampling is more computationally expensive than Latin Hypercube Sampling as it requires a larger number of samples to accurately estimate statistics.

Examples

```
method
  sampling
    sample_type random
    samples = 200
```

truncation_method

- [Keywords Area](#)
- [model](#)
- [active_subspace](#)
- [truncation_method](#)

Metric that estimates active subspace size

Specification

Alias: none

Argument(s): none

Default: constantine

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		bing_li	Use the Bing Li "ladle" diagnostic to truncate subspace

	Optional	constantine	Use the Constantine diagnostic to truncate subspace
	Optional	energy	Truncate the subspace based on eigenvalue energy
	Optional	cross_validation	Truncate the subspace to minimize surrogate cross-validation error

Description

Metric that controls how many basis vectors are retained in the active subspace.

Default Behavior

The default is to use the [constantine](#) diagnostic.

Usage Tips

If the automated subspace identification methods do not yield desirable results, consider using the explicit [dimension](#) truncation option.

bing_li

- [Keywords Area](#)
- [model](#)
- [active_subspace](#)
- [truncation_method](#)
- [bing_li](#)

Use the Bing Li "ladle" diagnostic to truncate subspace

Specification

Alias: none

Argument(s): none

Description

Uses a trade-off criterion to determine where to truncate the active subspace. The criterion is a function of the eigenvalues and eigenvectors of the active subspace gradient matrix. This function compares the decrease in eigenvalue amplitude with the increase in eigenvector variability under bootstrap sampling of the gradient matrix. The active subspace size is taken to be the index of the first minimum of this quantity.

Usage Tips

If this automated diagnostic does not yield desirable results, consider using the explicit [dimension](#) truncation option or one of the other truncation methods.

Theory

Below is a brief outline of the Bing Li method of active subspace identification. The first two steps are common to all active subspace truncation methods.

1. Compute the gradient of the quantity of interest, $q = f(\mathbf{x})$, at several locations sampled from the input space,

$$\nabla_{\mathbf{x}} f_i = \nabla f(\mathbf{x}_i).$$

2. Compute the eigendecomposition of the matrix $\hat{\mathbf{C}}$,

$$\hat{\mathbf{C}} = \frac{1}{M} \sum_{i=1}^M \nabla_{\mathbf{x}} f_i \nabla_{\mathbf{x}} f_i^T = \hat{\mathbf{W}} \hat{\mathbf{\Lambda}} \hat{\mathbf{W}}^T,$$

where $\hat{\mathbf{W}}$ has eigenvectors as columns, $\hat{\mathbf{\Lambda}} = \text{diag}(\hat{\lambda}_1, \dots, \hat{\lambda}_N)$ contains eigenvalues, and N is the total number of parameters.

3. Normalize the eigenvalues,

$$\lambda_i = \frac{\hat{\lambda}_i}{\sum_j^N \hat{\lambda}_j}.$$

4. Use bootstrap sampling of the gradients found in step 1 to compute replicate eigendecompositions,

$$\hat{\mathbf{C}}_j^* = \hat{\mathbf{W}}_j^* \hat{\mathbf{\Lambda}}_j^* (\hat{\mathbf{W}}_j^*)^T.$$

5. Compute variability of eigenvectors,

$$f_i^0 = \frac{1}{M_{boot}} \sum_j^{M_{boot}} \left\{ 1 - \left| \det \left(\hat{\mathbf{W}}_i^T \hat{\mathbf{W}}_{j,i}^* \right) \right| \right\},$$

where $\hat{\mathbf{W}}_i$ and $\hat{\mathbf{W}}_{j,i}^*$ both contain only the first i eigenvectors and M_{boot} is the number of bootstrap samples. The value of the variability at the first index, f_1^0 , is defined as zero.

6. Normalize the eigenvector variability,

$$f_i = \frac{f_i^0}{\sum_j^N f_j^0}.$$

7. The criterion, g_i , is defined as,

$$g_i = \lambda_i + f_i.$$

8. The index of first minimum of g_i is then the estimated active subspace rank.

For additional information, see Luo, Wei, and Bing Li. "Combining eigenvalues and variation of eigenvectors for order determination." SIAM, 2015.

constantine

- [Keywords Area](#)
- [model](#)
- [active_subspace](#)
- [truncation_method](#)
- [constantine](#)

Use the Constantine diagnostic to truncate subspace

Specification

Alias: none

Argument(s): none

Description

Uses a criterion based on the variability of the subspace estimate. Eigenvectors are computed for bootstrap samples of the gradient matrix. The subspace size associated with the minimum distance between bootstrap eigenvectors and the nominal eigenvectors is the estimated active subspace size.

Usage Tips

If this automated diagnostic does not yield desirable results, consider using the explicit [dimension](#) truncation option or one of the other truncation methods.

Theory

Below is a brief outline of the Constantine method of active subspace identification. The first two steps are common to all active subspace truncation methods.

1. Compute the gradient of the quantity of interest, $q = f(\mathbf{x})$, at several locations sampled from the input space,

$$\nabla_{\mathbf{x}} f_i = \nabla f(\mathbf{x}_i).$$

2. Compute the eigendecomposition of the matrix $\hat{\mathbf{C}}$,

$$\hat{\mathbf{C}} = \frac{1}{M} \sum_{i=1}^M \nabla_{\mathbf{x}} f_i \nabla_{\mathbf{x}} f_i^T = \hat{\mathbf{W}} \hat{\mathbf{\Lambda}} \hat{\mathbf{W}}^T,$$

where $\hat{\mathbf{W}}$ has eigenvectors as columns, $\hat{\mathbf{\Lambda}} = \text{diag}(\hat{\lambda}_1, \dots, \hat{\lambda}_N)$ contains eigenvalues, and N is the total number of parameters.

3. Use bootstrap sampling of the gradients found in step 1 to compute replicate eigendecompositions,

$$\hat{\mathbf{C}}_j^* = \hat{\mathbf{W}}_j^* \hat{\mathbf{\Lambda}}_j^* \left(\hat{\mathbf{W}}_j^* \right)^T.$$

4. Compute the average distance between nominal and bootstrap subspaces,

$$e_n^* = \frac{1}{M_{boot}} \sum_j^{M_{boot}} \text{dist}(\text{ran}(\hat{\mathbf{W}}_n), \text{ran}(\hat{\mathbf{W}}_{j,n}^*)) = \frac{1}{M_{boot}} \sum_j^{M_{boot}} \left\| \hat{\mathbf{W}}_n \hat{\mathbf{W}}_n^T - \hat{\mathbf{W}}_{j,n}^* \left(\hat{\mathbf{W}}_{j,n}^* \right)^T \right\|,$$

where M_{boot} is the number of bootstrap samples, $\hat{\mathbf{W}}_n$ and $\hat{\mathbf{W}}_{j,n}^*$ both contain only the first n eigenvectors, and $n < N$.

5. The estimated subspace rank, r , is then,

$$r = \arg \min_n e_n^*.$$

energy

- [Keywords Area](#)
- [model](#)
- [active_subspace](#)
- [truncation_method](#)
- [energy](#)

Truncate the subspace based on eigenvalue energy

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		truncation_- tolerance	Specify the maximum percentage (as a decimal) of the eigenvalue energy not captured by the active subspace representation.

Description

Uses a criterion based on the derivative matrix eigenvalue energy.

Usage Tips

This subspace truncation method may work best when working with non-normally distributed uncertain variables. If this automated diagnostic does not yield desirable results, consider using the explicit [dimension](#) truncation option or one of the other truncation methods.

Theory

Using the eigenvalue energy truncation metric, the subspace size is determined using the following equation:

$$n = \inf \left\{ d \in \mathbf{Z} \mid 1 \leq d \leq N \quad \wedge \quad 1 - \frac{\sum_{i=1}^d \lambda_i}{\sum_{i=1}^N \lambda_i} < \epsilon \right\}$$

where ϵ is the [truncation.tolerance](#), n is the estimated subspace size, N is the size of the full space, and λ_i are the eigenvalues of the derivative matrix.

truncation_tolerance

- [Keywords Area](#)
- [model](#)
- [active_subspace](#)
- [truncation_method](#)
- [energy](#)
- [truncation_tolerance](#)

Specify the maximum percentage (as a decimal) of the eigenvalue energy not captured by the active subspace representation.

Specification

Alias: none

Argument(s): REAL

Description

The `truncation_tolerance` is used in the energy truncation method to identify an active subspace. The `truncation_tolerance` is used in the following equation to determine the subspace size:

$$n = \inf \left\{ d \in \mathbf{Z} \mid 1 \leq d \leq N \quad \wedge \quad 1 - \frac{\sum_{i=1}^d \lambda_i}{\sum_{i=1}^N \lambda_i} < \epsilon \right\}$$

where ϵ is the `truncation_tolerance`, n is the estimated subspace size, N is the size of the full space, and λ_i are the eigenvalues of the derivative matrix.

The default value for `truncation_tolerance` is 1×10^{-6} .

cross_validation

- [Keywords Area](#)
- [model](#)

Tolerance for cross-validation error stabilization

Specification

Alias: none

Argument(s): REAL

Default: 1.0e-6

Description

Select smallest subspace where change in cross-validation error falls below specified tolerance.

max_rank

- [Keywords Area](#)
- [model](#)
- [active_subspace](#)
- [truncation_method](#)
- [cross_validation](#)
- [max_rank](#)

Maximum subspace dimension to consider

Specification

Alias: none

Argument(s): INTEGER

Default: number fullspace vars

Description

In cross-validation, only consider subspace dimensions from 1 to `max_rank`.

exhaustive

- [Keywords Area](#)
- [model](#)
- [active_subspace](#)
- [truncation_method](#)
- [cross_validation](#)
- [exhaustive](#)

Assess all admissible subspace dimensions

Specification

Alias: none

Argument(s): none

Default: on

Description

Assess cross-validation error for all admissible subspace dimensions, even if a particular dimension meets specified cross-validation tolerance(s).

dimension

- [Keywords Area](#)
- [model](#)
- [active_subspace](#)
- [dimension](#)

Explicitly specify the desired subspace size

Specification

Alias: none

Argument(s): INTEGER

Description

This control explicitly indicates the number of basis vectors to retain. The subspace model will include exactly `dimension` variables.

Default Behavior

Not active; the number of basis vectors will be chosen by one of the truncation methods.

Usage Tips

This control can be helpful when *a priori* studies give insight to the appropriate subspace size.

bootstrap_samples

- [Keywords Area](#)
- [model](#)
- [active_subspace](#)
- [bootstrap_samples](#)

Number of bootstrap replicates used in truncation metrics

Specification

Alias: none

Argument(s): INTEGER

Description

The number of bootstrap replicates used to estimate the active subspace size.

Default Behavior

Use 100 replicates.

build_surrogate

- [Keywords Area](#)
- [model](#)
- [active_subspace](#)
- [build_surrogate](#)

Construct moving least squares surrogate over active subspace

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		refinement_ samples	Number of supplementary surrogate build samples

Description

Once the active subspace variables have been identified, replace the fullspace truth model with a moving least squares surrogate model over the reduced variables. The surrogate is constructed using the fullspace function value samples collected during subspace identification, possibly supplemented with additional [refinement_samples](#) in the fullspace.

Default Behavior

No surrogate is constructed by default.

Examples

```
model
  active_subspace
  id_model = 'SUBSPACE'
  actual_model_pointer = 'FULLSPACE'
  initial_samples 100
  build_surrogate
  refinement_samples 10
```

refinement_samples

- [Keywords Area](#)
- [model](#)
- [active_subspace](#)
- [build_surrogate](#)
- [refinement_samples](#)

Number of supplementary surrogate build samples

Specification

Alias: none

Argument(s): INTEGERLIST

Default: 0

Description

Augment the function value data collected during subspace identification with the specified number of `refinement_samples` to build the surrogate model.

normalization

- [Keywords Area](#)
- [model](#)
- [active_subspace](#)
- [normalization](#)

Normalize gradient samples

Specification

7.3.7 random_field

- [Keywords Area](#)
- [model](#)
- [random_field](#)

Experimental capability to generate a random field representation. from data, from simulation runs, or from a covariance matrix. The representation may then be sampled for use as a random field input to another simulation. THIS IS AN EXPERIMENTAL CAPABILITY.

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		build_source	Specify how the random field will be built: from a data file, from simulation runs, or from a covariance matrix. THIS IS AN EXPERIMENTAL CAPABILITY.
	Optional		expansion_form	Specify the form of the expansion to be used in the random field representation. THIS IS AN EXPERIMENTAL CAPABILITY.
	Optional		expansion_bases	Specify the number of basis functions to be used in the random field representation. THIS IS AN EXPERIMENTAL CAPABILITY.
	Optional		truncation_-tolerance	Specify a percent of the response variance that should be captured with the random field representation. THIS IS AN EXPERIMENTAL CAPABILITY.

	Required	propagation_-model_pointer	Pointer to the model that will accept realizations of the random field and use them for subsequent analysis. Typically, this model will take the random field as inputs, e.g. a random field defining a pressure boundary or temperature boundary condition over a structure. THIS IS AN EXPERIMENTAL CAPABILITY.
--	-----------------	--	---

Description

Capability to generate a random field representation from data, from simulation runs, or from a covariance matrix. The random field may then be sampled for use as a random field input to another simulation. THIS IS AN EXPERIMENTAL CAPABILITY UNDER ACTIVE DEVELOPMENT.

Default Behavior There are three main sections of the `random_field` model. The first section tells Dakota what data to use to build the random field. This is specified with `build_source`. The source of data to build the random field may be a file with data (where the N rows of data correspond to N samples of the random field and the M columns correspond to field values), or it may be a simulation that generates field data, or it may be specified given a mesh and a covariance matrix governing how the field varies over the mesh. In the case of using a simulation to generate field data, the simulation is defined with `dace_method_pointer`. In the case of using a mesh and a covariance, the form of the covariance is defined with `analytic_covariance`.

The next section of the random field model specifies the form of the expansion, `expansion_form`. This can be either a Karhunen-Loeve expansion or a Principal components analysis. These are very similar: both involve the eigenvalues of the covariance matrix of the field data. The only difference is in the treatment of the estimation of the coefficients of the eigenvector basis functions. In the PCA case, we have developed an approach which makes the coefficients explicit functions of the uncertain variables used to generate the random field. The specification of the random field can also include the number of bases to retain or a truncation tolerance, which defines the percent variance that the expansion should capture.

The final section of the random field model allows the user to specify a pointer to a model over which the random field will be propagated, meaning the model which will be driven with the random field input. This part of the specification is optional: one can build a random field but not use it in a downstream model.

Examples

As stated above, this is an emerging capability. The syntax currently looks like the following:

```
random_field
  build_source
    rf_data_file | dace_method_pointer | analytic_covariance
```

```

expansion_form
  karhunen_loeve | principal_components
  expansion_bases
  truncation_tolerance
propagation_model_pointer
    
```

build_source

- [Keywords Area](#)
- [model](#)
- [random_field](#)
- [build_source](#)

Specify how the random field will be built: from a data file, from simulation runs, or from a covariance matrix. THIS IS AN EXPERIMENTAL CAPABILITY.

Specification

 Argument(s): none
 Child Keywords:

	Required/ Optional Required(<i>Choose One</i>)	Description of Group Build Data Source (Group 1)	Dakota Keyword rf_data_file	Dakota Keyword Description Specify that the random field will be built from a file of data. THIS IS AN EXPERIMENTAL CAPABILITY.
			dace_method_pointer	Pointer to a DACE method for purposes of generating an ensemble of field responses to be used in estimating a random field model. THIS IS AN EXPERIMENTAL CAPABILITY.

			analytic_covariance	Use an analytic covariance function for the purposes of generating a random field model. THIS IS AN EXPERIMENTAL CAPABILITY.
--	--	--	-------------------------------------	--

Description

As part of the capability to generate a random field representation, the user needs to specify the data used to generate the random field representation. This data may reside in a data file, it may be generated by running a set of simulations and generating field responses, or it may be generated by a covariance matrix defined over a mesh. THIS IS AN EXPERIMENTAL CAPABILITY UNDER ACTIVE DEVELOPMENT.

Default Behavior Currently, the `build_source` that is fully working is the `dace_method_pointer`. The others are not fully operational.

`rf_data_file`

- [Keywords Area](#)
- [model](#)
- [random_field](#)
- [build_source](#)
- [rf_data_file](#)

Specify that the random field will be built from a file of data. THIS IS AN EXPERIMENTAL CAPABILITY.

Specification

Alias: none

Argument(s): STRING

Default: none

Description

As part of the capability to generate a random field representation, the user needs to specify the data used to generate the random field representation. In the case of `rf_data_file`, the data should reside in that file. The rows of this file represent separate samples, and the columns represent the field data. For example, if you have 100 samples of a random field of length 500, the data file will be of dimension 100 x 500. Currently, this option is not operational. THIS IS AN EXPERIMENTAL CAPABILITY UNDER ACTIVE DEVELOPMENT.

Default Behavior Currently, the `build_source` that is fully working is the `dace_method_pointer`. The others are not fully operational.

dace_method_pointer

- [Keywords Area](#)
- [model](#)
- [random_field](#)
- [build_source](#)
- [dace_method_pointer](#)

Pointer to a DACE method for purposes of generating an ensemble of field responses to be used in estimating a random field model. THIS IS AN EXPERIMENTAL CAPABILITY.

Specification

Alias: none

Argument(s): STRING

Default: no design of experiments data

Description

As part of the capability to generate a random field representation, the user needs to specify the data used to generate the random field representation. One way to do this is to run a set of simulations and generating field responses. Dakota will then take the full set of field responses (e.g. multiple samples, where each sample has a field response) and construct a random field model representing the uncertainty in the ensemble. The `dace_method_pointer` is a pointer to a Design and Analysis of Computer Experiments (DACE) method, typically which is a sampling method. In this case, the sampling method should be on a simulation which can generate field responses (e.g. `field_responses`, `field_objectives`, or `field_calibration` terms.)

THIS IS AN EXPERIMENTAL CAPABILITY UNDER ACTIVE DEVELOPMENT.

Default Behavior Currently, the `build_source` that is fully working is the `dace_method_pointer`. The others are not fully operational.

analytic_covariance

- [Keywords Area](#)

Argument(s): none

Description

THIS IS AN EXPERIMENTAL CAPABILITY UNDER ACTIVE DEVELOPMENT.

Default Behavior The default expansion form is Karhunen-Loeve.

principal_components

- [Keywords Area](#)
- [model](#)
- [random_field](#)
- [expansion_form](#)
- [principal_components](#)

Specify Principal Components as the form of the expansion to be used in the random field representation. THIS IS AN EXPERIMENTAL CAPABILITY.

Specification

Alias: none

Argument(s): none

Description

Principal Components and Karhunen-Loeve are very similar functional forms of the expansion. They both use basis functions which are eigenvectors of the covariance matrix of the random field data. However, in principal components, we parameterize the coefficients of the expansion to be Gaussian process models which are functions of the uncertain parameters used to generate the initial ensemble of data representing the random field. THIS IS AN EXPERIMENTAL CAPABILITY UNDER ACTIVE DEVELOPMENT.

Default Behavior The default expansion form is Karhunen-Loeve.

expansion_bases

- [Keywords Area](#)
- [model](#)
- [random_field](#)
- [expansion_bases](#)

Specify the number of basis functions to be used in the random field representation. THIS IS AN EXPERIMENTAL CAPABILITY.

Specification

Alias: none

Argument(s): INTEGER

Description

This control allows the user to specify the number of basis functions to be used in the random field representation (e.g. either a Karhunen-Loeve or Principal Components expansion). Typically, a small number of basis functions (3-5) will be sufficient to represent a significant amount of the variance in the response field. However, this depends on the particulars of the problem. THIS IS AN EXPERIMENTAL CAPABILITY UNDER ACTIVE DEVELOPMENT.

Default Behavior If the user specifies neither `truncation_tolerance` nor `expansion_bases`, then the number of expansion bases that captures 95% of the variance will be used.

`truncation_tolerance`

- [Keywords Area](#)
- [model](#)
- [random_field](#)
- [truncation_tolerance](#)

Specify a percent of the response variance that should be captured with the random field representation. THIS IS AN EXPERIMENTAL CAPABILITY.

Specification

Alias: none

Argument(s): REAL

Description

This control allows the user to specify the percent variance to be capture in the random field representation (e.g. either a Karhunen-Loeve or Principal Components expansion). Typically, the user would specify something like 0.9 or 0.95, where 0.9 means that 90% of the variance of the response field will be captured by the random field. THIS IS AN EXPERIMENTAL CAPABILITY UNDER ACTIVE DEVELOPMENT.

Default Behavior If the user specifies neither `truncation_tolerance` nor `expansion_bases`, then the truncation tolerance is set to 0.95 and the number of expansion bases that captures 95% of the variance will be used.

`propagation_model_pointer`

- [Keywords Area](#)
- [model](#)
- [random_field](#)
- [propagation_model_pointer](#)

Pointer to the model that will accept realizations of the random field and use them for subsequent analysis. Typically, this model will take the random field as inputs, e.g. a random field defining a pressure boundary or temperature boundary condition over a structure. THIS IS AN EXPERIMENTAL CAPABILITY.

Specification

Alias: none

Argument(s): STRING

Description

After a random field representation has been generated, Dakota will generate samples of that random field based on the representation. These sample realizations can then be used to drive another set of simulation analyses. The `propagation_model_pointer` is the model on which the random field realizations will be propagated. THIS IS AN EXPERIMENTAL CAPABILITY UNDER ACTIVE DEVELOPMENT.

Default Behavior

7.3.8 variables_pointer

- [Keywords Area](#)
- [model](#)
- [variables_pointer](#)

Specify which variables block will be included with this model block

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: model use of last variables parsed

Description

The `variables_pointer` is used to specify which variables block will be used by the model, by cross-referencing with `id_variables` keyword in the `variables` block.

See [block_pointer](#) for details about pointers.

Default Behavior

When a variables pointer is not specified, the model will use the last variables block parsed from the input file.

7.3.9 responses_pointer

- [Keywords Area](#)
- [model](#)
- [responses_pointer](#)

Specify which reponses block will be used by this model block

Topics

This keyword is related to the topics:

- [block_pointer](#)

Specification

Alias: none

Argument(s): STRING

Default: model use of last responses parsed

Description

The `responses_pointer` is used to specify which responses block will be used by the model, by cross-referencing with `id_responses` keyword in the `responses` block.

See [block_pointer](#) for details about pointers.

Default Behavior

When a responses pointer is not specified, the model will use the last responses block parsed from the input file.

7.3.10 hierarchical_tagging

- [Keywords Area](#)
- [model](#)
- [hierarchical_tagging](#)

Enables hierarchical evaluation tagging

Specification

Alias: none

Argument(s): none

Default: no hierarchical tagging

Description

The hierarchical tagging option is useful for studies involving multiple models with a nested or hierarchical relationship. For example a nested model has a sub-method, which itself likely operates on a sub-model, or a hierarchical approximation involves coordination of low and high fidelity models. Specifying `hierarchical_tagging` will yield function evaluation identifiers ("tags") composed of the evaluation IDs of the models involved, e.g., `outermodel.innermodel.interfaceid = 4.9.2`. This communicates the outer contexts to the analysis driver when performing a function evaluation.

Examples

`test/dakota_uq_timeseries_ivp_optinterf.in` `test/dakota_uq_timeseries_sop_optinterf.in`

	Optional	<code>linear_equality_- scale_types</code>	Specify how each linear equality constraint is scaled
	Optional	<code>linear_equality_- scales</code>	Define the characteristic values to scale linear equalities

Description

The `variables` specification in a Dakota input file specifies the parameter set to be iterated by a particular method. In the case of

- An optimization study: These variables are adjusted in order to locate an optimal design.
- Parameter studies/sensitivity analysis/design of experiments: These parameters are perturbed to explore the parameter space.

- **Uncertainty analysis:** The variables are associated with distribution/interval characterizations which are used to compute corresponding distribution/interval characterizations for response functions.

To accommodate these different studies, Dakota supports different:

- **Variable types**
 - design
 - aleatory uncertain
 - epistemic uncertain
 - state
- **Variable domains**
 - continuous
 - discrete
 - * discrete range
 - * discrete integer set
 - * discrete string set
 - * discrete real set

Use the [variables](#) page to browse the available variables by type and domain.

Variable Types

- **Design Variables**
 - Design variables are those variables which are modified for the purposes of seeking an optimal design.
 - The most common type of design variables encountered in engineering applications are of the continuous type. These variables may assume any real value within their bounds.
 - All but a handful of the optimization algorithms in Dakota support continuous design variables exclusively.
- **Aleatory Uncertain Variables**
 - Aleatory uncertainty is also known as inherent variability, irreducible uncertainty, or randomness.
 - Aleatory uncertainty is predominantly characterized using probability theory. This is the only option implemented in Dakota.
- **Epistemic Uncertain Variables**
 - Epistemic uncertainty is uncertainty due to lack of knowledge.
 - In Dakota, epistemic uncertainty is assessed by interval analysis or the Dempster-Shafer theory of evidence
 - Continuous or discrete interval or set-valued variables are used to define set-valued probabilities or basic probability assignments (BPA) which define a belief structure.
 - Note that epistemic uncertainty can also be modeled with probability density functions (as done with aleatory uncertainty). Dakota does not support this capability.
- **State Variables**

- State variables consist of "other" variables which are to be mapped through the simulation interface, in that they are not to be used for design and they are not modeled as being uncertain.
- State variables provide a convenient mechanism for managing additional model parameterizations such as mesh density, simulation convergence tolerances, and time step controls.
- Only parameter studies and design of experiments methods will iterate on state variables.
- The `initial_value` is used as the only value for the state variable for all other methods, unless `active_state` is invoked.
- See more details on the [state_variables](#) page.

Variable Domains

Continuous variables are typically defined by bounds. Discrete variables can be defined in one of three ways, which are discussed on the page [discrete_variables](#).

Ordering of Variables

The ordering of variables is important, and a consistent ordering is employed throughout the Dakota software. The ordering is shown in `dakota.input.summary` (and in the hierarchical order of this reference manual) and can be summarized as:

1. design
 - (a) continuous
 - (b) discrete integer
 - (c) discrete string
 - (d) discrete real
2. aleatory uncertain
 - (a) continuous
 - (b) discrete integer
 - (c) discrete string
 - (d) discrete real
3. epistemic uncertain
 - (a) continuous
 - (b) discrete integer
 - (c) discrete string
 - (d) discrete real
4. state
 - (a) continuous
 - (b) discrete integer
 - (c) discrete string
 - (d) discrete real

Ordering of variable types below this granularity (e.g., from normal to histogram bin within aleatory uncertain - continuous) is defined somewhat arbitrarily, but is enforced consistently throughout the code.

Active Variables

The reason variable types exist is that methods have the capability to treat variable types differently. All methods have default behavior that determines which variable types are "active" and will be assigned values by the method. For example, optimization methods will only vary the design variables - by default.

The default behavior should be described on each method page, or on topics pages that relate to classes of methods. In addition, the default behavior can be modified using the [active](#) keyword.

At least one type of variables that are active for the method in use must have nonzero size (at least 1 active variable) or an input error message will result.

Inferred Default Values and Bounds

The concept of active variables allows any Dakota variable type to be used in any method context. Some methods, e.g., bound-constrained optimization or multi-dimensional or centered parameter studies, require bounds and/or an initial point on the variables, however uncertain variables may not be naturally defined in terms of these characteristics.

Distribution lower and upper bounds are explicit portions of the normal, lognormal, uniform, loguniform, triangular, and beta specifications, whereas they are implicitly defined for others. For example, bounds are naturally defined for histogram bin, histogram point, and interval variables (from the extreme values within the bin/point/interval specifications) as well as for binomial (0 to `num_trials`) and hypergeometric (0 to `min(num_drawn, num_selected)`) variables.

If not specified, distribution bounds are also inferred for normal and lognormal (if optional bounds are unspecified) as well as for exponential, gamma, gumbel, frechet, weibull, poisson, negative binomial, and geometric (which have no bounds specifications); these bounds are $[0, \mu + 3\sigma]$ for exponential, gamma, frechet, weibull, poisson, negative binomial, geometric, and unspecified lognormal, and $[\mu - 3\sigma, \mu + 3\sigma]$ for gumbel and unspecified normal.

When an initial point is needed, uncertain variables are initialized to their means, where mean values for bounded normal and bounded lognormal may be further adjusted to satisfy any user-specified distribution bounds, mean values for discrete integer range distributions are rounded down to the nearest integer, and mean values for discrete set distributions are rounded to the nearest set value.

Examples

Several examples follow. In the first example, two continuous design variables are specified:

```
variables,
  continuous_design = 2
  initial_point      0.9    1.1
  upper_bounds      5.8    2.9
  lower_bounds      0.5   -2.9
  descriptors       'radius' 'location'
```

In the next example, defaults are employed. In this case, `initial_point` will default to a vector of 0. values, `upper_bounds` will default to vector values of `DBL_MAX` (the maximum number representable in double precision for a particular platform), `lower_bounds` will default to a vector of `-DBL_MAX` values, and `descriptors` will default to a vector of `'cdv_i'` strings, where `i` ranges from one to two:

```
variables,
  continuous_design = 2
```

In the following example, the syntax for a normal-lognormal distribution is shown. One normal and one lognormal uncertain variable are completely specified by their means and standard deviations. In addition, the dependence structure between the two variables is specified using the `uncertain_correlation_matrix`.

```

variables,
  normal_uncertain    = 1
  means               = 1.0
  std_deviations      = 1.0
  descriptors         = 'TF1n'
  lognormal_uncertain = 1
  means               = 2.0
  std_deviations      = 0.5
  descriptors         = 'TF21n'
  uncertain_correlation_matrix = 1.0 0.2
                                0.2 1.0

```

An example of the syntax for a state variables specification follows:

```

variables,
  continuous_state = 1
  initial_state    = 4.0
  lower_bounds     = 0.0
  upper_bounds     = 8.0
  descriptors      = 'CS1'
  discrete_state_range = 1
  initial_state    = 104
  lower_bounds     = 100
  upper_bounds     = 110
  descriptors      = 'DS1'

```

And in a more advanced example, a variables specification containing a set identifier, continuous and discrete design variables, normal and uniform uncertain variables, and continuous and discrete state variables is shown:

```

variables,
  id_variables = 'V1'
  continuous_design = 2
  initial_point  = 0.9 1.1
  upper_bounds  = 5.8 2.9
  lower_bounds  = 0.5 -2.9
  descriptors   = 'radius' 'location'
  discrete_design_range = 1
  initial_point  = 2
  upper_bounds  = 1
  lower_bounds  = 3
  descriptors   = 'material'
  normal_uncertain = 2
  means          = 248.89, 593.33
  std_deviations = 12.4, 29.7
  descriptors    = 'TF1n' 'TF2n'
  uniform_uncertain = 2
  lower_bounds   = 199.3, 474.63
  upper_bounds   = 298.5, 712.
  descriptors    = 'TF1u' 'TF2u'
  continuous_state = 2
  initial_state  = 1.e-4 1.e-6
  descriptors    = 'EPSIT1' 'EPSIT2'
  discrete_state_set
    integer = 1
    initial_state = 100
    set_values   = 100 212 375
    descriptors  = 'load_case'

```

7.4.1 id_variables

- [Keywords Area](#)

- [variables](#)
- [id_variables](#)

Name the variables block; helpful when there are multiple

Topics

This keyword is related to the topics:

- [block_identifier](#)

Specification

Alias: none

Argument(s): STRING

Default: use of last variables parsed

Description

The optional `id_variables` keyword accepts a string that uniquely identifies this variables block. A model can then use these variables by specifying the same string in its `variables_pointer` specification.

Default Behavior

If the `id_variables` specification is omitted, a particular variables specification will be used by a model only if that model does not include an `variables_pointer` and the variables block was the last (or only) one parsed.

Usage Tips

- It is a best practice to always use explicit variables IDs and pointers to avoid confusion.
- If only one variables block exists, then `id_variables` can be safely omitted from the variables block (and `variables_pointer` omitted from the model specification(s)), since there is no ambiguity.

Examples

For example, a model specification including

```
model
  variables_pointer = 'V1'
```

will link to a response set with

```
  id_variables = 'V1'
```

7.4.2 active

- [Keywords Area](#)
- [variables](#)
- [active](#)

Set the active variables view a method will see

Specification

Alias: none

Argument(s): none

Default: Infer from response or method specification

Child Keywords:

	Required/- Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			all	Option for the active keyword
	Required(<i>Choose One</i>)	Active Variables (Group 1)	design	Option for the active keyword
			uncertain	Option for the active keyword
			aleatory	Option for the active keyword
			epistemic	Option for the active keyword
			state	Option for the active keyword

Description

There are certain situations where the user may want to explicitly control the subset of variables that is considered active for a certain Dakota method. This is done by specifying the keyword `active` in the variables specification block, followed by one of the following: `all`, `design`, `uncertain`, `aleatory`, `epistemic`, or `state`.

Specifying one of these subsets of variables will allow the Dakota method to operate on the specified variable types and override the default active subset.

If the user does not specify any explicit override of the active view of the variables, Dakota first considers the response function specification.

- If the user specifies objective functions or calibration terms in the response specification block, then we can infer that the active variables should be the design variables (since design variables are used within optimization and least squares methods).
- If the user instead specifies the generic response type of `response_functions`, then Dakota cannot infer the active variable subset from the response specification and will instead infer it from the method selection.
 1. If the method is a parameter study, or any of the methods available under `dace`, `psuade`, or `fsu` methods, the active view is set to all variables.
 2. For uncertainty quantification methods, if the method is `sampling`, then the view is set to `aleatory` if only aleatory variables are present, `epistemic` if only epistemic variables are present, or `uncertain` (covering both aleatory and epistemic) if both are present.
 3. If the uncertainty method involves interval estimation or evidence calculations, the view is set to `epistemic`.
 4. For other uncertainty quantification methods not mentioned in the previous sentences (e.g., reliability methods or stochastic expansion methods), the default view is set to `aleatory`.
 5. Finally, for verification studies using the Richardson extrapolation method, the active view is set to `state`.

6. Note that in surrogate-based optimization, where the surrogate is built on points defined by the method defined by the `dace_method_pointer`, the sampling used to generate the points is performed only over the design variables as a default unless otherwise specified (e.g. state variables will not be sampled for surrogate construction).

As alluded to in the previous section, the iterative method selected for use in Dakota determines what subset, or view, of the variables data is active in the iteration. The general case of having a mixture of various different types of variables is supported within all of the Dakota methods even though certain methods will only modify certain types of variables (e.g., optimizers and least squares methods only modify design variables, and uncertainty quantification methods typically only utilize uncertain variables). This implies that variables which are not under the direct control of a particular iterator will be mapped through the interface in an unmodified state. This allows for a variety of parameterizations within the model in addition to those which are being used by a particular iterator, which can provide the convenience of consolidating the control over various modeling parameters in a single file (the Dakota input file). An important related point is that the variable set that is active with a particular iterator is the same variable set for which derivatives are typically computed.

