<td>Perform anisotropic expansion refinement by preferentially adapting in dimensions that are detected to have higher ‘importance’.</td>
</tr>
</tbody>
</table>

**Description**

The p_refinement keyword specifies the usage of automated polynomial order refinement, which can be either uniform or dimension_adaptive.

The dimension_adaptive option is supported for the tensor-product quadrature and Smolyak sparse grid options and uniform is supported for tensor and sparse grids as well as regression approaches (collocation_points or collocation_ratio).

Each of these refinement cases makes use of the max_iterations and convergence_tolerance method independent controls. The former control limits the number of refinement iterations, and the latter control terminates refinement when the two-norm of the change in the response covariance matrix (or, in goal-oriented approaches, the two-norm of change in the statistical quantities of interest (QOI)) falls below the tolerance.

The dimension_adaptive case can be further specified to utilize sobol, decay, or generalized refinement controls. The former two cases employ anisotropic tensor/sparse grids in which the anisotropic dimension preference (leading to anisotropic integrations/expansions with differing refinement levels for different random dimensions) is determined using either total Sobol’ indices from variance-based decomposition (sobol case: high indices result in high dimension preference) or using spectral coefficient decay rates from a rate estimation technique similar to Richardson extrapolation (decay case: low decay rates result in high dimension preference). In these two cases as well as the uniform refinement case, the quadrature_order or sparse_grid_level are ramped by one on each refinement iteration until either of the two convergence controls is satisfied. For the uniform refinement case with regression approaches, the expansion_order is ramped by one on each iteration while the oversampling ratio (either defined by collocation_ratio or inferred from collocation_points based on the initial expansion) is held fixed. Finally, the generalized dimension_adaptive case is the default adaptive approach; it refers to the generalized sparse grid algorithm, a greedy approach in which candidate index sets are evaluated for their impact on the statistical QOI, the most influential sets are selected and used to generate additional candidates, and the index set frontier of a sparse grid is evolved in an unstructured and goal-oriented manner (refer to User’s Manual PCE descriptions for additional specifics).

For the case of p_refinement or the case of an explicit nested override, Gauss-Hermite rules are replaced with Genz-Keister nested rules and Gauss-Legendre rules are replaced with Gauss-Patterson nested rules, both of which exchange lower integrand precision for greater point reuse.

7.2.68.3.3.187 uniform

**Description**

Perform anisotropic expansion refinement by preferentially adapting in dimensions that are detected to hold higher 'importance' in resolving statistical quantities of interest.

Dimension importance must be estimated as part of the refinement process. Techniques include either sobol or generalized for stochastic collocation and either sobol, decay, or generalized for polynomial chaos. Each of these automated refinement approaches makes use of the max_iterations and convergence_tolerance iteration controls.

7.2.68.3.3.189 sobol

- Keywords Area
- method
- bayes_calibration
- wasabi
- emulator
- mf_pce
- p_refinement
- dimension_adaptive
- sobol

Estimate dimension preference for automated refinement of stochastic expansion using total Sobol' sensitivity indices.
Specification

Alias: none
Argument(s): none
Default: generalized

Description

Determine dimension preference for refinement of a stochastic expansion from the total Sobol’ sensitivity indices obtained from global sensitivity analysis. High indices indicate high importance for resolving statistical quantities of interest and therefore result in high dimension preference.

Examples

method,
  polynomial_chaos
  sparse_grid_level = 3
  dimension_adaptive p_refinement sobol
  max_iterations = 20
  convergence_tol = 1.e-4

7.2.68.3.3.190 decay

• Keywords Area

- mf_pce
- p_refinement
- dimension_adaptive
- generalized

Use the generalized sparse grid dimension adaptive algorithm to refine a sparse grid approximation of stochastic expansion.

Specification

**Alias:** none

**Argument(s):** none

Description

The generalized sparse grid algorithm is a greedy approach in which candidate index sets are evaluated for their impact on the statistical QOI, the most influential sets are selected and used to generate additional candidates, and the index set frontier of a sparse grid is evolved in an unstructured and goal-oriented manner (refer to User’s Manual PCE descriptions for additional specifics).

Examples

```
method, polynomial_chaos
    sparse_grid_level = 3
dimension_adaptive p_refinement decay
    max_iterations = 20
    convergence_tol = 1.e-4
```
• wasabi
• emulator
• mf_pce
• max_refinement_iterations

Maximum number of expansion refinement iterations

Specification

Alias: none
Argument(s): INTEGER
Default: 100

Description

Limits the number of times the expansion can be refined under various refinement strategies.

Examples

method,
polynomial_chaos
dimension_adaptive generalized
p_refinement
max_refinement_iterations = 20
convergence_tol = 1.e-4
sparse_grid_level = 1

7.2.68.3.3.193 allocation_control

• Keywords Area
• method
• bayes_calibration
• wasabi
• emulator
• mf_pce
• allocation_control

Sample allocation approach for multifidelity expansions

Specification

Alias: none
Argument(s): none
Child Keywords:
Description

Multifidelity surrogate approaches, including polynomial chaos, stochastic collocation, and function train, can optionally employ a integrated greedy competition across the model sequence, where each model index can supply one or more refinement candidates which are competed to determine the candidate with the greatest impact on the QoI statistics per unit cost. This greedy competition implicitly determines the optimal sample allocation across model indices.

Default Behavior

The default, when allocation_control is not specified, is to compute or adapt separately for each model index (individual instead of integrated refinement).

7.2.68.3.3.194 greedy

- Keywords Area
- method
- bayes_calibration
- wasabi
- emulator
- mf_pce
- allocation_control
- greedy

Sample allocation based on greedy refinement within multifidelity polynomial chaos

Specification

Alias: none

Argument(s): none

Description

Multifidelity polynomial chaos supports greedy refinement strategies, spanning regression and projection approaches for computing expansion coefficients. The key idea is that each level of the model hierarchy being approximated can generate one or more candidates for refinement. These candidates are competed against each other within a unified competition, and the candidate that induces the largest change in the statistical QoI (response covariance by default, or results of any $\zeta/p/\beta/\beta^*$ level mappings when specified), normalized by relative cost of evaluating the candidate, is selected and then used to generate additional candidates for consideration at its model level.
Examples

The following example of greedy multifidelity regression starts from a zeroth-order reference expansion (a constant) for each level, and generates candidate refinements for each level that are competed in an integrated greedy competition. The number of new samples for the incremented candidate expansion order is determined from the collocation ratio. In this case, the number of candidates for each level is limited to one uniform refinement of the current expansion order.

```
method,
  model_pointer = 'HIERARCH'
  multifidelity_polynomial_chaos
  allocation_control greedy
  p_refinement uniform
  expansion_order_sequence = 0
  collocation_ratio = .9  seed = 160415
  orthogonal_matching_pursuit
  convergence_tolerance 1.e-2
```

The next example employs generalized sparse grids within a greedy multifidelity competition. Each modeling level starts from a level 0 reference grid (a single point) and generates multiple admissible index set candidates. The full set of candidates across all model levels is competed within an integrated greedy competition, where the greedy selection metric is the induced change in the statistical QoI, normalized by the aggregate simulation cost of the index set candidate. In this case, there are multiple candidates for each model level and the number of candidates grows rapidly with random dimension and grid level.

```
method,
  model_pointer = 'HIERARCH'
  multifidelity_polynomial_chaos
  allocation_control greedy
  p_refinement dimension_adaptive generalized
  sparse_grid_level_sequence = 0 unrestricted
  convergence_tolerance 1.e-8
```

### 7.2.68.3.3.195 discrepancy_emulation

- Keywords Area
- method
- bayes_calibration
- wasabi
- emulator
- mf_pce
- discrepancy_emulation

Formulation for emulation of model discrepancies.

**Specification**

- **Alias:** none
- **Argument(s):** none
- **Default:** distinct
- **Child Keywords:**
In many uncertainty quantification approaches, model discrepancies are emulated using, e.g., polynomial chaos, stochastic collocation, or Gaussian process models. Two formulations are available for this emulation:

1. distinct emulation (default), in which we directly approximate the difference or ratio between the evaluations of two models or solution levels.

2. recursive emulation (experimental option), in which we approximate a difference or ratio among the new model evaluation and the emulator approximation of the previous model.

The latter approach is a form of hierarchical emulation in which we emulate the surplus between the previous emulator and the new modeling level. This approach has a few advantages: (i) it reduces bias by correcting for emulation errors that occur at previous levels, and (ii) it does not require paired model evaluations for each discrepancy level, which reduces cost, allows for disparate sample points, and simplifies data imports.

On the other hand, its primary disadvantage is that the aggregate emulation is only as good as its weakest link, in that a poor emulator recovery can create difficulty in accurately resolving discrepancies that are recursively dependent on it. Thus, the distinct approach may tend to be more expensive in exchange for greater robustness.

### Examples

```
method,
    multilevel_polynomial_chaos
    expansion_order_sequence = 2
    collocation_ratio = .9
    orthogonal_matching_pursuit
    discrepancy_emulation recursive
```

- restricted

Restrict the growth rates for nested and non-nested rules can be synchronized for consistency.

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** restricted (except for generalized sparse grids)
Description

In the quadrature and sparse grid cases, growth rates for nested and non-nested rules can be synchronized for consistency. For a non-nested Gauss rule used within a sparse grid, linear one-dimensional growth rules of \( m = 2l + 1 \) are used to enforce odd quadrature orders, where \( l \) is the grid level and \( m \) is the number of points in the rule. The precision of this Gauss rule is then \( i = 2m - 1 = 4l + 1 \). For nested rules, order growth with level is typically exponential; however, the default behavior is to restrict the number of points to be the lowest order rule that is available that meets the one-dimensional precision requirement implied by either a level \( l \) for a sparse grid (\( i = 4l + 1 \)) or an order \( m \) for a tensor grid (\( i = 2m - 1 \)). This behavior is known as "restricted growth" or "delayed sequences." To override this default behavior in the case of sparse grids, the unrestricted keyword can be used; it cannot be overridden for tensor grids using nested rules since it also provides a mapping to the available nested rule quadrature orders. An exception to the default usage of restricted growth is the dimension_adaptive p_refinement generalized sparse grid case described previously, since the ability to evolve the index sets of a sparse grid in an unstructured manner eliminates the motivation for restricting the exponential growth of nested rules.

7.2.68.3.205 unrestricted

Description

Use adaptive basis selection to choose the basis terms in a polynomial chaos expansion. Basis selection uses compressed sensing to identify a initial set of non zero PCE coefficients. Then these non-zero terms are expanded a set number of times (we suggest 3) and compressed sensing is then applied to these three new index sets. Cross validation is used to choose the best candidate basis. The best basis is then restricted again to the non-zero terms and expanded until no improvement can be gained by adding additional terms.

</tbody>
</table>
### Description

Set the number of points used to build a PCE via regression to be proportional to the number of terms in the expansion. To avoid requiring the user to calculate \( N \) from \( n \) and \( p \), the \text{collocation\_ratio} allows for specification of a constant factor applied to \( N \) (e.g., \text{collocation\_ratio} = 2. produces samples = 2N). In addition, the default linear relationship with \( N \) can be overridden using a real-valued exponent specified using \text{ratio\_order}. In this case, the number of samples becomes \( cN^o \) where \( c \) is the \text{collocation\_ratio} and \( o \) is the \text{ratio\_order}. The \text{use\_derivatives} flag informs the regression approach to include derivative matching equations (limited to gradients at present) in the least squares solutions, enabling the use of fewer collocation points for a given expansion order and dimension (number of points required becomes \( cN^o \)).

- **emulator**
- **mf_pce**
- **expansion_order_sequence**
- **collocation_ratio**
- **least_absolute_shrinkage**
- **l2_penalty**

The \(l_2\) penalty used when performing compressed sensing with elastic net.

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 0. (reverts to standard LASSO formulation)

**Description**

The \(l_2\) penalty used when performing compressed sensing with elastic net.
Use cross validation to choose the 'best' polynomial order of a polynomial chaos expansion.

**Specification**

**Alias**: none

**Argument(s)**: none

**Child Keywords**:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>noise_only</td>
<td>Restrict the cross validation process to estimating only the best noise tolerance.</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>max_cv_order_-candidates</td>
<td>Limit the number of cross-validation candidates for basis order</td>
</tr>
</tbody>
</table>

**Description**

Use cross validation to choose the 'best' polynomial degree of a polynomial chaos expansion. 10 fold cross validation is used to estimate the cross validation error of a total-order polynomial expansion for orders 1 through to order. The order chosen is the one that produces the lowest cross validation error. If there are not enough points to perform 10 fold cross validation then one-at-a-time cross validation will be performed.

**7.2.68.3.3.232 noise_only**

- **Keywords Area**
- **method**
- **bayes_calibration**
- **wasabi**
- **emulator**
Restrict the cross validation process to estimating only the best noise tolerance.

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** false  

**Description**

By default, cross validation estimates both the best noise tolerance and the best candidate basis order. For reasons of reducing computational cost by reducing the number of candidate solves, the user may wish to restrict this process to estimating only the best noise tolerance.

Generally speaking, computing the best noise tolerance through cross validation mitigates issues with over-fitting the data. Computing the best candidate basis order can also mitigate overfitting, while also controlling levels of mutual coherence resulting from high-order Vandermonde-like matrix systems.

### 7.2.68.3.233 max_cv_order_candidates

- **Keywords Area**
- **method**
- **bayes_calibration**
- **wasabi**
- **emulator**
- **mf_pce**
- **expansion_order_sequence**
- **collocation_ratio**
- **cross_validation**
- **max_cv_order_candidates**

Limit the number of cross-validation candidates for basis order

**Specification**

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** ushort max
Description

When generating refinement candidates by advancing the upper bound used for a cross-validation range, the number of cross-validation can eventually become excessive and hamper algorithm progress. This control limits the maximum number of candidates, which when active, will increase the lower bound for this range as the upper bound is advanced.

- multifidelity_function_train

7.2.68.3.3.234 ratio_order

Specify a non-linear the relationship between the expansion order of a polynomial chaos expansion and the number of samples that will be used to compute the PCE coefficients.

Specification

**Alias:** none

**Argument(s):** REAL

**Default:** 1.

Description

When using regression type methods (specified with either collocation_points or collocation_ratio), a total-order expansion can be specified using expansion_order. To avoid requiring the user to calculate N from n and p), the collocation_ratio allows for specification of a constant factor applied to N (e.g., collocation_ratio = 2. produces samples = 2N). In addition, the default linear relationship with N can be overridden using a real-valued exponent specified using ratio_order. In this case, the number of samples becomes $cN^o$ where $c$ is the collocation_ratio and $o$ is the ratio_order.
Perform bounds-scaling on response values prior to surrogate emulation

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** use original data

**Description**

Particularly in multifidelity methods based on regression solutions at each level of a model hierarchy, scaling can be an issue since the magnitude of discrepancy data may decay rapidly and regression solvers may employ absolute tolerances in places.

By activating `response_scaling`, the set of response data used for each recovery is scaled to $[0,1]$ based on the minimum value and range of the data set. This prevents loss of accuracy due to imbalances in scale across model levels.

**See Also**

These keywords may also be of interest:

- `multifidelity_polynomial_chaos`  
- `multifidelity_function_train`

7.2.68.3.3.236  use_derivatives

- **Keywords Area**  
- **method**  
- **bayes_calibration**  
- **wasabi**  
- **emulator**  
- **mf_pce**
• expansion_order_sequence
• collocation_ratio
• use_derivatives

Use derivative data to construct surrogate models

Specification

Alias: none
Argument(s): none
Default: use function values only

Description

The use_derivatives flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, its use with Surfpack Gaussian process is not recommended.

7.2.68.3.237 tensor_grid

• Keywords Area
• method
• bayes_calibration
• wasabi
• emulator
• mf_pce
• expansion_order_sequence
• collocation_ratio
• tensor_grid

Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.

Specification

Alias: none
Argument(s): none
Default: regression with LHS sample set (point collocation)

Description

The collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.
This describes the behavior of reuse of points in constructing polynomial chaos expansion models.

Specification

**Alias:** reuse_samples  
**Argument(s):** none  
**Default:** no sample reuse in coefficient estimation

Description

The `reuse_points` option controls the reuse behavior of points for various types of polynomial chaos expansions, including: `collocation_points`, `collocation_ratio`, `expansion_samples`, or `orthogonal_least_interpolation`. If any of these approaches are specified to create a set of points for the polynomial chaos expansion, one can specify `reuse_points` so that any points that have been previously generated (for example, from the `import_points` file) can be reused.

Maximum iterations in determining polynomial coefficients
7.2 Method

Specification

Alias: none

Argument(s): INTEGER

Default: 100

Description

When using an iterative polynomial coefficient estimation approach, e.g., cross-validation-based solvers, limits the maximum iterations in the coefficient solver.

<td></td>
<td>freeform</td>
<td>Selects freeform file format</td>
</tr>
<tr>
<td></td>
<td></td>
<td>active_only</td>
<td>Import only active variables from tabular data file</td>
</tr>
</tbody>
</table>

### Description

The `import_build_points_file` allows the user to specify a file that contains a list of points and truth model responses used to construct a surrogate model. These can be used by all methods that (explicitly, e.g. surrogate-based optimization, or implicitly, e.g. efficient global optimization) operate on a surrogate. In particular, these points and responses are used in place of truth model evaluations to construct the initial surrogate. When used to construct surrogate models or emulators these are often called build points or training data.

### Default Behavior

By default, methods do not import points from a file.

### Usage Tips

Dakota parses input files without regard to whitespace, but the `import_build_points_file` must be in one of three formats:

- annotated (default)
- custom_annotated
- freeform

### Examples

```plaintext
method polynomial_chaos
  expansion_order = 4
  import_build_points_file = 'dakota_uq_rosenbrock_pce_import.annot.pts.dat'
```

7.2.68.3.3.243 custom_annotated

- Keywords Area
- method
- bayes_calibration
- wasabi
- emulator
- mf_pce
- expansion_order_sequence
• import_build_points_file
• custom.annotated

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

• file_formats

Specification

Alias: none
Argument(s): none
Default: annotated format
Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>header</td>
<td>header</td>
<td>Enable header row in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td>eval_id</td>
<td>eval_id</td>
<td>Enable evaluation ID column in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td>interface_id</td>
<td>interface_id</td>
<td>Enable interface ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom.annotated, followed by options, in the relevant export/import context.