Examples

For example, the default behavior for a nondeterministic sampling method is to sample the uncertain variables. However, if the user specified `active all` in the variables specification block, the sampling would be performed over all variables (e.g. design and state variables in addition to the uncertain variables). This may be desired in situations such as surrogate-based optimization under uncertainty, where a surrogate may be constructed to span both design and uncertain variables. This is an example where we expand the active subset beyond the default, but in other situations, we may wish to restrict from the default. An example of this would be performing design of experiments in the presence of multiple variable types (for which all types are active by default), but only wanting to sample over the design variables for purposes of constructing a surrogate model for optimization.

Theory

The optional status of the different variable type specifications allows the user to specify only those variables which are present (rather than explicitly specifying that the number of a particular type of variables is zero). However, at least one type of variables that are active for the iterator in use must have nonzero size or an input error message will result.

7.4.3 mixed

- [Keywords Area](#)
- [variables](#)
- [mixed](#)

Maintain continuous/discrete variable distinction

Specification

Alias: none

Argument(s): none

Default: relaxed (branch and bound), mixed (all other methods)

Description

The variables domain specifies how the discrete variables are treated. If the user specifies `mixed` in the variable specification block, the continuous and discrete variables are treated separately. If the user specifies `relaxed` in the variable specification block, the discrete variables are relaxed and treated as continuous variables. This may be useful in optimization problems involving both continuous and discrete variables when a user would like to use an optimization method that is designed for continuous variable optimization. All Dakota methods have a default value of `mixed` for the domain type except for the branch-and-bound method which has a default domain type of `relaxed`. Note that the branch-and-bound method is under development at this time. Finally, note that the domain selection applies to all variable types: design, aleatory uncertain, epistemic uncertain, and state.

With respect to domain type, if the user does not specify an explicit override of `mixed` or `relaxed`, Dakota infers the domain type from the method. As mentioned above, all methods currently use a `mixed` domain as a default, except the branch-and-bound method which is under development.

- [continuous_design](#)
- [scale_types](#)

Specify scaling for the variables

Specification

Alias: `cdv_scale_types`

Argument(s): STRINGLIST

Default: `vector values = 'none'`

Description

For continuous variables, the `scale_types` specification includes strings specifying the scaling type for each component of the continuous design variables vector in methods that support scaling, when scaling is enabled.

Each entry in `scale_types` may be selected from `'none'`, `'value'`, `'auto'`, or `'log'`, to select no, characteristic value, automatic, or logarithmic scaling, respectively. If a single string is specified it will apply to all components of the continuous design variables vector. Each entry in `scales` may be a user-specified nonzero real characteristic value to be used in scaling each variable component. These values are ignored for scaling type `'none'`, required for `'value'`, and optional for `'auto'` and `'log'`. If a single real value is specified it will apply to all components of the continuous design variables vector.

Examples

Two continuous design variables, one scaled by a value, the other log scaled,

```
continuous_design = 2
  initial_point    -1.2      1.0
  lower_bounds     -2.0      0.001
  upper_bounds     2.0       2.0
  descriptors      'x1'     "x2"
  scale_types =    'value'  'log'
  scales =         4.0      0.1
```

scales

- [Keywords Area](#)
- [variables](#)
- [continuous_design](#)
- [scales](#)

Specify scaling for the variable.

Specification

Alias: `cdv_scales`

Argument(s): REALLIST

Default: vector values = 1 . (no scaling)

Description

For continuous variables, the `scale_types` specification includes strings specifying the scaling type for each component of the continuous design variables vector in methods that support scaling, when scaling is enabled. Each entry in `scale_types` may be selected from `'none'`, `'value'`, `'auto'`, or `'log'`, to select no, characteristic value, automatic, or logarithmic scaling, respectively. If a single string is specified it will apply to all components of the continuous design variables vector. Each entry in `scales` may be a user-specified nonzero real characteristic value to be used in scaling each variable component. These values are ignored for scaling type `'none'`, required for `'value'`, and optional for `'auto'` and `'log'`. If a single real value is specified it will apply to all components of the continuous design variables vector.

Examples

Two continuous design variables, both scaled by the characteristic value 4.0

```
continuous_design = 2
  initial_point    -1.2      1.0
  lower_bounds    -200      0.001
  upper_bounds     200      2.0
  descriptors      'x1'     "x2"
  scale_types     'value' 'none'
  scales = 10.0
```

descriptors

- [Keywords Area](#)
- [variables](#)
- [continuous_design](#)
- [descriptors](#)

Labels for the variables

Specification

Alias: `cdv_descriptors`

Argument(s): STRINGLIST

Default: `cdv_{i}`

Description

The optional variable labels specification `descriptors` is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

7.4.6 `discrete_design_range`

- [Keywords Area](#)
- [variables](#)
- [discrete_design_range](#)

Design variable - discrete range-valued

Topics

This keyword is related to the topics:

- [discrete_variables](#)
- [design_variables](#)

Specification

Alias: none

Argument(s): INTEGER

Default: no discrete design variables

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		initial_point	Initial values
	Optional		lower_bounds	Specify minimum values
	Optional		upper_bounds	Specify maximum values
	Optional		descriptors	Labels for the variables

Description

These variables take on a range of integer values from the specified lower bound to the specified upper bound (integer interval). The details of how to specify this discrete variable are located on the [discrete_variables](#) page.

initial_point

- [Keywords Area](#)
- [variables](#)
- [discrete_design_range](#)
- [initial_point](#)

Initial values

Specification

Alias: ddv_initial_point

Argument(s): INTEGERLIST

Default: 0

Description

The `initial_point` specifications provide the point in design space (variable values) from which an iterator is started. These default to the midpoint of bounds (continuous design variables) or the middle value (discrete design variables).

lower_bounds

- [Keywords Area](#)
- [variables](#)
- [discrete_design_range](#)
- [lower_bounds](#)

Specify minimum values

Specification

Alias: ddv_lower_bounds

Argument(s): INTEGERLIST

Default: INT_MIN

Description

Specify minimum values

upper_bounds

- [Keywords Area](#)
- [variables](#)
- [discrete_design_range](#)
- [upper_bounds](#)

Specify maximum values

Specification

Alias: ddv_upper_bounds

Argument(s): INTEGERLIST

Default: INT_MAX

Description

Specify maximum values

descriptors

- [Keywords Area](#)
- [variables](#)
- [discrete_design_range](#)
- [descriptors](#)

Labels for the variables

Specification

Alias: `ddv_descriptors`

Argument(s): STRINGLIST

Default: `ddriv_{i}`

Description

The optional variable labels specification `descriptors` is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

7.4.7 `discrete_design_set`

- [Keywords Area](#)
- [variables](#)
- [discrete_design_set](#)

Design variable - discrete set-valued

Topics

This keyword is related to the topics:

- [discrete_variables](#)
- [design_variables](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		integer	Integer-valued discrete design variables
	Optional		string	String-valued discrete design set variables

	Optional	real	Real-valued discrete design variables
--	-----------------	----------------------	---------------------------------------

Description

Discrete design variables whose values come from a set of admissible elements. Each variable specified must be of type integer, string, or real.

integer

- [Keywords Area](#)
- [variables](#)
- [discrete_design_set](#)
- [integer](#)

Integer-valued discrete design variables

Topics

This keyword is related to the topics:

- [discrete_variables](#)
- [design_variables](#)

Specification

Alias: none

Argument(s): INTEGER

Default: no discrete design set integer variables

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			elements_per_- variable	Number of admissible elements for each set variable
	Required		elements	The permissible values for each discrete variable

	Optional	categorical	Whether the set-valued variables are categorical or relaxable
	Optional	initial_point	Initial values
	Optional	descriptors	Labels for the variables

Description

A design variable whose values come from a specified set of admissible integers. The details of how to specify this discrete variable are located on the [discrete_variables](#) page.

Examples

Four integer variables whose values will be selected from the following sets during the search for an optimal design. $y_1 \in \{0, 1\}$, $y_2 \in \{0, 1\}$, $y_3 \in \{0, 5\}$ and $y_4 \in \{10, 15, 20, 23\}$.

```
discrete_design_set
integer 4
  descriptors      'y1'  'y2'  'y3'  'y4'
  elements_per_variable 2    2    2    4
  elements         0 1    0 1    0 5    10 15 20 23
```

elements_per_variable

- [Keywords Area](#)
- [variables](#)
- [discrete_design_set](#)
- [integer](#)
- [elements_per_variable](#)

Number of admissible elements for each set variable

Specification

Alias: num_set_values

Argument(s): INTEGERLIST

Default: equal distribution

Description

Discrete set variables (including design, uncertain, and state) take on only a fixed set of values. For each type (integer, string, or real), this keyword specifies how many admissible values are provided for each variable. If not specified, equal apportionment of elements among variables is assumed, and the number of elements must be evenly divisible by the number of variables.

elements

- [Keywords Area](#)
- [variables](#)
- [discrete_design_set](#)
- [integer](#)
- [elements](#)

The permissible values for each discrete variable

Specification

Alias: set_values

Argument(s): INTEGERLIST

Description

Specify the permissible values for discrete set variables (of type integer, string, or real). See the description on the [discrete_variables](#) page.

categorical

- [Keywords Area](#)
- [variables](#)
- [discrete_design_set](#)
- [integer](#)
- [categorical](#)

Whether the set-valued variables are categorical or relaxable

Specification

Alias: none

Argument(s): STRINGLIST

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword adjacency_matrix	Dakota Keyword Description 1-0 matrix defining which categorical variable levels are related.

Description

A list of strings of length equal to the number of set (integer, string, or real) variables indicating whether they are strictly categorical, meaning may only take on values from the provided set, or relaxable, meaning may take on any integer or real value between the lowest and highest specified element. Valid categorical strings include 'yes', 'no', 'true', and 'false', or any abbreviation in [yYnNtTff][.]*

Examples

Discrete_design_set variable, 'rotor_blades', can take on only integer values, 2, 4, or 7 by default. Since categorical is specified to be false, the integrality can be relaxed and 'rotor_blades' can take on any value between 2 and 7, e.g., 3, 6, or 5.5.

```
discrete_design_set
  integer 1
    elements 2 4 7
  descriptor 'rotor_blades'
  categorical 'no'
```

adjacency_matrix

- [Keywords Area](#)
- [variables](#)
- [discrete_design_set](#)
- [integer](#)
- [categorical](#)
- [adjacency_matrix](#)

1-0 matrix defining which categorical variable levels are related.

Specification

Alias: none

Argument(s): INTEGERLIST

Description

The adjacency_matrix keyword is associated with discrete_design_set variables that are specified to be categorical. Each such variable is associated with one $k \times k$ symmetric matrix, where k is the number of values (or levels) of the variable. Entry i, j of a matrix should be 1 if level i and level j are related by some subjective criteria or if $i = j$; it should be 0 otherwise. The matrices for all variables of the same type (string, real, or integer) are entered sequentially as a list of integers as shown in the examples below.

Default Behavior

The adjacency_matrix keyword is only relevant for discrete_design_set real and discrete_design_set integer variables if one or more of them have been specified to be categorical. It is always relevant for discrete_design_set string variables. If the user does not define an adjacency matrix, the default is method dependent. Currently, the only method that makes use of the adjacency matrix is [mesh_adaptive_search](#), which uses a tri-diagonal adjacency matrix by default.

Expected Output

The expected output is method dependent.

Usage Tips

If an adjacency matrix is defined for one type of (categorical) `discrete_design_set` variable, it must be defined for all variables of that type, even for those not defined to be categorical. Those for the non-categorical set variables will be ignored.

Examples

The following example shows a variables specification where some real and some integer `discrete_design_set` variables are categorical.

```
variables
  continuous_design = 3
    initial_point -1.0  1.5  2.0
    lower_bounds -10.0 -10.0 -10.0
    upper_bounds 10.0  10.0  10.0
    descriptors  'x1'  'x2'  'x3'
  discrete_design_range = 2
    initial_point 2  2
    lower_bounds  1  1
    upper_bounds  4  9
    descriptors  'y1'  'y2'
  discrete_design_set
    real = 2
      elements_per_variable = 4 5
      elements = 1.2 2.3 3.4 4.5 1.2 3.3 4.4 5.5 7.7
      descriptors  'y3'  'y4'
      categorical  'no'  'yes'
      adjacency_matrix 1 1 0 0 # Begin entry of 4x4 matrix for y3
                      1 1 1 0
                      0 1 1 1
                      0 0 1 1
                      1 0 1 0 1 # Begin entry of 5x5 matrix for y4
                      0 1 0 1 0
                      1 0 1 0 1
                      0 1 0 1 0
                      1 0 1 0 1
    integer = 2
      elements_per_variable = 2 3
      elements = 4 7 8 9 12
      descriptors  'z1'  'z2'
      categorical  'yes' 'yes'
```

Note that for the real case, the user wants to define an adjacency matrix for the categorical variable, so adjacency matrices for both variables must be specified. The matrix for the first one will be ignored. Note that no adjacency matrix is specified for either integer categorical variable. The default will be used in both cases. Currently the only method taking advantage of adjacency matrices is `mesh_adaptive_search`, which uses a tri-diagonal adjacency matrix by default. Thus, the matrices used would be

```
z1: 1 1
     1 1
z2: 1 1 0
     1 1 1
     0 1 1
```

The following example shows a variables specification for string variables. Note that string variables are always considered to be categorical. If an adjacency matrix is not specified, a method-dependent default matrix will be used.

```

variables,
  continuous_design = 2
  initial_point 0.5 0.5
  lower_bounds 0. 0.
  upper_bounds 1. 1.
  descriptors = 'x' 'y'
discrete_design_set string = 1
  elements = 'aniso1' 'aniso2' 'iso1' 'iso2' 'iso3'
  descriptors = 'ancomp'
adjacency_matrix 1 1 0 0 0
                  1 1 0 0 0
                  0 0 1 1 1
                  0 0 1 1 1
                  0 0 1 1 1

```

- [Keywords Area](#)
- [variables](#)
- [discrete_design_set](#)
- [string](#)
- [adjacency_matrix](#)

1-0 matrix defining which categorical variable levels are related.

Specification

Alias: none

Argument(s): INTEGERLIST

Description

The `adjacency_matrix` keyword is associated with `discrete_design_set` variables that are specified to be categorical. Each such variable is associated with one $k \times k$ symmetric matrix, where k is the number of values (or levels) of the variable. Entry i, j of a matrix should be 1 if level i and level j are related by some subjective criteria or if $i = j$; it should be 0 otherwise. The matrices for all variables of the same type (string, real, or integer) are entered sequentially as a list of integers as shown in the examples below.

Default Behavior

The `adjacency_matrix` keyword is only relevant for `discrete_design_set` real and `discrete_design_set` integer variables if one or more of them have been specified to be categorical. It is always relevant for `discrete_design_set` string variables. If the user does not define an adjacency matrix, the default is method dependent. Currently, the only method that makes use of the adjacency matrix is [mesh_adaptive_search](#), which uses a tri-diagonal adjacency matrix by default.

Expected Output

The expected output is method dependent.

Usage Tips

If an adjacency matrix is defined for one type of (categorical) `discrete_design_set` variable, it must be defined for all variables of that type, even for those not defined to be categorical. Those for the non-categorical set variables will be ignored.

Examples

The following example shows a variables specification where some real and some integer `discrete_design_set` variables are categorical.

```
variables
  continuous_design = 3
    initial_point  -1.0   1.5   2.0
    lower_bounds  -10.0 -10.0 -10.0
    upper_bounds   10.0  10.0  10.0
    descriptors    'x1'  'x2'  'x3'
  discrete_design_range = 2
    initial_point  2     2
    lower_bounds   1     1
    upper_bounds   4     9
    descriptors    'y1'  'y2'
  discrete_design_set
    real = 2
      elements_per_variable = 4 5
      elements = 1.2 2.3 3.4 4.5 1.2 3.3 4.4 5.5 7.7
      descriptors    'y3'          'y4'
      categorical    'no'          'yes'
      adjacency_matrix 1 1 0 0 # Begin entry of 4x4 matrix for y3
                      1 1 1 0
                      0 1 1 1
                      0 0 1 1
                      1 0 1 0 1 # Begin entry of 5x5 matrix for y4
                      0 1 0 1 0
                      1 0 1 0 1
                      0 1 0 1 0
                      1 0 1 0 1
    integer = 2
      elements_per_variable = 2 3
      elements = 4 7 8 9 12
      descriptors    'z1'  'z2'
      categorical    'yes'  'yes'
```

Note that for the real case, the user wants to define an adjacency matrix for the categorical variable, so adjacency matrices for both variables must be specified. The matrix for the first one will be ignored. Note that no adjacency matrix is specified for either integer categorical variable. The default will be used in both cases. Currently the only method taking advantage of adjacency matrices is `mesh_adaptive_search`, which uses a tri-diagonal adjacency matrix by default. Thus, the matrices used would be

```
z1: 1 1
    1 1
z2: 1 1 0
    1 1 1
    0 1 1
```

The following example shows a variables specification for string variables. Note that string variables are always considered to be categorical. If an adjacency matrix is not specified, a method-dependent default matrix will be used.

```
variables,
  continuous_design = 2
  initial_point 0.5 0.5
  lower_bounds 0. 0.
  upper_bounds 1. 1.
  descriptors = 'x' 'y'
  discrete_design_set string = 1
  elements = 'aniso1' 'aniso2' 'iso1' 'iso2' 'iso3'
  descriptors = 'ancomp'
  adjacency_matrix 1 1 0 0 0
                  1 1 0 0 0
                  0 0 1 1 1
                  0 0 1 1 1
                  0 0 1 1 1
```

adjacency_matrix

- [Keywords Area](#)
- [variables](#)
- [discrete_design_set](#)
- [real](#)
- [categorical](#)
- [adjacency_matrix](#)

1-0 matrix defining which categorical variable levels are related.

Specification

Alias: none

Argument(s): INTEGERLIST

Description

The `adjacency_matrix` keyword is associated with `discrete_design_set` variables that are specified to be categorical. Each such variable is associated with one $k \times k$ symmetric matrix, where k is the number of values (or levels) of the variable. Entry i, j of a matrix should be 1 if level i and level j are related by some subjective criteria or if $i = j$; it should be 0 otherwise. The matrices for all variables of the same type (string, real, or integer) are entered sequentially as a list of integers as shown in the examples below.

Default Behavior

The `adjacency_matrix` keyword is only relevant for `discrete_design_set` real and `discrete_design_set` integer variables if one or more of them have been specified to be categorical. It is always relevant for `discrete_design_set` string variables. If the user does not define an adjacency matrix, the default is method dependent. Currently, the only method that makes use of the adjacency matrix is [mesh_adaptive_search](#), which uses a tri-diagonal adjacency matrix by default.

Expected Output

The expected output is method dependent.

Usage Tips

If an adjacency matrix is defined for one type of (categorical) `discrete_design_set` variable, it must be defined for all variables of that type, even for those not defined to be categorical. Those for the non-categorical set variables will be ignored.

Examples

The following example shows a variables specification where some real and some integer `discrete_design_set` variables are categorical.

```
variables
  continuous_design = 3
    initial_point  -1.0   1.5   2.0
    lower_bounds  -10.0 -10.0 -10.0
    upper_bounds   10.0  10.0  10.0
    descriptors    'x1'  'x2'  'x3'
  discrete_design_range = 2
    initial_point  2     2
    lower_bounds   1     1
    upper_bounds   4     9
    descriptors    'y1'  'y2'
  discrete_design_set
    real = 2
      elements_per_variable = 4 5
      elements = 1.2 2.3 3.4 4.5 1.2 3.3 4.4 5.5 7.7
      descriptors    'y3'          'y4'
      categorical    'no'          'yes'
      adjacency_matrix 1 1 0 0 # Begin entry of 4x4 matrix for y3
                      1 1 1 0
                      0 1 1 1
                      0 0 1 1
                      1 0 1 0 1 # Begin entry of 5x5 matrix for y4
                      0 1 0 1 0
                      1 0 1 0 1
                      0 1 0 1 0
                      1 0 1 0 1
    integer = 2
      elements_per_variable = 2 3
      elements = 4 7 8 9 12
      descriptors    'z1'  'z2'
      categorical    'yes'  'yes'
```

Note that for the real case, the user wants to define an adjacency matrix for the categorical variable, so adjacency matrices for both variables must be specified. The matrix for the first one will be ignored. Note that no adjacency matrix is specified for either integer categorical variable. The default will be used in both cases. Currently the only method taking advantage of adjacency matrices is `mesh_adaptive_search`, which uses a tri-diagonal adjacency matrix by default. Thus, the matrices used would be

```
z1: 1 1
    1 1
z2: 1 1 0
    1 1 1
    0 1 1
```

The following example shows a variables specification for string variables. Note that string variables are always considered to be categorical. If an adjacency matrix is not specified, a method-dependent default matrix will be used.

```
variables,
  continuous_design = 2
  initial_point 0.5 0.5
  lower_bounds 0. 0.
  upper_bounds 1. 1.
  descriptors = 'x' 'y'
  discrete_design_set string = 1
  elements = 'aniso1' 'aniso2' 'iso1' 'iso2' 'iso3'
  descriptors = 'ancomp'
  adjacency_matrix 1 1 0 0 0
                  1 1 0 0 0
                  0 0 1 1 1
                  0 0 1 1 1
                  0 0 1 1 1
```

- [variables](#)
- [normal_uncertain](#)

Aleatory uncertain variable - normal (Gaussian)

Topics

This keyword is related to the topics:

- [continuous_variables](#)
- [aleatory_uncertain_variables](#)

Specification

Alias: none

Argument(s): INTEGER

Default: no normal uncertain variables

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required		means	First parameter of the distribution
	Required		std_deviations	Second parameter of the distribution
	Optional		lower_bounds	Specify minimum values
	Optional		upper_bounds	Specify maximum values
	Optional		initial_point	Initial values
	Optional		descriptors	Labels for the variables

Description

Within the normal uncertain optional group specification, the number of normal uncertain variables, the means, and standard deviations are required specifications, and the distribution lower and upper bounds and variable descriptors are optional specifications. The normal distribution is widely used to model uncertain variables such as population characteristics. It is also used to model the mean of a sample: as the sample size becomes very large, the Central Limit Theorem states that the distribution of the mean becomes approximately normal, regardless of the distribution of the original variables.

The density function for the normal distribution is:

$$f(x) = \frac{1}{\sqrt{2\pi}\sigma_N} e^{-\frac{1}{2}\left(\frac{x-\mu_N}{\sigma_N}\right)^2}$$

where μ_N and σ_N are the mean and standard deviation of the normal distribution, respectively.

Note that if you specify bounds for a normal distribution, the sampling occurs from the underlying distribution with the given mean and standard deviation, but samples are not taken outside the bounds (see "bounded normal" distribution type in[92]). This can result in the mean and the standard deviation of the sample data being different from the mean and standard deviation of the underlying distribution. For example, if you are sampling from a normal distribution with a mean of 5 and a standard deviation of 3, but you specify bounds of 1 and 7, the resulting mean of the samples will be around 4.3 and the resulting standard deviation will be around 1.6. This is because you have bounded the original distribution significantly, and asymmetrically, since 7 is closer to the original mean than 1.

Theory

When used with design of experiments and multidimensional parameter studies, distribution bounds are inferred. These bounds are $[\mu - 3\sigma, \mu + 3\sigma]$

For vector and centered parameter studies, an inferred initial starting point is needed for the uncertain variables. These variables are initialized to their means for these studies.

means

The optional variable labels specification `descriptors` is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

7.4.9 lognormal_uncertain

- [Keywords Area](#)
- [variables](#)
- [lognormal_uncertain](#)

Aleatory uncertain variable - lognormal

Topics

This keyword is related to the topics:

- [continuous_variables](#)
- [aleatory_uncertain_variables](#)

Specification

Alias: none

Argument(s): INTEGER

Default: no lognormal uncertain variables

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description

	Required(Choose One)	Lognormal Characterization (Group 1)	lambdas	First parameter of the lognormal distribution (option 3)
			means	First parameter of the lognormal distribution (options 1 & 2)
	Optional		lower_bounds	Specify minimum values
	Optional		upper_bounds	Specify maximum values
	Optional		initial_point	Initial values
	Optional		descriptors	Labels for the variables

Description

If the logarithm of an uncertain variable X has a normal distribution, that is $\log X \sim N(\mu, \sigma)$, then X is distributed with a lognormal distribution. The lognormal is often used to model:

1. time to perform some task
2. variables which are the product of a large number of other quantities, by the Central Limit Theorem
3. quantities which cannot have negative values.

Within the lognormal uncertain optional group specification, the number of lognormal uncertain variables, the means, and either standard deviations or error factors must be specified, and the distribution lower and upper bounds and variable descriptors are optional specifications. These distribution bounds can be used to truncate the tails of lognormal distributions, which as for bounded normal, can result in the mean and the standard deviation of the sample data being different from the mean and standard deviation of the underlying distribution (see "bounded lognormal" and "bounded lognormal-n" distribution types in [92]).

For the lognormal variables, one may specify either the mean μ and standard deviation σ of the actual lognormal distribution (option 1), the mean μ and error factor ϵ of the actual lognormal distribution (option 2), or the mean λ ("lambda") and standard deviation ζ ("zeta") of the underlying normal distribution (option 3).

The conversion equations from lognormal mean μ and either lognormal error factor ϵ or lognormal standard deviation σ to the mean λ and standard deviation ζ of the underlying normal distribution are as follows:

$$\zeta = \frac{\ln(\epsilon)}{1.645}$$

$$\zeta^2 = \ln\left(\frac{\sigma^2}{\mu^2} + 1\right)$$

$$\lambda = \ln(\mu) - \frac{\zeta^2}{2}$$

Conversions from λ and ζ back to μ and ϵ or σ are as follows:

$$\mu = e^{\lambda + \frac{\zeta^2}{2}}$$

$$\sigma^2 = e^{2\lambda + \zeta^2} (e^{\zeta^2} - 1)$$

$$\epsilon = e^{1.645\zeta}$$

The density function for the lognormal distribution is:

$$f(x) = \frac{1}{\sqrt{2\pi}\zeta x} e^{-\frac{1}{2}\left(\frac{\ln x - \lambda}{\zeta}\right)^2}$$

Theory

When used with design of experiments and multidimensional parameter studies, distribution bounds are inferred. These bounds are $[0, \mu + 3\sigma]$.

For vector and centered parameter studies, an inferred initial starting point is needed for the uncertain variables. These variables are initialized to their means for these studies.

lambdas

Specification

Alias: none

Argument(s): INTEGER

Default: no triangular uncertain variables

Child Keywords:

	Required/ Optional Required	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required		modes	Distribution parameter
	Required		lower_bounds	Specify minimum values
	Required		upper_bounds	Specify maximum values
	Optional		initial_point	Initial values
	Optional		descriptors	Labels for the variables

Description

The triangular distribution is often used when one does not have much data or information, but does have an estimate of the most likely value and the lower and upper bounds. Within the triangular uncertain optional group specification, the number of triangular uncertain variables, the modes, and the distribution lower and upper bounds are required specifications, and variable descriptors is an optional specification.

The density function for the triangular distribution is:

$$f(x) = \frac{2(x - L_T)}{(U_T - L_T)(M_T - L_T)}$$

if $L_T \leq x \leq M_T$, and

$$f(x) = \frac{2(U_T - x)}{(U_T - L_T)(U_T - M_T)}$$

if $M_T \leq x \leq U_T$, and 0 elsewhere. In these equations, L_T is the lower bound, U_T is the upper bound, and M_T is the mode of the triangular distribution.

- [variables](#)
- [exponential_uncertain](#)

Aleatory uncertain variable - exponential

Topics

This keyword is related to the topics:

- [continuous_variables](#)
- [aleatory_uncertain_variables](#)

Specification

Alias: none

Argument(s): INTEGER

Default: no exponential uncertain variables

Child Keywords:

	Required/ Optional Required	Description of Group	Dakota Keyword	Dakota Keyword Description
			betas	Parameter of the exponential distribution
	Optional		initial_point	Initial values
	Optional		descriptors	Labels for the variables

Description

The exponential distribution is often used for modeling failure rates.

The density function for the exponential distribution is given by:

$$f(x) = \frac{1}{\beta} e^{-\frac{x}{\beta}}$$

where $\mu_E = \beta$ and $\sigma_E^2 = \beta^2$.

Note that this distribution is a special case of the more general gamma distribution.

Theory

When used with design of experiments and multidimensional parameter studies, distribution bounds are inferred. These bounds are $[0, \mu + 3\sigma]$.

For vector and centered parameter studies, an inferred initial starting point is needed for the uncertain variables. These variables are initialized to their means for these studies.

	Required	betas	Second parameter of the beta distribution
	Required	lower_bounds	Specify minimum values
	Required	upper_bounds	Specify maximum values
	Optional	initial_point	Initial values
	Optional	descriptors	Labels for the variables

Description

Within the beta uncertain optional group specification, the number of beta uncertain variables, the alpha and beta parameters, and the distribution upper and lower bounds are required specifications, and the variable descriptors is an optional specification. The beta distribution can be helpful when the actual distribution of an uncertain variable is unknown, but the user has a good idea of the bounds, the mean, and the standard deviation of the uncertain variable. The density function for the beta distribution is

$$f(x) = \frac{\Gamma(\alpha + \beta)}{\Gamma(\alpha)\Gamma(\beta)} \frac{(x - L_B)^{\alpha-1}(U_B - x)^{\beta-1}}{(U_B - L_B)^{\alpha+\beta-1}}$$

where $\Gamma(\alpha)$ is the gamma function and $B(\alpha, \beta) = \frac{\Gamma(\alpha)\Gamma(\beta)}{\Gamma(\alpha+\beta)}$ is the beta function. To calculate the mean and standard deviation from the alpha, beta, upper bound, and lower bound parameters of the beta distribution, the following expressions may be used.

$$\mu_B = L_B + \frac{\alpha}{\alpha + \beta}(U_B - L_B)$$

$$\sigma_B^2 = \frac{\alpha\beta}{(\alpha + \beta)^2(\alpha + \beta + 1)}(U_B - L_B)^2$$

Solving these for α and β gives:

$$\alpha = (\mu_B - L_B) \frac{(\mu_B - L_B)(U_B - \mu_B) - \sigma_B^2}{\sigma_B^2(U_B - L_B)}$$

$$\beta = (U_B - \mu_B) \frac{(\mu_B - L_B)(U_B - \mu_B) - \sigma_B^2}{\sigma_B^2(U_B - L_B)}$$

Note that the uniform distribution is a special case of this distribution for parameters $\alpha = \beta = 1$.

Theory

For vector and centered parameter studies, an inferred initial starting point is needed for the uncertain variables. These variables are initialized to their means for these studies.

alphas

- [Keywords Area](#)
- [variables](#)
- [beta_uncertain](#)

	Required	alphas	First parameter of the gamma distribution
	Required	betas	Second parameter of the gamma distribution
	Optional	initial_point	Initial values
	Optional	descriptors	Labels for the variables

Description

The gamma distribution is sometimes used to model time to complete a task, such as a repair or service task. It is a very flexible distribution with its shape governed by alpha and beta.

The density function for the gamma distribution is given by:

$$f(x) = \frac{x^{\alpha-1} e^{-\frac{x}{\beta}}}{\beta^{\alpha} \Gamma(\alpha)}$$

where $\mu_{GA} = \alpha\beta$ and $\sigma_{GA}^2 = \alpha\beta^2$. Note that the exponential distribution is a special case of this distribution for parameter $\alpha = 1$.

Theory

When used with design of experiments and multidimensional parameter studies, distribution bounds are inferred. These bounds are $[0, \mu + 3\sigma]$.

For vector and centered parameter studies, an inferred initial starting point is needed for the uncertain variables. These variables are initialized to their means for these studies.

	Required		betas	Second parameter of the gumbel distribution
	Optional		initial_point	Initial values
	Optional		descriptors	Labels for the variables

Description

The Gumbel distribution is also referred to as the Type I Largest Extreme Value distribution. The distribution of maxima in sample sets from a population with a normal distribution will asymptotically converge to this distribution. It is commonly used to model demand variables such as wind loads and flood levels.

The density function for the Gumbel distribution is given by:

$$f(x) = \alpha e^{-\alpha(x-\beta)} \exp(-e^{-\alpha(x-\beta)})$$

where $\mu_{GU} = \beta + \frac{0.5772}{\alpha}$ and $\sigma_{GU} = \frac{\pi}{\sqrt{6}\alpha}$.

Theory

When used with design of experiments and multidimensional parameter studies, distribution bounds are inferred. These bounds are $[\mu - 3\sigma, \mu + 3\sigma]$

For vector and centered parameter studies, an inferred initial starting point is needed for the uncertain variables. These variables are initialized to their means for these studies.

7.4.19 histogram_bin_uncertain

- [Keywords Area](#)
- [variables](#)
- [histogram_bin_uncertain](#)

Aleatory uncertain variable - continuous histogram

Topics

This keyword is related to the topics:

- [continuous_variables](#)
- [aleatory_uncertain_variables](#)

Specification

Alias: none

Argument(s): INTEGER

Default: no histogram bin uncertain variables

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description

	Optional		pairs_per_variable	Number of pairs defining each histogram bin variable
	Required		abscissas	Real abscissas for a bin histogram
	Required (<i>Choose One</i>)	Density Values (Group 1)	ordinates	Ordinates specifying a "skyline" probability density function
			counts	Frequency or relative probability of each bin
	Optional		initial_point	Initial values
	Optional		descriptors	Labels for the variables

Description

Histogram uncertain variables are typically used to model a set of empirical data. The bin histogram (contrast: [histogram_point_uncertain](#)) is a continuous aleatory distribution characterized by bins of non-zero width where the uncertain variable may lie, together with the relative frequencies of each bin. Hence it can be used to specify a marginal probability density function arising from data.

The `histogram_bin_uncertain` keyword specifies the number of variables to be characterized as continuous histograms. The required sub-keywords are: [abscissas](#) (ranges of values the variable can take on) and either [ordinates](#) or [counts](#) (characterizing each variable's frequency information). When using histogram bin variables, each variable must be defined by at least one bin (with two bounding value pairs). When more than one histogram bin variable is active, [pairs_per_variable](#) can be used to specify unequal apportionment of provided bin pairs among the variables.

The [abscissas](#) specification defines abscissa values ("x" coordinates) for the probability density function of each histogram variable. When paired with [counts](#), the specifications provide sets of (x,c) pairs for each histogram variable where c defines a count (i.e., a frequency or relative probability) associated with a bin. If using bins of unequal width and specification of probability densities is more natural, then the [counts](#) specification can be replaced with an [ordinates](#) specification ("y" coordinates) in order to support interpretation of the input as (x,y) pairs defining the profile of a "skyline" probability density function.

Conversion between the two specifications is straightforward: a count/frequency is a cumulative probability quantity defined from the product of the ordinate density value and the x bin width. Thus, in the cases of bins of equal width, ordinate and count specifications are equivalent. In addition, ordinates and counts may be relative values; it is not necessary to scale them as all user inputs will be normalized.

To fully specify a bin-based histogram with n bins (potentially of unequal width), n+1 (x,c) or (x,y) pairs must be specified with the following features:

- x is the parameter value for the left boundary of a histogram bin and c is the corresponding count for that

bin. Alternatively, y defines the ordinate density value for this bin within a skyline probability density function. The right boundary of the bin is defined by the left boundary of the next pair.

- the final pair specifies the right end of the last bin and must have a c or y value of zero.
- the x values must be strictly increasing.
- all c or y values must be positive, except for the last which must be zero.
- a minimum of two pairs must be specified for each bin-based histogram variable.

Examples

The `pairs_per_variable` specification provides for the proper association of multiple sets of (x,c) or (x,y) pairs with individual histogram variables. For example, in this input snippet

```

histogram_bin_uncertain = 2
pairs_per_variable = 3      4
abscissas      = 5  8  10   .1 .2 .3 .4
counts         = 17 21  0    12 24 12 0
descriptors    = 'hbu_1'   'hbu_2'
```

`pairs_per_variable` associates the first 3 (x,c) pairs from `abscissas` and `counts` $\{(5,17),(8,21),(10,0)\}$ with one bin-based histogram variable, where one bin is defined between 5 and 8 with a count of 17 and another bin is defined between 8 and 10 with a count of 21. The following set of 4 (x,c) pairs $\{(.1,12),(.2,24),(.3,12),(.4,0)\}$ defines a second bin-based histogram variable containing three equal-width bins with counts 12, 24, and 12 (middle bin is twice as probable as the other two).

- [histogram_point_uncertain](#)

FAQ

Difference between bin and point histograms: A (continuous) bin histogram specifies bins of non-zero width, whereas a (discrete) point histogram specifies individual point values, which can be thought of as bins with zero width. In the terminology of LHS[92], the bin pairs specification defines a "continuous linear" distribution and the point pairs specification defines a "discrete histogram" distribution (although the points are real-valued, the number of possible values is finite).

`pairs_per_variable`

- [Keywords Area](#)
- [variables](#)
- [histogram_bin_uncertain](#)
- [pairs_per_variable](#)

Number of pairs defining each histogram bin variable

Specification

Alias: num_pairs

Argument(s): INTEGERLIST

Default: equal distribution

Description

By default, the list of `abscissas` and `counts` or `ordinates` will be evenly divided among the `histogram-bin-uncertain` variables. `pairs_per_variable` is a list of integers that specify the number of pairs to apportion to each variable.

abscissas

- [Keywords Area](#)

- [poisson_uncertain](#)

Aleatory uncertain discrete variable - Poisson

Topics

This keyword is related to the topics:

- [discrete_variables](#)
- [aleatory_uncertain_variables](#)

Specification

Alias: none

Argument(s): INTEGER

Default: no poisson uncertain variables

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description

	Required	lambdas	The parameter for the Poisson distribution, the expected number of events in the time interval of interest
	Optional	initial_point	Initial values
	Optional	descriptors	Labels for the variables

Description

The Poisson distribution is used to predict the number of discrete events that happen in a single time interval. The random events occur uniformly and independently. The expected number of occurrences in a single time interval is λ , which must be a positive real number. For example, if events occur on average 4 times per year and we are interested in the distribution of events over six months, λ would be 2. However, if we were interested in the distribution of events occurring over 5 years, λ would be 20.

The density function for the poisson distribution is given by:

$$f(x) = \frac{\lambda e^{-\lambda}}{x!}$$

where

- λ is the expected number of events occurring in a single time interval - x is the number of events that occur in this time period - $f(x)$ is the probability that x events occur in this time period

Theory

When used with design of experiments and multidimensional parameter studies, distribution bounds are inferred. These bounds are $[0, \mu + 3\sigma]$.

For vector and centered parameter studies, an inferred initial starting point is needed for the uncertain variables. These variables are initialized to their means for these studies.

Argument(s): INTEGER

Default: no binomial uncertain variables

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required		probability_per_- trial	A distribution parameter for the binomial distribution
	Required		num_trials	A distribution parameter
	Optional		initial_point	Initial values
	Optional		descriptors	Labels for the variables

Description

The binomial distribution describes probabilities associated with a series of independent Bernoulli trials. A Bernoulli trial is an event with two mutually exclusive outcomes, such as 0 or 1, yes or no, success or fail. The probability of success remains the same (the trials are independent).

The density function for the binomial distribution is given by:

$$f(x) = \binom{n}{x} p^x (1-p)^{(n-x)}$$

where p is the probability of failure per trial, n is the number of trials and x is the number of successes.

Theory

The binomial distribution is typically used to predict the number of failures or defective items in a total of n independent tests or trials, where each trial has the probability p of failing or being defective.

Labels for the variables

Specification

Alias: none

Argument(s): STRINGLIST

Default: `biuv_{i}`

Description

The optional variable labels specification `descriptors` is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

7.4.22 `negative_binomial_uncertain`

- [Keywords Area](#)
- [variables](#)
- [negative_binomial_uncertain](#)

Aleatory uncertain discrete variable - negative binomial

Topics

This keyword is related to the topics:

- [discrete_variables](#)
- [aleatory_uncertain_variables](#)

Specification

Alias: none

Argument(s): INTEGER

Default: no negative binomial uncertain variables

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required		probability_per_trial	A negative binomial distribution parameter
	Required		num_trials	A negative binomial distribution parameter
	Optional		initial_point	Initial values
	Optional		descriptors	Labels for the variables

Description

The density function for the negative binomial distribution is given by:

$$f(x) = \binom{n+x-1}{x} p^n (1-p)^x$$

where

- p is the probability of success per trial
- n is the number of successful trials
- X is the number of failures

Theory

The negative binomial distribution is typically used to predict the number of failures observed when repeating a test until a total of n successes have occurred, where each test has a probability p of success.

7.4.24 hypergeometric_uncertain

- [Keywords Area](#)
- [variables](#)
- [hypergeometric_uncertain](#)

Aleatory uncertain discrete variable - hypergeometric

Topics

This keyword is related to the topics:

- [discrete_variables](#)
- [aleatory_uncertain_variables](#)

Specification

Alias: none

Argument(s): INTEGER

Default: no hypergeometric uncertain variables

Child Keywords:

	Required/ Optional Required	Description of Group	Dakota Keyword	Dakota Keyword Description
			total_population	Parameter for the hypergeometric probability distribution describing the size of the total population
	Required		selected_ population	Distribution parameter for the hypergeometric distribution describing the size of the population subset of interest

	Required	<code>num_drawn</code>	Distribution parameter for the hypergeometric distribution describing the number of draws from a combined population
	Optional	<code>initial_point</code>	Initial values
	Optional	<code>descriptors</code>	Labels for the variables

Description

The hypergeometric probability density is used when sampling without replacement from a total population of elements where

- The resulting element of each sample can be separated into one of two non-overlapping sets
- The probability of success changes with each sample.

The density function for the hypergeometric distribution is given by:

$$f(x) = \frac{\binom{m}{x} \binom{N-m}{n-x}}{\binom{N}{n}}$$

where the three distribution parameters are:

- N is the total population
- m is the number of items in the selected population (e.g. the number of white balls in the full urn of N items)
- n is the size of the sample drawn (e.g. number of balls drawn)

In addition,

- x, the abscissa of the density function, indicates the number of successes (e.g. drawing a white ball)
- $\binom{a}{b}$ indicates a binomial coefficient ("a choose b")

Theory

The hypergeometric is often described using an urn model. For example, say we have a total population containing N balls, and we know that m of the balls are white and the remaining balls are green. If we draw n balls from the urn without replacement, the hypergeometric distribution describes the probability of drawing x white balls.

total_population

7.4.25 histogram_point_uncertain

- [Keywords Area](#)
- [variables](#)
- [histogram_point_uncertain](#)

Aleatory uncertain variable - discrete histogram

Topics

This keyword is related to the topics:

- [discrete_variables](#)
- [aleatory_uncertain_variables](#)

Specification

Alias: none

Argument(s): none

Default: no histogram point uncertain variables

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			integer	Integer valued point histogram variable
	Optional		string	String (categorical) valued point histogram variable

	Optional	real	Real valued point histogram variable
--	-----------------	----------------------	--------------------------------------

Description

Histogram uncertain variables are typically used to model a set of empirical data. When the variables take on only discrete values or categories, a discrete, or point histogram is used to describe their probability mass function (one could think of this as a [histogram_bin_uncertain](#) variable with "bins" of zero width). Dakota supports integer-, string-, and real-valued point histograms.

Point histograms are similar to [discrete_design_set](#) and [discrete_state_set](#), but as they are uncertain variables, include the relative probabilities of observing the different values within the set.

The `histogram_point_uncertain` keyword is followed by one or more of `integer`, `string`, or `real`, each of which specify the number of variables to be characterized as discrete histograms of that sub-type.

Each discrete histogram variable is specified by one or more abscissa/count pairs. The `abscissas`, are the possible values the variable can take on ("x" coordinates of type integer, string, or real), and must be specified in increasing order. These are paired with `counts c` which provide the frequency of the given value or string, relative to other possible values/strings.

Thus, to fully specify a point-based histogram with n points, n (x,c) pairs must be specified with the following features:

- x is the point value (integer, string, or real) and c is the corresponding count for that value.
- the x values must be strictly increasing (lexicographically for strings).
- all c values must be positive.
- a minimum of one pair must be specified for each point-based histogram.

Examples

The `pairs_per_variable` specification provides for the proper association of multiple sets of (x,c) or (x,y) pairs with individual histogram variables. For example, in the following specification,

```

histogram_point_uncertain
  integer           = 2
  pairs_per_variable = 2   3
  abscissas         = 3 4   100 200 300
  counts            = 1 1   1   2   1

```

`pairs_per_variable` associates the (x,c) pairs $\{(3,1),(4,1)\}$ with one point-based histogram variable (where the values 3 and 4 are equally probable) and associates the (x,c) pairs $\{(100,1),(200,2),(300,1)\}$ with a second point-based histogram variable (where the value 200 is twice as probable as either 100 or 300).

See Also

These keywords may also be of interest:

- [histogram_bin_uncertain](#)

FAQ

Difference between bin and point histograms: A (continuous) bin histogram specifies bins of non-zero width, whereas a (discrete) point histogram specifies individual point values, which can be thought of as bins with zero width. In the terminology of LHS[92], the bin pairs specification defines a "continuous linear" distribution and the point pairs specification defines a "discrete histogram" distribution (although the points are real-valued, the number of possible values is finite).

integer

- [Keywords Area](#)
- [variables](#)
- [histogram_point_uncertain](#)
- [integer](#)

Integer valued point histogram variable

Specification

Alias: none

Argument(s): INTEGER

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			pairs_per_variable	Number of pairs defining each histogram point integer variable
	Required		abscissas	Integer abscissas for a point histogram
	Required		counts	Counts for integer-valued point histogram
	Optional		initial_point	Initial values
	Optional		descriptors	Labels for the variables

Description

This probability mass function is integer-valued; the abscissa values must all be integers. The n abscissa values are paired with n `counts` which indicate the relative frequency (mass) of each integer relative to the other specified integers.

Examples

```

histogram_point_uncertain
  integer = 2
  pairs_per_variable = 2      3
  abscissas      = 3 4    100 200 300
  counts         = 1 1    1   2   1

```

There are two variables, the first one has two possible integer values which are equally probable. The second one has three options, and 200 is twice as probable as either 100 or 300.

pairs_per_variable

- [Keywords Area](#)
- [variables](#)
- [histogram_point_uncertain](#)
- [integer](#)
- [pairs_per_variable](#)

Number of pairs defining each histogram point integer variable

Specification

Alias: num_pairs

Argument(s): INTEGERLIST

Default: equal distribution

Description

By default, the list of `abscissas` and `counts` will be evenly divided among the histogram point integer variables. The number of `pairs_per_variable` specifies the apportionment of abscissa/count pairs among the histogram point integer variables. It must specify one integer ≥ 1 per variable that indicates how many of the (abscissa, count) = (x,c) pairs to associate with that variable.

abscissas

- [Keywords Area](#)
- [variables](#)
- [histogram_point_uncertain](#)
- [integer](#)
- [abscissas](#)

Integer abscissas for a point histogram

Specification

Alias: none

Argument(s): INTEGERLIST

Description

A list of integer abscissa ("x" coordinate) values characterizing the probability density function for each of the integer `histogram_point_uncertain` variables. These must be listed in increasing order for each variable, and are paired with `counts`. See [histogram_point_uncertain](#) for details and examples.

counts

- [Keywords Area](#)
- [variables](#)
- [histogram_point_uncertain](#)
- [integer](#)
- [counts](#)

Counts for integer-valued point histogram

Specification

Alias: none

Argument(s): REALLIST

Description

Count or frequency for each of `abscissas`. See [histogram_point_uncertain](#) for details and examples.

initial_point

- [Keywords Area](#)
- [variables](#)
- [histogram_point_uncertain](#)
- [integer](#)
- [initial_point](#)

Initial values

Specification

Alias: none

Argument(s): INTEGERLIST

Description

The `initial_point` specifications provide the point in design space (variable values) from which an iterator is started. These default to the midpoint of bounds (continuous design variables) or the middle value (discrete design variables).

descriptors

- [Keywords Area](#)
- [variables](#)
- [histogram_point_uncertain](#)
- [integer](#)
- [descriptors](#)

Labels for the variables

Specification

Alias: none

Argument(s): STRINGLIST

Default: hpiv_{i}

Description

The optional variable labels specification `descriptors` is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

string

- [Keywords Area](#)
- [variables](#)
- [histogram_point_uncertain](#)
- [string](#)

String (categorical) valued point histogram variable

Specification

Alias: none

Argument(s): INTEGER

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			pairs_per_variable	Number of pairs defining each histogram point string variable

	Required	abscissas	String abscissas for a point histogram
	Required	counts	Counts for string-valued point histogram
	Optional	initial_point	Initial values
	Optional	descriptors	Labels for the variables

Description

This probability mass function is string-valued; the abscissa values must all be strings. The n abscissa values are paired with n `counts` which indicate the relative frequency (mass) of each string relative to the other specified strings.

Examples

```

histogram_point_uncertain
string = 2
pairs_per_variable = 2          3
abscissas          = 'no' 'yes' 'function1' 'function2' 'function3'
counts             = 1     1     1         2         1
descriptors        = 'vote'   'which_function'

```

Here there are two variables, the first one ('vote') has two possible string values 'yes' and 'no' which are equally probable. The second one has three options for 'which_function', and 'function2' is twice as probable as 'function1' or 'function3'.

`pairs_per_variable`

- [Keywords Area](#)
- [variables](#)
- [histogram_point_uncertain](#)
- [string](#)
- [pairs_per_variable](#)

Number of pairs defining each histogram point string variable

Specification

Alias: `num_pairs`

Argument(s): INTEGERLIST

Default: equal distribution

Description

By default, the list of `abscissas` and `counts` will be evenly divided among the histogram point string variables. The number of `pairs_per_variable` specifies the apportionment of abscissa/count pairs among the histogram point string variables. It must specify one integer ≥ 1 per variable that indicates how many of the (abscissa, count) = (x,c) pairs to associate with that variable.

abscissas

- [Keywords Area](#)
- [variables](#)
- [histogram_point_uncertain](#)
- [string](#)
- [abscissas](#)

String abscissas for a point histogram

Specification

Alias: none

Argument(s): STRINGLIST

Description

A list of string abscissa ("x" coordinate) values characterizing the probability density function for each of the string `histogram_point_uncertain` variables. These must be listed in (lexicographically) increasing order for each variable, and are paired with `counts`. See [histogram_point_uncertain](#) for details and examples.

counts

- [Keywords Area](#)
- [variables](#)
- [histogram_point_uncertain](#)
- [string](#)
- [counts](#)

Counts for string-valued point histogram

Specification

Alias: none

Argument(s): REALLIST

Description

Count or frequency for each of `abscissas`. See [histogram_point_uncertain](#) for details and examples.

initial_point

- [Keywords Area](#)
- [variables](#)
- [histogram_point_uncertain](#)
- [string](#)
- [initial_point](#)

Initial values

Specification

Alias: none

Argument(s): STRINGLIST

Description

The `initial_point` specifications provide the point in design space (variable values) from which an iterator is started. These default to the midpoint of bounds (continuous design variables) or the middle value (discrete design variables).

descriptors

- [Keywords Area](#)
- [variables](#)
- [histogram_point_uncertain](#)
- [string](#)
- [descriptors](#)

Labels for the variables

Specification

Alias: none

Argument(s): STRINGLIST

Default: `hpsv_{i}`

Description

The optional variable labels specification `descriptors` is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

real

- [Keywords Area](#)
- [variables](#)
- [histogram_point_uncertain](#)
- [real](#)

Real valued point histogram variable

Specification

Alias: none

Argument(s): INTEGER

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			pairs_per_variable	Number of pairs defining each histogram point real variable
	Required		abscissas	Real abscissas for a point histogram
	Required		counts	Counts for real-valued point histogram
	Optional		initial_point	Initial values
	Optional		descriptors	Labels for the variables

Description

This probability mass function is real-valued; the abscissa values must all be integers. The n abscissa values are paired with n `counts` which indicate the relative frequency (mass) of each real relative to the other specified reals.

Examples

```

histogram_point_uncertain
  real = 2
  pairs_per_variable = 2           3
  abscissas          = 3.1415 4.5389 100 200.112345 300
  counts              = 1       1       1   2       1

```

There are two variables, the first one has two possible real values which are equally probable. The second one has three possible real value options, and 200.112345 is twice as probable as either 100 or 300.

pairs_per_variable

- [Keywords Area](#)

Argument(s): REALLIST

Description

Count or frequency for each of [abscissas](#). See [histogram_point_uncertain](#) for details and examples.

initial_point

- [Keywords Area](#)
- [variables](#)
- [histogram_point_uncertain](#)
- [real](#)
- [initial_point](#)

Initial values

Specification

Alias: none

Argument(s): REALLIST

Description

The `initial_point` specifications provide the point in design space (variable values) from which an iterator is started. These default to the midpoint of bounds (continuous design variables) or the middle value (discrete design variables).

descriptors

- [Keywords Area](#)
- [variables](#)
- [histogram_point_uncertain](#)
- [real](#)
- [descriptors](#)

Labels for the variables

Specification

Alias: none

Argument(s): STRINGLIST

Default: hpruv_{i}

Description

The optional variable labels specification `descriptors` is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

7.4.26 uncertain_correlation_matrix

- [Keywords Area](#)
- [variables](#)
- [uncertain_correlation_matrix](#)

Correlation among aleatory uncertain variables

Specification

Alias: none

Argument(s): REALLIST

Default: identity matrix (uncorrelated)

Description

Aleatory uncertain variables may have correlations specified through use of an `uncertain_correlation_matrix` specification. This specification is generalized in the sense that its specific meaning depends on the nondeterministic method in use.

When the method is a nondeterministic sampling method (i.e., [sampling](#)), then the correlation matrix specifies *rank correlations* [52].

When the method is a reliability (i.e., `local_reliability` or `global_reliability`) or stochastic expansion (i.e., `polynomial_chaos` or `stoch_collocation`) method, then the correlation matrix specifies *correlation coefficients* (normalized covariance)[42].

In either of these cases, specifying the identity matrix results in uncorrelated uncertain variables (the default). The matrix input should be symmetric and have all n^2 entries where n is the total number of aleatory uncertain variables.

Ordering of the aleatory uncertain variables is:

1. normal
2. lognormal
3. uniform
4. loguniform
5. triangular
6. exponential
7. beta
8. gamma
9. gumbel
10. frechet
11. weibull
12. histogram bin
13. poisson
14. binomial
15. negative binomial
16. geometric
17. hypergeometric
18. histogram point

When additional variable types are activated, they assume uniform distributions, and the ordering is as listed on [variables](#).

Examples

Consider the following random variables, distributions and correlations:

- X_1 , normal, uncorrelated with others
- X_2 , normal, correlated with X_3 , X_4 and X_5
- X_3 , weibull, correlated with X_5
- X_4 , exponential, correlated with X_3 , X_4 and X_5
- X_5 , normal, correlated with X_5 These correlations are captured by the following commands (order of the variables is respected).

```
uncertain_correlation_matrix
# ordering normal, exponential, weibull
# \f$X_1\f$ \f$X_2\f$ \f$X_5\f$ \f$X_4\f$ \f$X_3\f$
1.00 0.00 0.00 0.00 0.00
0.00 1.00 0.50 0.24 0.78
0.00 0.50 1.00 0.00 0.20
0.00 0.24 0.00 1.00 0.49
0.00 0.78 0.20 0.49 1.0
```

7.4.27 continuous_interval_uncertain

- [Keywords Area](#)

This keyword is related to the topics:

- [continuous_variables](#)
- [epistemic_uncertain_variables](#)

Specification

Alias: interval_uncertain

Argument(s): INTEGER

Default: no continuous interval uncertain variables

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			num_intervals	Specify the number of intervals for each variable
	Optional		interval_probabilities	Assign probability mass to each interval
	Required		lower_bounds	Specify minimum values
	Required		upper_bounds	Specify maximum values
	Optional		initial_point	Initial values

	Optional	descriptors	Labels for the variables
--	-----------------	-----------------------------	--------------------------

Description

Continuous interval uncertain variables are epistemic types. They can specify a single interval per variable which may be used in interval analysis, where the goal is to determine the interval bounds on the output corresponding to the interval bounds on the input. All values between the bounds are permissible. More detailed continuous interval representations can specify a set of belief structures based on intervals that may be contiguous, overlapping, or disjoint. This is used in specifying the inputs necessary for an epistemic uncertainty analysis using Dempster-Shafer theory of evidence.

Other epistemic types include:

- [discrete_interval_uncertain](#)
- `discrete_uncertain_set` [integer](#)
- `discrete_uncertain_set` [string](#)
- `discrete_uncertain_set` [real](#)

Examples

The following specification is for an interval analysis:

```
continuous_interval_uncertain = 2
lower_bounds = 2.0 4.0
upper_bounds = 2.5 5.0
```

The following specification is for a Dempster-Shafer analysis:

```
continuous_interval_uncertain = 2
num_intervals = 3 2
interval_probs = 0.25 0.5 0.25 0.4 0.6
lower_bounds = 2.0 4.0 4.5 1.0 3.0
upper_bounds = 2.5 5.0 6.0 5.0 5.0
```

Here there are 2 interval uncertain variables. The first one is defined by three intervals, and the second by two intervals. The three intervals for the first variable have basic probability assignments of 0.2, 0.5, and 0.3, respectively, while the basic probability assignments for the two intervals for the second variable are 0.4 and 0.6. The basic probability assignments for each interval variable must sum to one. The interval bounds for the first variable are [2, 2.5], [4, 5], and [4.5, 6], and the interval bounds for the second variable are [1.0, 5.0] and [3.0, 5.0]. Note that the intervals can be overlapping or disjoint. The BPA for the first variable indicates that it is twice as likely that the value occurs on the interval [4,5] than either [2,2.5] or [4.5,6].

Theory

The continuous interval uncertain variable is NOT a probability distribution. Although it may seem similar to a histogram, the interpretation of this uncertain variable is different. It is used in epistemic uncertainty analysis, where one is trying to model uncertainty due to lack of knowledge. The continuous interval uncertain variable is used in both interval analysis and in Dempster-Shafer theory of evidence.

- interval analysis -only one interval is allowed for each `continuous_interval_uncertain` variable
-the interval is defined by lower and upper bounds -the value of the random variable lies somewhere in this interval -output is the minimum and maximum function value conditional on the specified interval

- Dempster-Shafer theory of evidence -multiple intervals can be assigned to each `continuous_interval_uncertain` variable -a Basic Probability Assignment (BPA) is associated with each interval. The BPA represents a probability that the value of the uncertain variable is located within that interval. -each interval is defined by lower and upper bounds -outputs are called "belief" and "plausibility." Belief represents the smallest possible probability that is consistent with the evidence, while plausibility represents the largest possible probability that is consistent with the evidence. Evidence is the intervals together with their BPA.

num_intervals

- [Keywords Area](#)
- [variables](#)
- [continuous_interval_uncertain](#)
- [num_intervals](#)

Specify the number of intervals for each variable

Specification

Alias: `iuv_num_intervals`

Argument(s): INTEGERLIST

Default: Equal apportionment of intervals among variables

Description

In Dakota, epistemic uncertainty analysis is performed using either interval estimation or Dempster-Shafer theory of evidence. In these approaches, one does not assign a probability distribution to each uncertain input variable. Rather, one divides each uncertain input variable into one or more intervals. The input parameters are only known to occur within intervals; nothing more is assumed. `num_intervals` specifies the number of such intervals associated with each interval uncertain parameter.

interval_probabilities

- [Keywords Area](#)
- [variables](#)
- [continuous_interval_uncertain](#)
- [interval_probabilities](#)

Assign probability mass to each interval

Specification

Alias: `interval_probs` `iuv_interval_probs`

Argument(s): REALLIST

Default: Equal probability assignments for each interval ($1/\text{num_intervals}[i]$)

Description

The basic probability assignments for each interval variable must sum to one. For example, if an interval variable is defined with three intervals, the probabilities for these intervals could be 0.2, 0.5, and 0.3 which sum to one, but could not be 0.5,0.5, and 0.5 which do not sum to one.

lower_bounds

- [Keywords Area](#)

initial_point

- [Keywords Area](#)
- [variables](#)
- [continuous_interval_uncertain](#)
- [initial_point](#)

Initial values

Specification

Alias: none

Argument(s): REALLIST

Description

The `initial_point` specifications provide the point in design space (variable values) from which an iterator is started. These default to the midpoint of bounds (continuous design variables) or the middle value (discrete design variables).

descriptors

- [Keywords Area](#)
- [variables](#)
- [continuous_interval_uncertain](#)
- [descriptors](#)

Labels for the variables

Specification

Alias: `iuv_descriptors`

Argument(s): STRINGLIST

Default: `ciuv_{i}`

Description

The optional variable labels specification `descriptors` is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

7.4.28 discrete_interval_uncertain

- [Keywords Area](#)
- [variables](#)
- [discrete_interval_uncertain](#)

Epistemic uncertain variable - values from one or more discrete intervals

Topics

This keyword is related to the topics:

- [discrete_variables](#)
- [epistemic_uncertain_variables](#)

Specification

Alias: none

Argument(s): INTEGER

Default: No discrete interval uncertain variables

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		num_intervals	Specify the number of intervals for each variable
	Optional		interval_-probabilities	Assign probability mass to each interval
	Required		lower_bounds	Specify minimum values
	Required		upper_bounds	Specify maximum values
	Optional		initial_point	Initial values
	Optional		descriptors	Labels for the variables

Description

Discrete interval uncertain variables are epistemic types. They can specify a single interval per variable which may be used in interval analysis, where the goal is to determine the interval bounds on the output corresponding to the interval bounds on the input. Permissible values are any integer within the bound. More detailed continuous interval representations can specify a set of belief structures based on intervals that may be contiguous, overlapping, or disjoint. This is used in specifying the inputs necessary for an epistemic uncertainty analysis using Dempster-Shafer theory of evidence.

Other epistemic types include:

- [continuous_interval_uncertain](#)
- [discrete_uncertain_set](#) [integer](#)
- [discrete_uncertain_set](#) [string](#)
- [discrete_uncertain_set](#) [real](#)

Examples

Let d1 be 2, 3 or 4 with probability 0.2, 4 or 5 with probability 0.5 and 6 with probability 0.3. Let d2 be 4, 5 or 6 with probability 0.4 and 6, 7 or 8 with probability 0.6. The following specification is for a Dempster-Shafer analysis:

```
discrete_interval_uncertain = 2
num_intervals = 3 2
interval_probs = 0.2 0.5 0.3 0.4 0.6
lower_bounds = 2 4 6 4 6
upper_bounds = 4 5 6 6 8
```

Theory

- Dempster-Shafer theory of evidence -multiple intervals can be assigned to each `discrete_interval_uncertain` variable -a Basic Probability Assignment (BPA) is associated with each interval. The BPA represents a probability that the value of the uncertain variable is located within that interval. -each interval is defined by lower and upper bounds -outputs are called "belief" and "plausibility." Belief represents the smallest possible probability that is consistent with the evidence, while plausibility represents the largest possible probability that is consistent with the evidence. Evidence is the intervals together with their BPA.

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			integer	Discrete, epistemic uncertain variable - integers within a set
	Optional		string	Discrete, epistemic uncertain variable - strings within a set
	Optional		real	Discrete, epistemic uncertain variable - real numbers within a set

Description

Discrete uncertain variables whose values come from a set of admissible elements. Each variable specified must be of type integer, string, or real.

integer

- [Keywords Area](#)
- [variables](#)
- [discrete_uncertain_set](#)
- [integer](#)

Discrete, epistemic uncertain variable - integers within a set

Topics

This keyword is related to the topics:

- [discrete_variables](#)
- [epistemic_uncertain_variables](#)

Specification

Alias: none

Argument(s): INTEGER

Default: no discrete uncertain set integer variables

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			elements_per_- variable	Number of admissible elements for each set variable
	Required		elements	The permissible values for each discrete variable
	Optional		set_probabilities	This keyword defines the probabilities for the various elements of discrete sets.
	Optional		categorical	Whether the set-valued variables are categorical or relaxable
	Optional		initial_point	Initial values
	Optional		descriptors	Labels for the variables

Description

Discrete set variables may be used to specify categorical choices which are epistemic. For example, if we have three possible forms for a physics model (model 1, 2, or 3) and there is epistemic uncertainty about which one is correct, a discrete uncertain set may be used to represent this type of uncertainty.

This variable is defined by a set of integers, in which the discrete value may take any value within the integer set (for example, the set may be defined as 1, 2, and 4)

Other epistemic types include:

- [continuous_interval_uncertain](#)
- [discrete_interval_uncertain](#)
- discrete_uncertain_set [string](#)
- discrete_uncertain_set [real](#)

Examples

Let d1 be 2 or 13 and d2 be 4, 5 or 26. The following specification is for an interval analysis:

```
discrete_uncertain_set
integer
num_set_values 2      3
set_values     2 13  4 5 26
descriptors    'd1' 'd2'
```

Theory

The `discrete_uncertain_set-integer` variable is NOT a discrete random variable. It can be contrasted to a the histogram-defined random variables: [histogram_bin_uncertain](#) and [histogram_point_uncertain](#). It is used in epistemic uncertainty analysis, where one is trying to model uncertainty due to lack of knowledge.

The discrete uncertain set integer variable is used in both interval analysis and in Dempster-Shafer theory of evidence.

- interval analysis -the values are integers, equally weighted -the true value of the random variable is one of the integers in this set -output is the minimum and maximum function value conditional on the specified inputs
- Dempster-Shafer theory of evidence -the values are integers, but they can be assigned different weights -outputs are called "belief" and "plausibility." Belief represents the smallest possible probability that is consistent with the evidence, while plausibility represents the largest possible probability that is consistent with the evidence. Evidence is the values together with their weights.

elements_per_variable

- [Keywords Area](#)
- [variables](#)
- [discrete_uncertain_set](#)
- [integer](#)
- [elements_per_variable](#)

Number of admissible elements for each set variable

Specification

Alias: num_set_values

Argument(s): INTEGERLIST

Default: equal distribution

Description

Discrete set variables (including design, uncertain, and state) take on only a fixed set of values. For each type (integer, string, or real), this keyword specifies how many admissible values are provided for each variable. If not specified, equal apportionment of elements among variables is assumed, and the number of elements must be evenly divisible by the number of variables.

elements

- [Keywords Area](#)
- [variables](#)
- [discrete_uncertain_set](#)
- [integer](#)
- [elements](#)

The permissible values for each discrete variable

Specification

Alias: set_values

Argument(s): INTEGERLIST

Description

Specify the permissible values for discrete set variables (of type integer, string, or real). See the description on the [discrete_variables](#) page.

set_probabilities

- [Keywords Area](#)
- [variables](#)
- [discrete_uncertain_set](#)
- [integer](#)
- [set_probabilities](#)

This keyword defines the probabilities for the various elements of discrete sets.

Specification

Alias: set_probs

Argument(s): REALLIST

Default: Equal probability assignments for each set member (1/num_set_values[i])

Description

There are three types of `discrete_uncertain_set` variables: integer, string, or real sets. With each of these types, one defines the number of elements of the set per that variable, the values of those elements, and the associated probabilities. For example, if one has an integer discrete uncertain set variable with 3 elements {3,4,8}, then one could define the probabilities associated with those set elements as (for example) 0.2, 0.5, and 0.3. The `set_probabilities` for a particular variable should sum to one over all the elements in that set.

categorical

- [Keywords Area](#)
- [variables](#)
- [discrete_uncertain_set](#)
- [integer](#)
- [categorical](#)

Whether the set-valued variables are categorical or relaxable

Specification

Alias: none

Argument(s): STRINGLIST

Description

A list of strings of length equal to the number of set (integer, string, or real) variables indicating whether they are strictly categorical, meaning may only take on values from the provided set, or relaxable, meaning may take on any integer or real value between the lowest and highest specified element. Valid categorical strings include 'yes', 'no', 'true', and 'false', or any abbreviation in `[yYnNtTfF][.]*`

Examples

Discrete_design_set variable, 'rotor.blades', can take on only integer values, 2, 4, or 7 by default. Since categorical is specified to be false, the integrality can be relaxed and 'rotor.blades' can take on any value between 2 and 7, e.g., 3, 6, or 5.5.

```
discrete_design_set
  integer 1
    elements 2 4 7
  descriptor 'rotor_blades'
  categorical 'no'
```

initial_point

- [Keywords Area](#)
- [variables](#)
- [discrete_uncertain_set](#)
- [integer](#)

- [initial_point](#)

Initial values

Specification

Alias: none

Argument(s): INTEGERLIST

Description

The `initial_point` specifications provide the point in design space (variable values) from which an iterator is started. These default to the midpoint of bounds (continuous design variables) or the middle value (discrete design variables).

descriptors

- [Keywords Area](#)

Argument(s): REALLIST

Description

The `initial_point` specifications provide the point in design space (variable values) from which an iterator is started. These default to the midpoint of bounds (continuous design variables) or the middle value (discrete design variables).

descriptors

- [Keywords Area](#)
- [variables](#)
- [discrete_uncertain_set](#)
- [real](#)
- [descriptors](#)

Labels for the variables

Specification

Alias: none

Argument(s): STRINGLIST

Default: `dusrv_{i}`

Description

The optional variable labels specification `descriptors` is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

7.4.30 `continuous_state`

- [Keywords Area](#)
- [variables](#)
- [continuous_state](#)

State variable - continuous

Topics

This keyword is related to the topics:

- [state_variables](#)
- [continuous_variables](#)

Specification

Alias: none

Argument(s): INTEGER

Default: No continuous state variables

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		initial_state	Initial values for the state variables
	Optional		lower_bounds	Specify minimum values
	Optional		upper_bounds	Specify maximum values
	Optional		descriptors	Labels for the variables

Description

Continuous state variables are defined by bounds.