Usage Tips

• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1  0.9 1.1 0.0002 0.26 0.76
2  0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3  0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...
```

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none
Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips
• To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id.

• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

**Examples**

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```python
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
annotated
```

Resulting tabular file:

```plaintext
%eval_id interface x1  x2  obj_fn  nln_ineq_con_1  nln_ineq_con_2
1  NO_ID       0.9  1.1  0.0002  0.26          0.76
2  NO_ID       0.90009 1.1  0.0001996404857  0.2601620081  0.759955
3  NO_ID       0.89991 1.1  0.0002003604863  0.2598380081  0.760045
...```

7.2.68.3.3.248 freeform

• Keywords Area
  • method
  • bayes_calibration
  • wasabi
  • emulator
  • mf_pce
  • expansion_order_sequence
  • import_build_points_file
  • freeform

Selects freeform file format

**Topics**

This keyword is related to the topics:

• file_formats
Specification

Alias: none
Argument(s): none
Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

• Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```plaintext
environment
tabular_data
  tabular_data_file = 'dakota_summary.dat'
freeform
```

Resulting tabular file:

```
0.9  1.1  0.0002  0.26  0.76
0.90009 1.1 0.0001996404857 0.2601620081 0.759955
0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...

  • bayes_calibration
  • wasabi
  • emulator
  • mf_pce
• expansion_order_sequence
• import_build_points_file
• active_only

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

• file_formats

Specification

Alias: none
Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword active_only indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

7.2.68.3.3.250 orthogonal_least_interpolation

**Description**

Build a polynomial chaos expansion from simulation samples using orthogonal least interpolation. Unlike the other regression methods, `expansion_order` cannot be set. OLI will produce the lowest degree polynomial that interpolates the data.

7.2.68.3.251 collocation_points_sequence

- Keywords Area
- method
- bayes_calibration
- wasabi
- emulator
- mf_pce
- orthogonal_least_interpolation
- collocation_points_sequence

Sequence of collocation point counts used in a multi-stage expansion

**Specification**

**Alias:** none

**Argument(s):** INTEGERLIST
Description

Each level entry of the \texttt{collocation_points_sequence} applies to one expansion within a multi-stage expansion. Current multi-stage expansions that support collocation point sequences include multilevel and multifidelity polynomial chaos and multilevel and multifidelity function train expansions.

If adaptive refinement is active, then this sequence specifies the starting point for each level within either an individual or integrated refinement approach.

A corresponding scalar specification is documented at, e.g., \texttt{collocation_points}

See Also

These keywords may also be of interest:

- \texttt{collocation_points}

Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.

Specification

\textbf{Alias: none}

\textbf{Argument(s): INTEGERLIST}

\textbf{Default:} regression with LHS sample set (point collocation)

Description

The collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

7.2.68.3.3.253 \texttt{reuse_points}

- \texttt{emulator}
- \texttt{mf_pce}
- \texttt{orthogonal_least_interpolation}
- \texttt{tensor_grid}
This describes the behavior of reuse of points in constructing polynomial chaos expansion models.

### Specification

**Alias:** reuse_samples  
**Argument(s):** none  
**Default:** no sample reuse in coefficient estimation

### Description

The `reuse_points` option controls the reuse behavior of points for various types of polynomial chaos expansions, including: `collocation_points`, `collocation_ratio`, `expansion_samples`, or `orthogonal_least_interpolation`. If any of these approaches are specified to create a set of points for the polynomial chaos expansion, one can specify `reuse_points` so that any points that have been previously generated (for example, from the `import_points_file`) can be reused.

<th>Dakota Keyword Description</th>
</tr>
</thead>
</table>

Dakota Version 6.16 Reference Manual generated on May 12, 2022
The import_build_points_file allows the user to specify a file that contains a list of points and truth model responses used to construct a surrogate model. These can be used by all methods that (explicitly, e.g. surrogate-based optimization, or implicitly, e.g. efficient global optimization) operate on a surrogate. In particular, these points and responses are used in place of truth model evaluations to construct the initial surrogate. When used to construct surrogate models or emulators these are often called build points or training data.

Default Behavior
By default, methods do not import points from a file.

Usage Tips
Dakota parses input files without regard to whitespace, but the import_build_points_file must be in one of three formats:

- annotated (default)
- custom_annotated
- freeform

Examples

method polynomial_chaos
  expansion_order = 4
  import_build_points_file = ‘dakota_uq_rosenbrock_pce_import.annot.pts.dat’

7.2.68.3.3.255 custom_annotated

</tr>
<tr>
<td>Optional</td>
<td>interface_id</td>
<td>interface_id</td>
<td>Enable interface ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

Usage Tips

• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.
Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```plaintext
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
custom_annotated header eval_id

Resulting tabular file:

%eval_id x1  x2  obj_fn  nln_ineq_con_1  nln_ineq_con_2
1   0.9  1.1  0.0002  0.26  0.76

Selects annotated tabular file format

Topics
This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format

Description
An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior
By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.
Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
annotated
```

Resulting tabular file:

```

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- file_formats
Specification

Alias: none
Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword active_only indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

7.2.68.3.262 askey

- Keywords Area
- method
- bayes_calibration
- wasabi
- emulator
- mf_pce
- askey

Select the standardized random variables (and associated basis polynomials) from the Askey family that best match the user-specified random variables.

Specification

Alias: none
Argument(s): none
Default: extended (Askey + numerically-generated)

Description

The Askey option employs standard normal, standard uniform, standard exponential, standard beta, and standard gamma random variables in a transformed probability space. These selections correspond to Hermite, Legendre, Laguerre, Jacobi, and generalized Laguerre orthogonal polynomials, respectively.

Specific mappings for the basis polynomials are based on a closest match criterion, and include Hermite for normal (optimal) as well as bounded normal, lognormal, bounded lognormal, gumbel, frechet, and weibull (sub-optimal); Legendre for uniform (optimal) as well as loguniform, triangular, and bin-based histogram (sub-optimal); Laguerre for exponential (optimal); Jacobi for beta (optimal); and generalized Laguerre for gamma (optimal).

The normalized specification requests output of PCE coefficients that correspond to normalized orthogonal basis polynomials.
Specification

**Alias:** none

**Argument(s):** none

**Default:** PCE coefficients correspond to unnormalized basis polynomials

Description

The normalized specification requests output of PCE coefficients that correspond to normalized orthogonal basis polynomials.

7.2.68.3.3.265 export_expansion_file

- **Keywords Area**
- method
- bayes_calibration
- wasabi
- emulator
- mf_pce
- export_expansion_file

Export the coefficients and multi-index of a Polynomial Chaos Expansion (PCE) to a file.

Specification

**Alias:** none

**Argument(s):** STRING

Description

Export the coefficients and multi-index of a Polynomial Chaos Expansion (PCE) to a file. The multi-index written will be sparse. Specifically the expansion will consists only of the indices corresponding to the non-zero coefficients of the PCE.

7.2.68.3.3.266 diagonal_covariance

- **Keywords Area**
- method
- bayes_calibration
- wasabi
- emulator
- mf_pce
- diagonal_covariance

Display only the diagonal terms of the covariance matrix.
Specification

**Alias:** none

**Argument(s):** none

**Default:** diagonal_covariance for response vector > 10; else full_covariance

**Description**

With a large number of responses, the covariance matrix can be very large. *diagonal_covariance* is used to suppress the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

### 7.2.68.3.3.267 full_covariance

- **Keywords Area**
- **method**
- **bayes_calibration**
- **wasabi**

These keywords may also be of interest:

- stoch_collocation

Automatic polynomial order refinement

Specification

Alias: none

Argument(s): none

Default: no refinement

Child Keywords:
### Description

The `p_refinement` keyword specifies the usage of automated polynomial order refinement, which can be either `uniform` or `dimension_adaptive`.

The `dimension_adaptive` option is supported for the tensor-product quadrature and Smolyak sparse grid options and `uniform` is supported for tensor and sparse grids as well as regression approaches (`collocation_points` or `collocation_ratio`).

Each of these refinement cases makes use of the `max_iterations` and `convergence_tolerance` method independent controls. The former control limits the number of refinement iterations, and the latter control terminates refinement when the two-norm of the change in the response covariance matrix (or, in goal-oriented approaches, the two-norm of change in the statistical quantities of interest (QOI)) falls below the tolerance.

The `dimension_adaptive` case can be further specified to utilize `sobol`, `decay`, or `generalized` refinement controls. The former two cases employ anisotropic tensor/sparse grids in which the anisotropic dimension preference (leading to anisotropic integrations/expansions with differing refinement levels for different random dimensions) is determined using either total Sobol' indices from variance-based decomposition (`sobol` case: high indices result in high dimension preference) or using spectral coefficient decay rates from a rate estimation technique similar to Richardson extrapolation (`decay` case: low decay rates result in high dimension preference). In these two cases as well as the `uniform` refinement case, the `quadrature_order` or `sparse_grid_level` are ramped by one on each refinement iteration until either of the two convergence controls is satisfied. For the `uniform` refinement case with regression approaches, the `expansion_order` is ramped by one on each iteration while the oversampling ratio (either defined by `collocation_ratio` or inferred from `collocation_points` based on the initial expansion) is held fixed. Finally, the `generalized dimension_adaptive` case is the default adaptive approach; it refers to the generalized sparse grid algorithm, a greedy approach in which candidate index sets are evaluated for their impact on the statistical QOI, the most influential sets are selected and used to generate additional candidates, and the index set frontier of a sparse grid is evolved in an unstructured and goal-oriented manner (refer to User's Manual PCE descriptions for additional specifics).

For the case of `p_refinement` or the case of an explicit nested override, Gauss-Hermite rules are replaced with Genz-Keister nested rules and Gauss-Legendre rules are replaced with Gauss-Patterson nested rules, both of which exchange lower integrand precision for greater point reuse.

### Keywords

- `area`
- `method`
- `bayes_calibration`
- `wasabi`
- `emulator`
- `sc`
- `p_refinement`
- `uniform`

Refine an expansion uniformly in all dimensions.
Specification

Alias: none

Argument(s): none

Description

The quadrature_order or sparse_grid_level are ramped by one on each refinement iteration until either of the two convergence controls is satisfied. For the uniform refinement case with regression approaches, the expansion_order is ramped by one on each iteration while the oversampling ratio (either defined by collocation_ratio or inferred from collocation_points based on the initial expansion) is held fixed.

7.2.68.3.271 dimension_adaptive

- Keywords Area
- method
- bayes_calibration
- wasabi
- emulator
- sc
- p_refinement
- dimension_adaptive

Perform anisotropic expansion refinement by preferentially adapting in dimensions that are detected to have higher ‘importance’.

Specification

Alias: none

Argument(s): none

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group Dimension Adaptivity Estimation Approach (Group 1)</th>

</thead>
<tbody>
<tr>
<td>Required (Choose One)</td>
<td>sobol</td>
<td>Estimate dimension preference for automated refinement of stochastic expansion using total Sobol’ sensitivity indices.</td>
<td></td>
</tr>
</tbody>
</table>
### Description

Perform anisotropic expansion refinement by preferentially adapting in dimensions that are detected to hold higher 'importance' in resolving statistical quantities of interest.

Dimension importance must be estimated as part of the refinement process. Techniques include either sobol or generalized for stochastic collocation and either sobol, decay, or generalized for polynomial chaos. Each of these automated refinement approaches makes use of the `max_iterations` and `convergence_tolerance` iteration controls.

**7.2.68.3.272 sobol**

- **Keywords Area**
- **method**
- **bayes_calibration**
- **wasabi**
- **emulator**
- **sc**
- **p_refinement**
- **dimension_adaptive**
- **sobol**

Estimate dimension preference for automated refinement of stochastic expansion using total Sobol' sensitivity indices.

**Specification**

- **Alias:** none
- **Argument(s):** none
- **Default:** generalized

**Description**

Determine dimension preference for refinement of a stochastic expansion from the total Sobol' sensitivity indices obtained from global sensitivity analysis. High indices indicate high importance for resolving statistical quantities of interest and therefore result in high dimension preference.
Use the generalized sparse grid dimension adaptive algorithm to refine a sparse grid approximation of stochastic expansion.

### Specification

**Alias:** none

**Argument(s):** none

### Description

The generalized sparse grid algorithm is a greedy approach in which candidate index sets are evaluated for their impact on the statistical QOI, the most influential sets are selected and used to generate additional candidates, and the index set frontier of a sparse grid is evolved in an unstructured and goal-oriented manner (refer to User’s Manual PCE descriptions for additional specifics).

### Examples

```plaintext
method, polynomial_chaos
  sparse_grid_level = 3
dimension_adaptive p_refinement sobol
  max_iterations = 20
  convergence_tol = 1.e-4
```
Employ h-refinement to refine the grid

**Specification**

**Alias:** none  
**Argument(s):** none

</table>

**Description**

Automated expansion refinement can be selected as either p_refinement or h_refinement, and either refinement specification can be either uniform or dimension_adaptive. The dimension_adaptive case can be further specified as either sobol or generalized (decay not supported). Each of these automated refinement approaches makes use of the max_iterations and convergence_tolerance iteration controls. The h_refinement specification involves use of the same piecewise interpolants (linear or cubic Hermite splines) described above for the piecewise specification option (it is not necessary to redundantly specify piecewise in the case of h_refinement). In future releases, the hierarchical interpolation approach will enable local refinement in addition to the current uniform and dimension_-adaptive options.
Refine an expansion uniformly in all dimensions.

**Specification**

*Alias*: none  
*Argument(s)*: none

**Description**

The quadrature_order or sparse_grid_level are ramped by one on each refinement iteration until either of the two convergence controls is satisfied. For the uniform refinement case with regression approaches, the expansion_order is ramped by one on each iteration while the oversampling ratio (either defined by collocation_ratio or inferred from collocation_points based on the initial expansion) is held fixed.

```plaintext
7.2.68.3.276  dimension_adaptive
```

Perform anisotropic expansion refinement by preferentially adapting in dimensions that are detected to have higher ‘importance’.

**Description**

Perform anisotropic expansion refinement by preferentially adapting in dimensions that are detected to hold higher ‘importance’ in resolving statistical quantities of interest.

Dimension importance must be estimated as part of the refinement process. Techniques include either sobol or generalized for stochastic collocation and either sobol, decay, or generalized for polynomial chaos. Each of these automated refinement approaches makes use of the max_iterations and convergence_tolerance iteration controls.

7.2.68.3.3.277 sobol

- Keywords Area
- method
- bayes_calibration
- wasabi
- emulator
- sc
- h_refinement
- dimension_adaptive
- sobol

Estimate dimension preference for automated refinement of stochastic expansion using total Sobol’ sensitivity indices.

**Specification**

Alias: none

Argument(s): none

Default: generalized
Description

Determine dimension preference for refinement of a stochastic expansion from the total Sobol' sensitivity indices obtained from global sensitivity analysis. High indices indicate high importance for resolving statistical quantities of interest and therefore result in high dimension preference.

Examples

```
method, polynomial_chaos
  sparse_grid_level = 3
  dimension_adaptive p_refinement sobol
  max_iterations = 20
  convergence_tol = 1.e-4
```

7.2.68.3.3.278 generalized

- Keywords Area
- method
- bayes_calibration
- wasabi
- emulator
- sc
- h_refinement
- dimension_adaptive
- generalized

Use the generalized sparse grid dimension adaptive algorithm to refine a sparse grid approximation of stochastic expansion.

Specification

**Alias**: none

**Argument(s)**: none

Description

The generalized sparse grid algorithm is a greedy approach in which candidate index sets are evaluated for their impact on the statistical QOI, the most influential sets are selected and used to generate additional candidates, and the index set frontier of a sparse grid is evolved in an unstructured and goal-oriented manner (refer to User’s Manual PCE descriptions for additional specifics).

Examples

```
method, polynomial_chaos
  sparse_grid_level = 3
  dimension_adaptive p_refinement generalized
  max_iterations = 20
  convergence_tol = 1.e-4
```
Planned future capability for local pointwise refinement within a generalized sparse grid.

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

Sparse grid interpolation admits approaches for pointwise local refinement within the general framework of generalized sparse grids. This algorithmic capability is currently in a partial prototype stage.

**Maximum number of expansion refinement iterations**

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 100

**Description**

Limits the number of times the expansion can be refined under various refinement strategies.
Examples

    method,
      polynomial_chaos
        dimension_adaptive generalized
    p_refinement
      max_refinement_iterations = 20
      convergence_tol = 1.e-4
      sparse_grid_level = 1

<tr>
<td></td>
<td></td>
<td>non_nested</td>
<td>Enforce use of non-nested quadrature rules</td>
</tr>
</tbody>
</table>

Description

Multidimensional integration by a tensor-product of Gaussian quadrature rules (specified with quadrature_order, and, optionally, dimension_preference). The default rule selection is to employ non_nested Gauss rules including Gauss-Hermite (for normals or transformed normals), Gauss-Legendre (for uniforms or transformed uniforms), Gauss-Jacobi (for betas), Gauss-Laguerre (for exponentials), generalized Gauss-Laguerre (for gammas), and numerically-generated Gauss rules (for other distributions when using an Extended basis). For the case of p_refinement or the case of an explicit nested override, Gauss-Hermite rules are replaced with Genz-Keister nested rules and Gauss-Legendre rules are replaced with Gauss-Patterson nested rules, both of which exchange lower integrand precision for greater point reuse. By specifying a dimension_preference,
where higher preference leads to higher order polynomial resolution, the tensor grid may be rendered anisotropic. The dimension specified to have highest preference will be set to the specified \textit{quadrature\_order} and all other dimensions will be reduced in proportion to their reduced preference; any non-integral portion is truncated. To synchronize with tensor-product integration, a tensor-product expansion is used, where the order $p_i$ of the expansion in each dimension is selected to be half of the integrand precision available from the rule in use, rounded down. In the case of non-nested Gauss rules with integrand precision $2m_i - 1$, $p_i$ is one less than the quadrature order $m_i$ in each dimension (a one-dimensional expansion contains the same number of terms, $p + 1$, as the number of Gauss points). The total number of terms, $N$, in a tensor-product expansion involving $n$ uncertain input variables is

$$N = 1 + P = \prod_{i=1}^{n}(p_i + 1)$$

In some advanced use cases (e.g., multifidelity UQ), multiple grid resolutions can be employed; for this reason, the \textit{quadrature\_order} specification supports an array input.

A corresponding sequence specification is documented at, e.g., \textit{quadrature\_order\_sequence} and \textit{quadrature\_order\_sequence}

### Description

Multi-dimensional integration by the Smolyak sparse grid method (specified with `sparse_grid_level` and, optionally, `dimension_preference`). The underlying one-dimensional integration rules are the same as for the tensor-product quadrature case; however, the default rule selection is nested for sparse grids (Genz-Keister for normals/transformed normals and Gauss-Patterson for uniforms/transformed uniforms). This default can be overridden with an explicit `non_nested` specification (resulting in Gauss-Hermite for normals/transformed normals and Gauss-Legendre for uniforms/transformed uniforms). As for tensor quadrature, the `dimension_preference` specification enables the use of anisotropic sparse grids (refer to the PCE description in the User’s Manual for the anisotropic index set constraint definition). Similar to anisotropic tensor grids, the dimension with greatest preference will have resolution at the full `sparse_grid_level` and all other dimension resolutions will be reduced in proportion to their reduced preference. For PCE with either isotropic or anisotropic sparse grids, a summation of tensor-product expansions is used, where each anisotropic tensor-product quadrature rule underlying the sparse grid construction results in its own anisotropic tensor-product expansion as described in case 1. These anisotropic tensor-product expansions are summed into a sparse PCE using the standard Smolyak summation (again, refer to the User’s Manual for additional details). As for `quadrature_order`, the `sparse_grid_level` specification admits an array input for enabling specification of multiple grid resolutions used by certain advanced solution methodologies.

A corresponding sequence specification is documented at, e.g., `sparse_grid_level_sequence` and `sparse_grid_level_sequence`.

**Employ a nodal sparse grid construction in stochastic collocation**

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** nodal
Description

Stochastic collocation with sparse grids can employ either a nodal or hierarchical formulation. The nodal formulation does not require nested interpolation rules and is therefore more generally applicable. However, in the context of adaptive refinement, it can suffer from loss of precision due to subtractive cancellation.

7.2.68.3.3.288  hierarchical

- Keywords Area
- method
- bayes_calibration
- wasabi
- emulator
- sc
- sparse_grid_level
- hierarchical

Employ a hierarchical sparse grid construction

Specification

Alias: none
Argument(s): none

Description

Stochastic collocation with sparse grids can employ either a nodal or hierarchical formulation. The hierarchical formulation requires nested interpolation rules as it utilizes increments in collocation points along with hierarchical weights defined from a hierarchical basis formulation.

This keyword requests the hierarchical formulation, which has benefits for adaptive refinement by supporting direct computation of increments in targeted statistics (e.g. mean, covariance, reliability indices), avoiding loss of precision from subtractive cancellation.

7.2.68.3.3.289  restricted

- Keywords Area
- method
- bayes_calibration
- wasabi
- emulator
- sc
- sparse_grid_level
- restricted

Restrict the growth rates for nested and non-nested rules can be synchronized for consistency.
Alias: none
Argument(s): none
Default: restricted (except for generalized sparse grids)

Description

In the quadrature and sparse grid cases, growth rates for nested and non-nested rules can be synchronized for consistency. For a non-nested Gauss rule used within a sparse grid, linear one-dimensional growth rules of \( m = 2l + 1 \) are used to enforce odd quadrature orders, where \( l \) is the grid level and \( m \) is the number of points in the rule. The precision of this Gauss rule is then \( i = 2m - 1 = 4l + 1 \). For nested rules, order growth with level is typically exponential; however, the default behavior is to restrict the number of points to be the lowest order rule that is available that meets the one-dimensional precision requirement implied by either a level \( l \) for a sparse grid (\( i = 4l + 1 \)) or an order \( m \) for a tensor grid (\( i = 2m - 1 \)). This behavior is known as "restricted growth" or "delayed sequences.” To override this default behavior in the case of sparse grids, the unrestricted keyword can be used; it cannot be overridden for tensor grids using nested rules since it also provides a mapping to the available nested rule quadrature orders. An exception to the default usage of restricted growth is the dimension_adaptive p_refinement generalized sparse grid case described previously, since the ability to evolve the index sets of a sparse grid in an unstructured manner eliminates the motivation for restricting the exponential growth of nested rules.

7.2.68.3.3.290 unrestricted

- Keywords Area
- method
- bayes_calibration
- wasabi
- emulator
- sc
- sparse_grid_level
- unrestricted

Override the default restriction of growth rates for nested and non-nested rules that are by default synchronized for consistency.

Specification

Alias: none
Argument(s): none

Description

In the quadrature and sparse grid cases, growth rates for nested and non-nested rules can be synchronized for consistency. For a non-nested Gauss rule used within a sparse grid, linear one-dimensional growth rules of \( m = 2l + 1 \) are used to enforce odd quadrature orders, where \( l \) is the grid level and \( m \) is the number of points in the rule. The precision of this Gauss rule is then \( i = 2m - 1 = 4l + 1 \). For nested rules, order growth with level is typically exponential; however, the default behavior is to restrict the number of points to be the lowest order rule that is available that meets the one-dimensional precision requirement implied by either a level \( l \) for a sparse grid (\( i = 4l + 1 \)) or an order \( m \) for a tensor grid (\( i = 2m - 1 \)). This behavior is known as "restricted growth" or "delayed sequences.” To override this default behavior in the case of sparse grids, the unrestricted keyword can be used; it cannot be overridden for tensor grids using nested rules since it also provides a mapping to the available nested rule quadrature orders. 7.2.68.3.293 piecewise

- Keywords Area
- method
- bayes_calibration
- wasabi
- emulator
- sc
- piecewise

Use piecewise local basis functions

Specification

Alias: none

Argument(s): none

Default: extended (Askey + numerically-generated)

Description

SC also supports the option of piecewise local basis functions. These are piecewise linear splines, or in the case of gradient-enhanced interpolation via the use_derivatives specification, piecewise cubic Hermite splines. Both of these basis selections provide local support only over the range from the interpolated point to its nearest 1D neighbors (within a tensor grid or within each of the tensor grids underlying a sparse grid), which exchanges the fast convergence of global bases for smooth functions for robustness in the representation of nonsmooth response functions (that can induce Gibbs oscillations when using high-order global basis functions). When local basis functions are used, the usage of nonequidistant collocation points (e.g., the Gauss point selections described above) is not well motivated, so equidistant Newton-Cotes points are employed in this case, and all random variable types are transformed to standard uniform probability space.

7.2.68.3.294 askey

- Keywords Area
- method
- bayes_calibration
- wasabi
- emulator
- sc
- askey

Select the standardized random variables (and associated basis polynomials) from the Askey family that best match the user-specified random variables.
Specification

**Alias:** none

**Argument(s):** none

**Default:** extended (Askey + numerically-generated)

**Description**

The Askey option employs standard normal, standard uniform, standard exponential, standard beta, and standard gamma random variables in a transformed probability space. These selections correspond to Hermite, Legendre, Laguerre, Jacobi, and generalized Laguerre orthogonal polynomials, respectively.

Specific mappings for the basis polynomials are based on a closest match criterion, and include Hermite for normal (optimal) as well as bounded normal, lognormal, bounded lognormal, gumbel, frechet, and weibull (sub-optimal); Legendre for uniform (optimal) as well as loguniform, triangular, and bin-based histogram (sub-optimal); Laguerre for exponential (optimal); Jacobi for beta (optimal); and generalized Laguerre for gamma (optimal).

</tr>
</tbody>
</table>

**Description**

The `p_refinement` keyword specifies the usage of automated polynomial order refinement, which can be either `uniform` or `dimension_adaptive`.

The `dimension_adaptive` option is supported for the tensor-product quadrature and Smolyak sparse grid options and `uniform` is supported for tensor and sparse grids as well as regression approaches (`collocation_points` or `collocation_ratio`).

Each of these refinement cases makes use of the `max_iterations` and `convergence_tolerance` method independent controls. The former control limits the number of refinement iterations, and the latter control terminates refinement when the two-norm of the change in the response covariance matrix (or, in goal-oriented approaches, the two-norm of change in the statistical quantities of interest (QOI)) falls below the tolerance.

The `dimension_adaptive` case can be further specified to utilize `sobol`, `decay`, or `generalized` refinement controls. The former two cases employ anisotropic tensor/sparse grids in which the anisotropic dimension preference (leading to anisotropic integrations/expansions with differing refinement levels for different random dimensions) is determined using either total Sobol' indices from variance-based decomposition (`sobol` case: high indices result in high dimension preference) or using spectral coefficient decay rates from a rate estimation technique similar to Richardson extrapolation (`decay` case: low decay rates result in high dimension preference). In these two cases as well as the `uniform` refinement case, the `quadrature_order` or `sparse_grid_level` are ramped by one on each refinement iteration until either of the two convergence controls is satisfied. For the `uniform` refinement case with regression approaches, the `expansion_order` is ramped by one on each iteration while the oversampling ratio (either defined by `collocation_ratio` or inferred from `collocation_points` based on the initial expansion) is held fixed. Finally, the generalized `dimension_adaptive` case is the default adaptive approach; it refers to the generalized sparse grid algorithm, a greedy approach in which candidate index sets are evaluated for their impact on the statistical QOI, the most influential sets are selected and used to generate additional candidates, and the index set frontier of a sparse grid is evolved in an unstructured and goal-oriented manner (refer to User's Manual PCE descriptions for additional specifics).

For the case of `p_refinement` or the case of an explicit nested override, Gauss-Hermite rules are replaced with Genz-Keister nested rules and Gauss-Legendre rules are replaced with Gauss-Patterson nested rules, both of which exchange lower integrand precision for greater point reuse.

**Argument(s):** none

**Description**

The quadrature_order or sparse_grid_level are ramped by one on each refinement iteration until either of the two convergence controls is satisfied. For the uniform refinement case with regression approaches, the expansion_order is ramped by one on each iteration while the oversampling ratio (either defined by collocation_ratio or inferred from collocation_points based on the initial expansion) is held fixed.

- **sobol**

Estimate dimension preference for automated refinement of stochastic expansion using total Sobol’ sensitivity indices.

## Specification

**Alias:** none

**Argument(s):** none

**Default:** generalized
7.2 method

Description

Determine dimension preference for refinement of a stochastic expansion from the total Sobol' sensitivity indices obtained from global sensitivity analysis. High indices indicate high importance for resolving statistical quantities of interest and therefore result in high dimension preference.

Examples

```plaintext
method, polynomial_chaos
  sparse_grid_level = 3
  dimension_adaptive p_refinement sobol
    max_iterations = 20
    convergence_tol = 1.e-4
```

7.2.68.3.3.304 generalized

- Keywords Area
- method
- bayes_calibration
- wasabi
- emulator
- mf_sc
- p_refinement
- dimension_adaptive
- generalized

Use the generalized sparse grid dimension adaptive algorithm to refine a sparse grid approximation of stochastic expansion.

Specification

Alias: none

Argument(s): none

Description

The generalized sparse grid algorithm is a greedy approach in which candidate index sets are evaluated for their impact on the statistical QOI, the most influential sets are selected and used to generate additional candidates, and the index set frontier of a sparse grid is evolved in an unstructured and goal-oriented manner (refer to User’s Manual PCE descriptions for additional specifics).

Examples

```plaintext
method, polynomial_chaos
  sparse_grid_level = 3
  dimension_adaptive p_refinement generalized
    max_iterations = 20
    convergence_tol = 1.e-4
```
7.2.68.3.3.305 h_refinement

- Keywords Area
- method
- bayes_calibration
- wasabi
- emulator
- mf_sc
- h_refinement

Employ h-refinement to refine the grid

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

Automated expansion refinement can be selected as either p_refinement or h_refinement, and either refinement specification can be either uniform or dimension_adaptive. The dimension_adaptive case can be further specified as either sobol or generalized (decay not supported). Each of these automated refinement approaches makes use of the max_iterations and convergence_tolerance iteration controls. The h_refinement specification involves use of the same piecewise interpolants (linear or cubic Hermite splines) described above for the piecewise specification option (it is not necessary to redundantly specify piecewise in the case of h_refinement). In future releases, the hierarchical interpolation approach will enable local refinement in addition to the current uniform and dimension_adaptive options.

</thead>
<tbody>
<tr>
<td>Required (Choose One)</td>
<td>Multifidelity Sample Allocation Control (Group 1)</td>
<td>greedy</td>
</tr>
<tr>
<td></td>
<td>Sample allocation based on greedy refinement within multifidelity stochastic collocation</td>
<td></td>
</tr>
</tbody>
</table>

Description

Multifidelity surrogate approaches, including polynomial chaos, stochastic collocation, and function train, can optionally employ a integrated greedy competition across the model sequence, where each model index can supply one or more refinement candidates which are competed to determine the candidate with the greatest impact on the QoI statistics per unit cost. This greedy competition implicitly determines the optimal sample allocation across model indices.

Default Behavior

The default, when allocation_control is not specified, is to compute or adapt separately for each model index (individual instead of integrated refinement).
Sample allocation based on greedy refinement within multifidelity stochastic collocation

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

Multifidelity stochastic collocation supports greedy refinement strategies using tensor and sparse grids for both nodal and hierarchical collocation approaches. The key idea is that each level of the model hierarchy being approximated can generate one or more candidates for refinement. These candidates are competed against each other within an integrated competition, and the candidate that induces the largest change in the statistical QoI (response covariance by default, or results of any level mappings when specified), normalized by relative cost of evaluating the candidate, is selected and then used to generate additional candidates for consideration at its model level.

**Examples**

The following example of greedy multifidelity stochastic collocation using nodal interpolation starts from a zeroth-order expansion (a constant) for each level, and generates uniform candidate refinements for each level that are competed in a greedy competition. The number of new samples for the incremented candidate expansion order is determined from the quadrature rules of the new sparse grid level. In this case, the number of candidates for each level is limited to one uniform refinement of the current sparse grid level.

```dakota
method,
    model_pointer = ‘HIERARCH’
    multifidelity_stoch_collocation
    nodal
    allocation_control greedy
    p_refinement uniform
    sparse_grid_level_sequence = 0 unrestricted
    convergence_tolerance 1.e-3
```

The next example employs generalized sparse grids and hierarchical interpolation. Each level starts from a level 0 reference grid (a single point) and generates multiple admissible index set candidates. The full set of candidates across all levels is competed within a unified greedy competition, where the greedy selection metric is the induced change in the statistical QoI, normalized by the aggregate simulation cost of the index set candidate. In this case, there are multiple candidates for each level and the number of candidates grows rapidly with random dimension and grid level.
In many uncertainty quantification approaches, model discrepancies are emulated using, e.g., polynomial chaos, stochastic collocation, or Gaussian process models. Two formulations are available for this emulation:

1. **distinct** emulation (default), in which we directly approximate the difference or ratio between the evaluations of two models or solution levels.

2. **recursive** emulation (experimental option), in which we approximate a difference or ratio among the new model evaluation and the emulator approximation of the previous model.
The latter approach is a form of hierarchical emulation in which we emulate the surplus between the previous emulator and the new modeling level. This approach has a few advantages: (i) it reduces bias by correcting for emulation errors that occur at previous levels, and (ii) it does not require paired model evaluations for each discrepancy level, which reduces cost, allows for disparate sample points, and simplifies data imports.

On the other hand, its primary disadvantage is that the aggregate emulation is only as good as its weakest link, in that a poor emulator recovery can create difficulty in accurately resolving discrepancies that are recursively dependent on it. Thus, the distinct approach may tend to be more expensive in exchange for greater robustness.

Examples