Default behavior for most methods is that only the `initial_state` values are used.

See the [state_variables](#) page for details on the behavior of state variables.

`initial_state`

- [Keywords Area](#)
- [variables](#)
- [continuous_state](#)
- [initial_state](#)

Initial values for the state variables

Specification

Alias: `csv_initial_state`

Argument(s): REALLIST

Default: 0.0

Description

The `initial_state` specifications provide the initial values for the state variables.

This is an optional keyword. If it is not specified, the initial state will be inferred from the other keywords that define the state variable.

Defaults are:

- Continuous state variables - use the midpoint of the bounds
- Set variables - use the value with the index closest to the middle of the set
- Range variables - use the midpoint of the range

lower_bounds

- [Keywords Area](#)
- [variables](#)
- [continuous_state](#)
- [lower_bounds](#)

Specify minimum values

Specification

Alias: csv_lower_bounds

Argument(s): REALLIST

Default: -infinity

Description

Specify minimum values

upper_bounds

- [Keywords Area](#)
- [variables](#)
- [continuous_state](#)
- [upper_bounds](#)

Specify maximum values

Specification

Alias: csv_upper_bounds

Argument(s): REALLIST

Default: infinity

Description

Specify maximum values

descriptors

- [Keywords Area](#)
- [variables](#)
- [continuous_state](#)
- [descriptors](#)

Labels for the variables

Specification

Alias: csv_descriptors

Argument(s): STRINGLIST

Default: csv_{i}

Description

The optional variable labels specification `descriptors` is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

7.4.31 discrete_state_range

- [Keywords Area](#)
- [variables](#)
- [discrete_state_range](#)

State variables - discrete range-valued

Topics

This keyword is related to the topics:

- [discrete_variables](#)
- [state_variables](#)

Specification

Alias: none

Argument(s): INTEGER

Default: No discrete state variables

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			initial_state	Initial values for the state variables
	Optional		lower_bounds	Specify minimum values
	Optional		upper_bounds	Specify maximum values
	Optional		descriptors	Labels for the variables

Description

Discrete state variables defined by bounds (an integer interval).

The details of how to specify this discrete variable are located on the [discrete_variables](#) page.

See the [state_variables](#) page for details on the behavior of state variables.

initial_state

- [Keywords Area](#)
- [variables](#)
- [discrete_state_range](#)
- [initial_state](#)

Initial values for the state variables

Specification

Alias: dsv_initial_state

Argument(s): INTEGERLIST

Default: 0

Description

The `initial_state` specifications provide the initial values for the state variables.

This is an optional keyword. If it is not specified, the initial state will be inferred from the other keywords that define the state variable.

Defaults are:

- Continuous state variables - use the midpoint of the bounds
- Set variables - use the value with the index closest to the middle of the set
- Range variables - use the midpoint of the range

lower_bounds

- [Keywords Area](#)
- [variables](#)
- [discrete_state_range](#)
- [lower_bounds](#)

Specify minimum values

Specification

Alias: dsv_lower_bounds

Argument(s): INTEGERLIST

Default: INT_MIN

Description

Specify minimum values

upper_bounds

- [Keywords Area](#)
- [variables](#)
- [discrete_state_range](#)
- [upper_bounds](#)

Specify maximum values

Specification

Alias: `dsv_upper_bounds`

Argument(s): INTEGERLIST

Default: `INT_MAX`

Description

Specify maximum values

descriptors

- [Keywords Area](#)
- [variables](#)
- [discrete_state_range](#)
- [descriptors](#)

Labels for the variables

Specification

Alias: `dsv_descriptors`

Argument(s): STRINGLIST

Default: `dsriv_{i}`

Description

The optional variable labels specification `descriptors` is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

7.4.32 discrete_state_set

- [Keywords Area](#)
- [variables](#)
- [discrete_state_set](#)

State variable - discrete set-valued

Topics

This keyword is related to the topics:

- [discrete_variables](#)
- [state_variables](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			integer	Discrete state variables, each defined by a set of permissible integers
	Optional		string	String-valued discrete state set variables
	Optional		real	Discrete state variables, each defined by a set of permissible real numbers

Description

Discrete state variables whose values come from a set of admissible elements. Each variable specified must be of type integer, string, or real.

integer

- [Keywords Area](#)
- [variables](#)
- [discrete_state_set](#)
- [integer](#)

Discrete state variables, each defined by a set of permissible integers

Topics

This keyword is related to the topics:

- [discrete_variables](#)
- [state_variables](#)

Specification

Alias: none

Argument(s): INTEGER

Default: no discrete state set integer variables

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			elements_per_- variable	Number of admissible elements for each set variable
	Required		elements	The permissible values for each discrete variable
	Optional		categorical	Whether the set-valued variables are categorical or relaxable
	Optional		initial_state	Initial values for the state variables
	Optional		descriptors	Labels for the variables

Description

Discrete state variables defined by a set of permissible integers.

The details of how to specify this discrete variable are located on the [discrete_variables](#) page.

See the [state_variables](#) page for details on the behavior of state variables.

elements_per_variable

- [Keywords Area](#)
- [variables](#)
- [discrete_state_set](#)
- [integer](#)
- [elements_per_variable](#)

Number of admissible elements for each set variable

Specification

Alias: num_set_values

Argument(s): INTEGERLIST

Default: equal distribution

Description

Discrete set variables (including design, uncertain, and state) take on only a fixed set of values. For each type (integer, string, or real), this keyword specifies how many admissible values are provided for each variable. If not specified, equal apportionment of elements among variables is assumed, and the number of elements must be evenly divisible by the number of variables.

elements

- [Keywords Area](#)
- [variables](#)
- [discrete_state_set](#)
- [integer](#)
- [elements](#)

The permissible values for each discrete variable

Specification

Alias: set_values

Argument(s): INTEGERLIST

Description

Specify the permissible values for discrete set variables (of type integer, string, or real). See the description on the [discrete_variables](#) page.

categorical

- [Keywords Area](#)
- [variables](#)
- [discrete_state_set](#)
- [integer](#)
- [categorical](#)

Whether the set-valued variables are categorical or relaxable

Specification

Alias: none

Argument(s): STRINGLIST

Description

A list of strings of length equal to the number of set (integer, string, or real) variables indicating whether they are strictly categorical, meaning may only take on values from the provided set, or relaxable, meaning may take on any integer or real value between the lowest and highest specified element. Valid categorical strings include 'yes', 'no', 'true', and 'false', or any abbreviation in [yYnNtTfF][.]*

Examples

Discrete_design_set variable, 'rotor_blades', can take on only integer values, 2, 4, or 7 by default. Since categorical is specified to be false, the integrality can be relaxed and 'rotor_blades' can take on any value between 2 and 7, e.g., 3, 6, or 5.5.

```
discrete_design_set
  integer 1
    elements 2 4 7
  descriptor 'rotor_blades'
  categorical 'no'
```

initial_state

- [Keywords Area](#)
- [variables](#)
- [discrete_state_set](#)
- [integer](#)
- [initial_state](#)

Initial values for the state variables

Specification

Alias: none

Argument(s): INTEGERLIST

Default: middle set value, or rounded down

Description

The `initial_state` specifications provide the initial values for the state variables.

This is an optional keyword. If it is not specified, the initial state will be inferred from the other keywords that define the state variable.

Defaults are:

- Continuous state variables - use the midpoint of the bounds
- Set variables - use the value with the index closest to the middle of the set
- Range variables - use the midpoint of the range

descriptors

- [Keywords Area](#)
- [variables](#)
- [discrete_state_set](#)
- [integer](#)
- [descriptors](#)

Labels for the variables

Specification

Alias: none

Argument(s): STRINGLIST

Default: dssiv_{i}

Description

The optional variable labels specification `descriptors` is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

string

- [Keywords Area](#)
- [variables](#)
- [discrete_state_set](#)
- [string](#)

String-valued discrete state set variables

Topics

This keyword is related to the topics:

- [discrete_variables](#)
- [state_variables](#)

Specification

Alias: none

Argument(s): INTEGER

Default: no discrete state set string variables

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required		elements_per_- variable	Number of admissible elements for each set variable
	Optional		elements	The permissible values for each discrete variable
	Optional		initial_state	Initial values for the state variables
	Optional		descriptors	Labels for the variables

Description

Discrete state variables whose values come from a specified set of admissible strings. The details of how to specify this discrete variable are located on the [discrete_variables](#) page. See the [state_variables](#) page for details on the behavior of state variables. Each string element value must be quoted and may contain alphanumeric, dash, underscore, and colon. White space, quote characters, and backslash/metacharacters are not permitted.

elements_per_variable

- [Keywords Area](#)
- [variables](#)
- [discrete_state_set](#)
- [string](#)
- [elements_per_variable](#)

Number of admissible elements for each set variable

Specification

Alias: num_set_values

Argument(s): INTEGERLIST

Default: equal distribution

Description

Discrete set variables (including design, uncertain, and state) take on only a fixed set of values. For each type (integer, string, or real), this keyword specifies how many admissible values are provided for each variable. If not specified, equal apportionment of elements among variables is assumed, and the number of elements must be evenly divisible by the number of variables.

elements

- [Keywords Area](#)
- [variables](#)
- [discrete_state_set](#)
- [string](#)
- [elements](#)

The permissible values for each discrete variable

Specification

Alias: set_values

Argument(s): STRINGLIST

Description

Specify the permissible values for discrete set variables (of type integer, string, or real). See the description on the [discrete_variables](#) page.

initial_state

- [Keywords Area](#)
- [variables](#)
- [discrete_state_set](#)
- [string](#)
- [initial_state](#)

Initial values for the state variables

Specification

Alias: none

Argument(s): STRINGLIST

Default: middle set value, or rounded down

Description

The `initial_state` specifications provide the initial values for the state variables.

This is an optional keyword. If it is not specified, the initial state will be inferred from the other keywords that define the state variable.

Defaults are:

- Continuous state variables - use the midpoint of the bounds
- Set variables - use the value with the index closest to the middle of the set
- Range variables - use the midpoint of the range

descriptors

- [Keywords Area](#)
- [variables](#)
- [discrete_state_set](#)
- [string](#)
- [descriptors](#)

Labels for the variables

Specification

Alias: none

Argument(s): STRINGLIST

Default: dssv_{i}

Description

The optional variable labels specification `descriptors` is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

real

- [Keywords Area](#)
- [variables](#)
- [discrete_state_set](#)
- [real](#)

Discrete state variables, each defined by a set of permissible real numbers

Topics

This keyword is related to the topics:

- [discrete_variables](#)
- [state_variables](#)

Specification

Alias: none

Argument(s): INTEGER

Default: no discrete state set real variables

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			elements_per_- variable	Number of admissible elements for each set variable
	Required		elements	The permissible values for each discrete variable
	Optional		categorical	Whether the set-valued variables are categorical or relaxable
	Optional		initial_state	Initial values for the state variables
	Optional		descriptors	Labels for the variables

Description

Discrete state variables defined by a set of permissible real numbers.

The details of how to specify this discrete variable are located on the [discrete_variables](#) page.

See the [state_variables](#) page for details on the behavior of state variables.

elements_per_variable

- [Keywords Area](#)

    elements 2 4 7
  descriptor 'rotor_blades'
  categorical 'no'
```

initial_state

- [Keywords Area](#)
- [variables](#)
- [discrete_state_set](#)
- [real](#)
- [initial_state](#)

Initial values for the state variables

Specification

Alias: none

Argument(s): REALLIST

Default: middle set value, or rounded down

Description

The `initial_state` specifications provide the initial values for the state variables.

This is an optional keyword. If it is not specified, the initial state will be inferred from the other keywords that define the state variable.

Defaults are:

- Continuous state variables - use the midpoint of the bounds
- Set variables - use the value with the index closest to the middle of the set
- Range variables - use the midpoint of the range

descriptors

- [Keywords Area](#)
- [variables](#)
- [discrete_state_set](#)
- [real](#)
- [descriptors](#)

Labels for the variables

Specification

Alias: none

Argument(s): STRINGLIST

Default: dssrv_{i}

Description

The optional variable labels specification `descriptors` is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

7.4.33 `linear_inequality_constraint_matrix`

- [Keywords Area](#)
- [variables](#)
- [linear_inequality_constraint_matrix](#)

Define coefficients of the linear inequality constraints

Topics

This keyword is related to the topics:

- [linear_constraints](#)

Specification

Alias: none

Argument(s): REALLIST

Default: no linear inequality constraints

Description

In the inequality case, the constraint matrix A provides coefficients for the variables in the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where the bounds are optionally specified by `linear_inequality_lower_bounds`, and `linear_inequality_upper_bounds`. The bounds, if not specified, will default to -infinity, and 0, respectively, resulting in one-sided inequalities of the form

$$Ax \leq 0.0$$

The `linear_constraints` topics page (linked above) outlines a few additional things to consider when using linear constraints.

Examples

In the first example, an optimization involving two variables, x_1 and x_2 , is to be performed. These variables must satisfy two constraints:

$$\begin{aligned} 1.5 \cdot x_1 + 1.0 \cdot x_2 &\leq 5.0 \\ x_1 \leq x_2 &\implies x_1 - x_2 \leq 0.0 \end{aligned}$$

The pair of constraints can be written in matrix form as:

$$\begin{bmatrix} 1.5 & 1.0 \\ 1.0 & -1.0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} \leq \begin{bmatrix} 5.0 \\ 0.0 \end{bmatrix}$$

The coefficient matrix and right hand side of this matrix inequality are expressed to Dakota in the variables section of the input file:

```
variables
  continuous_design 2
  descriptors 'x1' 'x2'

  linear_inequality_constraint_matrix = 1.5  1.0
                                       1.0 -1.0

  linear_inequality_upper_bounds = 5.0
                                   0.0
```

The second example is more complex in two respects. First, some, but not all, of the constraints are "two sided", with both lower and upper bounds. Second, not all variables participate in all constraints. There are four variables, x_1 , x_2 , x_3 , and x_4 , and four constraints.

$$\begin{aligned} -2.0 &\leq 5.0 \cdot x_1 + 2.0 \cdot x_2 \leq 9.0 \\ 0.0 &\leq x_1 + x_3 \\ -8.0 &\leq x_2 + 6.0 \cdot x_4 \leq 8.0 \\ x_1 + x_2 + x_3 &\leq 9.0 \end{aligned}$$

Or, in matrix form,

$$\begin{bmatrix} -2.0 \\ 0.0 \\ -8.0 \\ -\infty \end{bmatrix} \leq \begin{bmatrix} 5.0 & 2.0 & 0.0 & 0.0 \\ 1.0 & 0.0 & 1.0 & 0.0 \\ 0.0 & 1.0 & 0.0 & 6.0 \\ 1.0 & 1.0 & 1.0 & 0.0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix} \leq \begin{bmatrix} 9.0 \\ \infty \\ 8.0 \\ 9.0 \end{bmatrix}$$

The Dakota specification for this matrix inequality is:

```
variables
  continuous_design 4
  descriptors 'x1' 'x2' 'x3' 'x4'

  linear_inequality_constraint_matrix = 5.0  2.0  0.0  0.0
                                       1.0  0.0  1.0  0.0
                                       0.0  1.0  0.0  6.0
                                       1.0  1.0  1.0  0.0

  linear_inequality_lower_bounds = -2.0
                                   0.0
                                   -8.0
```

```

                                -inf
linear_inequality_upper_bounds = 9.0
                                inf
                                8.0
                                9.0

```

7.4.34 linear_inequality_lower_bounds

- [Keywords Area](#)
- [variables](#)
- [linear_inequality_lower_bounds](#)

Define lower bounds for the linear inequality constraint

Topics

This keyword is related to the topics:

- [linear_constraints](#)

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = -infinity

Description

In the inequality case, the lower a_l and upper a_u bounds provide constraint limits for the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where A is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see [objective_functions](#)), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$Ax \leq 0.0$$

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than `+bigRealBoundSize` (1.e+30, as defined in `Minimizer`) are treated as `+infinity` and any lower bound values less than `-bigRealBoundSize` are treated as `-infinity`.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since `-DBL_MAX < -bigRealBoundSize`).

Examples

Examples of specifying linear inequality constraints to Dakota are provided on the [linear_inequality_constraint_matrix](#) page.

7.4.35 `linear_inequality_upper_bounds`

- [Keywords Area](#)
- [variables](#)
- [linear_inequality_upper_bounds](#)

Define upper bounds for the linear inequality constraint

Topics

This keyword is related to the topics:

- [linear_constraints](#)

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = 0 .

Description

In the inequality case, the lower a_l and upper a_u bounds provide constraint limits for the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where A is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see [objective_functions](#)), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$Ax \leq 0.0$$

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than `+bigRealBoundSize` (1.e+30, as defined in `Minimizer`) are treated as `+infinity` and any lower bound values less than `-bigRealBoundSize` are treated as `-infinity`.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since `-DBL_MAX < -bigRealBoundSize`).

Examples

Examples of specifying linear inequality constraints to Dakota are provided on the [linear_inequality_constraint_matrix](#) page.

7.4.36 `linear_inequality_scale_types`

- [Keywords Area](#)
- [variables](#)
- [linear_inequality_scale_types](#)

Specify how each linear inequality constraint is scaled

Topics

This keyword is related to the topics:

- [linear_constraints](#)

Specification

Alias: none

Argument(s): STRINGLIST

Default: vector values = "none"

Description

`linear_inequality_scale_types` provide strings specifying the scaling type for each linear inequality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- 'none' - no scaling
- 'value' - characteristic value if this is chosen, then `linear_inequality_scales` must be specified
- 'auto' - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied *after* any continuous variable scaling. For example, for variable scaling on continuous design variables x :

$$\tilde{x}^j = \frac{x^j - x_O^j}{x_M^j}$$

we have the following system for linear inequality constraints

$$a_L \leq A_i x \leq a_U$$

$$a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U$$

$$a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O$$

$$\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U$$

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to $[0,1]$.

7.4.37 linear_inequality_scales

- [Keywords Area](#)
- [variables](#)
- [linear_inequality_scales](#)

Define the characteristic values to scale linear inequalities

Topics

This keyword is related to the topics:

- [linear_constraints](#)

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = 1 . (no scaling)

Description

Each entry in `linear_inequality_scales` may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

Behavior depends on the choice of `linear_inequality_scale_type` :

- `scale_type` - behavior of `linear_inequality_scales`
- 'none' - ignored
- 'value' - required
- 'auto' - optional

If a single real value is specified it will apply to all components of the constraint.

Scaling for linear constraints is applied *after* any continuous variable scaling. For example, for variable scaling on continuous design variables x :

$$\tilde{x}^j = \frac{x^j - x_O^j}{x_M^j}$$

we have the following system for linear inequality constraints

$$a_L \leq A_i x \leq a_U$$

$$a_L \leq A_i (\text{diag}(x_M) \tilde{x} + x_O) \leq a_U$$

$$a_L - A_i x_O \leq A_i \text{diag}(x_M) \tilde{x} \leq a_U - A_i x_O$$

$$\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U$$

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to $[0,1]$.

7.4.38 linear_equality_constraint_matrix

- [Keywords Area](#)
- [variables](#)
- [linear_equality_constraint_matrix](#)

Define coefficients of the linear equalities

Topics

This keyword is related to the topics:

- [linear_constraints](#)

Alias: none

Argument(s): REALLIST

Default: no linear equality constraints

Description

In the equality case, the constraint matrix A provides coefficients for the variables on the left hand side of:

$$Ax = a_t$$

The [linear_constraints](#) topics page (linked above) outlines a few additional things to consider when using linear constraints.

Examples

An optimization involving three variables, x_1 , x_2 , and x_3 , is to be performed. These variables must satisfy a pair of linear equality constraints:

$$\begin{aligned} 1.5 \cdot x_1 + 1.0 \cdot x_2 &= 5.0 \\ 3.0 \cdot x_1 - 4.0 \cdot x_3 &= 0.0 \end{aligned}$$

The pair of constraints can be written in matrix form as:

$$\begin{bmatrix} 1.5 & 1.0 & 0.0 \\ 3.0 & 0.0 & -4.0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 5.0 \\ 0.0 \end{bmatrix}$$

The coefficient matrix and right hand side are expressed to Dakota in the [variables](#) section of the input file:

```
variables
  continuous_design 2
  descriptors 'x1' 'x2'

  linear_equality_constraint_matrix = 1.5  1.0  0.0
                                     3.0  0.0 -4.0

  linear_equality_targets = 5.0
                           0.0
```

For related examples, see the [linear_inequality_constraint_matrix](#) keyword page.

7.4.39 linear_equality_targets

- [Keywords Area](#)
- [variables](#)
- [linear_equality_targets](#)

Define target values for the linear equality constraints

Topics

This keyword is related to the topics:

- [linear_constraints](#)

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = 0 .

Description

In the equality case, the targets a_t provide the equality constraint right hand sides:

$$Ax = a_t$$

If this is not specified, the defaults for the equality constraint targets enforce a value of 0. for each constraint:
 $Ax = 0.0$

Examples

Examples of specifying linear equality constraints to Dakota are provided on the [linear_equality_constraint_matrix](#) page.

7.4.40 linear_equality_scale_types

- [Keywords Area](#)
- [variables](#)
- [linear_equality_scale_types](#)

Specify how each linear equality constraint is scaled

Topics

This keyword is related to the topics:

- [linear_constraints](#)

Specification

Alias: none

Argument(s): STRINGLIST

Default: vector values = "none"

Description

`linear_equality_scale_types` provide strings specifying the scaling type for each linear equality constraint, in methods that support scaling.

An entry may be selected for each constraint. The options are:

- 'none' - no scaling
- 'value' - characteristic value if this is chosen, then `linear_equality_scales` must be specified
- 'auto' - automatic scaling If a single string is specified it will apply to all constraints.

Scaling for linear constraints is applied *after* any continuous variable scaling.

For example, for variable scaling on continuous design variables x :

$$\tilde{x}^j = \frac{x^j - x_O^j}{x_M^j}$$

we have the following system for linear equality constraints

$$a_L \leq A_i x \leq a_U$$

$$a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U$$

$$a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O$$

$$\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U$$

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to $[0,1]$.

7.4.41 linear_equality_scales

- [Keywords Area](#)
- [variables](#)
- [linear_equality_scales](#)

Define the characteristic values to scale linear equalities

Topics

This keyword is related to the topics:

- [linear_constraints](#)

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = 1 . (no scaling)

Description

Each entry in `linear_equality_scales` may be a user-specified, nonzero characteristic value to be used in scaling each constraint.

See the scaling keyword in the [method](#) section for details on how to use this keyword.

Scaling for linear constraints is applied *after* any continuous variable scaling.

For example, for variable scaling on continuous design variables x :

$$\tilde{x}^j = \frac{x^j - x_O^j}{x_M^j}$$

we have the following system for linear inequality constraints

$$a_L \leq A_i x \leq a_U$$

$$a_L \leq A_i (\text{diag}(x_M) \tilde{x} + x_O) \leq a_U$$

$$a_L - A_i x_O \leq A_i \text{diag}(x_M) \tilde{x} \leq a_U - A_i x_O$$

$$\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U$$

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to $[0,1]$.

7.5 interface

- [Keywords Area](#)
- [interface](#)

Specifies how function evaluations will be performed in order to map the variables into the responses.

Topics

This keyword is related to the topics:

- [block](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			id_interface	Name the interface block; helpful when there are multiple
	Optional		analysis_drivers	Define how Dakota should run a function evaluation
	Optional		algebraic_- mappings	Use AMPL to define algebraic input-output mappings
	Optional		failure_capture	Determine how Dakota responds to analysis driver failure
	Optional		deactivate	Deactivate Dakota interface features for simplicity or efficiency
	Optional (Choose One)	Group 1	batch	Perform evaluations in batches
			asynchronous	Specify local evaluation or analysis concurrency
	Optional		evaluation_servers	Specify the number of evaluation servers when Dakota is run in parallel

	Optional	evaluation_-scheduling	Specify the scheduling of concurrent evaluations when Dakota is run in parallel
	Optional	processors_per_evaluation	Specify the number of processors per evaluation server when Dakota is run in parallel
	Optional	analysis_servers	Specify the number of analysis servers when Dakota is run in parallel
	Optional	analysis_-scheduling	Specify the scheduling of concurrent analyses when Dakota is run in parallel

Description

The interface section in a Dakota input file specifies how function evaluations will be performed in order to map the variables into the responses. The term "interface" refers to the bridge between Dakota and the underlying simulation code.

In this context, a "function evaluation" is the series of operations that takes the variables and computes the responses. This can be comprised of one or many codes, scripts, and glue, which are generically referred to as "analysis drivers" (and optional input/output filters). The mapping actions of [analysis_drivers](#) may be combined with explicit [algebraic_mappings](#)

Parallelism Options

- The [asynchronous](#) keyword enables concurrent local function evaluations or analyses via operating system process management. Its child keywords allow tailoring the evaluation and analysis concurrency.
- The evaluation servers, scheduling mode (master, peer static or dynamic), and processor keywords allow a user to override Dakota's default evaluation configuration when running in parallel (MPI) mode.
- The analysis servers and scheduling mode (master, peer static or dynamic) keywords allow a user to override Dakota's default analysis configuration when running in parallel (MPI) mode.

Note: see [direct](#) for the specific `processors_per_analysis` specification supported for direct interfaces.

The `ParallelLibrary` class and the Parallel Computing chapter of the Users Manual[4] provide additional details on parallel configurations.

Theory

Function evaluations are performed using either interfaces to simulation codes, algebraic mappings, or a combination of the two.

When employing mappings with simulation codes, the interface invokes the simulation using either forks, direct function invocations, or computational grid invocations.

- In the fork case, Dakota will treat the simulation as a black-box and communication between Dakota and the simulation occurs through parameter and result files. This is the most common case.
- In the direct function case, the simulation is internal to Dakota and communication occurs through the function parameter list. The direct case can involve linked simulation codes or test functions which are compiled into the Dakota executable. The test functions allow for rapid testing of algorithms without process creation overhead or engineering simulation expense.
- The grid case is deprecated, but was an experiment in interfacing Dakota to distributed computing engines.

When employing algebraic mappings, the AMPL solver library[29] is used to evaluate a directed acyclic graph (DAG) specification from a separate `stub.nl` file. Separate `stub.col` and `stub.row` files are also required to declare the string identifiers of the subset of inputs and outputs, respectively, that will be used in the algebraic mappings.

7.5.1 id_interface

- [Keywords Area](#)
- [interface](#)
- [id_interface](#)

Name the interface block; helpful when there are multiple

Topics

This keyword is related to the topics:

- [block_identifier](#)

Specification

Alias: none

Argument(s): STRING

Default: use of last interface parsed

Description

The optional `id_interface` keyword accepts a string that uniquely identifies this interface block. A model can then use this interface by specifying the same string in its `interface_pointer` specification.

Default Behavior

If the `id_interface` specification is omitted, a particular interface specification will be used by a model only if that model does not include an `interface_pointer` and the interface block was the last (or only) one parsed.

Usage Tips

- It is a best practice to always use explicit interface IDs and pointers to avoid confusion.

- If only one interface block exists, then `id_interface` can be safely omitted from the interface block (and `interface_pointer` omitted from the model specification(s)), since there is no ambiguity.

Examples

For example, a model specification including

```
model
  interface_pointer = 'I1'
```

will link to an interface with

```
id_interface = 'I1'
```

7.5.2 analysis_drivers

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)

Define how Dakota should run a function evaluation

Specification

Alias: none

Argument(s): STRINGLIST

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			input_filter	Run a pre-processing script before the analysis drivers
	Optional		output_filter	Run a post-processing script after the analysis drivers
	Required (<i>Choose One</i>)	Interface Type (Group 1)	system	(Not recommended) Launch analysis drivers with a system call

		<code>fork</code>	Launch analysis drivers using fork command
		<code>direct</code>	Run analysis drivers that are linked-to or compiled-with Dakota
		<code>matlab</code>	Run Matlab through a direct interface - requires special Dakota build
		<code>python</code>	Run Python through a direct interface - requires special Dakota build
		<code>scilab</code>	Run Scilab through a direct interface - requires special Dakota build
		<code>grid</code>	Deprecated grid computing interface
	Optional	<code>analysis_-components</code>	Provide additional identifiers to analysis drivers.

Description

The `analysis_drivers` keyword provides the names of one or more executable analysis programs or scripts, a.k.a. "drivers" which comprise a function evaluation. The optional and required sub-keywords specify how Dakota will manage directories and files, and run the driver(s).

Types of Interfaces

Dakota has two recommended ways of running analysis drivers:

- as an external processes (`fork`), or
- using internal code to couple to the analysis driver (`direct`)

Other options are available for advanced users, and are not as well documented, supported, or tested:

- external processes (`system`)
- internal coupling (`python`, `matlab`, `scilab`, `grid`)

Use Cases

The internally coupled codes have few options because many of the details are already handled with the coupling. Their behavior is described in the [direct](#) keyword.

For external processes using the [fork](#) keyword,

A function evaluation may comprise:

1. *A single analysis driver*: Function evaluation, including all pre- and post-processing is contained entirely within a single script/executable.
2. *A single analysis driver with filters*: Function evaluation is explicitly split into pre-processing (performed by the input filter), analysis, and post-processing (by the output filter).
3. *A single analysis driver with environment variables*: Function evaluation is contained within one analysis driver, but it requires environment variables to be set before running.
4. *Multiple analysis drivers*: Drivers are run sequentially or concurrently (See the [asynchronous](#) keyword) and can have any of the above options as well.

For fork and system interfaces, the `analysis_driver` list contains the names of one or more executable programs or scripts taking parameters files as input and producing results files as output. The first field in each analysis driver string must be an executable program or script for Dakota to spawn to perform the function evaluation. Drivers support:

- One set of nested quotes, for arguments with spaces
- Dakota will define special environment variables `DAKOTA_PARAMETERS_FILE` and `DAKOTA_RESULTS_FILE` which can be used in the driver script.
- Dakota will replace the tokens `{PARAMETERS}` and `{RESULTS}` in an analysis driver string with the names of the parameters and results files for that analysis/evaluation. Along with the [verbatim](#) keyword, which prevents Dakota from appending the names of the parameters and results files as command line arguments, this feature provides users with greater control over how their analysis drivers are invoked by Dakota.
- Variable definitions preceding the executable program or script, such as `'MY_VAR=2 run_analysis.sh'` are no longer supported.

For details and examples see the Simulation Interface Components section of the Interfaces chapter of the User's Manual; for details on the filters and environment variables, see the subsection on Syntax for Filter and Driver Strings.

Examples

Examples:

1. `analysis_drivers = 'run_simulation_part1.sh' 'run_simulation_part2.sh'`
2. `analysis_driver = 'run_simulation.sh -option "option 1"'`
3. `analysis_driver = 'simulation.exe -option value -dakota_params $DAKOTA_PARAMETERS_FILE -input sim.in -da`

FAQ

Where will Dakota look for the analysis_driver? Dakota will locate `analysis_driver` programs first in (or relative to) the present working directory (`."`, the `interface-analysis_drivers-fork-work_directory` if used, otherwise the directory in which Dakota is started), then the directory from which Dakota is started, then using the system `$PATH` environment variable (`Path%` on Windows).

Where should the driver be located? When the driver is a script it is most commonly placed in the same directory as the Dakota input file. When using a [work_directory](#), Dakota will also look for drivers in the specified working directory, so `link_files` or `copy_files` may specify the driver to get copied or linked into the work directory. When executable programs are used as drivers, they are often elsewhere on the filesystem. These can be specified using absolute paths, or by prepending the `PATH` environment variable so Dakota finds them.

What if Dakota fails to run my analysis_driver? Prepend the absolute location of the driver to the `PATH` environment variable before running Dakota, or specify an absolute path to the driver in the Dakota input file.

input_filter

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [input_filter](#)

Run a pre-processing script before the analysis drivers

Specification

Alias: none

Argument(s): STRING

Default: no input filter

Description

The optional `input_filter` and `output_filter` specifications provide the names of separate pre- and post-processing programs or scripts which assist in mapping Dakota parameters files into analysis input files and mapping analysis output files into Dakota results files, respectively.

If there is only a single analysis driver, then it is usually most convenient to combine pre- and post-processing requirements into a single analysis driver script and omit the separate input and output filters. However, in the case of multiple analysis drivers, the input and output filters provide a convenient location for non-repeated pre- and post-processing requirements. That is, input and output filters are only executed once per function evaluation, regardless of the number of analysis drivers, which makes them convenient locations for data processing operations that are shared among the analysis drivers.

The [verbatim](#) keyword applies to input and output filters as well as analysis drivers, and Dakota also will substitute the names of the parameters and results files for the tokens `{PARAMETERS}` and `{RESULTS}` in input and output filter strings, as explained in the documentation for [analysis_drivers](#).

output_filter

- [Keywords Area](#)
- [interface](#)

- [analysis_drivers](#)
- [output_filter](#)

Run a post-processing script after the analysis drivers

Specification

Alias: none

Argument(s): STRING

Default: no output filter

Description

The optional `input_filter` and `output_filter` specifications provide the names of separate pre- and post-processing programs or scripts which assist in mapping Dakota parameters files into analysis input files and mapping analysis output files into Dakota results files, respectively.

If there is only a single analysis driver, then it is usually most convenient to combine pre- and post-processing requirements into a single analysis driver script and omit the separate input and output filters. However, in the case of multiple analysis drivers, the input and output filters provide a convenient location for non-repeated pre- and post-processing requirements. That is, input and output filters are only executed once per function evaluation, regardless of the number of analysis drivers, which makes them convenient locations for data processing operations that are shared among the analysis drivers.

The `verbatim` keyword applies to input and output filters as well as analysis drivers, and Dakota also will substitute the names of the parameters and results files for the tokens `{PARAMETERS}` and `{RESULTS}` in input and output filter strings, as explained in the documentation for [analysis_drivers](#).

system

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [system](#)

(Not recommended) Launch analysis drivers with a system call

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			parameters_file	Specify the name of the parameters file

	Optional	results_file	Specify the name of the results file
	Optional	file_tag	Tag each parameters & results file name with the function evaluation number
	Optional	file_save	Keep the parameters & results files after the analysis driver completes
	Optional	labeled	Requires correct function value labels in results file
	Optional	aprepro	Write parameters files in APREPRO syntax
	Optional	work_directory	Perform each function evaluation in a separate working directory
	Optional	allow_existing_results	Change how Dakota deals with existing results files
	Optional	verbatim	Specify the command Dakota uses to launch analysis driver(s) and filters

Description

The system call interface is included in Dakota for portability and backward compatibility. Users are strongly encouraged to use the `fork` interface if possible, reverting to system only when necessary. To enable the system call interface, replace the `fork` keyword with `system`. All other keywords have identical meanings to those for the `fork` interface

See Also

These keywords may also be of interest:

- [fork](#)

parameters_file

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [system](#)
- [parameters_file](#)

Specify the name of the parameters file

Specification

Alias: none

Argument(s): STRING

Default: Unix temp files

Description

The parameters file is used by Dakota to pass the parameter values to the analysis driver. The name of the file can be optionally specified using the `parameters_file` keyword.

If this is not specified, the default data transfer files are temporary files with system-generated names (e.g., `/tmp/dakota_params_aaaa0886`).

results_file

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [system](#)
- [results_file](#)

Specify the name of the results file

Specification

Alias: none

Argument(s): STRING

Default: Unix temp files

Description

The results file must be written by the analysis driver. It is read by Dakota to determine the response values for each function evaluation.

The name of the file can be optionally specified using the `results_file` keyword.

If this is not specified, the default data transfer files are temporary files with system-generated names (e.g., `/tmp/dakota_results_aaaa0886`).

file_tag

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [system](#)
- [file_tag](#)

Tag each parameters & results file name with the function evaluation number

Specification

Alias: none

Argument(s): none

Default: no tagging

Description

If this keyword is used, Dakota will append a period and the function evaluation number to the names of the parameter and results files.

Default Behavior If this keyword is omitted, the default is no file tagging.

Usage Tips

- File tagging is most useful when multiple function evaluations are running simultaneously using files in a shared disk space. The analysis driver will be able to infer the function evaluation number from the file names.
- Note that when the `file_save` keyword is used, Dakota automatically renames parameters and results files, giving them tags after execution of the analysis driver if they otherwise would be overwritten by the next evaluation.

Examples

If the following is included in the `interface` section of the Dakota input:

```
parameters_file = params.in
results_file = results.out
file_tag
```

Then for the 3rd evaluation, Dakota will write `params.in.3`, and will expect `results.out.3` to be written by the analysis driver.

file_save

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [system](#)
- [file_save](#)

Keep the parameters & results files after the analysis driver completes

Specification

Alias: none

Argument(s): none

Default: file cleanup

Description

If `file_save` is used, Dakota will not delete the parameters and results files after the function evaluation is completed.

The default behavior is NOT to save these files.

If `file_tag` is not specified and the saved files would be overwritten by a future evaluation, Dakota renames them after the analysis driver has run by tagging them with the evaluation number.

File saving is most useful when debugging the data communication between Dakota and the simulation.

labeled

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [system](#)
- [labeled](#)

Requires correct function value labels in results file

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: Function value labels optional

Description

The `labeled` keyword directs Dakota to enforce a stricter results file format and enables more detailed error reporting.

When the `labeled` keyword is used, function values in results files must be accompanied by their corresponding descriptors. If the user did not supply response [descriptors](#) in her Dakota input file, then Dakota auto-generated descriptors are expected.

Distinct error messages are emitted for function values that are out-of-order, repeated, or missing. Labels that appear without a function value and unexpected data are also reported as errors. Dakota attempts to report all errors in a results file, not just the first it encounters. After reporting results file errors, Dakota aborts.

Labels for analytic gradients and Hessians currently are not supported.

Although the `labeled` keyword is optional, its use is recommended to help catch and identify problems with results files. The User's Manual contains further information about the results file format.

Default Behavior

By default, Dakota does not require labels for function values, and ignores them if they are present.

aprepro

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [system](#)
- [aprepro](#)

Write parameters files in APREPRO syntax

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: `dprepro`

Argument(s): none

Default: standard parameters file format

Description

The format of data in the parameters files can be modified for direct usage with the APREPRO pre-processing tool [77] using the `aprepro` specification

Without this keyword, the parameters file are written in DPrePro format. DPrePro is a utility included with Dakota, described in the Users Manual[4].

work_directory

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [system](#)
- [work_directory](#)

Perform each function evaluation in a separate working directory

Specification

Alias: none

Argument(s): none

Default: no work directory

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			named	The base name of the work directory created by Dakota
	Optional		directory_tag	Tag each work directory with the function evaluation number
	Optional		directory_save	Preserve the work directory after function evaluation completion
	Optional		link_files	Paths to be linked into each working directory
	Optional		copy_files	Files and directories to be copied into each working directory
	Optional		replace	Overwrite existing files within a work directory

Description

When performing concurrent evaluations, it is typically necessary to cloister simulation input and output files in separate directories to avoid conflicts. When the `work_directory` feature is enabled, Dakota will create a directory for each evaluation, with optional tagging (`directory_tag`) and saving (`directory_save`), as with files, and execute the analysis driver from that working directory.

The directory may be named with a string, or left anonymous to use an automatically-generated directory in the system's temporary file space, e.g., `/tmp/dakota_work_c93vb71z/`. The optional `link_files` and `copy_files` keywords specify files or directories which should appear in each working directory.

When using `work_directory`, the `analysis_drivers` may be given by an absolute path, located in (or relative to) the startup directory alongside the Dakota input file, in the list of template files linked or copied, or on the `$PATH` (Path% on Windows).

named

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [system](#)

- [work_directory](#)
- [named](#)

The base name of the work directory created by Dakota

Specification

Alias: none

Argument(s): STRING

Default: dakota_work_XXXXXXXX

Description

The `named` keyword is followed by a string, indicating the name of the work directory created by Dakota. If relative, the work directory will be created relative to the directory from which Dakota is invoked.

If `named` is not used, the default work directory is a temporary directory with a system-generated name (e.g., `/tmp/dakota_work_c93vb71z/`).

See Also

These keywords may also be of interest:

- [directory_tag](#)
- [directory_save](#)

directory_tag

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [system](#)
- [work_directory](#)
- [directory_tag](#)

Tag each work directory with the function evaluation number

Specification

Alias: `dir_tag`

Argument(s): none

Default: no work directory tagging

Description

If this keyword is used, Dakota will append a period and the function evaluation number to the work directory names.

If this keyword is omitted, the default is no tagging, and the same work directory will be used for ALL function evaluations. Tagging is most useful when multiple function evaluations are running simultaneously.

directory_save

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [system](#)
- [work_directory](#)
- [directory_save](#)

Preserve the work directory after function evaluation completion

Specification

Alias: dir_save

Argument(s): none

Default: remove work directory

Description

By default, when a working directory is created by Dakota using the `work_directory` keyword, it is deleted after the evaluation is completed. The `directory_save` keyword will cause Dakota to leave (not delete) the directory.

link_files

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [system](#)
- [work_directory](#)
- [link_files](#)

Paths to be linked into each working directory

Specification

Alias: none

Argument(s): STRINGLIST

Default: no linked files

Description

Specifies the paths (files or directories) that will be symbolically linked from each working directory. Wildcards using `*` and `?` are permitted. Linking is space-saving and useful for files not modified during the function evaluation. However, not all filesystems support linking, for example, support on Windows varies.

Examples

Specifying

```
link_files = 'siminput*.in' '/path/to/simdir1' 'simdir2/*'
```

will create copies

```
workdir/siminput*.in # links to each of rundir / siminput*.in
workdir/simdir1/     # whole directory simdir1 linked
workdir/*            # each entry in directory simdir2 linked
```

copy_files

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [system](#)
- [work_directory](#)
- [copy_files](#)

Files and directories to be copied into each working directory

Specification

Alias: none

Argument(s): STRINGLIST

Default: no copied files

Description

Specifies the files or directories that will be recursively copied into each working directory. Wildcards using * and ? are permitted.

Examples

Specifying

```
copy_files = 'siminput*.in' '/path/to/simdir1' 'simdir2/*'
```

will create copies

```
workdir/siminput*.in # files rundir/siminput*.in copied
workdir/simdir1/     # whole directory simdir1 recursively copied
workdir/*            # contents of directory simdir2 recursively copied
```

where rundir is the directory in which Dakota was started.

replace

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [system](#)
- [work_directory](#)
- [replace](#)

Overwrite existing files within a work directory

Specification

Alias: none

Argument(s): none

Default: do not overwrite files

Description

By default, Dakota will not overwrite any existing files in a work directory. The `replace` keyword changes this behavior to force overwriting.

allow_existing_results

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [system](#)
- [allow_existing_results](#)

Change how Dakota deals with existing results files

Specification

Alias: none

Argument(s): none

Default: results files removed before each evaluation

Description

By default Dakota will remove existing results files before invoking the `analysis_driver` to avoid problems created by stale files in the current directory. To override this behavior and not delete existing files, specify `allow_existing_results`.

verbatim

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [system](#)
- [verbatim](#)

Specify the command Dakota uses to launch analysis driver(s) and filters

Specification

Alias: none

Argument(s): none

Default: driver/filter invocation syntax augmented with file names

Description

The typical commands that Dakota uses to launch analysis drivers are:

```
> analysis_driver parameters_file_name results_file_name
```

Dakota will automatically arrange the executables and file names.

If the analysis driver requires a different syntax, the entire command can be specified as the analysis driver and the `verbatim` keyword will tell Dakota to use this as the command.

Note, this will not allow the use of `file_tag`, because the exact command must be specified.

For additional information on invocation syntax, see the Interfaces chapter of the Users Manual[4].

Examples

In the following example, the `analysis_driver` command is run without any edits from Dakota.

```
interface
  analysis_driver = "matlab -nodesktop -nojvm -r 'MatlabDriver_hardcoded_filenames; exit' "
  fork
    parameters_file 'params.in'
    results_file 'results.out'
    verbatim # this tells Dakota to fork the command exactly as written, instead of appending I/O filenames
```

The `-r` flag identifies the commands that will be run by matlab. The Matlab script has the `parameters_file` and `results_file` names hardcoded, so no additional arguments are required.

fork

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [fork](#)

Launch analysis drivers using fork command

Specification**Alias:** none**Argument(s):** none**Child Keywords:**

	Required/- Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		parameters_file	Specify the name of the parameters file
	Optional		results_file	Specify the name of the results file
	Optional		file_tag	Tag each parameters & results file name with the function evaluation number
	Optional		file_save	Keep the parameters & results files after the analysis driver completes
	Optional		labeled	Requires correct function value labels in results file
	Optional		aprepro	Write parameters files in APREPRO syntax
	Optional		work_directory	Perform each function evaluation in a separate working directory
	Optional		allow_existing_results	Change how Dakota deals with existing results files

	Optional	verbatim	Specify the command Dakota uses to launch analysis driver(s) and filters
--	-----------------	--------------------------	--

Description

The `fork` interface is the most common means by which Dakota launches a separate application analysis process.

The `fork` interface is recommended over `system` for most analysis drivers that are external to Dakota, i.e., any driver not linked in via the `direct` interface.

As explained in the Users Manual, the parameters and results file names are passed on the command line to the analysis driver(s). If input/output filters are specified, they will be run before/after the analysis drivers. The `verbatim` keyword is used to modify the default driver/filter commands.

For additional information on invocation syntax, see the Interfaces chapter of the Users Manual[4].

Examples

Spawn (fork) an external executable/script called 'rosenbrock' which reads variables from `params.in` and writes responses to `results.out`. Preserve the analysis files for each function evaluation with `tag` and `save`.

```
interface
  analysis_drivers = 'rosenbrock'
  fork
    parameters_file = 'params.in'
    results_file   = 'results.out'
    file_tag
    file_save
```

parameters_file

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [fork](#)
- [parameters_file](#)

Specify the name of the parameters file

Specification

Alias: none

Argument(s): STRING

Default: Unix temp files

Description

The parameters file is used by Dakota to pass the parameter values to the analysis driver. The name of the file can be optionally specified using the `parameters_file` keyword.

If this is not specified, the default data transfer files are temporary files with system-generated names (e.g., `/tmp/dakota_params_aaaa0886`).

results_file

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [fork](#)
- [results_file](#)

Specify the name of the results file

Specification

Alias: none

Argument(s): STRING

Default: Unix temp files

Description

The results file must be written by the analysis driver. It is read by Dakota to determine the response values for each function evaluation.

The name of the file can be optionally specified using the `results_file` keyword.

If this is not specified, the default data transfer files are temporary files with system-generated names (e.g., `/tmp/dakota_results_aaaa0886`).

file_tag

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [fork](#)
- [file_tag](#)

Tag each parameters & results file name with the function evaluation number

Specification

Alias: none

Argument(s): none

Default: no tagging

Description

If this keyword is used, Dakota will append a period and the function evaluation number to the names of the parameter and results files.

Default Behavior If this keyword is omitted, the default is no file tagging.

Usage Tips

- File tagging is most useful when multiple function evaluations are running simultaneously using files in a shared disk space. The analysis driver will be able to infer the function evaluation number from the file names.
- Note that when the `file_save` keyword is used, Dakota automatically renames parameters and results files, giving them tags after execution of the analysis driver if they otherwise would be overwritten by the next evaluation.

Examples

If the following is included in the `interface` section of the Dakota input:

```
parameters_file = params.in
results_file = results.out
file_tag
```

Then for the 3rd evaluation, Dakota will write `params.in.3`, and will expect `results.out.3` to be written by the analysis driver.

`file_save`

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [fork](#)
- [file_save](#)

Keep the parameters & results files after the analysis driver completes

Specification

Alias: none

Argument(s): none

Default: file cleanup

Description

If `file_save` is used, Dakota will not delete the parameters and results files after the function evaluation is completed.

The default behavior is NOT to save these files.

If `file_tag` is not specified and the saved files would be overwritten by a future evaluation, Dakota renames them after the analysis driver has run by tagging them with the evaluation number.

File saving is most useful when debugging the data communication between Dakota and the simulation.

labeled

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [fork](#)
- [labeled](#)

Requires correct function value labels in results file

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: Function value labels optional

Description

The `labeled` keyword directs Dakota to enforce a stricter results file format and enables more detailed error reporting.

When the `labeled` keyword is used, function values in results files must be accompanied by their corresponding descriptors. If the user did not supply response [descriptors](#) in her Dakota input file, then Dakota auto-generated descriptors are expected.

Distinct error messages are emitted for function values that are out-of-order, repeated, or missing. Labels that appear without a function value and unexpected data are also reported as errors. Dakota attempts to report all errors in a results file, not just the first it encounters. After reporting results file errors, Dakota aborts.

Labels for analytic gradients and Hessians currently are not supported.

Although the `labeled` keyword is optional, its use is recommended to help catch and identify problems with results files. The User's Manual contains further information about the results file format.

Default Behavior

By default, Dakota does not require labels for function values, and ignores them if they are present.

aprepro

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [fork](#)
- [aprepro](#)

Write parameters files in APREPRO syntax

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: dprepro

Argument(s): none

Default: standard parameters file format

Description

The format of data in the parameters files can be modified for direct usage with the APREPRO pre-processing tool [77] using the `aprepro` specification

Without this keyword, the parameters file are written in DPrePro format. DPrePro is a utility included with Dakota, described in the Users Manual[4].

work_directory

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [fork](#)
- [work_directory](#)

Perform each function evaluation in a separate working directory

Specification

Alias: none

Argument(s): none

Default: no work directory

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			named	The base name of the work directory created by Dakota

	Optional	directory_tag	Tag each work directory with the function evaluation number
	Optional	directory_save	Preserve the work directory after function evaluation completion
	Optional	link_files	Paths to be linked into each working directory
	Optional	copy_files	Files and directories to be copied into each working directory
	Optional	replace	Overwrite existing files within a work directory

Description

When performing concurrent evaluations, it is typically necessary to cloister simulation input and output files in separate directories to avoid conflicts. When the `work_directory` feature is enabled, Dakota will create a directory for each evaluation, with optional tagging (`directory_tag`) and saving (`directory_save`), as with files, and execute the analysis driver from that working directory.

The directory may be named with a string, or left anonymous to use an automatically-generated directory in the system's temporary file space, e.g., `/tmp/dakota_work_c93vb71z/`. The optional `link_files` and `copy_files` keywords specify files or directories which should appear in each working directory.

When using `work_directory`, the `analysis_drivers` may be given by an absolute path, located in (or relative to) the startup directory alongside the Dakota input file, in the list of template files linked or copied, or on the `$PATH` (Path% on Windows).

named

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [fork](#)
- [work_directory](#)
- [named](#)

The base name of the work directory created by Dakota

Specification

Alias: none

Argument(s): STRING

Default: dakota_work_XXXXXXX

Description

The named keyword is followed by a string, indicating the name of the work directory created by Dakota. If relative, the work directory will be created relative to the directory from which Dakota is invoked.

If named is not used, the default work directory is a temporary directory with a system-generated name (e.g., /tmp/dakota_work_c93vb71z/).

See Also

These keywords may also be of interest:

- [directory_tag](#)
- [directory_save](#)

directory_tag

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [fork](#)
- [work_directory](#)
- [directory_tag](#)

Tag each work directory with the function evaluation number

Specification

Alias: dir_tag

Argument(s): none

Default: no work directory tagging

Description

If this keyword is used, Dakota will append a period and the function evaluation number to the work directory names.

If this keyword is omitted, the default is no tagging, and the same work directory will be used for ALL function evaluations. Tagging is most useful when multiple function evaluations are running simultaneously.

directory_save

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [fork](#)
- [work_directory](#)
- [directory_save](#)

Preserve the work directory after function evaluation completion

Specification

Alias: dir_save

Argument(s): none

Default: remove work directory

Description

By default, when a working directory is created by Dakota using the `work_directory` keyword, it is deleted after the evaluation is completed. The `directory_save` keyword will cause Dakota to leave (not delete) the directory.

link_files

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [fork](#)
- [work_directory](#)
- [link_files](#)

Paths to be linked into each working directory

Specification

Alias: none

Argument(s): STRINGLIST

Default: no linked files

Description

Specifies the paths (files or directories) that will be symbolically linked from each working directory. Wildcards using `*` and `?` are permitted. Linking is space-saving and useful for files not modified during the function evaluation. However, not all filesystems support linking, for example, support on Windows varies.

Examples

Specifying

```
link_files = 'siminput*.in' '/path/to/simdir1' 'simdir2/*'
```

will create copies

```
workdir/siminput*.in # links to each of rundir / siminput*.in
workdir/simdir1/     # whole directory simdir1 linked
workdir/*            # each entry in directory simdir2 linked
```

copy_files

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [fork](#)
- [work_directory](#)
- [copy_files](#)

Files and directories to be copied into each working directory

Specification

Alias: none

Argument(s): STRINGLIST

Default: no copied files

Description

Specifies the files or directories that will be recursively copied into each working directory. Wildcards using * and ? are permitted.

Examples

Specifying

```
copy_files = 'siminput*.in' '/path/to/simdir1' 'simdir2/*'
```

will create copies

```
workdir/siminput*.in # files rundir/siminput*.in copied
workdir/simdir1/     # whole directory simdir1 recursively copied
workdir/*            # contents of directory simdir2 recursively copied
```

where rundir is the directory in which Dakota was started.

replace

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [fork](#)
- [work_directory](#)
- [replace](#)

Overwrite existing files within a work directory

Specification

Alias: none

Argument(s): none

Default: do not overwrite files

Description

By default, Dakota will not overwrite any existing files in a work directory. The `replace` keyword changes this behavior to force overwriting.

allow_existing_results

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [fork](#)
- [allow_existing_results](#)

Change how Dakota deals with existing results files

Specification

Alias: none

Argument(s): none

Default: results files removed before each evaluation

Description

By default Dakota will remove existing results files before invoking the `analysis_driver` to avoid problems created by stale files in the current directory. To override this behavior and not delete existing files, specify `allow_existing_results`.

verbatim

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [fork](#)
- [verbatim](#)

Specify the command Dakota uses to launch analysis driver(s) and filters

Specification

Alias: none

Argument(s): none

Default: driver/filter invocation syntax augmented with file names

Description

The typical commands that Dakota uses to launch analysis drivers are:

```
> analysis_driver parameters_file_name results_file_name
```

Dakota will automatically arrange the executables and file names.

If the analysis driver requires a different syntax, the entire command can be specified as the analysis driver and the `verbatim` keyword will tell Dakota to use this as the command.

Note, this will not allow the use of `file_tag`, because the exact command must be specified.

For additional information on invocation syntax, see the Interfaces chapter of the Users Manual[4].

Examples

In the following example, the `analysis_driver` command is run without any edits from Dakota.

```
interface
  analysis_driver = "matlab -nodesktop -nojvm -r 'MatlabDriver_hardcoded_filenames; exit' "
  fork
    parameters_file 'params.in'
    results_file 'results.out'
  verbatim # this tells Dakota to fork the command exactly as written, instead of appending I/O filenames
```

The `-r` flag identifies the commands that will be run by matlab. The Matlab script has the `parameters_file` and `results_file` names hardcoded, so no additional arguments are required.

direct

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [direct](#)

Run analysis drivers that are linked-to or compiled-with Dakota

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			processors_per_- analysis	Specify the number of processors per analysis when Dakota is run in parallel

Description

Direct interfaces are used to compile/link simulation programs into Dakota and to invoke Dakota's built-in algebraic test problems.

Direct simulation interfaces communicate variable and response data in-core instead of through the filesystem. This typically requires modification to simulator programs so that they can be linked into Dakota; however it can be more efficient due to elimination of external processes and auxiliary simulator output, more accurate due to higher numerics, and more flexible in terms of MPI parallelism.

Direct interfaces are also used to invoke internal test functions that perform parameter to response mappings for simple functions as inexpensively as possible. These problems are compiled directly into the Dakota executable as part of the direct function interface class and are used for algorithm testing.

Dakota supports direct interfaces to a few select simulation codes such as Matlab, Python, and Scilab. Another example is ModelCenter, a commercial simulation management framework from Phoenix Integration. To utilize this interface, a user must first define the simulation specifics within a ModelCenter session and then save these definitions to a ModelCenter configuration file. The `analysis_components` specification provides the means to communicate this configuration file to Dakota's ModelCenter interface.

Examples

The rosenbrock function is available as an executable, which can be launched with [fork](#), and is also compiled with Dakota. The internal version can be used with:

```
interface
  analysis_drivers = 'rosenbrock'
  direct
```

`processors_per_analysis`

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [direct](#)
- [processors_per_analysis](#)

Specify the number of processors per analysis when Dakota is run in parallel

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): INTEGER

Default: automatic (see discussion)

Description

For direct function interfaces, `processors_per_analysis` can be used to specify multiprocessor analysis partitions. As with the `evaluation_servers`, `analysis_servers`, `evaluation_self_scheduling`, `evaluation_static_scheduling`, `analysis_self_scheduling`, and `analysis_static_scheduling` specifications, `processors_per_analysis` provides a means for the user to override the automatic parallel configuration (refer to `ParallelLibrary` and the Parallel Computing chapter of the Users Manual [4]) for the number of processors used for each analysis partition.

Usage Tips

- If both `analysis_servers` and `processors_per_analysis` are specified and they are not in agreement, then `analysis_servers` takes precedence.

matlab

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [matlab](#)

Run Matlab through a direct interface - requires special Dakota build

Specification

Alias: none

Argument(s): none

Description

Dakota supports a library-linked interface to Matlab, but it must be explicitly enabled when compiling Dakota from source. Consult the Users Manual[4] for discussion and examples. Contact the Dakota users mailing list for assistance building and using Dakota with these interfaces.

The [analysis_drivers](#) specifies a Matlab file which implements the parameter to response mapping.

Examples

See `dakota/share/dakota/examples/linked.interfaces/Matlab`

python

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [python](#)

Run Python through a direct interface - requires special Dakota build

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			numpy	Enable the use of numpy in Dakota's Python interface

Description

Dakota supports a library-linked interface to Python, but it must be explicitly enabled when compiling Dakota from source. Consult the Users Manual[4] for discussion and examples. Contact the Dakota users mailing list for assistance building and using Dakota with these interfaces.

The [analysis_drivers](#) specifies a Python module:function which implements the parameter to response mapping. List data structures are the default, but NumPy is also supported, if enabled in the build.

Examples

See `dakota/share/dakota/examples/linked_interfaces/Python`

numpy

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [python](#)
- [numpy](#)

Enable the use of numpy in Dakota's Python interface

Specification

Alias: none

Argument(s): none

Default: Python list dataflow

Description

When the `numpy` keyword is used, Dakota expects responses in the form of a Python dictionary of numpy arrays. See the example in `dakota/share/dakota/examples/linked_interfaces/Python`.

scilab

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [scilab](#)

Run Scilab through a direct interface - requires special Dakota build

Specification

Alias: none

Argument(s): none

Description

Dakota supports a library-linked interface to Scilab, but it must be explicitly enabled when compiling Dakota from source. Consult the Users Manual[4] for discussion and examples. Contact the Dakota users mailing list for assistance building and using Dakota with these interfaces.

The [analysis_drivers](#) specifies a Scilab file which implements the parameter to response mapping.

Examples

See `dakota/share/dakota/examples/linked_interfaces/Scilab`

grid

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [grid](#)

Deprecated grid computing interface

Specification

Alias: none

Argument(s): none

Description

Interface Dakota directly to a grid (distributed) computing engine. This deprecated capability was historically used for interfaces with IDEA and JAVASpaces in the past and was intended as a placeholder for future work with Condor and/or Globus services. It is not currently operational.

analysis_components

- [Keywords Area](#)
- [interface](#)
- [analysis_drivers](#)
- [analysis_components](#)

Provide additional identifiers to analysis drivers.

Specification

Alias: none

Argument(s): STRINGLIST

Default: no additional identifiers

Description

The optional `analysis_components` specification allows the user to provide additional identifiers (e.g., mesh file names) for use by the analysis drivers. This is particularly useful when the same analysis driver is to be reused multiple times for slightly different analyses. The specific content within the strings is open-ended and can involve whatever syntax is convenient for a particular analysis driver. The number of analysis components n_c should be an integer multiple of the number of drivers n_d , and the first n_c/n_d component strings will be passed to the first driver, etc.

7.5.3 algebraic_mappings

- [Keywords Area](#)
- [interface](#)
- [algebraic_mappings](#)

Use AMPL to define algebraic input-output mappings

Specification

Alias: none

Argument(s): STRING

Default: no algebraic mappings

Description

Dakota can evaluate algebraic input-output mappings using AMPL [26]. The mappings are expressed in 3 files: `stub.nl`, `stub.col`, and `stub.row`, where `stub` is a particular root name describing a particular problem. The file names are communicated to Dakota using the `algebraic_mappings` keyword. It may either specify the full `stub.nl` filename, or alternatively, just the `stub` basename.

Dakota then extracts the input and output identifier strings from `stub.col` and `stub.row` and employs the AMPL solver library[29] to process the directed acyclic graphc (DAG) specification in `stub.nl`. The variable and objective function names declared within AMPL should be a subset of the variable and response descriptors specified in the `variables` and `responses` blocks. Ordering is not important, as Dakota will reorder data as needed.

Examples

An interface employing both algebraic and simulation-based mappings. The results from the individual algebraic and simulation mappings are overlaid based on the variable and response descriptors used by the individual mappings.