```
method,
   multilevel_polynomial_chaos
   expansion_order_sequence = 2
   collocation_ratio = .9
   orthogonal_matching_pursuit
   discrepancy_emulation recursive
```

7.2.68.3.3.323 nodal

- Keywords Area
- method
- bayes_calibration
- wasabi
- emulator
- mf_sc
- sparse_grid_level_sequence
- nodal

Employ a nodal sparse grid construction in stochastic collocation

Specification

Alias: none
Argument(s): none
Default: nodal

Description

Stochastic collocation with sparse grids can employ either a nodal or hierarchical formulation. The nodal formulation does not require nested interpolation rules and is therefore more generally applicable. However, in the context of adaptive refinement, it can suffer from loss of precision due to subtractive cancellation.
7.2.68.3.3.324 hierarchical

- Keywords Area
- method
- bayes_calibration
- wasabi
- emulator
- mf_sc
- sparse_grid_level_sequence
- hierarchical

Employ a hierarchical sparse grid construction

Specification

Alias: none

Argument(s): none

Description

Stochastic collocation with sparse grids can employ either a nodal or hierarchical formulation. The hierarchical formulation requires nested interpolation rules as it utilizes increments in collocation points along with hierarchical weights defined from a hierarchical basis formulation.

This keyword requests the hierarchical formulation, which has benefits for adaptive refinement by supporting direct computation of increments in targeted statistics (e.g. mean, covariance, reliability indices), avoiding loss of precision from subtractive cancellation.

7.2.68.3.3.325 restricted

- Keywords Area
- method
- bayes_calibration
- wasabi
- emulator
- mf_sc
- sparse_grid_level_sequence
- restricted

Restrict the growth rates for nested and non-nested rules can be synchronized for consistency.

Specification

Alias: none

Argument(s): none

Default: restricted (except for generalized sparse grids)
In the quadrature and sparse grid cases, growth rates for nested and non-nested rules can be synchronized for consistency. For a non-nested Gauss rule used within a sparse grid, linear one-dimensional growth rules of \( m = 2l + 1 \) are used to enforce odd quadrature orders, where \( l \) is the grid level and \( m \) is the number of points in the rule. The precision of this Gauss rule is then \( i = 2m - 1 = 4l + 1 \). For nested rules, order growth with level is typically exponential; however, the default behavior is to restrict the number of points to be the lowest order rule that is available that meets the one-dimensional precision requirement implied by either a level \( l \) for a sparse grid ( \( i = 4l + 1 \) ) or an order \( m \) for a tensor grid ( \( i = 2m - 1 \) ). This behavior is known as "restricted growth" or "delayed sequences." To override this default behavior in the case of sparse grids, the unrestricted keyword can be used; it cannot be overridden for tensor grids using nested rules since it also provides a mapping to the available nested rule quadrature orders. An exception to the default usage of restricted growth is the dimension_adaptive p_refinement generalized sparse grid case described previously, since the ability to evolve the index sets of a sparse grid in an unstructured manner eliminates the motivation for restricting the exponential growth of nested rules.

7.2.68.3.3.326 unrestricted

- Keywords Area
- method
- bayes_calibration
- wasabi
- emulator
- mf_sc
- sparse_grid_level_sequence
- unrestricted

Override the default restriction of growth rates for nested and non-nested rules that are by default synchronized for consistency.

**Specification**

*Alias*: none

*Argument(s)*: none

**Description**

In the quadrature and sparse grid cases, growth rates for nested and non-nested rules can be synchronized for consistency. For a non-nested Gauss rule used within a sparse grid, linear one-dimensional growth rules of \( m = 2l + 1 \) are used to enforce odd quadrature orders, where \( l \) is the grid level and \( m \) is the number of points in the rule. The precision of this Gauss rule is then \( i = 2m - 1 = 4l + 1 \). For nested rules, order growth with level is typically exponential; however, the default behavior is to restrict the number of points to be the lowest order rule that is available that meets the one-dimensional precision requirement implied by either a level \( l \) for a sparse grid ( \( i = 4l + 1 \) ) or an order \( m \) for a tensor grid ( \( i = 2m - 1 \) ). This behavior is known as "restricted growth" or "delayed sequences." To override this default behavior in the case of sparse grids, the unrestricted keyword can be used; it cannot be overridden for tensor grids using nested rules since it also provides a mapping to the available nested rule quadrature orders. An exception to the default usage of restricted growth is the dimension_adaptive p_refinement generalized sparse grid case described previously, since the ability to evolve the index sets of a sparse grid in an unstructured manner eliminates the motivation for restricting the exponential growth of nested rules.
7.2.68.3.3.327  nested

- non_nested

Enforce use of non-nested quadrature rules

**Specification**

**Alias**: none

**Argument(s)**: none
Description

Enforce use of non-nested quadrature rules if available. For instance if the aleatory variables are Gaussian use the non-nested Gauss-Hermite rule

7.2.68.3.3.329  piecewise

- Keywords Area
- method
- bayes_calibration
- wasabi
- emulator
- mf_sc
- piecewise

Use piecewise local basis functions

Specification

Alias: none
Argument(s): none
Default: extended (Askey + numerically-generated)

Description

SC also supports the option of piecewise local basis functions. These are piecewise linear splines, or in the case of gradient-enhanced interpolation via the use_derivatives specification, piecewise cubic Hermite splines. Both of these basis selections provide local support only over the range from the interpolated point to its nearest 1D neighbors (within a tensor grid or within each of the tensor grids underlying a sparse grid), which exchanges the fast convergence of global bases for smooth functions for robustness in the representation of nonsmooth response functions (that can induce Gibbs oscillations when using high-order global basis functions). When local basis functions are used, the usage of nonequidistant collocation points (e.g., the Gauss point selections described above) is not well motivated, so equidistant Newton-Cotes points are employed in this case, and all random variable types are transformed to standard uniform probability space.

7.2.68.3.3.330  askey

- Keywords Area
- method
- bayes_calibration
- wasabi
- emulator
- mf_sc
- askey

Select the standardized random variables (and associated basis polynomials) from the Askey family that best match the user-specified random variables.
**Specification**

**Alias:** none

**Argument(s):** none

**Default:** extended (Askey + numerically-generated)

**Description**

The Askey option employs standard normal, standard uniform, standard exponential, standard beta, and standard gamma random variables in a transformed probability space. These selections correspond to Hermite, Legendre, Laguerre, Jacobi, and generalized Laguerre orthogonal polynomials, respectively.

Specific mappings for the basis polynomials are based on a closest match criterion, and include Hermite for normal (optimal) as well as bounded normal, lognormal, bounded lognormal, gumbel, frechet, and weibull (sub-optimal); Legendre for uniform (optimal) as well as loguniform, triangular, and bin-based histogram (sub-optimal); Laguerre for exponential (optimal); Jacobi for beta (optimal); and generalized Laguerre for gamma (optimal).

**See Also**

These keywords may also be of interest:

7.2.68.3.3.322 use_derivatives

- Keywords Area
- method
- bayes_calibration
- wasabi
- emulator
- mf_sc
- use_derivatives

Use derivative data to construct surrogate models

Specification

**Alias:** none

**Argument(s):** none

**Default:** use function values only

Description

The `use_derivatives` flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, its use with Surfpack Gaussian process is not recommended.

7.2.68.3.3.333 diagonal_covariance

- Keywords Area
- method
- bayes_calibration
- wasabi
- emulator
- mf_sc
- diagonal_covariance

Display only the diagonal terms of the covariance matrix
7.2 method

Specification

Alias: none

Argument(s): none

Default: diagonal_covariance for response vector > 10; else full_covariance

Description

With a large number of responses, the covariance matrix can be very large. diagonal_covariance is used to suppress the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

7.2.68.3.3.334 full_covariance

- Keywords Area
- method
- bayes_calibration
- wasabi
- emulator
- mf_sc
- full_covariance

Display the full covariance matrix

7.2.68.3.4 standardized_space

- Keywords Area
- method
- bayes_calibration
- wasabi
- standardized_space

Perform Bayesian inference in standardized probability space

Specification

Alias: none

Argument(s): none
Description

This option transforms the inference process (MCMC sampling and any emulator model management) into a standardized probability space.

The variable transformations performed are as described in askey.

Default Behavior

The default for the Gaussian process and no emulator options is to perform inference in the original probability space (no transformation). Polynomial chaos and stochastic collocation emulators, on the other hand, are always formed in standardized probability space, such that the inference process is also performed in this standardized space.

Expected Output

The user will see the truth model evaluations performed in the original space, whereas any method diagnostics relating to the MCMC samples (e.g., QUESO data in the outputData directory) will report points and response data (response gradients and Hessians, if present, will differ but response values will not) that correspond to the transformed space.

Usage Tips

Selecting standardized_space generally has the effect of scaling the random variables to be of comparable magnitude, which can improve the efficiency of the Bayesian inference process.

Examples

```bash
method, bayes_calibration queso
  samples = 2000 seed = 348
  dram
  standardized_space
```

Description

The DiffeRential Evolution Adaptive Metropolis algorithm is described in [89]. For the DREAM method, one can define the number of chains used with chains (minimum 3). The total number of generations per chain in DREAM is the number of samples (samples) divided by the number of chains (chains). The number of chains randomly selected to be used in the crossover each time a crossover occurs is crossover_chain_pairs. There is an extra adaptation during burn-in, in which DREAM estimates a distribution of crossover probabilities that favors large jumps over smaller ones in each of the chains. Normalization is required to ensure that all of the input dimensions contribute equally. In this process, a discrete number of candidate points for each crossover value is generated. This parameter is num_cr. The gr_threshold is the convergence tolerance for the Gelman-Rubin statistic which will govern the convergence of the multiple chain process. The integer jump_step forces a long jump every jump_step generations. For more details about these parameters, see [89].

Attention: While the emulator specification for DREAM includes the keyword posterior_adaptive, it is not yet operational.

7.2.68.4.1 chain_samples

• Keywords Area
• method
• bayes_calibration
• dream
• chain_samples

Number of Markov Chain Monte Carlo posterior samples

Specification

Alias: samples

Argument(s): INTEGER

Default: method-dependent

Description

The chain_samples keyword indicates the number of draws from the posterior distribution to perform. When an emulator is active, this will be the number of samples on the constructed surrogate model.

Default Behavior

The default number of chain samples is method-dependent. QUESO and MUQ methods use 1000. DREAM uses (number of generations) x (number of chains), resulting in chain_samples close to that specified.

Usage Tips

MCMC methods typically require a large number of chain samples to converge, often thousands to millions.

Examples

method
  bayes_calibration queso
  chain_samples = 20000
7.2.68.4.2 seed

- Keywords Area
- method
- bayes_calibration
- dream
- seed

Seed of the random number generator

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** system-generated (non-repeatable)

**Description**

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

**Default Behavior**

If not specified, the seed is randomly generated.

**Expected Output**

If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

**Usage Tips**

If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

**Examples**

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

7.2.68.4.3 chains

- num_cr

Number of candidate points for each crossover.

Topics

This keyword is related to the topics:

- bayesian_calibration

Specification

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** 1

Description

In DREAM, there is an extra adaptation during burn-in, in which DREAM estimates a distribution of crossover probabilities that favors large jumps over smaller ones in each of the chains. Normalization is required to ensure that all of the input dimensions contribute equally. In this process, a discrete number of candidate points for each crossover value is generated. This parameter is num_cr.
7.2.68.4.5  crossover_chain_pairs

- Keywords Area
- method
- bayes_calibration
- dream
- crossover_chain_pairs

Number of chains used in crossover.

**Topics**

This keyword is related to the topics:

- bayesian_calibration

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 3

**Description**

The number of chains randomly selected to be used in the crossover each time a crossover occurs.

7.2.68.4.6  gr_threshold

- Keywords Area
- method
- bayes_calibration
- dream
- gr_threshold

Convergence tolerance for the Gelman-Rubin statistic

**Topics**

This keyword is related to the topics:

- bayesian_calibration

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 1.2
Description

The gr_threshold is the convergence tolerance for the Gelman-Rubin statistic which will govern the convergence of the multiple chain process.

7.2.68.4.7 jump_step

- Keywords Area
- method
- bayes_calibration
- dream
- jump_step

Number of generations a long jump step is taken

Topics

This keyword is related to the topics:

- bayesian_calibration

Specification

Alias: none
Argument(s): INTEGER
Default: 5

Description

The integer jump_step forces a long jump every jump_step generations in DREAM.

</tr>
</tbody>
</table>

**Description**

Use the Gaussian process (GP) surrogate from Surfpack, which is specified using the `surfpack` keyword.

An alternate version of GP surrogates was available in prior versions of Dakota. **For now, both versions are supported but the dakota version is deprecated and intended to be removed in a future release.**

_Known Issue: When using discrete variables, there have been sometimes significant differences in surrogate behavior observed across computing platforms in some cases. The cause has not yet been fully diagnosed and is currently under investigation. In addition, guidance on appropriate construction and use of surrogates with discrete variables is under development. In the meantime, users should therefore be aware that there is a risk of inaccurate results when using surrogates with discrete variables._

### 7.2.68.4.8.2 surfpack

- **Keywords Area**
- method
- bayes_calibration
- dream
- emulator
- gaussian_process
- surfpack

Use the Surfpack version of Gaussian Process surrogates

**Specification**

**Alias:** none

**Argument(s):** none
Description

This keyword specifies the use of the Gaussian process that is incorporated in our surface fitting library called Surfpack.

Several user options are available:

1. Optimization methods:
   Maximum Likelihood Estimation (MLE) is used to find the optimal values of the hyper-parameters governing the trend and correlation functions. By default the global optimization method DIRECT is used for MLE, but other options for the optimization method are available. See optimization_method.

   The total number of evaluations of the likelihood function can be controlled using the max_trials keyword followed by a positive integer. Note that the likelihood function does not require running the "truth" model, and is relatively inexpensive to compute.

2. Trend Function:
   The GP models incorporate a parametric trend function whose purpose is to capture large-scale variations. See trend.

3. Correlation Lengths:
   Correlation lengths are usually optimized by Surfpack, however, the user can specify the lengths manually. See correlation_lengths.

4. Ill-conditioning
   One of the major problems in determining the governing values for a Gaussian process or Kriging model is the fact that the correlation matrix can easily become ill-conditioned when there are too many input points close together. Since the predictions from the Gaussian process model involve inverting the correlation matrix, ill-conditioning can lead to poor predictive capability and should be avoided.

   Note that a sufficiently bad sample design could require correlation lengths to be so short that any interpolatory GP model would become inept at extrapolation and interpolation.

   The surfpack model handles ill-conditioning internally by default, but behavior can be modified using.

5. Gradient Enhanced Kriging (GEK).
   The use_derivatives keyword will cause the Surfpack GP to be constructed from a combination of function value and gradient information (if available).

   See notes in the Theory section.

Theory

Gradient Enhanced Kriging

Incorporating gradient information will only be beneficial if accurate and inexpensive derivative information is available, and the derivatives are not infinite or nearly so. Here "inexpensive" means that the cost of evaluating a function value plus gradient is comparable to the cost of evaluating only the function value, for example gradients computed by analytical, automatic differentiation, or continuous adjoint techniques. It is not cost effective to use derivatives computed by finite differences. In tests, GEK models built from finite difference derivatives were also significantly less accurate than those built from analytical derivatives. Note that GEK's correlation matrix tends to have a significantly worse condition number than Kriging for the same sample design.

This issue was addressed by using a pivoted Cholesky factorization of Kriging's correlation matrix (which is a small sub-matrix within GEK's correlation matrix) to rank points by how much unique information they contain. This reordering is then applied to whole points (the function value at a point immediately followed by gradient information at the same point) in GEK's correlation matrix. A standard non-pivoted Cholesky is then applied to the reordered GEK correlation matrix and a bisection search is used to find the last equation that meets the constraint on the (estimate of) condition number. The cost of performing pivoted Cholesky on Kriging's correlation matrix is usually negligible compared to the cost of the non-pivoted Cholesky factorization of GEK's correlation matrix. In tests, it also resulted in more accurate GEK models than when pivoted Cholesky or whole-point-block pivoted Cholesky was performed on GEK's correlation matrix.
Select the built in Gaussian Process surrogate

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

A second version of GP surrogates was available in prior versions of Dakota. **For now, both versions are supported but the dakota version is deprecated and intended to be removed in a future release.**

Historically these models were drastically different, but in Dakota 5.1, they became quite similar. They now differ in that the Surfpack GP has a richer set of features/options and tends to be more accurate than the Dakota version. Due to how the Surfpack GP handles ill-conditioned correlation matrices (which significantly contributes to its greater accuracy), the Surfpack GP can be a factor of two or three slower than Dakota's. As of Dakota 5.2, the Surfpack implementation is the default in all contexts except Bayesian calibration.

More details on the `gaussian_process` dakota model can be found in [60].

Dakota’s GP deals with ill-conditioning in two ways. First, when it encounters a non-invertible correlation matrix it iteratively increases the size of a “nugget,” but in such cases the resulting approximation smooths rather than interpolates the data. Second, it has a `point_selection` option (default off) that uses a greedy algorithm to select a well-spaced subset of points prior to the construction of the GP. In this case, the GP will only interpolate the selected subset. Typically, one should not need point selection in trust-region methods because a small number of points are used to develop a surrogate within each trust region. Point selection is most beneficial when constructing with a large number of points, typically more than order one hundred, though this depends on the number of variables and spacing of the sample points.

This differs from the `point_selection` option of the Dakota GP which initially chooses a well-spaced subset of points and finds the correlation parameters that are most likely for that one subset.

**Number of initial model evaluations used in build phase**
Specification

**Alias:** none

**Argument(s):** INTEGER

**Description**

The number of build points or training points used in the initial phase of an algorithm or model construction. Typically these are the initial set of data points used to construct (train) a surrogate model (emulator). If the number of build_samples is less than the minimum number of points required to build the surrogate, Dakota will augment the samples to obtain the minimum required.

**Examples**

Perform GP-based adaptive importance sampling, building the GP with 100 points and then performing 100 approximate evaluations to evaluate the probability.

```dakota
method
gpais
  build_samples = 100
  samples_on_emulator = 100
  max_iterations = 5
  response_levels = -1.065
```

### 7.2.68.4.8.5 posterior_adaptive

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- gaussian_process
- posterior_adaptive

Adapt emulator model to increase accuracy in high posterior probability regions

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

Following an emulator-based MCMC process, this option refines the emulator by selecting points in regions of high posterior probability, performing truth evaluations at these points, updating the emulator, and reperforming the MCMC process. The adaptation is continued until the maximum number of iterations is exceeded or the convergence tolerance is met.
Examples

bayes_calibration queso
  chain_samples = 2000 seed = 348
delayed_rejection
evaluator
  gaussian_process surfpack build_samples = 30
  posterior_adaptive max_iterations = 10
  proposal_covariance derivatives

7.2.68.4.8.6 import_build_points_file

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- gaussian_process
- import_build_points_file

File containing points you wish to use to build a surrogate

Specification

Alias: import_points_file

Argument(s): STRING

Default: no point import from a file

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional (Choose One)</td>
<td>Tabular Format (Group 1)</td>
<td>custom_annotated</td>
<td>Selects custom-annotated tabular file format</td>
</tr>
<tr>

<td></td>
<td>annotated</td>
<td>Selects annotated tabular file format</td>
</tr>
<tr>
<td></td>
<td></td>
<td>freeform</td>
<td>Selects freeform file format</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>active_only</td>
<td>Import only active variables from tabular data file</td>
</tr>
</tbody>
</table>

Description

The import_build_points_file allows the user to specify a file that contains a list of points and truth model responses used to construct a surrogate model. These can be used by all methods that (explicitly, e.g. surrogate-based optimization, or implicitly, e.g. efficient global optimization) operate on a surrogate. In particular, these points and responses are used in place of truth model evaluations to construct the initial surrogate. When used to construct surrogate models or emulators these are often called build points or training data.
Default Behavior
By default, methods do not import points from a file.

Usage Tips
Dakota parses input files without regard to whitespace, but the import_build_points_file must be in one of three formats:

- annotated (default)
- custom_annotated
- freeform

Examples

```plaintext
method
polynomial_chaos
  expansion_order = 4
  import_build_points_file = 'dakota_uq_rosenbrock_pce_import.annot.pts.dat'
```

7.2.68.4.8.7 custom_annotated

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- gaussian_process
- import_build_points_file
- custom_annotated

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
</table>
A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exportsIMPORTS as well. Custom-annotated allows user options for whether header row, eval.id column, and interface id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval.id (no interface_id), and data for variables and responses. Input file fragment:

```
environment
  tabular_data.tabular_data_file = 'dakota_summary.dat'
  custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 0.9 1.1 0.0002 0.26 0.76
2 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...```

- **annotated**

Selects annotated tabular file format

**Topics**

This keyword is related to the topics:

- `file_formats`
Specification

**Alias:** none

**Argument(s):** none

**Default:** annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The `annotated` keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify `custom_annotated` header `eval_id`

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to `annotated` format, though `freeform` remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
  tabular_data_file = 'dakota_summary.dat'
  annotated

Resulting tabular file:

<table>
<thead>
<tr>

- import_build_points_file
- freeform

Selects freeform file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none
Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
freeform
```

Resulting tabular file:

```
0.9   1.1   0.0002  0.26   0.76
0.90009 1.1 0.0001996404857 0.2601620081 0.759955
0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...
```

- gaussian_process
- import_build_points_file
- active_only

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

</tr>
</tbody>
</table>

**Description**

The *p_refinement* keyword specifies the usage of automated polynomial order refinement, which can be either *uniform* or *dimension_adaptive*.

The *dimension_adaptive* option is supported for the tensor-product quadrature and Smolyak sparse grid options and *uniform* is supported for tensor and sparse grids as well as regression approaches (*collocation_points* or *collocation_ratio*).

Each of these refinement cases makes use of the *max_iterations* and *convergence_tolerance* method independent controls. The former control limits the number of refinement iterations, and the latter control terminates refinement when the two-norm of the change in the response covariance matrix (or, in goal-oriented approaches, the two-norm of change in the statistical quantities of interest (QOI)) falls below the tolerance.

The *dimension_adaptive* case can be further specified to utilize *sobol*, *decay*, or *generalized* refinement controls. The former two cases employ anisotropic tensor/sparse grids in which the anisotropic dimension preference (leading to anisotropic integrations/expansions with differing refinement levels for different random dimensions) is determined using either total Sobol’ indices from variance-based decomposition (*sobol* case: high indices result in high dimension preference) or using spectral coefficient decay rates from a rate estimation technique similar to Richardson extrapolation (*decay* case: low decay rates result in high dimension preference). In these two cases as well as the *uniform* refinement case, the *quadrature_order* or *sparse_grid_level* are ramped by one on each refinement iteration until either of the two convergence controls is satisfied. For the *uniform* refinement case with regression approaches, the *expansion_order* is ramped by one on each iteration while the oversampling ratio (either defined by *collocation_ratio* or inferred from *collocation_points* based on the initial expansion) is held fixed. Finally, the *generalized dimension_adaptive* case is the default adaptive approach; it refers to the generalized sparse grid algorithm, a greedy approach in which candidate index sets are evaluated for their impact on the statistical QOI, the most influential sets are selected and used to generate additional candidates, and the index set frontier of a sparse grid is evolved in an unstructured and goal-oriented manner (refer to User’s Manual PCE descriptions for additional specifics).

For the case of *p_refinement* or the case of an explicit nested override, Gauss-Hermite rules are replaced with Genz-Keister nested rules and Gauss-Legendre rules are replaced with Gauss-Patterson nested rules, both of which exchange lower integrand precision for greater point reuse.

</tbody>
</table>

**Description**

Perform anisotropic expansion refinement by preferentially adapting in dimensions that are detected to hold higher ‘importance’ in resolving statistical quantities of interest.

Dimension importance must be estimated as part of the refinement process. Techniques include either sobol or generalized for stochastic collocation and either sobol, decay, or generalized for polynomial chaos. Each of these automated refinement approaches makes use of the max_iterations and convergence_tolerance iteration controls.

7.2.68.4.8.18 sobol

<td>non_nested</td>
<td>Enforce use of non-nested quadrature rules</td>
</tr>
</tbody>
</table>

**Description**

Multidimensional integration by a tensor-product of Gaussian quadrature rules (specified with `quadrature_order` and, optionally, `dimension_preference`). The default rule selection is to employ non_nested Gauss rules including Gauss-Hermite (for normals or transformed normals), Gauss-Legendre (for uniforms or transformed uniforms), Gauss-Jacobi (for betas), Gauss-Laguerre (for exponentials), generalized Gauss-Laguerre (for gammas), and numerically-generated Gauss rules (for other distributions when using an Extended basis). For the case of `p_refinement` or the case of an explicit `nested` override, Gauss-Hermite rules are replaced with Genz-Keister nested rules and Gauss-Legendre rules are replaced with Gauss-Patterson nested rules, both of which exchange lower integrand precision for greater point reuse. By specifying a `dimension_preference`, where higher preference leads to higher order polynomial resolution, the tensor grid may be rendered anisotropic. The dimension specified to have highest preference will be set to the specified `quadrature_order` and all other dimensions will be reduced in proportion to their reduced preference; any non-integral portion is truncated. To synchronize with tensor-product integration, a tensor-product expansion is used, where the order \( p_i \) of the expansion in each dimension is selected to be half of the integrand precision available from the rule in use, rounded down. In the case of non-nested Gauss rules with integrand precision \( 2m_i - 1 \), \( p_i \) is one less than the quadrature order \( m_i \) in each dimension (a one-dimensional expansion contains the same number of terms, \( p_i + 1 \), as the number of Gauss points). The total number of terms, \( N \), in a tensor-product expansion involving \( n \) uncertain input variables is

\[
N = 1 + P = \prod_{i=1}^{n} (p_i + 1)
\]

In some advanced use cases (e.g., multifidelity UQ), multiple grid resolutions can be employed; for this reason, the `quadrature_order` specification supports an array input.

A corresponding sequence specification is documented at, e.g., `quadrature_order_sequence` and `quadrature_order_sequence`

Child Keywords:
### Description

Multi-dimensional integration by the Smolyak sparse grid method (specified with `sparse_grid_level` and, optionally, `dimension_preference`). The underlying one-dimensional integration rules are the same as for the tensor-product quadrature case; however, the default rule selection is nested for sparse grids (Genz-Keister for normals/transformed normals and Gauss-Patterson for uniforms/transformed uniforms). This default can be overridden with an explicit `non_nested` specification (resulting in Gauss-Hermite for normals/transformed normals and Gauss-Legendre for uniforms/transformed uniforms). As for tensor quadrature, the `dimension_preference` specification enables the use of anisotropic sparse grids (refer to the PCE description in the User's Manual for the anisotropic index set constraint definition). Similar to anisotropic tensor grids, the dimension with greatest preference will have resolution at the full `sparse_grid_level` and all other dimension resolutions will be reduced in proportion to their reduced preference. For PCE with either isotropic or anisotropic sparse grids, a summation of tensor-product expansions is used, where each anisotropic tensor-product quadrature rule underlying the sparse grid construction results in its own anisotropic tensor-product expansion as described in case 1. These anisotropic tensor-product expansions are summed into a sparse PCE using the standard Smolyak summation (again, refer to the User's Manual for additional details). As for `quadrature_order`, the `sparse_grid_level` specification admits an array input for enabling specification of multiple grid resolutions used by certain advanced solution methodologies.

A corresponding sequence specification is documented at, e.g., `sparse_grid_level_sequence` and `sparse_grid_level_sequence`.

- pce
- sparse_grid_level
- restricted

Restrict the growth rates for nested and non-nested rules can be synchronized for consistency.
7.2 method

Specification

Alias: none
Argument(s): none
Default: restricted (except for generalized sparse grids)

Description

In the quadrature and sparse grid cases, growth rates for nested and non-nested rules can be synchronized for consistency. For a non-nested Gauss rule used within a sparse grid, linear one-dimensional growth rules of \( m = 2l + 1 \) are used to enforce odd quadrature orders, where \( l \) is the grid level and \( m \) is the number of points in the rule. The precision of this Gauss rule is then \( i = 2m - 1 = 4l + 1 \). For nested rules, order growth with level is typically exponential; however, the default behavior is to restrict the number of points to be the lowest order rule that is available that meets the one-dimensional precision requirement implied by either a level \( l \) for a sparse grid (\( i = 4l + 1 \)) or an order \( m \) for a tensor grid (\( i = 2m - 1 \)). This behavior is known as "restricted growth" or "delayed sequences." To override this default behavior in the case of sparse grids, the unrestricted keyword can be used; it cannot be overridden for tensor grids using nested rules since it also provides a mapping to the available nested rule quadrature orders. An exception to the default usage of restricted growth is the dimension_adaptive p_refinement generalized sparse grid case described previously, since the ability to evolve the index sets of a sparse grid in an unstructured manner eliminates the motivation for restricting the exponential growth of nested rules.

  • method
  • bayes_calibration
  • dream
  • emulator
  • pce
  • cubature_integrand

Cubature using Stroud rules and their extensions

Specification

Alias: none

Argument(s): INTEGER

Description

Multi-dimensional integration by Stroud cubature rules [80] and extensions [94], as specified with cubature_integrand. A total-order expansion is used, where the isotropic order $p$ of the expansion is half of the integrand order, rounded down. The total number of terms $N$ for an isotropic total-order expansion of order $p$ over $n$ variables is given by

$$N = 1 + P = 1 + \sum_{s=1}^{p} \frac{1}{s!} \prod_{r=0}^{s-1} (n + r) = \frac{(n + p)!}{n!p!}$$

Since the maximum integrand order is currently five for normal and uniform and two for all other types, at most second- and first-order expansions, respectively, will be used. As a result, cubature is primarily useful for global sensitivity analysis, where the Sobol' indices will provide main effects and, at most, two-way interactions. In addition, the random variable set must be independent and identically distributed (iid), so the use of askey or wiener transformations may be required to create iid variable sets in the transformed space (as well as to allow usage of the higher order cubature rules for normal and uniform). Note that global sensitivity analysis often assumes uniform bounded regions, rather than precise probability distributions, so the iid restriction would not be problematic in that case.

### Description

When the expansion_order for a polynomial chaos expansion is specified, the coefficients may be computed by integration based on random samples or by regression using either random or sub-sampled tensor product.
quadrature points.

Multidimensional integration by Latin hypercube sampling (specified with `expansion_samples`). In this case, the expansion order \( p \) cannot be inferred from the numerical integration specification and it is necessary to provide an `expansion_order` to specify \( p \) for a total-order expansion.

Linear regression (specified with either `collocation_points` or `collocation_ratio`). A total-order expansion is used and must be specified using `expansion_order` as described in the previous option. To avoid requiring the user to calculate \( N \) from \( n \) and \( p \), the `collocation_ratio` allows for specification of a constant factor applied to \( N \) (e.g., `collocation_ratio = 2.` produces samples = \( 2N \)). In addition, the default linear relationship with \( N \) can be overridden using a real-valued exponent specified using `ratio_order`. In this case, the number of samples becomes \( cN^o \) where \( c \) is the `collocation_ratio` and \( o \) is the `ratio_order`. The `use_derivatives` flag informs the regression approach to include derivative matching equations (limited to gradients at present) in the least squares solutions, enabling the use of fewer collocation points for a given expansion order and dimension (number of points required becomes \( cN^o \)). When admissible, a constrained least squares approach is employed in which response values are first reproduced exactly and error in reproducing response derivatives is minimized. Two collocation grid options are supported: the default is Latin hypercube sampling ("point collocation"), and an alternate approach of "probabilistic collocation" is also available through inclusion of the `tensor_grid` keyword. In this alternate case, the collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

If `collocation_points` or `collocation_ratio` is specified, the PCE coefficients will be determined by regression. If no regression specification is provided, appropriate defaults are defined. Specifically SVD-based least-squares will be used for solving over-determined systems and under-determined systems will be solved using LASSO. For the situation when the number of function values is smaller than the number of terms in a PCE, but the total number of samples including gradient values is greater than the number of terms, the resulting over-determined system will be solved using equality constrained least squares. Technical information on the various methods listed below can be found in the Linear regression section of the Theory Manual. Some of the regression methods (OMP, LASSO, and LARS) are able to produce a set of possible PCE coefficient vectors (see the Linear regression section in the Theory Manual). If cross validation is inactive, then only one solution, consistent with the `noise_tolerance`, will be returned. If cross validation is active, Dakota will choose between possible coefficient vectors found internally by the regression method across the set of expansion orders (1,...,`expansion_order`) and the set of specified noise tolerances and return the one with the lowest cross validation error indicator.

A set of weights specifying the relative importance of each uncertain variable (dimension)

**Specification**

- **Alias:** `none`
- **Argument(s):** `REALLIST`
- **Default:** isotropic grids
Description

A set of weights specifying the relative importance of each uncertain variable (dimension). Using this specification leads to anisotropic integrations with differing refinement levels for different random dimensions.

*Child Keywords*:
### Description

Use adaptive basis selection to choose the basis terms in a polynomial chaos expansion. Basis selection uses compressed sensing to identify an initial set of non-zero PCE coefficients. Then these non-zero terms are expanded a set number of times (we suggest 3) and compressed sensing is then applied to these three new index sets. Cross validation is used to choose the best candidate basis. The best basis is then restricted again to the non-zero terms and expanded until no improvement can be gained by adding additional terms.

<td>Limit the number of cross-validation candidates for basis order</td>
</tr>
</tbody>
</table>

**Description**

Use cross validation to choose the 'best' polynomial degree of a polynomial chaos expansion. 10 fold cross validation is used to estimate the cross validation error of a total-order polynomial expansion for orders 1 through to order. The order chosen is the one that produces the lowest cross validation error. If there are not enough points to perform 10 fold cross validation then one-at-a-time cross validation will be performed.

**7.2.68.4.8.56 noise_only**

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- pce
- expansion_order
- collocation_points
- cross_validation
- noise_only

Restrict the cross validation process to estimating only the best noise tolerance.

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** false

**Description**

By default, cross validation estimates both the best noise tolerance and the best candidate basis order. For reasons of reducing computational cost by reducing the number of candidate solves, the user may wish to restrict this process to estimating only the best noise tolerance.

Generally speaking, computing the best noise tolerance through cross validation mitigates issues with over-fitting the data. Computing the best candidate basis order can also mitigate overfitting, while also controlling levels of mutual coherence resulting from high-order Vandermonde-like matrix systems.
max_cv_order_candidates

• Keywords Area
  • method
  • bayes_calibration
  • dream
  • emulator
  • pce
  • expansion_order
  • collocation_points
  • cross_validation
  • max_cv_order_candidates

Limit the number of cross-validation candidates for basis order

Specification

Alias: none

Argument(s): INTEGER

Default: ushort max

Description

When generating refinement candidates by advancing the upper bound used for a cross-validation range, the number of cross-validation can eventually become excessive and hamper algorithm progress. This control limits the maximum number of candidates, which when active, will increase the lower bound for this range as the upper bound is advanced.

See Also

• multifidelity_polynomial_chaos
• function_train
• multifidelity_function_train
Specify a non-linear relationship between the expansion order of a polynomial chaos expansion and the number of samples that will be used to compute the PCE coefficients.

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 1.

**Description**

When using regression type methods (specified with either collocation_points or collocation_ratio), a total-order expansion can be specified using expansion_order. To avoid requiring the user to calculate N from n and p), the collocation_ratio allows for specification of a constant factor applied to N (e.g., collocation_ratio = 2. produces samples = 2N). In addition, the default linear relationship with N can be overridden using a real-valued exponent specified using ratio_order. In this case, the number of samples becomes $cN\,^{o}$ where $c$ is the collocation_ratio and $o$ is the ratio_order.

Perform bounds-scaling on response values prior to surrogate emulation.
7.2 method

Specification

Alias: none
Argument(s): none
Default: use original data

Description

Particularly in multifidelity methods based on regression solutions at each level of a model hierarchy, scaling can be an issue since the magnitude of discrepancy data may decay rapidly and regression solvers may employ absolute tolerances in places.

By activating response_scaling, the set of response data used for each recovery is scaled to $[0,1]$ based on the minimum value and range of the data set. This prevents loss of accuracy due to imbalances in scale across model levels.

See Also

These keywords may also be of interest:

- multifidelity_polynomial_chaos
- multifidelity_function_train

7.2.68.4.8.60 use_derivatives

Specification

Alias: none
Argument(s): none
Default: use function values only

Description

The use_derivatives flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, its use with Surfpack Gaussian process is not recommended.
Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** regression with LHS sample set (point collocation)

**Description**

The collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

This describes the behavior of reuse of points in constructing polynomial chaos expansion models.
7.2 method

Specification

**Alias:** reuse_samples

**Argument(s):** none

**Default:** no sample reuse in coefficient estimation

Description

The `reuse_points` option controls the reuse behavior of points for various types of polynomial chaos expansions, including: \texttt{collocation_points}, \texttt{collocation_ratio}, \texttt{expansion_samples}, or \texttt{orthogonal_least_interpolation}. If any of these approaches are specified to create a set of points for the polynomial chaos expansion, one can specify `reuse_points` so that any points that have been previously generated (for example, from the \texttt{import_points} file) can be reused.

## Description

Set the number of points used to build a PCE via regression to be proportional to the number of terms in the expansion. To avoid requiring the user to calculate $N$ from $n$ and $p$, the `collocation_ratio` allows for specification of a constant factor applied to $N$ (e.g., `collocation_ratio = 2` produces samples = $2N$). In addition, the default linear relationship with $N$ can be overridden using a real-valued exponent specified using `ratio_order`. In this case, the number of samples becomes $cN^o$ where $c$ is the `collocation_ratio` and $o$ is the `ratio_order`. The `use_derivatives` flag informs the regression approach to include derivative matching equations (limited to gradients at present) in the least squares solutions, enabling the use of fewer collocation points for a given expansion order and dimension (number of points required becomes $cN^o$).

<td>Restrict the cross validation process to estimating only the best noise tolerance.</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>max_cv_order_candidates</td>
<td>Limit the number of cross-validation candidates for basis order</td>
</tr>
</tbody>
</table>

Description

Use cross validation to choose the 'best' polynomial degree of a polynomial chaos expansion. 10 fold cross validation is used to estimate the cross validation error of a total-order polynomial expansion for orders 1 through to order. The order chosen is the one that produces the lowest cross validation error. If there are not enough points to perform 10 fold cross validation then one-at-a-time cross validation will be performed.

7.2.68.4.8.79 noise_only

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- pce
- expansion_order
- collocation_ratio
- cross_validation
- noise_only

Restrict the cross validation process to estimating only the best noise tolerance.
Specification

Alias: none
Argument(s): none
Default: false

Description

By default, cross validation estimates both the best noise tolerance and the best candidate basis order. For reasons of reducing computational cost by reducing the number of candidate solves, the user may wish to restrict this process to estimating only the best noise tolerance.

Generally speaking, computing the best noise tolerance through cross validation mitigates issues with over-fitting the data. Computing the best candidate basis order can also mitigate overfitting, while also controlling levels of mutual coherence resulting from high-order Vandermonde-like matrix systems.

7.2.68.4.8.80 max_cv_order_candidates

• Keywords Area
• method
• bayes_calibration
• dream
• emulator
• pce
• expansion_order
• collocation_ratio
• cross_validation
• max_cv_order_candidates

Limit the number of cross-validation candidates for basis order

Specification

Alias: none
Argument(s): INTEGER
Default: ushort max

Description

When generating refinement candidates by advancing the upper bound used for a cross-validation range, the number of cross-validation can eventually become excessive and hamper algorithm progress. This control limits the maximum number of candidates, which when active, will increase the lower bound for this range as the upper bound is advanced.

- multifidelity_function_train

7.2.68.4.8.81 ratio_order

Specify a non-linear the relationship between the expansion order of a polynomial chaos expansion and the number of samples that will be used to compute the PCE coefficients.

Specification

Alias: none
Argument(s): REAL
Default: 1.

Description

When using regression type methods (specified with either collocation_points or collocation_ratio), a total-order expansion can be specified using expansion_order. To avoid requiring the user to calculate N from n and p), the collocation_ratio allows for specification of a constant factor applied to N (e.g., collocation_ratio = 2. produces samples = 2N). In addition, the default linear relationship with N can be overridden using a real-valued exponent specified using ratio_order. In this case, the number of samples becomes $cN^o$ where $c$ is the collocation_ratio and $o$ is the ratio_order.
7.2.68.4.8.82 response_scaling

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- pce
- expansion_order
- collocation_ratio
- response_scaling

Perform bounds-scaling on response values prior to surrogate emulation

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** use original data

**Description**

Particularly in multifidelity methods based on regression solutions at each level of a model hierarchy, scaling can be an issue since the magnitude of discrepancy data may decay rapidly and regression solvers may employ absolute tolerances in places.

By activating `response_scaling`, the set of response data used for each recovery is scaled to \([0,1]\) based on the minimum value and range of the data set. This prevents loss of accuracy due to imbalances in scale across model levels.

**See Also**

These keywords may also be of interest:

- `multifidelity_polynomial_choas`
- `multifidelity_function_train`

7.2.68.4.8.83 use_derivatives

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- pce
The `use_derivatives` flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, its use with Surfpack Gaussian process is not recommended.

### 7.2. Method

- **expansion_order**
- **collocation_ratio**
- **use_derivatives**

Use derivative data to construct surrogate models.

#### Specification

**Alias:** none

**Argument(s):** none

**Default:** use function values only

#### Description

The `use_derivatives` flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, its use with Surfpack Gaussian process is not recommended.

### 7.2.68.4. Tensor Grid

- **Keywords Area**
- **method**
- **bayes_calibration**
- **dream**
- **emulator**
- **pce**
- **expansion_order**
- **collocation_ratio**
- **tensor_grid**

Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.

#### Specification

**Alias:** none

**Argument(s):** none

**Default:** regression with LHS sample set (point collocation)

#### Description

The collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.
7.2.68.4.8.85 reuse_points

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- pce
- expansion_order
- collocation_ratio
- reuse_points

This describes the behavior of reuse of points in constructing polynomial chaos expansion models.

**Specification**

**Alias:** reuse_samples

**Argument(s):** none

**Default:** no sample reuse in coefficient estimation

**Description**

The `reuse_points` option controls the reuse behavior of points for various types of polynomial chaos expansions, including: `collocation_points`, `collocation_ratio`, `expansion_samples`, or `orthogonal_least_interpolation`. If any of these approaches are specified to create a set of points for the polynomial chaos expansion, one can specify `reuse_points` so that any points that have been previously generated (for example, from the `import_points` file) can be reused.

7.2.68.4.8.86 max_solver_iterations

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- pce
- expansion_order
- collocation_ratio
- max_solver_iterations

Maximum iterations in determining polynomial coefficients
7.2 method

Specification

Alias: none
Argument(s): INTEGER
Default: 100

Description

When using an iterative polynomial coefficient estimation approach, e.g., cross-validation-based solvers, limits the maximum iterations in the coefficient solver.

7.2.68.4.8.87 expansion_samples

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- pce
- expansion_order
- expansion_samples

Number of simulation samples used to estimate the expected value of a set of PCE coefficients.

Specification

Alias: none
Argument(s): INTEGER

</tr>
<tr>
<td></td>
<td></td>
<td>Selects annotated tabular file format</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Selects freeform file format</td>
<td></td>
</tr>
</tbody>
</table>

Description

The import_build_points_file allows the user to specify a file that contains a list of points and truth model responses used to construct a surrogate model. These can be used by all methods that (explicitly, e.g. surrogate-based optimization, or implicitly, e.g. efficient global optimization) operate on a surrogate. In particular, these points and responses are used in place of truth model evaluations to construct the initial surrogate. When used to construct surrogate models or emulators these are often called build points or training data.

Default Behavior

By default, methods do not import points from a file.

Usage Tips

Dakota parses input files without regard to whitespace, but the import_build_points_file must be in one of three formats:

- annotated (default)
- custom_annotated
- freeform

Examples