```
interface,
  algebraic_mappings = 'ampl/fma.nl'
  fork
    analysis_driver = 'text_book'
    parameters_file = 'tb.in'
    results_file    = 'tb.out'
```

7.5.4 failure_capture

- [Keywords Area](#)
- [interface](#)
- [failure_capture](#)

Determine how Dakota responds to analysis driver failure

Specification

Alias: none

Argument(s): none

Default: abort

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required(<i>Choose One</i>)	Failure Mitigation (Group 1)	abort	(Default) Abort the Dakota job
			retry	Rerun failed analyses

			recover	Substitute dummy values for the responses
			continuation	Cause Dakota to step toward the failed "target" simulation from a nearby successful "source"

Description

Dakota can deal with analysis failure in a few ways.

The first step is that Dakota must detect analysis failure. Importantly, Dakota always expects a results file to be written by the analysis driver, even when a failure has occurred. If the file does not exist when the analysis driver exits, a Dakota error results, causing Dakota itself to terminate. The analysis driver communicates an analysis failure to Dakota by writing a results file beginning with the (case-insensitive) word "fail". Any file contents after "fail" are ignored.

Once Dakota detects analysis failure, the failure can be mitigated in four ways:

- [abort](#) (the default)
- [retry](#)
- [recover](#)
- [continuation](#)

Refer to the Simulation Code Failure Capturing chapter of the Users Manual[4] for additional information.

abort

- [Keywords Area](#)
- [interface](#)
- [failure_capture](#)
- [abort](#)

(Default) Abort the Dakota job

Specification

Alias: none

Argument(s): none

Description

Stop the Dakota job, as well as any other running analysis drivers when a failure is communicated.

retry

- [Keywords Area](#)
- [interface](#)
- [failure_capture](#)
- [retry](#)

Rerun failed analyses

Specification

Alias: none

Argument(s): INTEGER

Description

Number of times to retry a failing analysis

recover

- [Keywords Area](#)
- [interface](#)
- [failure_capture](#)
- [recover](#)

Substitute dummy values for the responses

Specification

Alias: none

Argument(s): REALLIST

Description

When a simulation failure is detected, substitute the provided dummy function values in the response. Gradient and Hessian are not supported.

continuation

- [Keywords Area](#)
- [interface](#)
- [failure_capture](#)
- [continuation](#)

Cause Dakota to step toward the failed "target" simulation from a nearby successful "source"

Specification

Alias: none

Argument(s): none

Description

When `failure_capture continuation` is enabled and an evaluation fails, then Dakota will attempt to march incrementally from a previous good evaluation (the "source") toward the failing one (the "target"). Further details about the algorithm employed by Dakota are supplied in the User's Manual [4].

7.5.5 deactivate

- [Keywords Area](#)
- [interface](#)
- [deactivate](#)

Deactivate Dakota interface features for simplicity or efficiency

Specification

Alias: none

Argument(s): none

Default: Active set vector control, function evaluation cache, and restart file features are active

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			active_set_vector	Deactivate the Active Set Vector
	Optional		evaluation_cache	Do not retain function evaluation history in memory
	Optional		strict_cache_ equality	Do not require strict cache equality when finding duplicates
	Optional		restart_file	Deactivate writing to the restart file

Description

The optional `deactivate` specification block allows a user to deactivate interface features in order to simplify interface development, increase execution speed, and/or reduce memory and disk requirements. Any or all of these features may be specified concurrently.

- Active set vector (ASV) control: deactivate so that Dakota expects the same response data (all functions, gradients, Hessian) back from the simulation on every evaluation, instead of only those components required by the method for this particular function evaluation.
- Function evaluation cache: save memory by not caching the function evaluation history. May result in additional (duplicate) function evaluations.
- Strict cache equality: allow a relaxed tolerance when detecting duplicate function evaluations. Can be useful when importing data or restarting across machines.
- Restart file: improve efficiency and eliminate restart file storage at the risk of not being able to recover a failed or partial Dakota study.

active_set_vector

- [Keywords Area](#)
- [interface](#)
- [deactivate](#)
- [active_set_vector](#)

Deactivate the Active Set Vector

Specification

Alias: none

Argument(s): none

Description

Allows the user to turn off any variability in ASV values so that active set logic can be omitted in the user's simulation interface. This option trades some efficiency for simplicity in interface development.

The default behavior is to request the minimum amount of data required by an algorithm at any given time, which implies that the ASV values may vary from one function evaluation to the next. Since the user's interface must return the data set requested by the ASV values, this interface must contain additional logic to account for any variations in ASV content.

Deactivating this ASV control causes Dakota to always request a "full" data set (the full function, gradient, and Hessian data that is available from the interface as specified in the responses specification) on each function evaluation.

For example, if ASV control has been deactivated and the responses section specifies four response functions, analytic gradients, and no Hessians, then the ASV on every function evaluation will be $\{ 3 3 3 3 \}$, regardless of what subset of this data is currently needed. While wasteful of computations in many instances, this simplifies the interface and allows the user to return the same data set on every evaluation. Conversely, if ASV control is active (the default behavior), then the ASV requests in this example might vary from $\{ 1 1 1 1 \}$ to $\{ 2 0 0 2 \}$, etc., according to the specific data needed on a particular function evaluation. This will require the user's interface to read the ASV requests and perform the appropriate logic in conditionally returning only the data requested.

Usage Tips

- In general, the default ASV behavior is recommended for the sake of computational efficiency, unless interface development time is a critical concern.

- Whether active or inactive, the data returned to Dakota from the user's interface must match the ASV passed in, or else a response recovery error will result. However, when the ASV control is deactivated, the ASV values are invariant and need not be checked on every evaluation.
- Deactivating the ASV control can have a positive effect on load balancing for parallel Dakota executions. Thus, there is significant overlap in this ASV control option with speculative gradients. There is also overlap with the mode override approach used with certain optimizers to combine individual value, gradient, and Hessian requests.

evaluation_cache

- [Keywords Area](#)
- [interface](#)
- [deactivate](#)
- [evaluation_cache](#)

Do not retain function evaluation history in memory

Specification

Alias: none

Argument(s): none

Description

Do not retain the complete function evaluation history in memory.

This can be important for reducing memory requirements in large-scale applications (i.e., applications with a large number of variables or response functions) and for eliminating the overhead of searching for duplicates within the function evaluation cache prior to each new function evaluation (e.g., for improving speed in problems with 1000's of inexpensive function evaluations or for eliminating overhead when performing timing studies).

However, the downside is that unnecessary computations may be performed since duplication in function evaluation requests may not be detected. For this reason, this option is not recommended when function evaluations are costly.

Note: duplication detection within Dakota can be deactivated, but duplication detection features within specific optimizers may still be active.

strict_cache_equality

- [Keywords Area](#)
- [interface](#)
- [deactivate](#)
- [strict_cache_equality](#)

Do not require strict cache equality when finding duplicates

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			cache_tolerance	Specify tolerance when identifying duplicate function evaluations

Description

By default, Dakota's evaluation cache and restart capabilities are based on strict binary equality. This provides a performance advantage, as it permits a hash-based data structure to be used to search the evaluation cache. However, deactivating strict equality may prevent cache misses, which can occur when attempting to use a restart file on a machine different from the one on which it was generated.

cache_tolerance

- [Keywords Area](#)
- [interface](#)
- [deactivate](#)
- [strict_cache_equality](#)
- [cache_tolerance](#)

Specify tolerance when identifying duplicate function evaluations

Specification

Alias: none

Argument(s): REAL

Description

Described on parent page

restart_file

- [Keywords Area](#)
- [interface](#)
- [deactivate](#)
- [restart_file](#)

Deactivate writing to the restart file

Specification

Alias: none

Argument(s): none

Description

Eliminate the output of each new function evaluation to the binary restart file. This can increase speed and reduce disk storage requirements, but at the expense of a loss in the ability to recover and continue a run that terminates prematurely (e.g., due to a system crash or network problem).

Usage Tips

- This option is not recommended when function evaluations are costly or prone to failure.
- Using the `deactivate restart_file` specification will result in a zero length restart file with the default name `dakota.rst`.

7.5.6 batch

- [Keywords Area](#)
- [interface](#)
- [batch](#)

Perform evaluations in batches

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): none

Default: sequential interface usage

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			size	Limit the number of evaluations in a batch

Description

When the optional `batch` keyword is used, Dakota performs evaluations in batches. In batch mode, Dakota writes the parameters for multiple (a batch of) evaluations to a single file, invokes the analysis driver once for the whole batch, and expects to find results for the entire batch in a single file after the analysis driver has exited. Batch mode may be useful when a user desires to take greater control over job management. For example, the analysis driver can perform the evaluations in the batch in any sequence or in concurrent sub-batches.

The names of the parameters file and results file are provided as command line arguments to the analysis driver, just as in a conventional, non-batch evaluation. By default, all currently available evaluations will be performed in a single batch, but the batch size can be limited using the [size](#) keyword.

Batch mode has a few important limitations.

- Only one batch at a time may be executed. Asynchronous execution of multiple concurrent batches is not supported.
- No [input_filter](#) or [output_filter](#) is permitted.
- Only one `analysis_driver` is allowed.
- `failure_capture` modes are restricted to [abort](#) and [recover](#).

Some of these restrictions may be lifted in future Dakota releases.

File Formats

A batch parameters file written by Dakota is simply a concatenated set of parameters files for the set of evaluations, either in [aprepro](#) or default Dakota format.

The batch results file is also a concatenated set of results files for the individual evaluations. However, because Dakota's results file format is not as rich as its parameters file format, evaluations in the batch results file must be separated by a line that begins with the '#' character.

The order of evaluations in the batch results file must match the order in the batch parameters file.

Tagging and Work Directories

When Dakota's [work_directory](#) feature is enabled, one directory is created per batch. If [file_tag](#) or [directory_-tag](#) is used, parameters/results files and work directories are tagged with a batch Id, which is an integer that begins with 1 and increments for each new batch.

size

- [Keywords Area](#)
- [interface](#)
- [batch](#)
- [size](#)

Limit the number of evaluations in a batch

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): INTEGER

Default: local: unlimited batch size, hybrid: zero batch size

Description

When `batch` execution is enabled, the default behavior is to add all available evaluations to the current batch. The `size` keyword limits the number of evaluations in a batch.

7.5.7 asynchronous

- [Keywords Area](#)
- [interface](#)
- [asynchronous](#)

Specify local evaluation or analysis concurrency

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): none

Default: synchronous interface usage

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			evaluation_- concurrency	Determine how many concurrent evaluations Dakota will schedule
	Optional		local_evaluation_- scheduling	Control how local asynchronous jobs are scheduled
	Optional		analysis_- concurrency	Limit the number of analysis drivers within an evaluation that Dakota will schedule

Description

The optional `asynchronous` keyword specifies use of asynchronous protocols (i.e., background system calls, nonblocking forks, POSIX threads) when evaluations or analyses are invoked. Evaluation and analysis concurrency can be independently controlled, as can the scheduling mode (static vs. dynamic) of the local evaluations.

Default Behavior

- when running Dakota on a single processor in `asynchronous` mode, the default concurrency of evaluations and analyses is all concurrency that is available. The `evaluation_concurrency` and `analysis_concurrency` specifications can be used to limit this concurrency in order to avoid machine overload or usage policy violation.

- when running Dakota on multiple processors in message passing mode, the default concurrency of evaluations and analyses on each of the servers is one (i.e., the parallelism is exclusively that of the message passing). With the `evaluation_concurrency` and `analysis_concurrency` specifications, a hybrid parallelism can be selected through combination of message passing parallelism with asynchronous parallelism on each server.

evaluation_concurrency

- [Keywords Area](#)
- [interface](#)
- [asynchronous](#)
- [evaluation_concurrency](#)

Determine how many concurrent evaluations Dakota will schedule

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): INTEGER

Default: local: unlimited concurrency, hybrid: no concurrency

Description

When `asynchronous` execution is enabled, the default behavior is to launch all available evaluations simultaneously. The `evaluation_concurrency` keyword can be used to limit the number of concurrent evaluations.

local_evaluation_scheduling

- [Keywords Area](#)
- [interface](#)
- [asynchronous](#)
- [local_evaluation_scheduling](#)

Control how local asynchronous jobs are scheduled

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): none

Default: dynamic

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required (<i>Choose One</i>)	Scheduling Mode (Group 1)	dynamic	Dynamic local scheduling (sequential)
			static	Static local scheduling (tiled)

Description

When performing asynchronous local evaluations, the `local_evaluation_scheduling` keyword controls how new evaluation jobs are dispatched when one completes.

The two options are:

- `dynamic`
- `static`

If the `local_evaluation_scheduling` is specified as `dynamic` (the default), each completed evaluation will be replaced by the next in the local evaluation queue.

If `local_evaluation_scheduling` is specified as `static`, each completed evaluation will be replaced by an evaluation number that is congruent modulo the `evaluation_concurrency`. This is helpful for relative node scheduling as described in `dakota/share/dakota/examples/parallelism`. For example, assuming only asynchronous local concurrency (no MPI), if the local concurrency is 6 and job 2 completes, it will be replaced with job 8.

For the case of hybrid parallelism, static local scheduling results in evaluation replacements that are modulo the total capacity, defined as the product of the evaluation concurrency and the number of evaluation servers. Both of these cases can result in idle processors if runtimes are non-uniform, so the default dynamic scheduling is preferred when relative node scheduling is not required.

dynamic

- [Keywords Area](#)
- [interface](#)
- [asynchronous](#)
- [local_evaluation_scheduling](#)
- [dynamic](#)

Dynamic local scheduling (sequential)

Specification

Alias: none

Argument(s): none

Description

If the `local_evaluation_scheduling` is specified as dynamic (the default), each completed evaluation will be replaced by the next in the local evaluation queue.

static

- [Keywords Area](#)
- [interface](#)
- [asynchronous](#)
- [local_evaluation_scheduling](#)
- [static](#)

Static local scheduling (tiled)

Specification

Alias: none

Argument(s): none

Description

If `local_evaluation_scheduling` is specified as static, each completed evaluation will be replaced by an evaluation number that is congruent modulo the `evaluation_concurrency`. This is helpful for relative node scheduling as described in `dakota/share/dakota/examples/parallelism`. For example, assuming only asynchronous local concurrency (no MPI), if the local concurrency is 6 and job 2 completes, it will be replaced with job 8.

For the case of hybrid parallelism, static local scheduling results in evaluation replacements that are modulo the total capacity, defined as the product of the evaluation concurrency and the number of evaluation servers. Both of these cases can result in idle processors if runtimes are non-uniform, so the default dynamic scheduling is preferred when relative node scheduling is not required.

analysis_concurrency

- [Keywords Area](#)
- [interface](#)
- [asynchronous](#)
- [analysis_concurrency](#)

Limit the number of analysis drivers within an evaluation that Dakota will schedule

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): INTEGER

Default: local: unlimited concurrency, hybrid: no concurrency

Description

When `asynchronous` execution is enabled and each evaluation involves multiple analysis drivers, then the default behavior is to launch all drivers simultaneously. The `analysis_concurrency` keyword can be used to limit the number of concurrently run drivers.

7.5.8 `evaluation_servers`

- [Keywords Area](#)
- [interface](#)
- [evaluation_servers](#)

Specify the number of evaluation servers when Dakota is run in parallel

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): INTEGER

Default: automatic (see discussion)

Description

The optional `evaluation_servers` specification supports user override of the automatic parallel configuration for the number of evaluation servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the evaluation parallelism level. Refer to `ParallelLibrary` and the `Parallel Computing` chapter of the Users Manual [4] for additional information.

7.5.9 `evaluation_scheduling`

- [Keywords Area](#)
- [interface](#)
- [evaluation_scheduling](#)

Specify the scheduling of concurrent evaluations when Dakota is run in parallel

Specification

Alias: none

Argument(s): none

Default: automatic (see discussion)

Child Keywords:

	Required/ Optional Required (<i>Choose One</i>)	Description of Group Server Mode (Group 1)	Dakota Keyword	Dakota Keyword Description
			master	Specify a dedicated master partition for parallel evaluation scheduling
			peer	Specify a peer partition for parallel evaluation scheduling

Description

When Dakota is run in parallel, the partition type and scheduling for the evaluation servers are determined automatically. If these settings are undesirable, they may be overridden by the user using the `evaluation_scheduling` keyword.

master

- [Keywords Area](#)
- [interface](#)
- [evaluation_scheduling](#)
- [master](#)

Specify a dedicated master partition for parallel evaluation scheduling

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): none

Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a dedicated master partition. In a dedicated master partition, one processor (the "master") dynamically schedules work on the evaluation servers. This reduces the number of processors available to create servers by 1.

peer

- [Keywords Area](#)
- [interface](#)
- [evaluation_scheduling](#)
- [peer](#)

Specify a peer partition for parallel evaluation scheduling

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/- Optional Required <i>(Choose One)</i>	Description of Group Scheduling Mode (Group 1)	Dakota Keyword	Dakota Keyword Description
			dynamic	Specify dynamic scheduling in a peer partition when Dakota is run in parallel.
			static	Specify static scheduling in a peer partition when Dakota is run in parallel.

Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a peer partition. In a peer partition, all processors are available to be assigned to evaluation servers. The scheduling, `static` or `dynamic`, must also be specified.

dynamic

- [Keywords Area](#)
- [interface](#)
- [evaluation_scheduling](#)
- [peer](#)
- [dynamic](#)

Specify dynamic scheduling in a peer partition when Dakota is run in parallel.

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): none

Default: dynamic (see discussion)

Description

In `dynamic` scheduling, evaluations are assigned to servers as earlier evaluations complete. Dynamic scheduling is advantageous when evaluations are of uneven duration.

static

- [Keywords Area](#)
- [interface](#)
- [evaluation_scheduling](#)
- [peer](#)
- [static](#)

Specify static scheduling in a peer partition when Dakota is run in parallel.

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): none

Description

In `static` scheduling, all available evaluations are assigned to servers in a predetermined fashion. Each completed evaluation is replaced with one congruent modulo the evaluation concurrency. For example, with 6 servers, eval number 2 will be replaced by eval number 8.

7.5.10 processors_per_evaluation

- [Keywords Area](#)
- [interface](#)
- [processors_per_evaluation](#)

Specify the number of processors per evaluation server when Dakota is run in parallel

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): INTEGER

Default: automatic (see discussion)

Description

The optional `processors_per_evaluation` specification supports user override of the automatic parallel configuration for the number of processors in each evaluation server. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired server size at the evaluation parallelism level. Refer to `ParallelLibrary` and the Parallel Computing chapter of the Users Manual [4] for additional information.

7.5.11 analysis_servers

- [Keywords Area](#)
- [interface](#)
- [analysis_servers](#)

Specify the number of analysis servers when Dakota is run in parallel

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): INTEGER

Default: automatic (see discussion)

Description

The optional `analysis_servers` specification supports user override of the automatic parallel configuration for the number of analysis servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the analysis parallelism level. Refer to `ParallelLibrary` and the Parallel Computing chapter of the Users Manual [4] for additional information.

7.5.12 analysis_scheduling

- [Keywords Area](#)
- [interface](#)
- [analysis_scheduling](#)

Specify the scheduling of concurrent analyses when Dakota is run in parallel

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): none

Default: automatic (see discussion)

Child Keywords:

	Required/- Optional Required <i>(Choose One)</i>	Description of Group Scheduling Mode (Group 1)	Dakota Keyword	Dakota Keyword Description
			master	Specify a dedicated master partition for parallel analysis scheduling
			peer	Specify a peer partition for parallel analysis scheduling

Description

When Dakota is run in parallel, the partition type for the analysis servers is determined automatically. If this setting is undesirable, it may be overridden by the user using the `analysis_scheduling` keyword.

master

- [Keywords Area](#)
- [interface](#)
- [analysis_scheduling](#)
- [master](#)

Specify a dedicated master partition for parallel analysis scheduling

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): none

Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a dedicated master partition. In a dedicated master partition, one processor (the "master") dynamically schedules work on the analysis servers. This reduces the number of processors available to create servers by 1.

peer

- [Keywords Area](#)
- [interface](#)
- [analysis_scheduling](#)
- [peer](#)

Specify a peer partition for parallel analysis scheduling

Topics

This keyword is related to the topics:

- [concurrency_and_parallelism](#)

Specification

Alias: none

Argument(s): none

Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a peer partition. In a peer partition, all processors are available to be assigned to analysis servers. Note that unlike the case of `evaluation_scheduling`, it is not possible to specify `static` or `dynamic`.

7.6 responses

- [Keywords Area](#)
- [responses](#)

Description of the model output data returned to Dakota upon evaluation of an interface.

Topics

This keyword is related to the topics:

- [block](#)

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword id_responses descriptors	Dakota Keyword Description Name the responses block; helpful when there are multiple Labels for the responses
	Required (<i>Choose One</i>)	Response Type (Group 1)	objective_functions	Response type suitable for optimization
			calibration_terms	Response type suitable for calibration or least squares
			response_functions	Generic response type
	Required (<i>Choose One</i>)	Gradient Type (Group 2)	no_gradients	Gradients will not be used
			analytic_gradients	Analysis driver will return gradients
			mixed_gradients	Gradients are needed and will be obtained from a mix of numerical and analytic sources
			numerical_gradients	Gradients are needed and will be approximated by finite differences

	Required(Choose One)	Hessian Type (Group 3)		
			no_hessians	Hessians will not be used
			numerical_hessians	Hessians are needed and will be approximated by finite differences
			quasi_hessians	Hessians are needed and will be approximated by secant updates (BFGS or SR1) from a series of gradient evaluations
			analytic_hessians	Hessians are needed and are available directly from the analysis driver
			mixed_hessians	Hessians are needed and will be obtained from a mix of numerical, analytic, and "quasi" sources

Description

The `responses` specification in a Dakota input file indicates the types of data that can be returned by an interface when invoked during Dakota's execution. The specification includes three groups and two optional keywords.

The response type group indicates the type and number of responses expected by Dakota. It must be one of three types:

1. Optimization: objective and constraint functions
2. Calibration: calibration (least squares) terms and constraint functions
3. Uncertainty Quantification: generic response functions

The response type specified should be consistent with the iterative technique called for in the method specification. Certain general-purpose iterative techniques, such as parameter studies and design of experiments methods, can be used with any of these response types.

The gradient type group indicates the availability of first derivatives (gradient vectors) for the response functions.

The gradient specification also links back to the iterative method used. Gradients commonly are needed when the iterative study involves gradient-based optimization, local reliability analysis for uncertainty quantification, or local sensitivity analysis. They can optionally be used to build some types of surrogate models.

The Hessian type group specifies the availability of second derivatives (Hessian matrices) for the response functions.

Hessian availability for the response functions is similar to the gradient availability specifications, with the addition of support for "quasi-Hessians". The Hessian specification also links back to the iterative method in use; Hessians commonly would be used in gradient-based optimization by full Newton methods or in reliability analysis with second-order limit state approximations or second-order probability integrations.

Examples

Several examples follow. The first example shows an optimization data set containing an objective function and two nonlinear inequality constraints. These three functions have analytic gradient availability and no Hessian availability.

```
responses
  objective_functions = 1
    nonlinear_inequality_constraints = 2
  analytic_gradients
  no_hessians
```

The next example shows a typical specification for a calibration data set. The six residual functions will have numerical gradients computed using the dakota finite differencing routine with central differences of 0.1% (plus/minus delta relative to current variables value = .001*value).

```
responses
  calibration_terms = 6
  numerical_gradients
    method_source dakota
    interval_type central
    fd_gradient_step_size = .001
  no_hessians
```

The last example shows a generic specification that could be used with a nondeterministic sampling iterator. The three response functions have no gradient or Hessian availability; therefore, only function values will be used by the iterator.

```
responses
  response_functions = 3
  no_gradients
  no_hessians
```

Parameter study and design of experiments iterators are not restricted in terms of the response data sets which may be catalogued; they may be used with any of the function specification examples shown above.

Theory

Responses specify the total data set that is available for use by the method over the course of iteration. This is distinguished from the data subset described by an active set vector (see Dakota File Data Formats in the Users Manual [Adams et al., 2010]) indicating the particular subset of the response data needed for a particular function evaluation. Thus, the responses specification is a broad description of the data to be used during a study whereas the active set vector indicates the subset currently needed.

7.6.1 `id_responses`

- [Keywords Area](#)
- [responses](#)
- [id_responses](#)

Name the responses block; helpful when there are multiple

Topics

This keyword is related to the topics:

- [block_identifier](#)

Specification

Alias: none

Argument(s): STRING

Default: use of last responses parsed

Description

The optional `id_responses` keyword accepts a string that uniquely identifies this responses block. A model can then use these responses by specifying the same string in its `responses_pointer` specification.

Default Behavior

If the `id_responses` specification is omitted, a particular responses specification will be used by a model only if that model does not include an `responses_pointer` and the responses block was the last (or only) one parsed.

Usage Tips

- It is a best practice to always use explicit responses IDs and pointers to avoid confusion.
- If only one responses block exists, then `id_responses` can be safely omitted from the responses block (and `responses_pointer` omitted from the model specification(s)), since there is no ambiguity.

Examples

For example, a model specification including

```
model
  responses_pointer = 'R1'
```

will link to a response set with

```
id_responses = 'R1'
```

7.6.2 `descriptors`

- [Keywords Area](#)
- [responses](#)
- [descriptors](#)

Labels for the responses

Specification

Alias: `response_descriptors`

Argument(s): STRINGLIST

Default: root strings plus numeric identifiers

Description

A list of strings which identify the responses. These are used in console and tabular output. Response descriptors are ordered by primary response functions (objective, calibration, or response functions), followed by inequality, then equality constraints, if present.

Default Behavior

The default descriptor strings use a response type-dependent root string plus a one-based numeric identifier:

- Objective functions: `obj_fn_i`
- Calibration terms: `least_sq_term_i`
- Nonlinear inequality constraints: `nl_n_ineq_con_i`
- Nonlinear equality constraints: `nl_n_eq_con_i`
- Response functions: `response_fn_`

Expected Output Dakota will label the various response functions in console and tabular output.

Usage Tips When specifying descriptors for scalar and/or field responses, include as many descriptors as top-level scalar + field responses, e.g.,

```
responses
descriptors 'scalar1' 'scalar2' 'scalar3' 'field1' 'field2'
response_functions 5
scalar_responses 3
field_responses 2
field_lengths 42 24
```

Dakota will append a numeric identifier for each field entry, for a total of 42 `field1_j` and 24 `field2_k` in this example.

Examples