```method
    polynomial_chaos
        expansion_order = 4
        import_build_points_file = 'dakota_uq_rosenbrock_pce_import.annot.pts.dat'
```

```custom_annotated
    ...```

7.2.68.4.8.90  custom_annotated

• emulator
• pce
• expansion_order
• import_build_points_file
• custom_annotated

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

• file_formats

Specification

Alias: none
Argument(s): none
Default: annotated format

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>header</td>
<td>Enable header row in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>eval_id</td>
<td>Enable evaluation ID column in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>interface_id</td>
<td>Enable interface ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.
Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id  x1    x2    obj_fn  nln_ineq_con_1  nln_ineq_con_2
1        0.9    1.1    0.0002  0.26          0.76          
2        0.90009 1.1  0.0001996404857 0.2601620081 0.759955      
3        0.89991 1.1  0.0002003604863 0.2598380081 0.760045      
...      
```

- pce
- expansion_order
- import_build_points_file
- annotated

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips
• To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom.annotated header eval_id

• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```
  environment
    tabular_data
      tabular_data_file = 'dakota_summary.dat'
      annotated

  Resulting tabular file:

  %eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
  1   NO_ID  0.9  1.1  0.0002  0.26  0.76
  2   NO_ID  0.90009  1.1  0.0001996404857  0.2601620081  0.759955
  3   NO_ID  0.89991  1.1  0.0002003604863  0.2598380081  0.760045
  ...
```

• file_formats
7.2. Method

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** annotated format

**Description**

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

**Default Behavior**

The **annotated** format is the default for tabular export/import. To change this behavior, specify **freeform** in the relevant export/import context.

**Usage Tips**

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to **annotated** format, though **freeform** remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In **freeform**, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the **freeform** option.

**Examples**

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```python
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    freeform
 Resulting tabular file:

    0.9  1.1  0.0002  0.26  0.76
  0.90009  1.1  0.0001996404857  0.2601620081  0.759955
  0.89991  1.1  0.0002003604863  0.2598380081  0.760045
...
```

7.2.68.4.8.96 active_only

- **Keywords Area**
- **method**
- **bayes_calibration**
- **dream**
- **emulator**
- **pce**
Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword active_only indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

Adapt emulator model to increase accuracy in high posterior probability regions

Specification

Alias: none

Argument(s): none
Description

Following an emulator-based MCMC process, this option refines the emulator by selecting points in regions of high posterior probability, performing truth evaluations at these points, updating the emulator, and reperforming the MCMC process. The adaptation is continued until the maximum number of iterations is exceeded or the convergence tolerance is met.

Examples

```
bayes_calibration queso
  chain_samples = 2000 seed = 348
  delayed_rejection
  emulator
gaussian_process surfpack build_samples = 30
  posterior_adaptive max_iterations = 10
  proposal_covariance derivatives
```

Adapt emulator model to increase accuracy in high posterior probability regions

### Description

Build a polynomial chaos expansion from simulation samples using orthogonal least interpolation. Unlike the other regression methods `expansion_order` cannot be set. OLI will produce the lowest degree polynomial that interpolates the data

7.2.68.4.8.99 `collocation_points`

**Keywords Area**

- `method`
- `bayes_calibration`
- `dream`
- `emulator`
- `pce`
- `orthogonal_least_interpolation`
- `collocation_points`

Number of collocation points used to estimate expansion coefficients

### Specification

**Alias:** none

**Argument(s):** INTEGER

### Description

Specify the number of collocation points used to estimate expansion coefficients using regression approaches.

A corresponding sequence specification is documented at, e.g., `collocation_points_sequence` and `collocation_points_sequence`
7.2 method

See Also

These keywords may also be of interest:

- expansion_order_sequence
- collocation_ratio
- collocation_points_sequence

7.2.68.4.8.100 tensor_grid

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- pce
- orthogonal_least_interpolation
- tensor_grid

Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.

Specification

Alias: none
Argument(s): INTEGERLIST
Default: regression with LHS sample set (point collocation)

Description

The collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

7.2.68.4.8.101 reuse_points

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- pce
- orthogonal_least_interpolation
- reuse_points

This describes the behavior of reuse of points in constructing polynomial chaos expansion models.
Specification

Alias: reuse_samples

Argument(s): none

Default: no sample reuse in coefficient estimation

Description

The `reuse_samples` option controls the reuse behavior of points for various types of polynomial chaos expansions, including: `collocation_points`, `collocation_ratio`, `expansion_samples`, or `orthogonal_least_interpolation`. If any of these approaches are specified to create a set of points for the polynomial chaos expansion, one can specify `reuse_samples` so that any points that have been previously generated (for example, from the `import_points_file`) can be reused.

7.2.68.4.8.102 import_build_points_file

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- pce
- orthogonal_least_interpolation
- import_build_points_file

File containing points you wish to use to build a surrogate

Specification

Alias: import_points_file

Argument(s): STRING

Default: no point import from a file

Child Keywords:

<table>
<thead>

<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Optional</td>
<td>active_only</td>
<td>Import only active variables from tabular data file</td>
</tr>
</tbody>
</table>

### Description

The `import_build_points_file` allows the user to specify a file that contains a list of points and truth model responses used to construct a surrogate model. These can be used by all methods that (explicitly, e.g. surrogate-based optimization, or implicitly, e.g. efficient global optimization) operate on a surrogate. In particular, these points and responses are used in place of truth model evaluations to construct the initial surrogate. When used to construct surrogate models or emulators these are often called build points or training data.

### Default Behavior

By default, methods do not import points from a file.

### Usage Tips

Dakota parses input files without regard to whitespace, but the `import_build_points_file` must be in one of three formats:

- annotated (default)
- custom_annotated
- freeform

### Examples

```plaintext
method
polynomial_chaos
  expansion_order = 4
  import_build_points_file = 'dakota_uq_rosenbrock_pce_import.annot.pts.dat'
```

### custom_annotated

- Keywords Area
- method
- bayes_calibration

<td>Enable evaluation ID column in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>interface_id</td>
<td>Enable interface ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

**Description**

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

**Default Behavior**

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

**Usage Tips**

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

**Examples**

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

• `import_build_points_file`
• `annotated`

Selects annotated tabular file format

**Topics**

This keyword is related to the topics:

• `file_formats`

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** annotated format

**Description**

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

**Default Behavior**

By default, Dakota imports and exports tabular files in annotated format. The `annotated` keyword can be used to explicitly specify this.

**Usage Tips**

• To specify pre-Dakota 6.1 tabular format, which did not include `interface_id`, specify `custom_annotated` header eval_id

• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to `annotated` format, though `freeform` remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

**Examples**

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```plaintext
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
annotated
```

Resulting tabular file:

```plaintext
%eval_id interface x1   x2   obj_fn nln_ineq_con_1 nln_ineq_con_2
1      NO_ID      0.9   1.1   0.0002 0.26       0.76       0.76

  - import_build_points_file
  - freeform

Selects freeform file format

Topics

This keyword is related to the topics:

- file_formats

Specification

**Alias:** none

**Argument(s):** none

**Default:** annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.
Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```matlab
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
freeform
```

Resulting tabular file:

- 0.9 1.1 0.0002 0.26 0.76
- 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
- 0.89991 1.1 0.0002003604863 0.2598380081 0.760045

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- pce
- orthogonal_least_interpolation
- import_build_points_file
- active_only

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- file_formats

Specification

**Alias:** none

**Argument(s):** none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword **active_only** indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.
Adapt emulator model to increase accuracy in high posterior probability regions

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

Following an emulator-based MCMC process, this option refines the emulator by selecting points in regions of high posterior probability, performing truth evaluations at these points, updating the emulator, and reperforming the MCMC process. The adaptation is continued until the maximum number of iterations is exceeded or the convergence tolerance is met.

**Examples**

```
bayes_calibration queso
  chain_samples = 2000 seed = 348
  delayed_rejection
  emulator
    gaussian_process surfpack build_samples = 30
    posterior_adaptive max_iterations = 10
    proposal_covariance derivatives
```

**7.2.68.4.8.111  askey**

Select the standardized random variables (and associated basis polynomials) from the Askey family that best match the user-specified random variables.
Specification

**Alias**: none

**Argument(s)**: none

**Default**: extended (Askey + numerically-generated)

Description

The Askey option employs standard normal, standard uniform, standard exponential, standard beta, and standard gamma random variables in a transformed probability space. These selections correspond to Hermite, Legendre, Laguerre, Jacobi, and generalized Laguerre orthogonal polynomials, respectively.

Specific mappings for the basis polynomials are based on a closest match criterion, and include Hermite for normal (optimal) as well as bounded normal, lognormal, bounded lognormal, gumbel, frechet, and weibull (sub-optimal); Legendre for uniform (optimal) as well as loguniform, triangular, and bin-based histogram (sub-optimal); Laguerre for exponential (optimal); Jacobi for beta (optimal); and generalized Laguerre for gamma (optimal).

**Description**

Multilevel expansions, including regression-based polynomial chaos expansion (PCE) and function train (FT) expansions, require a sample allocation strategy. Three options are currently available:

- allocation based on assuming a convergence rate for the estimator variance (for regression PCE)
- restricted isometry property (RIP) sampling (for regression PCE via compressed sensing)
- rank sampling (for FT)

**Default Behavior**

Current defaults, when `allocation_control` is not specified, are estimator variance for PCE and rank sampling for FT.

<th>Dakota Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>estimator_rate</td>
<td>Rate of convergence of mean estimator within multilevel polynomial chaos</td>
</tr>
</tbody>
</table>

Description

Multilevel Monte Carlo performs optimal resource allocation based on a known estimator variance for the mean statistic:

\[ \text{Var}[\hat{Q}] = \frac{\sigma_Q^2}{N} \]

Replacing the simple ensemble average estimator in Monte Carlo with a polynomial chaos estimator results in a different and unknown relationship between the estimator variance and the number of samples. In one approach to multilevel PCE, we can employ a parameterized estimator variance:

\[ \text{Var}[\hat{Q}] = \frac{\sigma_Q^2}{\gamma N^\kappa} \]

for free parameters \( \gamma \) and \( \kappa \), with default values that may be overridden as part of this specification block.

This approach is supported for regression-based PCE approaches (over-determined least squares, under-determined compressed sensing, or orthogonal least interpolation).

In practice, it can be challenging to estimate a smooth convergence rate for estimator variance in the presence of abrupt transitions in the quality of sparse recoveries. As a result, sample allocation by greedy refinement is generally preferred.

Examples

This example starts with sparse recovery for a second-order candidate expansion at each level. As the number of samples is adapted for each level, as dictated by the convergence of the estimator variance, the candidate expansion order is incremented as needed in order to synchronize with the specified collocation ratio.

  • estimator_rate

Rate of convergence of mean estimator within multilevel polynomial chaos

Specification

Alias: none

Argument(s): REAL

Default: 2

Description

Multilevel Monte Carlo performs optimal resource allocation based on a known estimator variance for the mean statistic:

$$Var[\hat{Q}] = \frac{\sigma_Q^2}{N}$$

Replacing the simple ensemble average estimator in Monte Carlo with a polynomial chaos estimator results in a different and unknown relationship between the estimator variance and the number of samples. In one approach to multilevel PCE, we can employ a parameterized estimator variance:

$$Var[\hat{Q}] = \frac{\sigma_Q^2}{\gamma N^\kappa}$$

for free parameters $\gamma$ and $\kappa$.

The default values are $\gamma = 1$ and $\kappa = 2$ (adopts a more aggressive sample profile by assuming a faster convergence rate than Monte Carlo). This advanced specification option allows to user to specify $\kappa$, overriding the default.
Sample allocation based on restricted isometry property (RIP) within multilevel polynomial chaos

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

Multilevel polynomial chaos with compressed sensing may allocate the number of samples per level based on the restricted isometry property (RIP), applied to recovery at level \( l \):

\[
N_l \geq s_l \log^3(s_l) L_l \log(C_l)
\]

for sparsity \( s \), cardinality \( C \), and mutual coherence \( L \). The adaptive algorithm starts from a pilot sample, shapes the profile based on observed sparsity, and iterates until convergence. In practice, RIP sampling levels are quite conservative, and a collocation ratio constraint ( \( N_l \leq rC_l \), where \( r \) defaults to 2) must be enforced on the profile.

The algorithm relies on observed sparsity, it is appropriate for use with regularized solvers for compressed sensing. It employs orthogonal matching pursuit (OMP) by default and automatically activates cross-validation in order to choose the best noise parameter value for the recovery.

This capability is **experimental**. Sample allocation by greedy refinement is generally preferred.

**Examples**

This example starts with sparse recovery for a second-order candidate expansion at each level. As the number of samples is adapted for each level, as dictated by the number of sparse coefficient sets recovered for each level, the candidate expansion order is incremented as needed in order to synchronize with the specified collocation ratio.

```dakota
method,
  model_pointer = 'HIERARCH'
  multilevel_polynomial_chaos
    orthogonal_matching_pursuit
      expansion_order_sequence = 2
      pilot_samples = 10
      collocation_ratio = .9
      allocation_control rip_sampling
      seed = 1237
      convergence_tolerance = .01
```

Dakota Version 6.16 Reference Manual generated on May 12, 2022
Formulation for emulation of model discrepancies.

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** distinct

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group Discrepancy Emulation Approach (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required (Choose One)</td>
<td>distinct</td>
<td>recursive</td>
<td>Recursive formulation for emulation of model discrepancies.</td>
</tr>
</tbody>
</table>

**Description**

In many uncertainty quantification approaches, model discrepancies are emulated using, e.g., polynomial chaos, stochastic collocation, or Gaussian process models. Two formulations are available for this emulation:

1. **distinct** emulation (default), in which we directly approximate the difference or ratio between the evaluations of two models or solution levels.

2. **recursive** emulation (experimental option), in which we approximate a difference or ratio among the new model evaluation and the emulator approximation of the previous model.

The latter approach is a form of hierarchical emulation in which we emulate the surplus between the previous emulator and the new modeling level. This approach has a few advantages: (i) it reduces bias by correcting for emulation errors that occur at previous levels, and (ii) it does not require paired model evaluations for each discrepancy level, which reduces cost, allows for disparate sample points, and simplifies data imports.

On the other hand, its primary disadvantage is that the aggregate emulation is only as good as its weakest link, in that a poor emulator recovery can create difficulty in accurately resolving discrepancies that are recursively dependent on it. Thus, the **distinct** approach may tend to be more expensive in exchange for greater robustness.
Examples

method, multilevel_polynomial_chaos
   expansion_order_sequence = 2
   collocation_ratio = .9
   orthogonal_matching_pursuit
   discrepancy_emulation recursive

**expansion_samples_sequence**  
Sequence of expansion samples used in a multi-stage polynomial chaos expansion. Each level entry of the `expansion_samples_sequence` applies to one expansion within a multi-stage expansion. Current multi-stage expansions that support expansion samples sequences include multilevel and multifidelity polynomial chaos. If adaptive refinement is active, then this sequence specifies the starting point for each level within either an individual or integrated refinement approach. A corresponding scalar specification is documented at, e.g., `expansion_samples`.

---

Dakota Version 6.16 Reference Manual generated on May 12, 2022
Optional | `import_build_points_file` | File containing points you wish to use to build a surrogate

**Description**

Each level entry of the `expansion_order_sequence` applies to one expansion within a multi-stage expansion. Current multi-stage expansions that support expansion order sequences include multilevel or multifidelity polynomial chaos.

If adaptive refinement is active, then this sequence specifies the starting point for each level within either an individual or integrated refinement approach.