```
responses
descriptors 'cost' 'impact' 'safety'
objective_functions 2
nonlinear_inequality_constraints 1
```

7.6.3 objective_functions

- [Keywords Area](#)
- [responses](#)
- [objective_functions](#)

Response type suitable for optimization

Specification**Alias:** num_objective_functions**Argument(s):** INTEGER**Child Keywords:**

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			sense	Whether to minimize or maximize each objective function
	Optional		primary_scale_ types	Choose a scaling type for each response
	Optional		primary_scales	Supply a characteristic value to scale each response
	Optional		weights	Specify weights for each objective function
	Optional		nonlinear_ inequality_ constraints	Group to specify nonlinear inequality constraints
	Optional		nonlinear_equality_ constraints	Group to specify nonlinear equality constraints
	Optional		scalar_objectives	Number of scalar objective functions
	Optional		field_objectives	Number of field objective functions

Description

Specifies the number (1 or more) of objective functions f_j returned to Dakota for use in the general optimization problem formulation:

$$\begin{aligned}
 \text{minimize:} \quad & f(\mathbf{x}) = \sum_j w_j f_j \\
 & \mathbf{x} \in \mathcal{R}^n \\
 \text{subject to:} \quad & \mathbf{g}_L \leq \mathbf{g}(\mathbf{x}) \leq \mathbf{g}_U \\
 & \mathbf{h}(\mathbf{x}) = \mathbf{h}_t \\
 & \mathbf{a}_L \leq \mathbf{A}_i \mathbf{x} \leq \mathbf{a}_U \\
 & \mathbf{A}_e \mathbf{x} = \mathbf{a}_t \\
 & \mathbf{x}_L \leq \mathbf{x} \leq \mathbf{x}_U
 \end{aligned}$$

Unless [sense](#) is specified, Dakota will minimize the objective functions.

The keywords [nonlinear_inequality_constraints](#) and [nonlinear_equality_constraints](#) specify the number of nonlinear inequality constraints g , and nonlinear equality constraints h , respectively. When interfacing to external applications, the responses must be returned to Dakota in this order in the [results.file](#) :

1. objective functions
2. [nonlinear_inequality_constraints](#)
3. [nonlinear_equality_constraints](#)

An optimization problem's linear constraints are provided to the solver at startup only and do not need to be included in the data returned on every function evaluation. Linear constraints are therefore specified in the [variables](#) block through the [linear_inequality_constraint_matrix](#) A_i and [linear_equality_constraint_matrix](#) A_e .

Lower and upper bounds on the design variables x are also specified in the [variables](#) block.

The optional keywords relate to scaling the objective functions (for better numerical results), formulating the problem as minimization or maximization, and dealing with multiple objective functions through [weights](#) w . If scaling is used, it is applied before multi-objective weighted sums are formed, so, e.g, when both weighting and characteristic value scaling are present the ultimate objective function would be:

$$f = \sum_{j=1}^n w_j \frac{f_j}{s_j}$$

See Also

These keywords may also be of interest:

- [calibration_terms](#)
- [response_functions](#)
- [method](#)
- [variables](#)

sense

- [Keywords Area](#)
- [responses](#)
- [objective_functions](#)
- [sense](#)

Whether to minimize or maximize each objective function

Specification

Alias: none

Argument(s): STRINGLIST

Default: vector values = 'minimize'

Description

The `sense` keyword is used to declare whether each objective function should be minimized or maximized. The argument options are:

- "minimization" (can be abbreviated to "min")
- "maximization" (can be abbreviated to "max")

The number of strings should either be equal to the number of objective functions, or one. If a single string is specified it will apply to each objective function.

primary_scale_types

- [Keywords Area](#)
- [responses](#)
- [objective_functions](#)
- [primary_scale_types](#)

Choose a scaling type for each response

Specification

Alias: `objective_function_scale_types`

Argument(s): STRINGLIST

Default: no scaling

Description

The `primary_scale_types` keyword specifies one or number of primary functions strings indicating the scaling type for each response value in methods that support scaling, when scaling is enabled. If only one type is specified, it will apply to each primary response function.

See the scaling information under specific methods, e.g., `method-*-scaling` for details on how to use this keyword.

Note that primary response functions (objective, calibration, or response functions) cannot be automatically scaled due to lack of bounds, so valid scale types are 'none' 'value' and 'log'.

If scaling is specified, it is applied after any data and/or observation error covariance transformations and before multi-objective or residual weights. sums are formed.

primary_scales

- [Keywords Area](#)
- [responses](#)
- [objective_functions](#)
- [primary_scales](#)

Supply a characteristic value to scale each reponse

Specification

Alias: `objective_function_scales`

Argument(s): REALLIST

Default: 1.0 (no scaling)

Description

Each entry in `primary_scales` is a user-specified nonzero characteristic value to scale each response. The argument may be of length 1 or the number of primary response functions. If only one scale is specified, it will apply to each primary response function.

See the scaling information under specific methods, e.g., `method-*-scaling` for details on how to use this keyword.

If scaling is specified, it is applied before multi-objective weighted sums are formed.

weights

- [Keywords Area](#)
- [responses](#)
- [objective_functions](#)
- [weights](#)

Specify weights for each objective function

Specification

Alias: `multi_objective_weights`

Argument(s): REALLIST

Default: equal weights

Description

For multi-objective optimization problems (where the number of objective functions is greater than 1), then a `weights` specification provides a simple weighted-sum approach to combining multiple objectives into a single objective:

$$f = \sum_{i=1}^n w_i f_i$$

Default Behavior If weights are not specified, then each response is given equal weighting:

$$f = \sum_{i=1}^n \frac{f_i}{n}$$

where, in both of these cases, a "minimization" sense will retain a positive weighting for a minimizer and a "maximization" sense will apply a negative weighting.

If scaling is specified, it is applied before multi-objective weighted sums are formed.

nonlinear_inequality_constraints

- [Keywords Area](#)
- [responses](#)
- [objective_functions](#)
- [nonlinear_inequality_constraints](#)

Group to specify nonlinear inequality constraints

Topics

This keyword is related to the topics:

- [nonlinear_constraints](#)

Specification

Alias: num_nonlinear_inequality_constraints

Argument(s): INTEGER

Default: 0

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		lower_bounds	Specify minimum values
	Optional		upper_bounds	Specify maximum values
	Optional		scale_types	Choose how each constraint is scaled
	Optional		scales	Characteristic values for scaling

Description

Specifies the number of nonlinear inequality constraint functions returned by the interface.

The `lower_bounds` and `upper_bounds` specifications provide the lower and upper bounds for 2-sided nonlinear inequalities of the form

$$g_l \leq g(x) \leq g_u$$

When constraint bounds are not specified, the problem is assumed to have one-sided inequalities bounded above by zero:

$$g(x) \leq 0.0.$$

This provides backwards compatibility with previous Dakota versions.

In a user bounds specification, any upper bound values greater than `+bigRealBoundSize` (1.e+30, as defined in `Minimizer`) are treated as `+infinity` and any lower bound values less than `-bigRealBoundSize` are treated as `-infinity`. This feature is commonly used to drop one of the bounds in order to specify a 1-sided

constraint (just as the default lower bounds drop out since $-\text{DBL_MAX} < -\text{bigRealBoundSize}$). The same approach is used for nonexistent linear inequality bounds and for nonexistent design variable bounds.

The `scale_types` and `scales` keywords are related to scaling of $g(x)$. See the scaling information under specific methods, e.g., `method-*-scaling` for details on how to use this keyword.

lower_bounds

- [Keywords Area](#)
- [responses](#)
- [objective_functions](#)
- [nonlinear_inequality_constraints](#)
- [lower_bounds](#)

Specify minimum values

Specification

Alias: `nonlinear_inequality_lower_bounds`

Argument(s): REALLIST

Default: vector values = -infinity

Description

Specify minimum values

upper_bounds

- [Keywords Area](#)
- [responses](#)
- [objective_functions](#)
- [nonlinear_inequality_constraints](#)
- [upper_bounds](#)

Specify maximum values

Specification

Alias: `nonlinear_inequality_upper_bounds`

Argument(s): REALLIST

Default: vector values = 0 .

Description

Specify maximum values

scale_types

- [Keywords Area](#)
- [responses](#)
- [objective_functions](#)
- [nonlinear_inequality_constraints](#)
- [scale_types](#)

Choose how each constraint is scaled

Specification

Alias: nonlinear_inequality_scale_types

Argument(s): STRINGLIST

Default: no scaling

Description

Type of scaling to apply to nonlinear constraints: 'none', 'value', 'auto' or 'log'. If a single string is specified it will apply to all components of the relevant nonlinear constraint vector.

See the scaling information under specific methods, e.g., method-*-scaling for details on how to use this keyword.

scales

- [Keywords Area](#)
- [responses](#)
- [objective_functions](#)
- [nonlinear_inequality_constraints](#)
- [scales](#)

Characteristic values for scaling

Specification

Alias: nonlinear_inequality_scales

Argument(s): REALLIST

Default: 1.0 (no scaling)

Description

See the scaling information under specific methods, e.g., method-*-scaling for details on how to use this keyword.

nonlinear_equality_constraints

- [Keywords Area](#)
- [responses](#)
- [objective_functions](#)
- [nonlinear_equality_constraints](#)

Group to specify nonlinear equality constraints

Topics

This keyword is related to the topics:

- [nonlinear_constraints](#)

Specification

Alias: num_nonlinear_equality_constraints

Argument(s): INTEGER

Default: 0

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		targets	Target values for the nonlinear equality constraint
	Optional		scale_types	Choose how each constraint is scaled
	Optional		scales	Characteristic values for scaling

Description

Specifies the number of nonlinear equality constraint functions returned by the interface.

The `targets` specification provides the targets for nonlinear equalities of the form

$$h(x) = h_t$$

and the defaults for the equality targets enforce a value of 0. for each constraint

$$h(x) = 0.0$$

The `scale_types` and `scales` keywords are related to scaling of $h(x)$. See the scaling information under specific methods, e.g., `method-*-scaling` for details on how to use this keyword.

targets

- [Keywords Area](#)

- [nonlinear_equality_constraints](#)
- [targets](#)

Target values for the nonlinear equality constraint

Specification

Alias: nonlinear_equality_targets

Argument(s): REALLIST

Default: vector values = 0 .

Description

The `targets` specification provides the targets for nonlinear equalities of the form

$$g(x) = g_t$$

and the defaults for the equality targets enforce a value of 0 . 0 for each constraint:

$$g(x) = 0.0$$

scale_types

- [Keywords Area](#)
- [responses](#)
- [objective_functions](#)
- [nonlinear_equality_constraints](#)
- [scale_types](#)

Choose how each constraint is scaled

Specification

Alias: nonlinear_equality_scale_types

Argument(s): STRINGLIST

Default: no scaling

Description

Type of scaling to apply to nonlinear constraints: 'none', 'value', 'auto' or 'log'. If a single string is specified it will apply to all components of the relevant nonlinear constraint vector.

See the scaling information under specific methods, e.g., method-*-scaling for details on how to use this keyword.

scales

- [Keywords Area](#)
- [responses](#)
- [objective_functions](#)
- [nonlinear_equality_constraints](#)
- [scales](#)

Characteristic values for scaling

Specification

Alias: nonlinear_equality_scales

Argument(s): REALLIST

Default: 1.0 (no scaling)

Description

See the scaling information under specific methods, e.g., method-*-scaling for details on how to use this keyword.

scalar_objectives

- [Keywords Area](#)
- [responses](#)
- [objective_functions](#)
- [scalar_objectives](#)

Number of scalar objective functions

Specification

Alias: num_scalar_objectives

Argument(s): INTEGER

Description

This keyword describes the number of scalar objective functions. It is meant to be used in conjunction with `field_objectives`, which describes the number of field objectives functions. The total number of objective functions, both scalar and field, is given by `objective_functions`. If only scalar objective functions are specified, it is not necessary to specify the number of scalar terms explicitly: one can simply say `objective_functions = 5` and get 5 scalar objectives. However, if there are three scalar objectives and 2 field objectives, then `objective_functions = 5` but `scalar_objectives = 3` and `field_objectives = 2`.

Objective functions are responses that are used with optimization methods in Dakota. Currently, each term in a field objective is added to the total objective function presented to the optimizer. For example, if you have one field objective with 100 terms (e.g. a time-temperature trace with 100 time points and 100 corresponding temperature points), the 100 temperature values will be added to create the overall objective.

Number of field objective functions

Specification

Alias: `num_field_objectives`

Argument(s): INTEGER

Child Keywords:

	Required/ Optional Required	Description of Group	Dakota Keyword	Dakota Keyword Description
			lengths	Lengths of field responses
	Optional		num_coordinates_per_field	Number of independent coordinates for field responses
	Optional		read_field_coordinates	Add context to data: flag to indicate that field coordinates should be read

Description

This keyword describes the number of field objective functions. A field function is a set of related response values collected over a range of independent coordinate values which may or may not be specified by the user. For example, voltage over time would be a field function, where voltage is the `field_objective` and time is the independent coordinate. Similarly, temperature over time and space would be a field response, where the independent coordinates would be both time and spatial coordinates such as (x,y) or (x,y,z), depending on the application. The main difference between scalar objectives and field objectives is that for field data, we plan to implement methods that take advantage of the correlation or relationship between the field values.

Note that if there is one `field_objective`, and it has length 100 (meaning 100 values), then the user's simulation code must return 100 values. Also, if there are both scalar and field objectives, the user should specify the number of scalar objectives as `scalar_objectives`. If there are only field objectives, it still is necessary to specify both `objective_functions = NN` and `field_objectives = NN`, where NN is the number of field objectives.

Objective functions are responses that are used with optimization methods in Dakota. Currently, each term in a field objective is added to the total objective function presented to the optimizer. For example, if you have one field objective with 100 terms (e.g. a time-temperature trace with 100 time points and 100 corresponding temperature points), the 100 temperature values will be added to create the overall objective.

lengths

- [Keywords Area](#)
- [responses](#)
- [objective_functions](#)
- [field_objectives](#)
- [lengths](#)

Lengths of field responses

Specification

Alias: none

Argument(s): INTEGERLIST

Description

This keyword describes the lengths of each field response. It is an integer vector of length `field_responses`. For example, if the `field_responses = 2`, an example would be `lengths = 50 200`, indicating that the first field response has 50 field elements but the second one has 200. The coordinate values (e.g. the independent variables) corresponding to these field responses are read in files labeled `response_descriptor.coords`.

num_coordinates_per_field

- [Keywords Area](#)
- [responses](#)
- [objective_functions](#)
- [field_objectives](#)
- [num_coordinates_per_field](#)

Number of independent coordinates for field responses

Specification

Alias: none

Argument(s): INTEGERLIST

Description

This keyword describes the number of independent coordinates for each field response. It is an integer vector of length `field_responses`. For example, if the `field_responses = 2`, an example would be `num_coordinates_per_field = 2 1` means that the first field response has two sets of independent coordinates (perhaps x , y locations), but the second response only has one (for example, time where the field response is only dependent upon time). The actual coordinate values (e.g. the independent variables) corresponding to these field responses are defined in a file call `response_descriptor.coords`, where `response_descriptor` is the name of the individual field.

read_field_coordinates

- [Keywords Area](#)
- [responses](#)
- [objective_functions](#)
- [field_objectives](#)
- [read_field_coordinates](#)

Add context to data: flag to indicate that field coordinates should be read

Specification

Alias: none

Argument(s): none

Description

Field coordinates specify independent variables (e.g. spatial or temporal coordinates) upon which the field depends. For example, the voltage level above might be a function of time, so time is the field coordinate. If the user has field coordinates to read, they need to specify `read_field_coordinates`. The field coordinates will then be read from a file named `response_descriptor.coords`, where `response_descriptor` is the user-provided descriptor for the field response. The number of columns in the `coords` file should be equal to the number of field coordinates.

7.6.4 calibration_terms

- [Keywords Area](#)
- [responses](#)
- [calibration_terms](#)

Response type suitable for calibration or least squares

Specification

Alias: `least_squares_terms` `num_least_squares_terms`

Argument(s): INTEGER

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		scalar_calibration_-terms	Number of scalar calibration terms
	Optional		field_calibration_-terms	Number of field calibration terms
	Optional		primary_scale_-types	Choose a scaling type for each response
	Optional		primary_scales	Supply a characteristic value to scale each response

	Optional	weights	Apply different weights to each response
	Optional (Choose One)	Calibration Data (Group 1)	calibration_data
			Supply field or mixed field/scalar calibration data
		calibration_data_-file	Supply scalar calibration data only
	Optional	simulation_-variance	Variance applied to simulation responses
	Optional	nonlinear_-inequality_-constraints	Group to specify nonlinear inequality constraints
	Optional	nonlinear_equality_-constraints	Group to specify nonlinear equality constraints

Description

Responses for a calibration study are specified using `calibration_terms` and optional keywords for weighting/scaling, data, and constraints. In general when calibrating, Dakota automatically tunes parameters θ to minimize discrepancies or residuals between the model and the data:

$$R_i = y_i^{Model}(\theta) - y_i^{Data}.$$

Note that the problem specification affects what must be returned to Dakota in the [results_file](#) :

- If calibration data *is not specified*, then each of the calibration terms returned to Dakota through the [interface](#) is a residual R_i to be driven toward zero.
- If calibration data *is specified*, then each of the calibration terms returned to Dakota must be a response $y_i^{Model}(\theta)$, which Dakota will difference with the data in the specified data file.

Constraints

(See general problem formulation at [objective_functions](#).) The keywords [nonlinear_inequality_constraints](#) and [nonlinear_equality_constraints](#) specify the number of nonlinear inequality constraints g , and nonlinear equality constraints h , respectively. When interfacing to external applications, the responses must be returned to Dakota in this order in the [results_file](#) :

1. calibration terms
2. nonlinear inequality constraints

3. nonlinear equality constraints

An optimization problem's linear constraints are provided to the solver at startup only and do not need to be included in the data returned on every function evaluation. Linear constraints are therefore specified in the `variables` block through the `linear_inequality_constraint_matrix` A_i and `linear_equality_constraint_matrix` A_e .

Lower and upper bounds on the design variables x are also specified in the `variables` block.

Problem Transformations

Weighting or scaling calibration terms is often appropriate to account for measurement error or to condition the problem for easier solution. Weighting or scaling transformations are applied in the following order:

1. When present, observation error variance σ_i or full covariance Σ , optionally specified through `experiment_variance_type`, is applied to residuals first:

$$R_i^{(1)} = \frac{R_i}{\sigma_i} = \frac{y_i^{Model}(\theta) - y_i^{Data}}{\sigma_i}, \text{ or}$$

$$R^{(1)} = \Sigma^{-1/2} R = \Sigma^{-1/2} (y^{Model}(\theta) - y^{Data}),$$

resulting in the typical variance-weighted least squares formulation

$$\min_{\theta} R(\theta)^T \Sigma^{-1} R(\theta)$$

2. Any active scaling transformations are applied next, e.g., for characteristic value scaling:

$$R_i^{(2)} = \frac{R_i^{(1)}}{s_i}$$

3. Finally the optional weights are applied in a way that preserves backward compatibility:

$$R_i^{(3)} = \sqrt{w_i} R_i^{(2)}$$

so the ultimate least squares formulation, e.g., in a scaled and weighted case would be

$$f = \sum_{i=1}^n w_i \left(\frac{y_i^{Model} - y_i^{Data}}{s_i} \right)^2$$

Note that specifying observation error variance and weights are mutually exclusive in a calibration problem.

Theory

Dakota calibration terms are typically used to solve problems of parameter estimation, system identification, and model calibration/inversion. Local least squares calibration problems are most efficiently solved using special-purpose least squares solvers such as Gauss-Newton or Levenberg-Marquardt; however, they may also be solved using any general-purpose optimization algorithm in Dakota. While Dakota can solve these problems with either least squares or optimization algorithms, the response data sets to be returned from the simulator are different when using `objective_functions` versus `calibration_terms`.

Least squares calibration involves a set of residual functions, whereas optimization involves a single objective function (sum of the squares of the residuals), i.e.,

$$f = \sum_{i=1}^n R_i^2 = \sum_{i=1}^n (y_i^{Model}(\theta) - y_i^{Data})^2$$

where f is the objective function and the set of R_i are the residual functions, most commonly defined as the difference between a model response and data. Therefore, function values and derivative data in the least squares case involve the values and derivatives of the residual functions, whereas the optimization case involves values and derivatives of the sum of squares objective function. This means that in the least squares calibration case, the user must return each of n residuals separately as a separate calibration term. Switching between the two approaches sometimes requires different simulation interfaces capable of returning the different granularity of response data required, although Dakota supports automatic recasting of residuals into a sum of squares for presentation to an optimization method. Typically, the user must compute the difference between the model results and the observations when computing the residuals. However, the user has the option of specifying the observational data (e.g. from physical experiments or other sources) in a file.

- [scalar_calibration_terms](#)

Number of scalar calibration terms

Specification

Alias: none

Argument(s): INTEGER

Description

This keyword describes the number of scalar calibration terms. It is meant to be used in conjunction with `field_calibration_terms`, which describes the number of field calibration terms. The total number of calibration terms, both scalar and field, is given by `calibration_terms`. If only scalar calibration terms are specified, it is not necessary to specify the number of scalar terms explicitly: one can simply say `calibration_terms = 5` and get 5 scalar terms. However, if there are three scalar terms and 2 field terms, then `calibration_terms = 5` but `scalar_calibration_terms = 3` and `field_calibration_terms = 2`.

Calibration terms are responses that are used with calibration methods in Dakota, such as least squares optimizers. Currently, each scalar term is added to the total sum-of-squares error function presented to the optimizer. However, each individual field value is added as well. For example, if you have one field calibration term with length 100 (e.g. a time - temperature trace with 100 time points and 100 temperature points), the 100 temperature values will be added to create the overall sum-of-squares error function used in calibration.

Number of field calibration terms

Specification

Alias: none

Argument(s): INTEGER

Child Keywords:

	Required/ Optional Required	Description of Group	Dakota Keyword	Dakota Keyword Description
			lengths	Lengths of field responses
	Optional		num_coordinates_- per_field	Number of independent coordinates for field responses
	Optional		read_field_- coordinates	Add context to data: flag to indicate that field coordinates should be read

Description

This keyword describes the number of field calibration terms. A set of field calibration terms is a set of related response values collected over a range of independent coordinate values which may or may not be specified by the user. For example, voltage over time would be a field function, where voltage is the `field_objective` and time is the independent coordinate. Similarly, temperature over time and space would be a field response, where the independent coordinates would be both time and spatial coordinates such as (x,y) or (x,y,z), depending on the application. The main difference between scalar calibration terms and field calibration terms is that for field data, we plan to implement methods that take advantage of the correlation or relationship between the field values. For example, with calibration, if we want to calibrate parameters that result in a good model fit to a time-temperature curve, we may have to do some interpolation between the experimental data and the simulation data. That capability requires knowledge of the independent coordinates.

Note that if there is one `field_calibration_terms`, and it has length 100 (meaning 100 values), then the user's simulation code must return 100 values. Also, if there are both scalar and field calibration, the user should specify the number of scalar terms as `scalar_calibration_terms`. If there are only field calibration

terms, it still is necessary to specify both `field_calibration_terms = NN` and `calibration_terms = NN`, where NN is the number of field calibration terms.

Calibration terms are responses that are used with calibration methods in Dakota, such as least squares optimizers. Currently, each scalar term is added to the total sum-of-squares error function presented to the optimizer. However, each individual field value is added as well. For example, if you have one field calibration term with length 100 (e.g. a time-temperature trace with 100 time points and 100 temperature points), the 100 temperature values will be added to create the overall sum-of-squares error function used in calibration. We have an initial capability to interpolate the field data from the user's simulation to the experimental data. For example, if the user has thermocouple readings at 20 time points, it will be an experimental field response with 20 time points and 20 temperature values. Dakota takes the 100 simulation time-temperature values (from the example above) and interpolates those to the 20 experimental points, to create 20 residual terms (simulation minus experimental data points) that will be used in calibration.

- [calibration_terms](#)
- [field_calibration_terms](#)
- [read_field_coordinates](#)

Add context to data: flag to indicate that field coordinates should be read

Specification

Alias: none

Argument(s): none

Description

Field coordinates specify independent variables (e.g. spatial or temporal coordinates) upon which the field depends. For example, the voltage level above might be a function of time, so time is the field coordinate. If the user has field coordinates to read, they need to specify `read_field_coordinates`. The field coordinates will then be read from a file named `response_descriptor.coords`, where `response_descriptor` is the user-provided descriptor for the field response. The number of columns in the `coords` file should be equal to the number of field coordinates.

primary_scale_types

- [Keywords Area](#)
- [responses](#)
- [calibration_terms](#)
- [primary_scale_types](#)

Choose a scaling type for each response

Specification

Alias: `calibration_term_scale_types` `least_squares_term_scale_types`

Argument(s): STRINGLIST

Default: no scaling

Description

The `primary_scale_types` keyword specifies one or number of primary functions strings indicating the scaling type for each response value in methods that support scaling, when scaling is enabled. If only one type is specified, it will apply to each primary response function.

See the scaling information under specific methods, e.g., `method-*-scaling` for details on how to use this keyword.

Note that primary response functions (objective, calibration, or response functions) cannot be automatically scaled due to lack of bounds, so valid scale types are `'none'` `'value'` and `'log'`.

If scaling is specified, it is applied after any data and/or observation error covariance transformations and before multi-objective or residual weights. sums are formed.

primary_scales

- [Keywords Area](#)
- [responses](#)
- [calibration_terms](#)
- [primary_scales](#)

Supply a characteristic value to scale each response

Specification

Alias: calibration_term_scales least_squares_term_scales

Argument(s): REALLIST

Default: 1.0 (no scaling)

Description

Each entry in `primary_scales` is a user-specified nonzero characteristic value to scale each response. The argument may be of length 1 or the number of primary response functions. If only one scale is specified, it will apply to each primary response function.

See the scaling information under specific methods, e.g., `method-*-scaling` for details on how to use this keyword.

If scaling is specified, it is applied before multi-objective weighted sums are formed.

weights

- [Keywords Area](#)
- [responses](#)
- [calibration_terms](#)
- [weights](#)

Apply different weights to each response

Specification

Alias: calibration_weights least_squares_weights

Argument(s): REALLIST

Default: equal weights

Description

Specifies relative emphasis on residual elements:

$$f = \sum_{i=1}^n w_i R_i^2 = \sum_{i=1}^n w_i (y_i^{Model} - y_i^{Data})^2$$

When scaling is also active, it is applied prior to weighting.

calibration_data

- [Keywords Area](#)
- [responses](#)
- [calibration_terms](#)
- [calibration_data](#)

Supply field or mixed field/scalar calibration data

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		num_experiments	Add context to data: number of different experiments
	Optional		num_config_-variables	Add context to data: number of configuration variables.
	Optional		experiment_-variance_type	Add context to data: specify the type of experimental error
	Optional		scalar_data_file	Specify a scalar data file to complement field data files (mixed case)
	Optional		interpolate	Flag to indicate interpolation of simulation values.

Description

`calibration_data` specifies a keyword block that indicates that Dakota should read in experimental data for calibration. This block is primarily to support the reading of field calibration data. For simpler, scalar-only response cases, see [calibration_data_file](#). The user will typically specify the number of experiments, `num_experiments`. If this is not specified, it is assumed there is only one experiment.

Up to four types of data may be read. They are read from a collection of files, one per response descriptor, per experiment. In this discussion, DESC refers to the response descriptor and NUM to the experiment number.

1. **Values:** The scalar or field-valued response function values, e.g., temperature values, voltage levels. These are read from files named `DESC.NUM.dat` (one per response descriptor, per experiment), e.g, `volts.1.dat`, `volts.2.dat`. Scalar files will contain a single value, while field files will each contain a column of field response values. Without [interpolate](#) enabled, the lengths of these files must match those specified using the `responses-calibration_terms-field_calibration_terms-lengths` keyword.
2. **Coordinates:** Field coordinates specify independent variables (e.g., spatial or temporal coordinates) upon which the field depends. For example, the voltage might be a function of time, so time is the field coordinate. These are read from files named `DESC.NUM.coords`, each containing [num_coordinates_per_field](#) columns. The number of rows must be the same as in the values files described in the previous bullet.

3. **Variations:** If `experiment_variance_type` is specified, variance values are read from files `DESC.NUM.-sigma`. Note that a single `experiment_variance_type` may be specified, or a unique `experiment_variance_type` per response descriptor (per scalar or field). If the `experiment_variance_type` is:
 - 'scalar': a single variance value will be read from the file.
 - 'diagonal' (field responses only): a column vector of variance values (length equal to the number of experimental data points) will be read from the file. The values are the variances of each field value for this descriptor.
 - 'matrix' (field responses only): a matrix of covariance values (square with size the number of experimental values) will be read from the file. The matrix is a full covariance matrix for the components of this field response. While covariance among entries in a field response may be specified, covariance among experiments is not permitted.
4. **Configuration variables:** specify the conditions corresponding to different experiments. When `responses-calibration_terms-calibration_data-num_config_variables` is specified, the configuration variable values for each experiment should be placed in a file named `experiment.NUM.config`, where the number of items in that config file are the `num_config_variables`. These variables are used as auxiliary state variables for the simulation (for example) and are not calibrated.

Aggregating scalar data: The above description is primarily relevant for field data (with files for field values, field coordinates, field variances). If the user also has scalar experimental data, it may be entered as described above, i.e., one file named `DESC.NUM.dat` per scalar response. However, an alternative is to provide the data for all scalar responses in aggregate in the simpler `scalar_data_file` format, with the number of rows of that file equal to the number of experiments. The scalar data file may be used in combination with the the separate field files described above.

Interpolation: One important feature of field data is the capability to interpolate between points in the field. For example, we may have simulation data at a set of responses y at time points t : $(t_{s1}, y_{s1}), (t_{s2}, y_{s2}),$ etc. In this example, t is the independent coordinate for the simulation, and the simulation time and response points are denoted with subscripts $s1, s2, s3,$. If the user has experimental data that is taken at different time points: $(t_{e1}, y_{e1}), (t_{e2}, y_{e2}), \dots,$ it is necessary to interpolate the simulation data to provide estimates of the simulation response at the experimental time points to construct the residual terms (model - experiment) at the experimental time points. Dakota can perform 1-D interpolation. The user must specify the keyword `interpolate`, and also provide the field coordinates as well as field values for the experiment data.

If the `interpolate` keyword is not specified, Dakota will assume that the simulation field data and the experiment field data is taken at the same set of independent coordinate values and simply construct the difference between these field terms to create the set of residuals for the sum-of-squares calculation. When `interpolate` is specified, the simulation coordinates are assumed fixed and the same for each simulation. These simulation coordinates are provided in `DESC.coords`. However, the experiment coordinates for each experiment can be different, and are provided in the files numbered by experiment with the file names given by `DESC.NUM.coords`, as indicated above.

Examples

Consider this field example with three field-valued responses (volts as a function of 7 time points, amps as a function of 3 time points, and power as a function of 5 time points). The experiments each have one coordinate (time) per field. The experiments were conducted given values of two configuration variables. There are four experiments (note that there often is only one experiment).

```
responses
  descriptors = 'volts' 'amps' 'power'
```

```

calibration_terms = 3

#define field terms
field_calibration_terms = 3
  lengths = 7 3 5
  num_coordinates_per_field = 1 1 1
  read_field_coordinates

# specify the data
calibration_data
  num_experiments = 4
  num_config_variables = 2
  experiment_variance_type 'diagonal' 'scalar' 'matrix'

```

The field data will be read from separate files:

1. **Values:** 7 values for voltage as a function of time will be read from each of `volts.1.dat ... volts.4.dat`, while the 3 values of amperage come from `amps.1.dat, ..., amps.4.dat` and the 5 values of power will come from `power.1.dat, ..., power.4.dat`.
2. **Coordinates:** The corresponding time values will be read from a single column vector in each of the files `volts.*.coords`, `amps.*.coords`, and `power.*.coords`.
3. **Variations:** Will be read per-experiment (no covariance among experiments is permitted). The variance information is depicted graphically in [experiment_variance_type](#)
 - Volts specifies 'diagonal' covariance, so a column vector of length 7 with the diagonal variances will be read from each of `volts.1.sigma, ..., volts.4.sigma`.
 - Amps specifies 'scalar' covariance, so a single variance value will read from each of `amps.1.-sigma, ..., amps.4.sigma`.
 - Power specifies 'matrix' covariance, so a square 5 x 5 covariance matrix will be read from each of `power.1.sigma, ..., power.4.sigma`.
4. **Configuration variables:** Will be read from a set of files named `experiment.1.config, ..., experiment.4.config`.

num_experiments

- [Keywords Area](#)
- [responses](#)
- [calibration_terms](#)
- [calibration_data](#)
- [num_experiments](#)

Add context to data: number of different experiments

Specification

Alias: none

Argument(s): INTEGER

Default: 1

Description

The number of different experiments. Dakota will expand the total number of residual terms based on the number of calibration terms and the number of experiments. For example, if the number of calibration terms are five scalars, and there are three experiments, the total number of residuals in the least squares formulation will be 15. See [calibration_data](#) or [calibration_data_file](#).

num_config_variables

- [Keywords Area](#)
- [responses](#)
- [calibration_terms](#)
- [calibration_data](#)
- [num_config_variables](#)

Add context to data: number of configuration variables.

Specification

Alias: none

Argument(s): INTEGER

Default: 0

Description

If there are multiple experiments, there can be different configuration variables (e.g. experimental settings, boundary conditions, etc.) per experiment. See [calibration_data](#) or [calibration_data_file](#).

During calibration, configuration variables are state variables which will be passed to the simulation, and are not treated as calibration parameters.

experiment_variance_type

- [Keywords Area](#)
- [responses](#)
- [calibration_terms](#)
- [calibration_data](#)
- [experiment_variance_type](#)

Add context to data: specify the type of experimental error

Specification

Alias: variance_type

Argument(s): STRINGLIST

Default: none

Description

There are four options for specifying the experimental error (e.g. the measurement error in the data you provide for calibration purposes): 'none' (default), 'scalar', 'diagonal', or 'matrix.'

If the user specifies scalar, they can provide a scalar variance per calibration term. Note that for scalar calibration terms, only 'none' or 'scalar' are options for the measurement variance. However, for field calibration terms, there are two additional options. 'diagonal' allows the user to provide a vector of measurement variances (one for each term in the calibration field). This vector corresponds to the diagonal of the full covariance matrix of measurement errors. If the user specifies 'matrix', they can provide a full covariance matrix (not just the diagonal terms), where each element (i,j) of the covariance matrix represents the covariance of the measurement error between the i-th and j-th field values.

Usage Tips

Variance information is specified on a per-response group (descriptor), per-experiment basis. Off-diagonal covariance between response groups or between experiments is not supported.

Examples

The figure below shows an observation vector with 5 responses; 2 scalar + 3 field (each field of length > 1). The corresponding covariance matrix has scalar variances σ_1^2, σ_2^2 for each of the scalars s_1, s_2 , diagonal covariance D_3 for field f_3 , scalar covariance σ_4^2 for field f_4 , and full matrix covariance C_5 for field f_5 . In total, Dakota supports block diagonal covariance Σ across the responses, with blocks Σ_i , which could be fully dense within a given field response group. Covariance across the highest-level responses (off-diagonal blocks) is not supported, nor is covariance between experiments.

scalar_data_file

- [Keywords Area](#)
- [responses](#)
- [calibration_terms](#)
- [calibration_data](#)
- [scalar_data_file](#)

Specify a scalar data file to complement field data files (mixed case)

Specification

Alias: none

Argument(s): STRING

Child Keywords:

	Required/- Optional <i>Optional(Choose One)</i>	Description of Group Tabular Format (Group 1)	Dakota Keyword custom_annotated	Dakota Keyword Description Selects custom-annotated tabular file format for experiment data
			annotated	Selects annotated tabular file format for experiment data
			freeform	Selects free-form tabular file format for experiment data

Description

When calibrating both scalar and field calibration terms, to associated experimental data, the scalar data may be provided in the file named by `scalar_data_file`. This file follows the same format as: [calibration_data_file](#).

Default Behavior

If `scalar_data_file` is omitted, all calibration data, including for scalar responses, will be read from the generic field `calibration_data` format.

custom_annotated

- [Keywords Area](#)
- [responses](#)
- [calibration_terms](#)
- [calibration_data](#)
- [scalar_data_file](#)
- [custom_annotated](#)

Selects custom-annotated tabular file format for experiment data

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		header	Enable header row in custom-annotated tabular file
	Optional		exp_id	Enable experiment ID column in custom-annotated tabular file

Description

A custom-annotated tabular file is a whitespace-separated text file containing experiment data, including configuration variables, observations, and/or observation errors, depending on context. For experiment import, custom-annotated allows user options for whether `header` row and `exp_id` column appear in the tabular file, thus bridging `freeform` and (fully) annotated.

Default Behavior

By default, Dakota imports tabular experiment data files in annotated format. The `custom_annotated` keyword, followed by options can be used to select other formats.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

Examples

Import an experimental data file containing a header row, no leading `exp_id` column, and experiment data in a calibration study

```
responses
...
scalar_data_file 'shock_experiment.dat'
  custom_annotated header
```

Example data file with two measured quantities, three experiments:

```
% velocity stress
18.23 83.21
34.14 93.24
22.41 88.92
```

header

- [annotated](#)

Selects annotated tabular file format for experiment data

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. For experiment data files, each subsequent row contains an experiment ID, followed by data for configuration variables, observations, and/or observation errors, depending on context.

Default Behavior

By default, Dakota imports tabular experiment data files in annotated format. The `annotated` keyword can be used to explicitly specify this.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

Examples

Import an annotated experimental data file containing a header row, leading `exp_id` column, and experiment data in a calibration study

```
responses
...
scalar_data_file 'shock_experiment.dat'
  annotated
```

Example data file with two measured quantities, three experiments:

```
%exp_id    velocity    stress
1          18.23      83.21
2          34.14      93.24
3          22.41      88.92
```

freeform

- [Keywords Area](#)
- [responses](#)
- [calibration_terms](#)
- [calibration_data](#)
- [scalar_data_file](#)
- [freeform](#)

Selects free-form tabular file format for experiment data

Topics

This keyword is related to the topics:

- [file_formats](#)

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. For experiment data files, each row contains data for configuration variables, observations, and/or observation errors, depending on context.

Default Behavior

By default, Dakota imports tabular experiment data files in annotated format. Specify `freeform` to instead select this format.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though `freeform` remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

Examples

Import a free-form experimental data file containing raw experiment data in a calibration study

```
responses
...
scalar_data_file 'shock_experiment.dat'
  freeform
```

Example data file with two measured quantities, three experiments:

18.23	83.21
34.14	93.24
22.41	88.92

interpolate

- [Keywords Area](#)
- [responses](#)
- [calibration_terms](#)
- [calibration_data](#)
- [interpolate](#)

Flag to indicate interpolation of simulation values.

Specification

Alias: none

Argument(s): none

Description

If `interpolate` is specified, Dakota will interpolate between the simulation data and the experiment data to calculate the residuals for calibration methods. Specifically, the simulation data is interpolated onto the experimental data points. So, if the simulation data is a field of length 100 with one independent coordinate, and the experiment data is of length 5 with one independent coordinate, the interpolation is done between the 100 (t,f) simulation points (where t is the independent coordinate and f is the simulation field value) onto the five (t_e, f_e) points to obtain the residual differences between the simulation and experiment. See [calibration_data](#).

calibration_data_file

- [Keywords Area](#)
- [responses](#)
- [calibration_terms](#)
- [calibration_data_file](#)

Supply scalar calibration data only

Specification

Alias: least_squares_data_file

Argument(s): STRING

Default: none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional(<i>Choose One</i>)	Tabular Format (Group 1)	custom_annotated	Selects custom-annotated tabular file format for experiment data
			annotated	Selects annotated tabular file format for experiment data
			freeform	Selects free-form tabular file format for experiment data
	Optional		num_experiments	Add context to data: number of different experiments
	Optional		num_config_variables	Add context to data: number of configuration variables.
	Optional		experiment_variance_type	Add context to data: specify the type of experimental error

Description

Enables text file import of experimental observations for use in calibration, for scalar responses only, with optional scalar variance information. For more complex data import cases see [calibration_data](#) Dakota will calibrate model variables to best match these data.

Key options include:

- **format:** whether the data file is in `annotated`, `custom_annotated`, or `freeform` format
- **content:** where `num_experiments`, `num_config_variables`, and `experiment_variance_type` indicate which columns appear in the data.

In the most general case, the content of the data file is described by the arguments of three optional parameters.

- `num_experiments (N_{exp})`

Default: $N_{exp} = 1$

This indicates that the data represent multiple experiments, where each experiment might be conducted with different values of configuration variables. An experiment can also be thought of as a replicate, where the experiments are run at the same values of the configuration variables.

- `num_config_variables (N_{cfg})`

Configuration variables specify the values of experimental conditions at which data were collected. The variables in these columns must correspond to state variables in the calibration study. The simulation model will be run at each configuration and compared to the appropriate experiment data.

- `experiment_variance_type ('none' or 'scalar')`

This indicates if the data file contains variances for measurement error of the experimental data. The default is 'none'.

While some components may be omitted, the most complete version of a an annotated calibration data file could include columns corresponding to experiment ID, configuration variables, function value observations, and variances (observation errors), shown here in annotated format:

```
%exp_id | configuration xvars | y data observations | y data variances
1        7.8 7                21.9372  1.8687        0.25  0.04
2        8.6 2                19.0779  4.8976        0.25  0.04
3        8.4 8                38.2758  4.4559        0.25  0.04
4        4.2 1                39.7600  6.4631        0.25  0.04
```

Each row in the file corresponds to an experiment or replicate observation of an experiment to be compared to the model output. This example shows 4 experiments, governed by two configuration variables (one real-valued and one integer-valued), two responses (QOIs), and corresponding observation errors with standard deviation 0.5 and 0.2.

Usage Tips

- The `calibration_data_file` keyword is used when *only* scalar calibration terms are present. If there are field calibration terms, instead use [calibration_data](#). For mixed scalar and field calibration terms, one may use the [scalar_data_file](#) specification, which uses the format described on this page.

Examples

Simple Case: In the simplest case, no data content descriptors are specified:

```
responses
  calibration_terms = 2
  descriptors = 'volts' 'amps'
  calibration_data_file = 'circuit.dat'
  annotated
```

And the data file `circuit.dat` must contain only the y^{Data} observations which represent a single experimental observation. In this case, the data file should have $N_{terms} = 2$ columns (for volts, amps) and 1 row, where N_{terms} is the value of [calibration_terms](#). The data file is shown here in annotated format:

```
%exp_id | y data observations
1        21.9372  1.8687
```

For each function evaluation, Dakota will run the analysis driver, which must return $N_{terms} = 2$ model responses. Then the residuals are computed as:

$$R_i = y_i^{Model} - y_i^{Data}.$$

These residuals can be weighted using [weights](#).

Multiple experiments: One might specify `num_experiments` N_E indicating that there are multiple experiments. When multiple experiments are present, Dakota will expand the number of residuals for the repeat measurement data and difference with the data accordingly. For example, if the user has $N_E = 4$ experiments in the example above with 2 calibration terms, the input file would contain

```
responses
  calibration_terms = 2
  descriptors = 'volts' 'amps'
  calibration_data_file = 'circuit.dat'
  annotated
  num_experiments = 4
```

And the `calibration_data_file` would need to contain 2 rows (one for each experiment), and each row should contain 2 experimental data values that will be differenced with respect to the appropriate model response:

```
%exp_id | y data observations
1         21.9372  1.8687
2         19.0779  4.8976
3         38.2758  4.4559
4         39.7600  6.4631
```

To summarize, Dakota will calculate the sum of the squared residuals as:

$$f = \sum_{i=1}^{N_E} R_i^2$$

where the residuals now are calculated as:

$$R_i = y_i^{Model}(\theta) - y_i^{Data}.$$

With experimental variances: If information is known about the measurement error and the uncertainty in the measurement, that can be specified by sending the measurement error variance to Dakota. In this case, the keyword `experiment_variance_type` is added, followed by a string of variance types of length one or of length N_{terms} , where N_{terms} is the value of [calibration_terms](#). The `experiment_variance_type` for each response can be 'none' or 'scalar'. NOTE: you must specify the same `experiment_variance_type` for all scalar terms. That is, they will all be 'none' or all be 'scalar.'

```
responses
  calibration_terms = 2
  descriptors = 'volts' 'amps'
  calibration_data_file = 'circuit.dat'
  annotated
  experiment_variance_type 'scalar'
```

For each response that has a 'scalar' variance type, each row of the datafile will now have $N_{terms} = 2$ of y data values (volts, amps) followed by $N_{terms} = 2$ columns that specify the measurement error (in units of variance, not standard deviation) for volts, amps. An example with two experiments in annotated format:

```
%exp_id | y data observations | y data variances
1         21.9372  1.8687         0.25  0.04
```

Dakota will run the analysis driver, which must return N_{terms} responses. Then the residuals are computed as:

$$R_i = \frac{y_i^{Model} - y_i^{Data}}{\sqrt{var_i}}$$

for $i = 1 \dots N_{terms}$.

Putting all the options together: Specifying all these options together might look like

```

responses
  calibration_terms = 2
  descriptors = 'volts' 'amps'
  calibration_data_file = 'circuit.dat'
  annotated
  num_experiments = 4
  experiment_variance_type 'scalar'

```

Dakota will expect a data file

%exp_id	configuration	xvars	y data observations	y data variances
1	7.8	7	21.9372 1.8687	0.25 0.04
2	8.6	2	19.0779 4.8976	0.25 0.04
3	8.4	8	38.2758 4.4559	0.25 0.04
4	4.2	1	39.7600 6.4631	0.25 0.04

To compute residuals for each experiment, e.g., exp_id = 4, Dakota will

1. Evaluate the computational model at the specified configuration (state variables = [4.2, 1]).
2. Difference the resulting 2 function values with the data [39.7600 volts, 6.4631 amps]
3. Weight by the standard deviation = $\sqrt{[0.25 \ 0.04]}$

- [calibration_data_file](#)
- [experiment_variance_type](#)

Add context to data: specify the type of experimental error

Specification

Alias: variance_type

Argument(s): STRINGLIST

Default: none

Description

There are four options for specifying the experimental error (e.g. the measurement error in the data you provide for calibration purposes): 'none' (default), 'scalar', 'diagonal', or 'matrix.'

If the user specifies scalar, they can provide a scalar variance per calibration term. Note that for scalar calibration terms, only 'none' or 'scalar' are options for the measurement variance. However, for field calibration terms, there are two additional options. 'diagonal' allows the user to provide a vector of measurement variances (one for each term in the calibration field). This vector corresponds to the diagonal of the full covariance matrix of measurement errors. If the user specifies 'matrix', they can provide a full covariance matrix (not just the diagonal terms), where each element (i,j) of the covariance matrix represents the covariance of the measurement error between the i-th and j-th field values.

Usage Tips

Variance information is specified on a per-response group (descriptor), per-experiment basis. Off-diagonal covariance between response groups or between experiments is not supported.

Examples

The figure below shows an observation vector with 5 responses; 2 scalar + 3 field (each field of length > 1). The corresponding covariance matrix has scalar variances σ_1^2, σ_2^2 for each of the scalars s_1, s_2 , diagonal covariance D_3 for field f_3 , scalar covariance σ_4^2 for field f_4 , and full matrix covariance C_5 for field f_5 . In total, Dakota supports block diagonal covariance Σ across the responses, with blocks Σ_i , which could be fully dense within a given field response group. Covariance across the highest-level responses (off-diagonal blocks) is not supported, nor is covariance between experiments.

simulation_variance

- [Keywords Area](#)
- [responses](#)
- [calibration_terms](#)
- [simulation_variance](#)

Variance applied to simulation responses

Specification

Alias: none

Argument(s): REALLIST

Default: no variance

Description

The variance that is applied to simulations run by Dakota, i.e. using the `analysis_drivers` command. The user may supply a single variance or a vector of variances of length equal to the number of responses. In both cases, the values provided are treated as scalar variance types. If a single variance is provided, it is applied to all responses produced by the simulation code. If a vector is provided, each variance is applied to the corresponding response output produced by the simulation code.

It is important to note that the the variance defined by this keyword differs from that defined using `experiment_variance_type`. These two commands apply to user-provided calibration data, specified, for example, by `calibration_data` or `calibration_data_file`. However, `simulation_variance` applies to those responses produced by simulation code that is run by Dakota, as described above.

Usage Tips

Currently, this keyword is only in use as part of the algorithm implemented by `experimental_design`. In this algorithm, two models (usually, one high-fidelity and one low-fidelity) are provided to Dakota, each with their own `responses` section of the input script, and each of which is allowed its own `simulation_variance`. The variance specified in the `responses` block belonging to the high-fidelity model is applied to any *new* high-fidelity data that is produced by Dakota running the high-fidelity model. In the `experimental_design` algorithm, low-fidelity model responses are used during the calibration of the model parameters, the calculation of the mutual information, and the calculation of any posterior statistics after the algorithm is complete. The `simulation_variance` is applied to the low-fidelity model responses that are used in the calculation of the mutual information. See the User's and Theory Manuals for more information.

Examples

The example below shows two `responses` blocks, one for the low-fidelity model and one for the high-fidelity model. Both contain `simulation_variance` commands that will apply to the low- and high-fidelity model responses, respectively.