Description

Use adaptive basis selection to choose the basis terms in a polynomial chaos expansion. Basis selection uses compressed sensing to identify a initial set of non zero PCE coefficients. Then these non-zero terms are expanded a set number of times (we suggest 3) and compressed sensing is then applied to these three new index sets. Cross validation is used to choose the best candidate basis. The best basis is then restricted again to the non-zero terms and expanded until no improvement can be gained by adding additional terms.

</tbody>
</table>

**Description**

Set the number of points used to build a PCE via regression to be proportional to the number of terms in the expansion. To avoid requiring the user to calculate $N$ from $n$ and $p$, the collocation_ratio allows for specification of a constant factor applied to $N$ (e.g., collocation_ratio = 2. produces samples = 2N). In addition, the default linear relationship with $N$ can be overridden using a real-valued exponent specified using ratio_order. In this case, the number of samples becomes $cN^o$ where $c$ is the collocation_ratio and $o$ is the ratio_order. The use_derivatives flag informs the regression approach to include derivative matching equations (limited to gradients at present) in the least squares solutions, enabling the use of fewer collocation points for a given expansion order and dimension (number of points required becomes $cN^o$).
Specification

Alias: pilot_samples
Argument(s): INTEGERLIST

Description

Each level entry of the collocation_points_sequence applies to one expansion within a multi-stage expansion. Current multi-stage expansions that support collocation point sequences include multilevel and multifidelity polynomial chaos and multilevel and multifidelity function train expansions.

If adaptive refinement is active, then this sequence specifies the starting point for each level within either an individual or integrated refinement approach.

A corresponding scalar specification is documented at, e.g., collocation_points

<td>Calculate the coefficients of a polynomial chaos expansion using equality constrained least squares.</td>
</tr>
</tbody>
</table>

### Description

Compute the coefficients of a polynomial expansion using least squares. Specifically SVD-based least-squares will be used for solving over-determined systems. For the situation when the number of function values is smaller than the number of terms in a PCE, but the total number of samples including gradient values is greater than the number of terms, the resulting over-determined system will be solved using equality constrained least squares.

7.2.68.4.8.136 svd

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- ml_pce
- expansion_order_sequence

**Description**

Compute the coefficients of a polynomial expansion by using the LASSO problem.
The noise tolerance used when performing cross validation in the presence of noise or truncation errors.

Specification

Alias: none

Argument(s): REALLIST

Default: 1e-3 for BPDN, 0. otherwise (algorithms run until termination)

Description

The noise tolerance used when performing cross validation in the presence of noise or truncation errors.

7.2.68.4.8.147 l2_penalty

The $l_2$ penalty used when performing compressed sensing with elastic net.

Specification

Alias: none

Argument(s): REAL

Default: 0. (reverts to standard LASSO formulation)

Description

The $l_2$ penalty used when performing compressed sensing with elastic net.
Cross validation

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- ml_pce
- expansion_order_sequence
- collocation_ratio
- cross_validation

Use cross validation to choose the 'best' polynomial order of a polynomial chaos expansion.

Specification

Alias: none

Argument(s): none

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>noise_only</td>
<td>max_cv_order_candidates</td>
<td>Restrict the cross validation process to estimating only the best noise tolerance. Limit the number of cross-validation candidates for basis order</td>
</tr>
</tbody>
</table>

Description

Use cross validation to choose the 'best' polynomial degree of a polynomial chaos expansion. 10 fold cross validation is used to estimate the cross validation error of a total-order polynomial expansion for orders 1 through to order. The order chosen is the one that produces the lowest cross validation error. If there are not enough points to perform 10 fold cross validation then one-at-a-time cross validation will be performed.
Restrict the cross validation process to estimating only the best noise tolerance.

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** false

**Description**

By default, cross validation estimates both the best noise tolerance and the best candidate basis order. For reasons of reducing computational cost by reducing the number of candidate solves, the user may wish to restrict this process to estimating only the best noise tolerance.

Generally speaking, computing the best noise tolerance through cross validation mitigates issues with over-fitting the data. Computing the best candidate basis order can also mitigate overfitting, while also controlling levels of mutual coherence resulting from high-order Vandermonde-like matrix systems.

7.2.68.4.8.150 max_cv_order_candidates

**Limit the number of cross-validation candidates for basis order**

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** ushort max
Description

When generating refinement candidates by advancing the upper bound used for a cross-validation range, the number of cross-validation can eventually become excessive and hamper algorithm progress. This control limits the maximum number of candidates, which when active, will increase the lower bound for this range as the upper bound is advanced.

See Also

These keywords may also be of interest:

- increment_max_order
- increment_max_rank_order
- polynomial_chaos
- multifidelity_polynomial_chaos
- function_train
- multifidelity_function_train

Specify a non-linear relationship between the expansion order of a polynomial chaos expansion and the number of samples that will be used to compute the PCE coefficients.

Specification

**Alias:** none

**Argument(s):** REAL

**Default:** 1.

**Description**

When using regression type methods (specified with either collocation_points or collocation_ratio), a total-order expansion can be specified using expansion_order. To avoid requiring the user to calculate N from n and p), the collocation_ratio allows for specification of a constant factor applied to N (e.g., collocation_ratio = 2 produces samples = 2N). In addition, the default linear relationship with N can be overridden using a real-valued exponent specified using ratio_order. In this case, the number of samples becomes $cN^{o}$ where $c$ is the collocation_ratio and $o$ is the ratio_order.
7.2.68.4.8.152 response_scaling

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- ml_pce
- expansion_order_sequence
- collocation_ratio
- response_scaling

Perform bounds-scaling on response values prior to surrogate emulation

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** use original data

**Description**

Particularly in multifidelity methods based on regression solutions at each level of a model hierarchy, scaling can be an issue since the magnitude of discrepancy data may decay rapidly and regression solvers may employ absolute tolerances in places.

By activating `response_scaling`, the set of response data used for each recovery is scaled to $[0,1]$ based on the minimum value and range of the data set. This prevents loss of accuracy due to imbalances in scale across model levels.

**See Also**

These keywords may also be of interest:

- multifidelity_polynomial_chaos
- multifidelity_function_train

7.2.68.4.8.153 use_derivatives

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- ml_pce
• expansion_order_sequence
• collocation_ratio
• use_derivatives

Use derivative data to construct surrogate models

**Specification**

**Alias**: none  
**Argument(s)**: none  
**Default**: use function values only

**Description**

The `use_derivatives` flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, its use with Surfpack Gaussian process is not recommended.

7.2.68.4.8.154 tensor_grid

• Keywords Area  
• method  
• bayes_calibration  
• dream  
• emulator  
• ml_pce  
• expansion_order_sequence  
• collocation_ratio  
• tensor_grid

Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.

**Specification**

**Alias**: none  
**Argument(s)**: none  
**Default**: regression with LHS sample set (point collocation)

**Description**

The collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.
7.2.68.4.8.155  reuse_points

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- ml_pce
- expansion_order_sequence
- collocation_ratio
- reuse_points

This describes the behavior of reuse of points in constructing polynomial chaos expansion models.

Specification

Alias: reuse_samples

Argument(s): none

Default: no sample reuse in coefficient estimation

Description

The reuse_points option controls the reuse behavior of points for various types of polynomial chaos expansions, including: collocation_points, collocation_ratio, expansion_samples, or orthogonal_least_interpolation. If any of these approaches are specified to create a set of points for the polynomial chaos expansion, one can specify reuse_points so that any points that have been previously generated (for example, from the import_points file) can be reused.

**Child Keywords:**
## Description

The `import_build_points_file` allows the user to specify a file that contains a list of points and truth model responses used to construct a surrogate model. These can be used by all methods that (explicitly, e.g., surrogate-based optimization, or implicitly, e.g., efficient global optimization) operate on a surrogate. In particular, these points and responses are used in place of truth model evaluations to construct the initial surrogate. When used to construct surrogate models or emulators these are often called build points or training data.

### Default Behavior

By default, methods do not import points from a file.

### Usage Tips

Dakota parses input files without regard to whitespace, but the `import_build_points_file` must be in one of three formats:

- annotated (default)
- custom_annotated
- freeform

### Examples

```
method
  polynomial_chaos
    expansion_order = 4
    import_build_points_file = 'dakota_uq_rosenbrock_pce_import.annot.pts.dat'
```

<td></td>
<td>interface_id</td>
<td>Enable interface ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

Usage Tips

• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```plaintext
environment
tabular_data
    tabular_data_file = 'dakota_summary.dat'
custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id x1   x2   obj_fn nln_ineq_con_1 nln_ineq_con_2
1 0.9 1.1 0.0002 0.26 0.76
2 0.90009 1.1 0.0001996404857 0.2601620081 0.759955

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none
Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips
• To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify `custom.annotated header eval_id`

• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to `annotated` format, though `freeform` remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```plaintext
evironment
tabular_data
tabular_data_file = 'dakota_summary.dat'
annotated
```

Resulting tabular file:

```plaintext
%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 NO_ID 0.9 1.1 0.0002 0.26 0.76
2 NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 NO_ID 0.89991 1.1 0.0002003604863 0.2598380081 0.760045

7.2.68.4.8.165 freeform

• Keywords Area

• method

• bayes_calibration

• dream

• emulator

• ml_pce

• expansion_order_sequence

• import_build_points_file

• freeform

Selects `freeform` file format

Topics

This keyword is related to the topics:

• file_formats
Specification

Alias: none
Argument(s): none
Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    freeform

Resulting tabular file:

```

7.2.68.4.8.166 active_only

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- ml_pce
7.2 method

- expansion_order_sequence
- import_build_points_file
- active_only

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

7.2.68.4.8.167 orthogonal_least_interpolation

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- ml_pce
- orthogonal_least_interpolation

Build a polynomial chaos expansion from simulation samples using orthogonal least interpolation.

Specification

Alias: least_interpolation oli
Argument(s): none
Child Keywords:
### Description

Build a polynomial chaos expansion from simulation samples using orthogonal least interpolation. Unlike the other regression methods `expansion_order` cannot be set. OLI will produce the lowest degree polynomial that interpolates the data.

#### 7.2.68.4.8.168  collocation_points_sequence

- **Keywords Area**
- **method**
- **bayes_calibration**
- **dream**
- **emulator**
- **ml_pce**
- **orthogonal_least_interpolation**
- **collocation_points_sequence**

Sequence of collocation point counts used in a multi-stage expansion

### Specification

**Alias:** none  
**Argument(s):** `INTEGERLIST`
Description

Each level entry of the `collocation_points_sequence` applies to one expansion within a multi-stage expansion. Current multi-stage expansions that support collocation point sequences include multilevel and multifidelity polynomial chaos and multilevel and multifidelity function train expansions.

If adaptive refinement is active, then this sequence specifies the starting point for each level within either an individual or integrated refinement approach.

A corresponding scalar specification is documented at, e.g., `collocation_points`

See Also

These keywords may also be of interest:

- `collocation_points`

7.2.68.4.8.169 tensor_grid

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- ml_pce
- orthogonal_least_interpolation
- tensor_grid

Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.

Specification

**Alias:** none

**Argument(s):** INTEGERLIST

**Default:** regression with LHS sample set (point collocation)

Description

The collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

7.2.68.4.8.170 reuse_points

- Keywords Area
- method
- bayes_calibration
- dream
This describes the behavior of reuse of points in constructing polynomial chaos expansion models.

**Specification**

**Alias:** reuse_samples  
**Argument(s):** none  
**Default:** no sample reuse in coefficient estimation

**Description**

The `reuse_points` option controls the reuse behavior of points for various types of polynomial chaos expansions, including: `collocation_points`, `collocation_ratio`, `expansion_samples`, or `orthogonal_least_interpolation`. If any of these approaches are specified to create a set of points for the polynomial chaos expansion, one can specify `reuse_points` so that any points that have been previously generated (for example, from the `import_points_file`) can be reused.

7.2.68.4.8.171  **import_build_points_file**

This file contains the points you wish to use to build a surrogate.

**Specification**

**Alias:** import_points_file  
**Argument(s):** STRING  
**Default:** no point import from a file

**Child Keywords:**

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

• file_formats
Specification

**Alias:** none

**Argument(s):** none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

7.2.68.4.8.179 askey

- **Keywords Area**
- **method**
- **bayes_calibration**
- **dream**
- **emulator**
- **ml_pce**
- **askey**

Select the standardized random variables (and associated basis polynomials) from the Askey family that best match the user-specified random variables.

Specification

**Alias:** none

**Argument(s):** none

**Default:** extended (Askey + numerically-generated)

Description

The Askey option employs standard normal, standard uniform, standard exponential, standard beta, and standard gamma random variables in a transformed probability space. These selections correspond to Hermite, Legendre, Laguerre, Jacobi, and generalized Laguerre orthogonal polynomials, respectively.

Specific mappings for the basis polynomials are based on a closest match criterion, and include Hermite for normal (optimal) as well as bounded normal, lognormal, bounded lognormal, gumbel, frechet, and weibull (sub-optimal); Legendre for uniform (optimal) as well as loguniform, triangular, and bin-based histogram (sub-optimal); Laguerre for exponential (optimal); Jacobi for beta (optimal); and generalized Laguerre for gamma (optimal).

See Also

These keywords may also be of interest:

- **polynomial_chaos**
- **wiener**
Use standard normal random variables (along with Hermite orthogonal basis polynomials) when transforming to a standardized probability space.

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** extended (Askey + numerically-generated)

**Description**

The Wiener option employs standard normal random variables in a transformed probability space, corresponding to a Hermite orthogonal polynomial basis. This is the same nonlinear variable transformation used by local and global reliability methods (and therefore has the same variable support).

**See Also**

These keywords may also be of interest:

- polynomial_chaos
- askey

The normalized specification requests output of PCE coefficients that correspond to normalized orthogonal basis polynomials.
Specification

**Alias:** none

**Argument(s):** none

**Default:** PCE coefficients correspond to unnormalized basis polynomials

Description

The normalized specification requests output of PCE coefficients that correspond to normalized orthogonal basis polynomials.

7.2.68.4.8.182  export_expansion_file

- **method**
- **bayes_calibration**
- **dream**
- **emulator**
- **ml_pce**
- **export_expansion_file**

Export the coefficients and multi-index of a Polynomial Chaos Expansion (PCE) to a file.

Specification

**Alias:** none

**Argument(s):** STRING

Description

Export the coefficients and multi-index of a Polynomial Chaos Expansion (PCE) to a file. The multi-index written will be sparse. Specifically the expansion will consist of the indices corresponding to the non-zero coefficients of the PCE.

7.2.68.4.8.183  diagonal_covariance

- **Keywords Area**
- **method**
- **bayes_calibration**
- **dream**
- **emulator**
- **ml_pce**
- **diagonal_covariance**

Display only the diagonal terms of the covariance matrix.
Specification

**Alias:** none

**Argument(s):** none

**Default:** diagonal_covariance for response vector > 10; else full_covariance

**Description**

With a large number of responses, the covariance matrix can be very large. `diagonal_covariance` is used to suppress the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

### 7.2.68.4.8.184 full_covariance

- **Keywords Area**
- **method**
- **bayes_calibration**
- **dream**

**diagonal_covariance**

Display only the diagonal terms of the covariance matrix.

**full_covariance**

Display the full covariance matrix.

### Description

Selects a multifidelity polynomial chaos expansion (MF PCE) surrogate model to use in the Bayesian likelihood calculations. Most specification options are carried over for using MF PCE as a surrogate within the Bayesian framework.

### See Also

These keywords may also be of interest:

- multifidelity_polynomial_chaos
- p_refinement

### Specification

**Alias**: none

**Argument(s)**: none

**Default**: no refinement

**Child Keywords**:
### Description

The `p_refinement` keyword specifies the usage of automated polynomial order refinement, which can be either `uniform` or `dimension_adaptive`.

The `dimension_adaptive` option is supported for the tensor-product quadrature and Smolyak sparse grid options and `uniform` is supported for tensor and sparse grids as well as regression approaches (collocation-points or collocation_ratio).

Each of these refinement cases makes use of the max_iterations and convergence_tolerance method independent controls. The former control limits the number of refinement iterations, and the latter control terminates refinement when the two-norm of the change in the response covariance matrix (or, in goal-oriented approaches, the two-norm of change in the statistical quantities of interest (QOI)) falls below the tolerance.

The `dimension_adaptive` case can be further specified to utilize sobol, decay, or generalized refinement controls. The former two cases employ anisotropic tensor/sparse grids in which the anisotropic dimension preference (leading to anisotropic integrations/expansions with differing refinement levels for different random dimensions) is determined using either total Sobol' indices from variance-based decomposition (sobol case: high indices result in high dimension preference) or using spectral coefficient decay rates from a rate estimation technique similar to Richardson extrapolation (decay case: low decay rates result in high dimension preference). In these two cases as well as the `uniform` refinement case, the quadrature_order or sparse_grid_level are ramped by one on each refinement iteration until either of the two convergence controls is satisfied. For the `uniform` refinement case with regression approaches, the expansion_order is ramped by one on each iteration while the oversampling ratio (either defined by collocation_ratio or inferred from collocation_points based on the initial expansion) is held fixed. Finally, the generalized dimension_adaptive case is the default adaptive approach; it refers to the generalized sparse grid algorithm, a greedy approach in which candidate index sets are evaluated for their impact on the statistical QOI, the most influential sets are selected and used to generate additional candidates, and the index set frontier of a sparse grid is evolved in an unstructured and goal-oriented manner (refer to User's Manual PCE descriptions for additional specifics).

For the case of `p_refinement` or the case of an explicit nested override, Gauss-Hermite rules are replaced with Genz-Keister nested rules and Gauss-Legendre rules are replaced with Gauss-Patterson nested rules, both of which exchange lower integrand precision for greater point reuse.

Refine an expansion uniformly in all dimensions.

Specification

Alias: none
Argument(s): none

Description

The quadrature_order or sparse_grid_level are ramped by one on each refinement iteration until either of the two convergence controls is satisfied. For the uniform refinement case with regression approaches, the expansion_order is ramped by one on each iteration while the oversampling ratio (either defined by collocation_ratio or inferred from collocation_points based on the initial expansion) is held fixed.

Perform anisotropic expansion refinement by preferentially adapting in dimensions that are detected to have higher 'importance'.

Specification

Alias: none
Argument(s): none
Child Keywords:
### Description

Perform anisotropic expansion refinement by preferentially adapting in dimensions that are detected to hold higher 'importance' in resolving statistical quantities of interest.

Dimension importance must be estimated as part of the refinement process. Techniques include either sobol or generalized for stochastic collocation and either sobol, decay, or generalized for polynomial chaos. Each of these automated refinement approaches makes use of the max_iterations and convergence_tolerance iteration controls.

#### 7.2.68.4.8.189 sobol

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- mf_pce
- p_refinement
- dimension_adaptive
- sobol

Estimate dimension preference for automated refinement of stochastic expansion using total Sobol' sensitivity indices.
Specification

Alias: none
Argument(s): none
Default: generalized

Description

Determine dimension preference for refinement of a stochastic expansion from the total Sobol’ sensitivity indices obtained from global sensitivity analysis. High indices indicate high importance for resolving statistical quantities of interest and therefore result in high dimension preference.

Examples