```
responses,
  id_responses = 'low-fidelity'
  calibration_terms = 1
  simulation_variance = 0.5

responses,
  id_responses = 'high-fidelity'
  calibration_terms = 1
  calibration_data_file = 'dakota_bayes_expdesign.dat'
  freeform
  num_config_variables = 1
  num_experiments = 1
  experiment_variance_type = 'none'
  simulation_variance = 1.2
```

nonlinear_inequality_constraints

- [Keywords Area](#)
- [responses](#)
- [calibration_terms](#)
- [nonlinear_inequality_constraints](#)

Group to specify nonlinear inequality constraints

Topics

This keyword is related to the topics:

- [nonlinear_constraints](#)

Specification

Alias: num_nonlinear_inequality_constraints

Argument(s): INTEGER

Default: 0

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			lower_bounds	Specify minimum values
	Optional		upper_bounds	Specify maximum values
	Optional		scale_types	Choose how each constraint is scaled
	Optional		scales	Characteristic values for scaling

Description

Specifies the number of nonlinear inequality constraint functions returned by the interface.

The `lower_bounds` and `upper_bounds` specifications provide the lower and upper bounds for 2-sided nonlinear inequalities of the form

$$g_l \leq g(x) \leq g_u$$

When constraint bounds are not specified, the problem is assumed to have one-sided inequalities bounded above by zero:

$$g(x) \leq 0.0.$$

This provides backwards compatibility with previous Dakota versions.

In a user bounds specification, any upper bound values greater than `+bigRealBoundSize` (`1.e+30`, as defined in `Minimizer`) are treated as `+infinity` and any lower bound values less than `-bigRealBoundSize` are treated as `-infinity`. This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since `-DBL_MAX < -bigRealBoundSize`). The same approach is used for nonexistent linear inequality bounds and for nonexistent design variable bounds.

The `scale_types` and `scales` keywords are related to scaling of $g(x)$. See the scaling information under specific methods, e.g., `method-*-scaling` for details on how to use this keyword.

7.6.5 response_functions

- [Keywords Area](#)
- [responses](#)
- [response_functions](#)

Generic response type

Specification

Alias: num_response_functions

Argument(s): INTEGER

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			scalar_responses	Number of scalar response functions
	Optional		field_responses	Number of field responses functions

Description

A generic response data set is specified using `response_functions`. Each of these functions is simply a response quantity of interest with no special interpretation taken by the method in use.

Whereas objective, constraint, and residual functions have special meanings for optimization and least squares algorithms, the generic response function data set need not have a specific interpretation and the user is free to define whatever functional form is convenient.

Theory

This type of data set is used by uncertainty quantification methods, in which the effect of parameter uncertainty on response functions is quantified, and can also be used in parameter study and design of experiments methods (although these methods are not restricted to this data set), in which the effect of parameter variations on response functions is evaluated.

scalar_responses

- [Keywords Area](#)
- [responses](#)
- [response_functions](#)
- [scalar_responses](#)

Number of scalar response functions

Specification

Alias: num_scalar_responses

Argument(s): INTEGER

Description

This keyword describes the number of scalar response functions. It is meant to be used in conjunction with `field_responses`, which describes the number of field response functions. The total number of response functions, both scalar and field, is given by `response_functions`. If only scalar responses functions are specified, it is not necessary to specify the number of scalar terms explicitly: one can simply say `response_functions = 5` and get 5 scalar responses. However, if there are three scalar responses and 2 field responses, then `response_functions = 5` but `scalar_responses = 3` and `field_responses = 2`.

This type of data set is used by uncertainty quantification methods, in which the effect of parameter uncertainty on response functions is quantified, and can also be used in parameter study and design of experiments methods (although these methods are not restricted to this data set), in which the effect of parameter variations on response functions is evaluated.

- [responses](#)
- [response_functions](#)
- [field_responses](#)

Number of field responses functions

Specification

Alias: num_field_responses

Argument(s): INTEGER

Child Keywords:

	Required/ Optional Required	Description of Group	Dakota Keyword	Dakota Keyword Description
			lengths	Lengths of field responses
	Optional		num_coordinates_ per_field	Number of independent coordinates for field responses
	Optional		read_field_ coordinates	Add context to data: flag to indicate that field coordinates should be read

Description

This keyword describes the number of field response functions. A field function is a set of related response values collected over a range of independent coordinate values which may or may not be specified by the user. For example, voltage over time would be a field function, where voltage is the `field_objective` and time is the independent coordinate. Similarly, temperature over time and space would be a field response, where the independent coordinates would be both time and spatial coordinates such as (x,y) or (x,y,z), depending on the application. The main difference between scalar responses and field responses is that for field data, we plan to implement methods that take advantage of the correlation or relationship between the field values.

Note that if there is one `field_response`, and it has length 100 (meaning 100 values), then the user's simulation code must return 100 values. Also, if there are both scalar and field responses, the user should specify the number of scalar responses as `scalar_responses`. If there are only field responses, it still is necessary to specify both `response_functions = NN` and `field_responses = NN`, where NN is the number of field responses.

This type of data set is used by uncertainty quantification methods, in which the effect of parameter uncertainty on response functions is quantified, and can also be used in parameter study and design of experiments methods (although these methods are not restricted to this data set), in which the effect of parameter variations on response functions is evaluated. Currently, field response functions will be translated back to scalar responses. So, a field of length 100 will be treated as 100 separate scalar responses. However, in future versions of Dakota, we plan to implement methods which can exploit the nature of field data.

These keywords may also be of interest:

- [field_responses](#)

num_coordinates_per_field

- [Keywords Area](#)
- [responses](#)
- [response_functions](#)
- [field_responses](#)
- [num_coordinates_per_field](#)

Number of independent coordinates for field responses

Specification

Alias: none

Argument(s): INTEGERLIST

Description

This keyword describes the number of independent coordinates for each field response. It is an integer vector of length `field_responses`. For example, if the `field_responses = 2`, an example would be `num_coordinates_per_field = 2 1` means that the first field response has two sets of independent coordinates (perhaps x, y locations), but the second response only has one (for example, time where the field response is only dependent upon time). The actual coordinate values (e.g. the independent variables) corresponding to these field responses are defined in a file call `response_descriptor.coords`, where `response_descriptor` is the name of the individual field.

These keywords may also be of interest:

- [field_responses](#)

read_field_coordinates

- [Keywords Area](#)
- [responses](#)
- [response_functions](#)
- [field_responses](#)
- [read_field_coordinates](#)

Add context to data: flag to indicate that field coordinates should be read

Specification

Alias: none

Argument(s): none

Description

Field coordinates specify independent variables (e.g. spatial or temporal coordinates) upon which the field depends. For example, the voltage level above might be a function of time, so time is the field coordinate. If the user has field coordinates to read, they need to specify `read_field_coordinates`. The field coordinates will then be read from a file named `response_descriptor.coords`, where `response_descriptor` is the user-provided descriptor for the field response. The number of columns in the `coords` file should be equal to the number of field coordinates.

7.6.6 no_gradients

- [Keywords Area](#)
- [responses](#)
- [no_gradients](#)

Gradients will not be used

Specification

Alias: none

Argument(s): none

Description

The `no_gradients` specification means that gradient information is not needed in the study. Therefore, it will neither be retrieved from the simulation nor computed with finite differences. The `no_gradients` keyword is a complete specification for this case.

See Also

These keywords may also be of interest:

- [numerical_gradients](#)

7.6.7 `analytic_gradients`

- [Keywords Area](#)
- [responses](#)
- [analytic_gradients](#)

Analysis driver will return gradients

Specification

Alias: none

Argument(s): none

Description

The `analytic_gradients` specification means that gradient information is available directly from the simulation (finite differencing is not required). The simulation must return the gradient data in the Dakota format (enclosed in single brackets; see Dakota File Data Formats in the Users Manual[4]) for the case of file transfer of data. The `analytic_gradients` keyword is a complete specification for this case.

- [mixed_gradients](#)

7.6.8 `mixed_gradients`

- [Keywords Area](#)
- [responses](#)
- [mixed_gradients](#)

Gradients are needed and will be obtained from a mix of numerical and analytic sources

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Required	Description of Group	Dakota Keyword	Dakota Keyword Description
	Required		id_numerical_- gradients	Identify which numerical gradient corresponds to which response
			id_analytic_- gradients	Identify which analytical gradient corresponds to which response
	Optional		method_source	Specify which finite difference routine is used
	Optional (Choose One)	Gradient Source (Group 1)	dakota	(Default) Use internal Dakota finite differences algorithm
			vendor	Use non-Dakota fd algorithm
	Optional		interval_type	Specify how to compute gradients and Hessians
	Optional (Choose One)	Finite Difference Type (Group 2)	forward	(Default) Use forward differences
			central	Use central differences
	Optional		fd_step_size	Step size used when computing gradients and Hessians

Description

The `mixed_gradients` specification means that some gradient information is available directly from the simulation (analytic) whereas the rest will have to be finite differenced (numerical). This specification allows the user to make use of as much analytic gradient information as is available and then finite difference for the rest.

The `method_source`, `interval_type`, and `fd_gradient_step_size` specifications pertain to those functions listed by the `id_numerical_gradients` list.

Examples

For example, the objective function may be a simple analytic function of the design variables (e.g., weight) whereas the constraints are nonlinear implicit functions of complex analyses (e.g., maximum stress).

Specify which finite difference routine is used

Specification

Alias: none

Argument(s): none

Default: dakota

Description

The `method_source` setting specifies the source of the finite differencing routine that will be used to compute the numerical gradients:

- `dakota` (default)
- `vendor`

`dakota` denotes Dakota's internal finite differencing algorithm and `vendor` denotes the finite differencing algorithm supplied by the iterator package in use (DOT, CONMIN, NPSOL, NL2SOL, NLSSOL, ROL, and OPT++ each have their own internal finite differencing routines). The `dakota` routine is the default since it can execute in parallel and exploit the concurrency in finite difference evaluations (see Exploiting Parallelism in the Users Manual [4]).

However, the `vendor` setting can be desirable in some cases since certain libraries will modify their algorithm when the finite differencing is performed internally. Since the selection of the `dakota` routine hides the use of finite differencing from the optimizers (the optimizers are configured to accept user-supplied gradients, which some algorithms assume to be of analytic accuracy), the potential exists for the `vendor` setting to trigger the use of an algorithm more optimized for the higher expense and/or lower accuracy of finite-differencing. For example, NPSOL uses gradients in its line search when in user-supplied gradient mode (since it assumes they are inexpensive), but uses a value-based line search procedure when internally finite differencing. The use of a value-based line search will often reduce total expense in serial operations. However, in parallel operations, the use of gradients in the NPSOL line search (user-supplied gradient mode) provides excellent load balancing without need to resort to speculative optimization approaches.

In summary, then, the `dakota` routine is preferred for parallel optimization, and the `vendor` routine may be preferred for serial optimization in special cases.

dakota

- [Keywords Area](#)
- [responses](#)
- [mixed_gradients](#)
- [dakota](#)

(Default) Use internal Dakota finite differences algorithm

Specification

Alias: none

Argument(s): none

Default: relative

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			ignore_bounds	Do not respect bounds when computing gradients or Hessians

	Optional(<i>Choose One</i>)	Step Scaling (Group 1)	relative	(Default) Scale step size by the parameter value
			absolute	Do not scale step-size
			bounds	Scale step-size by the domain of the parameter

Description

The `dakota` routine is the default since it can execute in parallel and exploit the concurrency in finite difference evaluations (see Exploiting Parallelism in the Users Manual [4]).

When the `method_source` is `dakota`, the user may also specify the type of scaling desired when determining the finite difference step size. The choices are `absolute`, `bounds`, and `relative`. For `absolute`, the step size will be applied as is. For `bounds`, it will be scaled by the range of each parameter. For `relative`, it will be scaled by the parameter value.

ignore_bounds

- [Keywords Area](#)
- [responses](#)
- [mixed_gradients](#)
- [dakota](#)
- [ignore_bounds](#)

Do not respect bounds when computing gradients or Hessians

Specification

Alias: none

Argument(s): none

Default: bounds respected

Description

When Dakota computes gradients or Hessians by finite differences and the variables in question have bounds, it by default chooses finite-differencing steps that keep the variables within their specified bounds. Older versions of Dakota generally ignored bounds when computing finite differences. To restore the older behavior, one can add keyword `ignore_bounds` to the response specification when `method_source dakota` (or just `dakota`) is also specified.

In forward difference or backward difference computations, honoring bounds is straightforward.

To honor bounds when approximating $\partial f / \partial x_i$, i.e., component i of the gradient of f , by central differences, Dakota chooses two steps h_1 and h_2 with $h_1 \neq h_2$, such that $x + h_1 e_i$ and $x + h_2 e_i$ both satisfy the bounds, and then computes

$$\frac{\partial f}{\partial x_i} \cong \frac{h_2^2(f_1 - f_0) - h_1^2(f_2 - f_0)}{h_1 h_2 (h_2 - h_1)},$$

with $f_0 = f(x)$, $f_1 = f(x + h_1 e_i)$, and $f_2 = f(x + h_2 e_i)$.

- [Keywords Area](#)
- [responses](#)
- [mixed_gradients](#)
- [interval_type](#)

Specify how to compute gradients and Hessians

Specification

Alias: none

Argument(s): none

Default: forward

Description

The `interval_type` setting is used to select between `forward` and `central` differences in the numerical gradient calculations. The `dakota`, `DOT` `vendor`, and `OPT++` `vendor` routines have both forward and central differences available, the `CONMIN`, `NL2SOL` and `ROL` `vendor` routines support forward differences only, and the `NPSOL` and `NLSSOL` `vendor` routines start with forward differences and automatically switch to central differences as the iteration progresses (the user has no control over this). The following forward difference expression

$$\nabla f(\mathbf{x}) \cong \frac{f(\mathbf{x} + h\mathbf{e}_i) - f(\mathbf{x})}{h}$$

and the following central difference expression

$$\nabla f(\mathbf{x}) \cong \frac{f(\mathbf{x} + h\mathbf{e}_i) - f(\mathbf{x} - h\mathbf{e}_i)}{2h}$$

are used to estimate the i^{th} component of the gradient vector.

fd_step_size

- [Keywords Area](#)
- [responses](#)
- [mixed_gradients](#)
- [fd_step_size](#)

Step size used when computing gradients and Hessians

Specification

Alias: fd_gradient_step_size

Argument(s): REALLIST

Default: 0.001

Description

`fd_step_size` specifies the relative finite difference step size to be used in the computations. Either a single value may be entered for use with all parameters, or a list of step sizes may be entered, one for each parameter.

The latter option of a list of step sizes is only valid for use with the Dakota finite differencing routine. For Dakota with an interval scaling type of `absolute`, the differencing interval will be `fd_step_size`.

For Dakota with and interval scaling type of `bounds`, the differencing intervals are computed by multiplying `fd_step_size` with the range of the parameter. For Dakota (with an interval scaling type of `relative`), `DOT`, `CONMIN`, and `OPT++`, the differencing intervals are computed by multiplying the `fd_step_size` with the current parameter value. In this case, a minimum absolute differencing interval is needed when the current parameter value is close to zero. This prevents finite difference intervals for the parameter which are too small to distinguish differences in the response quantities being computed. Dakota, DOT, CONMIN, and OPT++ all use $.01 * \text{fd_step_size}$ as their minimum absolute differencing interval. With a `fd_step_size = .001`, for example, Dakota, DOT, CONMIN, and OPT++ will use intervals of $.001 * \text{current value}$ with a minimum interval of $1.e-5$. NPSOL and NLSSOL use a different formula for their finite difference intervals: $\text{fd_step_size} * (1 + |\text{current parameter value}|)$. This definition has the advantage of eliminating the need for a minimum absolute differencing interval since the interval no longer goes to zero as the current parameter value goes to zero.

ROL's finite difference step size can not be controlled via Dakota. Therefore, `fd_step_size` will be ignored when ROL's finite differencing routines are used (vendor FD gradients are specified). ROL's differencing intervals are computed by multiplying the current parameter value with the square root of machine precision.

7.6.9 numerical_gradients

- [Keywords Area](#)
- [responses](#)
- [numerical_gradients](#)

Gradients are needed and will be approximated by finite differences

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional	Gradient Source (Group 1)	method_source	Specify which finite difference routine is used
	Optional(<i>Choose One</i>)		dakota	(Default) Use internal Dakota finite differences algorithm

`method_source`

- [Keywords Area](#)

- [responses](#)
- [numerical_gradients](#)
- [method_source](#)

Specify which finite difference routine is used

Specification

Alias: none

Argument(s): none

Default: dakota

Description

The `method_source` setting specifies the source of the finite differencing routine that will be used to compute the numerical gradients:

- `dakota` (default)
- `vendor`

`dakota` denotes Dakota's internal finite differencing algorithm and `vendor` denotes the finite differencing algorithm supplied by the iterator package in use (DOT, CONMIN, NPSOL, NL2SOL, NLSSOL, ROL, and OPT++ each have their own internal finite differencing routines). The `dakota` routine is the default since it can execute in parallel and exploit the concurrency in finite difference evaluations (see Exploiting Parallelism in the Users Manual [4]).

However, the `vendor` setting can be desirable in some cases since certain libraries will modify their algorithm when the finite differencing is performed internally. Since the selection of the `dakota` routine hides the use of finite differencing from the optimizers (the optimizers are configured to accept user-supplied gradients, which some algorithms assume to be of analytic accuracy), the potential exists for the `vendor` setting to trigger the use of an algorithm more optimized for the higher expense and/or lower accuracy of finite-differencing. For example, NPSOL uses gradients in its line search when in user-supplied gradient mode (since it assumes they are inexpensive), but uses a value-based line search procedure when internally finite differencing. The use of a value-based line search will often reduce total expense in serial operations. However, in parallel operations, the use of gradients in the NPSOL line search (user-supplied gradient mode) provides excellent load balancing without need to resort to speculative optimization approaches.

In summary, then, the `dakota` routine is preferred for parallel optimization, and the `vendor` routine may be preferred for serial optimization in special cases.

dakota

- [Keywords Area](#)
- [responses](#)
- [numerical_gradients](#)
- [dakota](#)

(Default) Use internal Dakota finite differences algorithm

Specification

Alias: none

Argument(s): none

Default: relative

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			ignore_bounds	Do not respect bounds when computing gradients or Hessians
	Optional (<i>Choose One</i>)	Step Scaling (Group 1)	relative	(Default) Scale step size by the parameter value
			absolute	Do not scale step-size
			bounds	Scale step-size by the domain of the parameter

Description

The `dakota` routine is the default since it can execute in parallel and exploit the concurrency in finite difference evaluations (see Exploiting Parallelism in the Users Manual [4]).

When the `method_source` is `dakota`, the user may also specify the type of scaling desired when determining the finite difference step size. The choices are `absolute`, `bounds`, and `relative`. For `absolute`, the step size will be applied as is. For `bounds`, it will be scaled by the range of each parameter. For `relative`, it will be scaled by the parameter value.

`ignore_bounds`

- [Keywords Area](#)
- [responses](#)
- [numerical_gradients](#)
- [dakota](#)
- [ignore_bounds](#)

Do not respect bounds when computing gradients or Hessians

Specification

Alias: none

Argument(s): none

Default: bounds respected

Description

When Dakota computes gradients or Hessians by finite differences and the variables in question have bounds, it by default chooses finite-differencing steps that keep the variables within their specified bounds. Older versions of Dakota generally ignored bounds when computing finite differences. To restore the older behavior, one can add keyword `ignore_bounds` to the response specification when `method_source dakota` (or just `dakota`) is also specified.

In forward difference or backward difference computations, honoring bounds is straightforward.

To honor bounds when approximating $\partial f/\partial x_i$, i.e., component i of the gradient of f , by central differences, Dakota chooses two steps h_1 and h_2 with $h_1 \neq h_2$, such that $x + h_1 e_i$ and $x + h_2 e_i$ both satisfy the bounds, and then computes

$$\frac{\partial f}{\partial x_i} \simeq \frac{h_2^2(f_1 - f_0) - h_1^2(f_2 - f_0)}{h_1 h_2 (h_2 - h_1)},$$

with $f_0 = f(x)$, $f_1 = f(x + h_1 e_i)$, and $f_2 = f(x + h_2 e_i)$.

interval_type

- [Keywords Area](#)
- [responses](#)
- [numerical_gradients](#)
- [interval_type](#)

Specify how to compute gradients and Hessians

Specification

Alias: none

Argument(s): none

Default: forward

Description

The `interval_type` setting is used to select between forward and central differences in the numerical gradient calculations. The `dakota`, `DOT` vendor, and `OPT++` vendor routines have both forward and central differences available, the `CONMIN`, `NL2SOL` and `ROL` vendor routines support forward differences only, and the `NPSOL` and `NLSSOL` vendor routines start with forward differences and automatically switch to central differences as the iteration progresses (the user has no control over this). The following forward difference expression

$$\nabla f(\mathbf{x}) \cong \frac{f(\mathbf{x} + h\mathbf{e}_i) - f(\mathbf{x})}{h}$$

and the following central difference expression

$$\nabla f(\mathbf{x}) \cong \frac{f(\mathbf{x} + h\mathbf{e}_i) - f(\mathbf{x} - h\mathbf{e}_i)}{2h}$$

are used to estimate the i^{th} component of the gradient vector.

fd_step_size

- [Keywords Area](#)
- [responses](#)
- [numerical_gradients](#)
- [fd_step_size](#)

Step size used when computing gradients and Hessians

Specification

Alias: fd_gradient_step_size

Argument(s): REALLIST

Default: 0.001

Description

fd_step_size specifies the relative finite difference step size to be used in the computations. Either a single value may be entered for use with all parameters, or a list of step sizes may be entered, one for each parameter.

The latter option of a list of step sizes is only valid for use with the Dakota finite differencing routine. For Dakota with an interval scaling type of *absolute*, the differencing interval will be fd_step_size.

For Dakota with an interval scaling type of *bounds*, the differencing intervals are computed by multiplying fd_step_size with the range of the parameter. For Dakota (with an interval scaling type of *relative*), DOT, CONMIN, and OPT++, the differencing intervals are computed by multiplying the fd_step_size with the current parameter value. In this case, a minimum absolute differencing interval is needed when the current

parameter value is close to zero. This prevents finite difference intervals for the parameter which are too small to distinguish differences in the response quantities being computed. Dakota, DOT, CONMIN, and OPT++ all use `.01*fd_step_size` as their minimum absolute differencing interval. With a `fd_step_size = .001`, for example, Dakota, DOT, CONMIN, and OPT++ will use intervals of `.001*current value` with a minimum interval of `1.e-5`. NPSOL and NLSSOL use a different formula for their finite difference intervals: `fd_step_size*(1+|current parameter value|)`. This definition has the advantage of eliminating the need for a minimum absolute differencing interval since the interval no longer goes to zero as the current parameter value goes to zero.

ROL's finite difference step size can not be controlled via Dakota. Therefore, `fd_step_size` will be ignored when ROL's finite differencing routines are used (vendor FD gradients are specified). ROL's differencing intervals are computed by multiplying the current parameter value with the square root of machine precision.

7.6.10 no_hessians

- [Keywords Area](#)
- [responses](#)
- [no_hessians](#)

Hessians will not be used

Specification

Alias: none

Argument(s): none

Description

The `no_hessians` specification means that the method does not require Dakota to manage the computation of any Hessian information. Therefore, it will neither be retrieved from the simulation nor computed by Dakota. The `no_hessians` keyword is a complete specification for this case. Note that, in some cases, Hessian information may still be being approximated internal to an algorithm (e.g., within a quasi-Newton optimizer such as `optpp-q_newton`); however, Dakota has no direct involvement in this process and the responses specification need not include it.

See Also

These keywords may also be of interest:

- [numerical_hessians](#)
- [quasi_hessians](#)
- [analytic_hessians](#)
- [mixed_hessians](#)

7.6.11 numerical_hessians

- [Keywords Area](#)
- [responses](#)
- [numerical_hessians](#)

Hessians are needed and will be approximated by finite differences

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
			fd_step_size	Step size used when computing gradients and Hessians
	Optional(<i>Choose One</i>)	Step Scaling (Group 1)	relative	(Default) Scale step size by the parameter value
			absolute	Do not scale step-size
			bounds	Scale step-size by the domain of the parameter
	Optional(<i>Choose One</i>)	Finite Difference Type (Group 2)	forward	(Default) Use forward differences
			central	Use central differences

Description

The `numerical_hessians` specification means that Hessian information is needed and will be computed with finite differences using either first-order gradient differencing (for the cases of `analytic_gradients` or for the functions identified by `id_analytic_gradients` in the case of `mixed_gradients`) or first- or second-order function value differencing (all other gradient specifications). In the former case, the following expression

$$\nabla^2 f(\mathbf{x})_i \cong \frac{\nabla f(\mathbf{x} + h\mathbf{e}_i) - \nabla f(\mathbf{x})}{h}$$

estimates the i^{th} Hessian column, and in the latter case, the following expressions

$$\nabla^2 f(\mathbf{x})_{i,j} \cong \frac{f(\mathbf{x} + h_i\mathbf{e}_i + h_j\mathbf{e}_j) - f(\mathbf{x} + h_i\mathbf{e}_i) - f(\mathbf{x} - h_j\mathbf{e}_j) + f(\mathbf{x})}{h_i h_j}$$

and

$$\nabla^2 f(\mathbf{x})_{i,j} \cong \frac{f(\mathbf{x} + h\mathbf{e}_i + h\mathbf{e}_j) - f(\mathbf{x} + h\mathbf{e}_i - h\mathbf{e}_j) - f(\mathbf{x} - h\mathbf{e}_i + h\mathbf{e}_j) + f(\mathbf{x} - h\mathbf{e}_i - h\mathbf{e}_j)}{4h^2}$$

provide first- and second-order estimates of the ij^{th} Hessian term. Prior to Dakota 5.0, Dakota always used second-order estimates. In Dakota 5.0 and newer, the default is to use first-order estimates (which honor bounds on the variables and require only about a quarter as many function evaluations as do the second-order estimates), but specifying `central` after `numerical_hessians` causes Dakota to use the old second-order estimates, which do not honor bounds. In optimization algorithms that use Hessians, there is little reason to use second-order differences in computing Hessian approximations.

fd_step_size

- [Keywords Area](#)
- [responses](#)
- [numerical_hessians](#)
- [fd_step_size](#)

Step size used when computing gradients and Hessians

Specification

Alias: `fd_hessian_step_size`

Argument(s): REALLIST

Default: 0.001 (forward), 0.002 (central)

Description

`fd_step_size` specifies the relative finite difference step size to be used in the computations. Either a single value may be entered for use with all parameters, or a list of step sizes may be entered, one for each parameter.

The latter option of a list of step sizes is only valid for use with the Dakota finite differencing routine. For Dakota with an interval scaling type of `absolute`, the differencing interval will be `fd_step_size`.

For Dakota with an interval scaling type of `bounds`, the differencing intervals are computed by multiplying `fd_step_size` with the range of the parameter. For Dakota (with an interval scaling type of `relative`), `DOT`, `CONMIN`, and `OPT++`, the differencing intervals are computed by multiplying the `fd_step_size` with the current parameter value. In this case, a minimum absolute differencing interval is needed when the current parameter value is close to zero. This prevents finite difference intervals for the parameter which are too small

to distinguish differences in the response quantities being computed. Dakota, DOT, CONMIN, and OPT++ all use `.01*fd_step_size` as their minimum absolute differencing interval. With a `fd_step_size = .001`, for example, Dakota, DOT, CONMIN, and OPT++ will use intervals of `.001*current value` with a minimum interval of `1.e-5`. NPSOL and NLSSOL use a different formula for their finite difference intervals: `fd_step_size*(1+|current parameter value|)`. This definition has the advantage of eliminating the need for a minimum absolute differencing interval since the interval no longer goes to zero as the current parameter value goes to zero.

ROL's finite difference step size can not be controlled via Dakota. Therefore, `fd_step_size` will be ignored when ROL's finite differencing routines are used (vendor FD gradients are specified). ROL's differencing intervals are computed by multiplying the current parameter value with the square root of machine precision.

7.6.12 quasi_hessians

- [Keywords Area](#)
- [responses](#)
- [quasi_hessians](#)

Hessians are needed and will be approximated by secant updates (BFGS or SR1) from a series of gradient evaluations

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional Required (<i>Choose One</i>)	Description of Group Quasi-Hessian Approximation (Group 1)	Dakota Keyword	Dakota Keyword Description
			bfgs	Use BFGS method to compute quasi-hessians
			sr1	Use the Symmetric Rank 1 update method to compute quasi-Hessians

Description

The `quasi_hessians` specification means that Hessian information is needed and will be approximated using secant updates (sometimes called "quasi-Newton updates", though any algorithm that approximates Newton's method is a quasi-Newton method).

Compared to finite difference numerical Hessians, secant approximations do not expend additional function evaluations in estimating all of the second-order information for every point of interest. Rather, they accumulate approximate curvature information over time using the existing gradient evaluations.

The supported secant approximations include the Broyden-Fletcher-Goldfarb-Shanno (BFGS) update (specified with the keyword `bfgs`) and the Symmetric Rank 1 (SR1) update (specified with the keyword `sr1`).

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description

	Optional		id_numerical_hessians	Identify which numerical-Hessian corresponds to which response (Default) Scale step size by the parameter value
	Optional (Choose One)	Step Scaling (Group 1)	relative	
			absolute	Do not scale step-size
			bounds	Scale step-size by the domain of the parameter
	Optional (Choose One)	Finite Difference Type (Group 2)	forward	(Default) Use forward differences
			central	Use central differences
	Optional		id_quasi_hessians	Identify which quasi-Hessian corresponds to which response
	Optional		id_analytic_hessians	Identify which analytical Hessian corresponds to which response

Description

The `mixed_hessians` specification means that some Hessian information is available directly from the simulation (analytic) whereas the rest will have to be estimated by finite differences (numerical) or approximated by secant updating. As for mixed gradients, this specification allows the user to make use of as much analytic information as is available and then estimate/approximate the rest.

The `id_analytic_hessians` list specifies by number the functions which have analytic Hessians, and the `id_numerical_hessians` and `id_quasi_hessians` lists specify by number the functions which must use numerical Hessians and secant Hessian updates, respectively. Each function identifier, from 1 through the total number of functions, must appear once and only once within the union of the `id_analytic_hessians`, `id_numerical_hessians`, and `id_quasi_hessians` lists.

The `fd_hessian_step_size` and `bfgs`, `damped bfgs`, or `srl` secant update selections are as described previously in [responses](#) and pertain to those functions listed by the `id_numerical_hessians` and `id_quasi_hessians` lists.

Step size used when computing gradients and Hessians

Specification

Alias: fd_hessian_step_size

Argument(s): REALLIST

Default: 0.001 (forward), 0.002 (central)

Description

fd_step_size specifies the relative finite difference step size to be used in the computations. Either a single value may be entered for use with all parameters, or a list of step sizes may be entered, one for each parameter.

The latter option of a list of step sizes is only valid for use with the Dakota finite differencing routine. For Dakota with an interval scaling type of *absolute*, the differencing interval will be fd_step_size.

For Dakota with an interval scaling type of *bounds*, the differencing intervals are computed by multiplying fd_step_size with the range of the parameter. For Dakota (with an interval scaling type of *relative*), DOT, CONMIN, and OPT++, the differencing intervals are computed by multiplying the fd_step_size with the current parameter value. In this case, a minimum absolute differencing interval is needed when the current parameter value is close to zero. This prevents finite difference intervals for the parameter which are too small to distinguish differences in the response quantities being computed. Dakota, DOT, CONMIN, and OPT++ all use $.01 * \text{fd_step_size}$ as their minimum absolute differencing interval. With a fd_step_size = .001, for example, Dakota, DOT, CONMIN, and OPT++ will use intervals of $.001 * \text{current value}$ with a minimum interval of $1.e-5$. NPSOL and NLSSOL use a different formula for their finite difference intervals: $\text{fd_step_size} * (1 + |\text{current parameter value}|)$. This definition has the advantage of eliminating the need for a minimum absolute differencing interval since the interval no longer goes to zero as the current parameter value goes to zero.

ROL's finite difference step size can not be controlled via Dakota. Therefore, fd_step_size will be ignored when ROL's finite differencing routines are used (vendor FD gradients are specified). ROL's differencing intervals are computed by multiplying the current parameter value with the square root of machine precision.

Use BFGS method to compute quasi-hessians

Specification

Alias: none

Argument(s): none

Child Keywords:

	Required/ Optional	Description of Group	Dakota Keyword	Dakota Keyword Description
	Optional		damped	Numerical safeguarding for BFGS updates

Description

Broyden-Fletcher-Goldfarb-Shanno (BFGS) update will be used to compute quasi-Hessians.

$$B_{k+1} = B_k - \frac{B_k s_k s_k^T B_k}{s_k^T B_k s_k} + \frac{y_k y_k^T}{y_k^T s_k}$$

where B_k is the k^{th} approximation to the Hessian, $s_k = x_{k+1} - x_k$ is the step and $y_k = \nabla f_{k+1} - \nabla f_k$ is the corresponding yield in the gradients.

Notes

- Initial scaling of $\frac{y_k^T y_k}{y_k^T s_k} I$ is used for B_0 prior to the first update.
- Numerical safeguarding is used to protect against numerically small denominators within the updates.
- This safeguarding skips the update if $|y_k^T s_k| < 10^{-6} s_k^T B_k s_k$
- Additional safeguarding can be added using the `damped` option, which utilizes an alternative damped BFGS update when the curvature condition $y_k^T s_k > 0$ is nearly violated.

Use the Symmetric Rank 1 update method to compute quasi-Hessians

Specification

Alias: none

Argument(s): none

Description

The Symmetric Rank 1 (SR1) update (specified with the keyword `sr1`) will be used to compute quasi-Hessians.

$$B_{k+1} = B_k + \frac{(y_k - B_k s_k)(y_k - B_k s_k)^T}{(y_k - B_k s_k)^T s_k}$$

where B_k is the k^{th} approximation to the Hessian, $s_k = x_{k+1} - x_k$ is the step and $y_k = \nabla f_{k+1} - \nabla f_k$ is the corresponding yield in the gradients.

Notes

- Initial scaling of $\frac{y_k^T y_k}{y_k^T s_k} I$ is used for B_0 prior to the first update.
- Numerical safeguarding is used to protect against numerically small denominators within the updates.
- This safeguarding skips the update if $|(y_k - B_k s_k)^T s_k| < 10^{-6} \|s_k\|_2 \|y_k - B_k s_k\|_2$

id_analytic_hessians

- [Keywords Area](#)
- [responses](#)
- [mixed_hessians](#)
- [id_analytic_hessians](#)

Identify which analytical Hessian corresponds to which response

Topics

This keyword is related to the topics:

- [objective_function_pointer](#)

Specification

Alias: none

Argument(s): INTEGERLIST

Description

The `id_analytic_hessians` list specifies by number the functions which have analytic Hessians, and the `id_numerical_hessians` and `id_quasi_hessians` lists specify by number the functions which must use numerical Hessians and secant Hessian updates, respectively. Each function identifier, from 1 through the total number of functions, must appear once and only once within the union of the `id_analytic_hessians`, `id_numerical_hessians`, and `id_quasi_hessians` lists.