```
method,
polynomial_chaos
  sparse_grid_level = 3
  dimension_adaptive_p_refinement sobol
  max_iterations = 20
  convergence_tol = 1.e-4
```

7.2.68.4.8.190 decay

- Keywords Area
  - method
  - bayes_calibration
  - dream
  - emulator
  - mf_pce
  - p_refinement
  - dimension_adaptive
  - decay

Estimate spectral coefficient decay rates to guide dimension-adaptive refinement.

Specification

Alias: none
Argument(s): none

Description

Estimate spectral coefficient decay rates from a rate estimation technique similar to Richardson extrapolation. These decay rates are used to guide dimension-adaptive refinement, where slower decay rates result in higher dimension preference.
Examples

```
method, polynomial_chaos
    sparse_grid_level = 3
dimension_adaptive p_refinement decay
    max_iterations = 20
    convergence_tol = 1.e-4
```

7.2.68.4.8.191 generalized

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- mf_pce
- p_refinement
- dimension_adaptive
- generalized

Use the generalized sparse grid dimension adaptive algorithm to refine a sparse grid approximation of stochastic expansion.

Specification

**Alias:** none

**Argument(s):** none

Description

The generalized sparse grid algorithm is a greedy approach in which candidate index sets are evaluated for their impact on the statistical QOI, the most influential sets are selected and used to generate additional candidates, and the index set frontier of a sparse grid is evolved in an unstructured and goal-oriented manner (refer to User’s Manual PCE descriptions for additional specifics).

Examples

```
method, polynomial_chaos
    sparse_grid_level = 3
dimension_adaptive p_refinement generalized
    max_iterations = 20
    convergence_tol = 1.e-4
```

7.2.68.4.8.192 max_refinement_iterations

- Keywords Area
- method
- bayes_calibration
Maximum number of expansion refinement iterations

Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** 100

**Description**

Limits the number of times the expansion can be refined under various refinement strategies.

**Examples**

```plaintext
method,
polynomial_chaos
dimension_adaptive generalized
p_refinement
max_refinement_iterations = 20
convergence_tol = 1.e-4
sparse_grid_level = 1
```

7.2.68.4.8.193 allocation_control

**Keywords Area**

- method
- bayes_calibration
- dream
- emulator
- mf_pce
- allocation_control

Sample allocation approach for multifidelity expansions

**Specification**

**Alias:** none

**Argument(s):** none

**Child Keywords:**
Multifidelity surrogate approaches, including polynomial chaos, stochastic collocation, and function train, can optionally employ a integrated greedy competition across the model sequence, where each model index can supply one or more refinement candidates which are competed to determine the candidate with the greatest impact on the QoI statistics per unit cost. This greedy competition implicitly determines the optimal sample allocation across model indices.

**Default Behavior**

The default, when allocation_control is not specified, is to compute or adapt separately for each model index (individual instead of integrated refinement).

7.2.68.4.8.194 greedy

- Keywords Area
  - method
  - bayes_calibration
  - dream
  - emulator
  - mf_pce
  - allocation_control
  - greedy

Sample allocation based on greedy refinement within multifidelity polynomial chaos

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

Multifidelity polynomial chaos supports greedy refinement strategies, spanning regression and projection approaches for computing expansion coefficients. The key idea is that each level of the model hierarchy being approximated can generate one or more candidates for refinement. These candidates are competed against each other within a unified competition, and the candidate that induces the largest change in the statistical QoI (response covariance by default, or results of any $z/p/β/β^*$ level mappings when specified), normalized by relative cost of evaluating the candidate, is selected and then used to generate additional candidates for consideration at its model level.
Examples

The following example of greedy multifidelity regression starts from a zeroth-order reference expansion (a constant) for each level, and generates candidate refinements for each level that are competed in an integrated greedy competition. The number of new samples for the incremented candidate expansion order is determined from the collocation ratio. In this case, the number of candidates for each level is limited to one uniform refinement of the current expansion order.

```
method,
    model_pointer = 'HIERARCH'
    multifidelity_polynomial_chaos
        allocation_control greedy
        p_refinement uniform
        expansion_order_sequence = 0
        collocation_ratio = .9  seed = 160415
        orthogonal_matching_pursuit
        convergence_tolerance 1.e-2
```

The next example employs generalized sparse grids within a greedy multifidelity competition. Each modeling level starts from a level 0 reference grid (a single point) and generates multiple admissible index set candidates. The full set of candidates across all model levels is competed within an integrated greedy competition, where the greedy selection metric is the induced change in the statistical QoI, normalized by the aggregate simulation cost of the index set candidate. In this case, there are multiple candidates for each model level and the number of candidates grows rapidly with random dimension and grid level.

```
method,
    model_pointer = 'HIERARCH'
    multifidelity_polynomial_chaos
        allocation_control greedy
        p_refinement dimension_adaptive generalized
        sparse_grid_level_sequence = 0 unrestricted
        convergence_tolerance 1.e-8
```

7.2.68.4.8.195 discrepancy_emulation

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- mf_pce
- discrepancy_emulation

Formulation for emulation of model discrepancies.

Specification

**Alias:** none

**Argument(s):** none

**Default:** distinct

**Child Keywords:**
Description

In many uncertainty quantification approaches, model discrepancies are emulated using, e.g., polynomial chaos, stochastic collocation, or Gaussian process models. Two formulations are available for this emulation:

1. distinct emulation (default), in which we directly approximate the difference or ratio between the evaluations of two models or solution levels.

2. recursive emulation (experimental option), in which we approximate a difference or ratio among the new model evaluation and the emulator approximation of the previous model.

The latter approach is a form of hierarchical emulation in which we emulate the surplus between the previous emulator and the new modeling level. This approach has a few advantages: (i) it reduces bias by correcting for emulation errors that occur at previous levels, and (ii) it does not require paired model evaluations for each discrepancy level, which reduces cost, allows for disparate sample points, and simplifies data imports.

On the other hand, its primary disadvantage is that the aggregate emulation is only as good as its weakest link, in that a poor emulator recovery can create difficulty in accurately resolving discrepancies that are recursively dependent on it. Thus, the distinct approach may tend to be more expensive in exchange for greater robustness.

Examples

```
method,
       multilevel_polynomial_chaos
       expansion_order_sequence = 2
       collocation_ratio = .9
       orthogonal_matching_pursuit
       discrepancy_emulation recursive
```

- restricted

Restrict the growth rates for nested and non-nested rules can be synchronized for consistency.

**Specification**

**Alias**: none

**Argument(s)**: none

**Default**: restricted (except for generalized sparse grids)
Description

In the quadrature and sparse grid cases, growth rates for nested and non-nested rules can be synchronized for consistency. For a non-nested Gauss rule used within a sparse grid, linear one-dimensional growth rules of $m = 2l + 1$ are used to enforce odd quadrature orders, where $l$ is the grid level and $m$ is the number of points in the rule. The precision of this Gauss rule is then $i = 2m - 1 = 4l + 1$. For nested rules, order growth with level is typically exponential; however, the default behavior is to restrict the number of points to be the lowest order rule that is available that meets the one-dimensional precision requirement implied by either a level $l$ for a sparse grid ($i = 4l + 1$) or an order $m$ for a tensor grid ($i = 2m - 1$). This behavior is known as "restricted growth" or "delayed sequences." To override this default behavior in the case of sparse grids, the unrestricted keyword can be used; it cannot be overridden for tensor grids using nested rules since it also provides a mapping to the available nested rule quadrature orders. An exception to the default usage of restricted growth is the dimension_adaptive p_refinement generalized sparse grid case described previously, since the ability to evolve the index sets of a sparse grid in an unstructured manner eliminates the motivation for restricting the exponential growth of nested rules.

</tr>
</tbody>
</table>

Description

Use adaptive basis selection to choose the basis terms in a polynomial chaos expansion. Basis selection uses compressed sensing to identify a initial set of non zero PCE coefficients. Then these non-zero terms are expanded a set number of times (we suggest 3) and compressed sensing is then applied to these three new index sets. Cross validation is used to choose the best candidate basis. The best basis is then restricted again to the non-zero terms and expanded until no improvement can be gained by adding additional terms.

- expansion_order_sequence
- basis_type
- adapted
- advancements

The maximum number of steps used to expand a basis step.

Specification

Alias: none
Argument(s): INTEGER

Description

Use adaptive basis selection to choose the basis terms in a polynomial chaos expansion. Basis selection uses compressed sensing to identify a initial set of non zero PCE coefficients. Then these non-zero terms are expanded a set number of times (we suggest 3) and compressed sensing is then applied to these three new index sets. Cross validation is used to choose the best candidate basis. The best basis is then restricted again to the non-zero terms and expanded until no improvement can be gained by adding additional terms.

Description

Set the number of points used to build a PCE via regression to be proportional to the number of terms in the expansion. To avoid requiring the user to calculate N from n and p, the collocation_ratio allows for specification of a constant factor applied to N (e.g., collocation_ratio = 2. produces samples = 2N). In addition, the default linear relationship with N can be overridden using a real-valued exponent specified using ratio_order. In this case, the number of samples becomes \( cN^o \) where \( c \) is the collocation_ratio and \( o \) is the ratio_order. The use_derivatives flag informs the regression approach to include derivative matching equations (limited to gradients at present) in the least squares solutions, enabling the use of fewer collocation points for a given expansion order and dimension (number of points required becomes \( cN^o / p^{o+1} \)).

Table: LSQ Regression Approaches

- **Optional (Choose One)**
  - LSQ Regression Approach (Group 1)
    - svd

**Description**

Compute the coefficients of a polynomial expansion using least squares. Specifically SVD-based least-squares will be used for solving over-determined systems. For the situation when the number of function values is smaller than the number of terms in a PCE, but the total number of samples including gradient values is greater than the number of terms, the resulting over-determined system will be solved using equality constrained least squares.

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

Calculate the coefficients of a polynomial chaos expansion using the singular value decomposition. When the number of model runs exceeds the number of terms in the PCE, the solution returned will be the least-squares solution, otherwise the solution will be the minimum norm solution computed using the pseudo-inverse.
Calculate the coefficients of a polynomial chaos expansion using equality constrained least squares.

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

Calculate the coefficients of a polynomial chaos expansion using equality constrained least squares.

Compute the coefficients of a polynomial expansion using orthogonal matching pursuit (OMP).

</tr>
<tr>
<td>Optional</td>
<td></td>
<td>max_cv_order_candidates</td>
<td>Limit the number of cross-validation candidates for basis order</td>
</tr>
</tbody>
</table>

**Description**

Use cross validation to choose the 'best' polynomial degree of a polynomial chaos expansion. 10 fold cross validation is used to estimate the cross validation error of a total-order polynomial expansion for orders 1 through to order. The order chosen is the one that produces the lowest cross validation error. If there are not enough points to perform 10 fold cross validation then one-at-a-time cross validation will be performed.
Restrict the cross validation process to estimating only the best noise tolerance.

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** false  

**Description**

By default, cross validation estimates both the best noise tolerance and the best candidate basis order. For reasons of reducing computational cost by reducing the number of candidate solves, the user may wish to restrict this process to estimating only the best noise tolerance.

Generally speaking, computing the best noise tolerance through cross validation mitigates issues with over-fitting the data. Computing the best candidate basis order can also mitigate overfitting, while also controlling levels of mutual coherence resulting from high-order Vandermonde-like matrix systems.

7.2.68.4.8.233  max_cv_order_candidates

**Specification**

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** ushort max  

Limit the number of cross-validation candidates for basis order
Description

When generating refinement candidates by advancing the upper bound used for a cross-validation range, the number of cross-validation can eventually become excessive and hamper algorithm progress. This control limits the maximum number of candidates, which when active, will increase the lower bound for this range as the upper bound is advanced.

- multifidelity_function_train

7.2.68.4.8.234  ratio_order

Specify a non-linear the relationship between the expansion order of a polynomial chaos expansion and the number of samples that will be used to compute the PCE coefficients.

Specification

Alias: none

Argument(s): REAL

Default: 1.

Description

When using regression type methods (specified with either collocation_points or collocation_ratio), a total-order expansion can be specified using expansion_order. To avoid requiring the user to calculate N from n and p, the collocation_ratio allows for specification of a constant factor applied to N (e.g., collocation_ratio = 2. produces samples = 2N). In addition, the default linear relationship with N can be overridden using a real-valued exponent specified using ratio_order. In this case, the number of samples becomes $cN^o$ where $c$ is the collocation_ratio and $o$ is the ratio_order.
7.2.68.4.8.235  response_scaling

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- mf_pce
- expansion_order_sequence
- collocation_ratio
- response_scaling

Perform bounds-scaling on response values prior to surrogate emulation

**Specification**

**Alias**: none

**Argument(s)**: none

**Default**: use original data

**Description**

Particularly in multifidelity methods based on regression solutions at each level of a model hierarchy, scaling can be an issue since the magnitude of discrepancy data may decay rapidly and regression solvers may employ absolute tolerances in places.

By activating `response_scaling`, the set of response data used for each recovery is scaled to \([0,1]\) based on the minimum value and range of the data set. This prevents loss of accuracy due to imbalances in scale across model levels.

- method
- bayes_calibration
- dream
- emulator
- mf_pce
7.2 method

- expansion_order_sequence
- collocation_ratio
- use_derivatives

Use derivative data to construct surrogate models

Specification

Alias: none
Argument(s): none
Default: use function values only

Description

The `use_derivatives` flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, it's use with Surfpack Gaussian process is not recommended.

7.2.68.4.8.237 tensor_grid

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- mf_pce
- expansion_order_sequence
- collocation_ratio
- tensor_grid

Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.

Specification

Alias: none
Argument(s): none
Default: regression with LHS sample set (point collocation)

Description

The collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.
7.2.68.4.8.238 reuse_points

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- mf_pce
- expansion_order_sequence
- collocation_ratio
- reuse_points

This describes the behavior of reuse of points in constructing polynomial chaos expansion models.

Specification

Alias: reuse_samples

Argument(s): none

Default: no sample reuse in coefficient estimation

Description

The reuse_points option controls the reuse behavior of points for various types of polynomial chaos expansions, including: collocation_points, collocation_ratio, expansion_samples, or orthogonal_least_interpolation. If any of these approaches are specified to create a set of points for the polynomial chaos expansion, one can specify reuse_points so that any points that have been previously generated (for example, from the import_points file) can be reused.

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- mf_pce
- expansion_order_sequence
- import_build_points_file

File containing points you wish to use to build a surrogate
Specification

**Alias:** import_points_file

**Argument(s):** STRING

**Default:** no point import from a file

**Child Keywords:**
### Description

The `import_build_points_file` allows the user to specify a file that contains a list of points and truth model responses used to construct a surrogate model. These can be used by all methods that (explicitly, e.g. surrogate-based optimization, or implicitly, e.g. efficient global optimization) operate on a surrogate. In particular, these points and responses are used in place of truth model evaluations to construct the initial surrogate. When used to construct surrogate models or emulators these are often called build points or training data.

### Default Behavior

By default, methods do not import points from a file.

### Usage Tips

Dakota parses input files without regard to whitespace, but the `import_build_points_file` must be in one of three formats:

- annotated (default)
- custom_annotated
- freeform

### Examples

```
method
    polynomial_chaos
        expansion_order = 4
        import_build_points_file = 'dakota_uq_rosenbrock_pce_import.annot.pts.dat'
```

7.2.68.4.8.243 custom_annotated

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- mf_pce
- expansion_order_sequence
• `import_build_points_file`

• `custom.annotated`

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

• `file_formats`

Specification

**Alias:** none

**Argument(s):** none

**Default:** annotated format

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>header</td>
<td><code>header</code></td>
<td>Enable header row in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td><code>eval_id</code></td>
<td><code>eval_id</code></td>
<td>Enable evaluation ID column in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td><code>interface_id</code></td>
<td><code>interface_id</code></td>
<td>Enable interface ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

**Description**

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, `eval_id` column, and `interface_id` column appear in the tabular file, thus bridging freeform and (fully) annotated.

**Default Behavior**

The **annotated** format is the default for tabular export/import. To control which header row and columns are in the input/output, specify `custom.annotated`, followed by options, in the relevant export/import context.

**Usage Tips**

• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to **annotated format**, though **freeform** remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
  tabular_data_file = 'dakota_summary.dat'
  custom_annotated header eval_id

Resulting tabular file:

%eval_id x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 0.9 1.1 0.0002 0.26 0.76
2 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...
```

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- file_formats

Specification

**Alias**: none

**Argument(s)**: none

**Default**: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

**Default Behavior**

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

**Usage Tips**
7.2 method

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify `custom.annotated`
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```environments
    tabular_data
    tabular_data_file = 'dakota_summary.dat'
annotated
```

Resulting tabular file:

```
%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 NO_ID 0.9 1.1 0.0002 0.26 0.76
2 NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 NO_ID 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...```

7.2.68.4.8.248 freeform

- emulator
- mf_pce
- expansion_order_sequence
- import_build_points_file
- freeform

Selects freeform file format

Topics

This keyword is related to the topics:

- file_formats
Specification

Alias: none
Argument(s): none
Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
  tabular_data
  tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

```
0.9   1.1  0.0002  0.26  0.76
0.90009  1.1  0.0001996404857  0.2601620081  0.759955
0.89991  1.1  0.0002003604863  0.2598380081  0.760045
...```

7.2.68.4.8.249  active_only

7.2 method

- `expansion_order_sequence`
- `import_build_points_file`
- `active_only`

Import only active variables from tabular data file

**Topics**

This keyword is related to the topics:

- `file_formats`

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

7.2.68.4.8.250 `orthogonal_least_interpolation`

- `Keywords Area`
- `method`
- `bayes_calibration`
- `dream`
- `emulator`
- `mf_pce`
- `orthogonal_least_interpolation`

Build a polynomial chaos expansion from simulation samples using orthogonal least interpolation.

**Specification**

**Alias:** least_interpolation oli

**Argument(s):** none

**Child Keywords:**
## Description

Build a polynomial chaos expansion from simulation samples using orthogonal least interpolation. Unlike the other regression methods `expansion_order` cannot be set. OLI will produce the lowest degree polynomial that interpolates the data.

### 7.2.68.4.8.251 collocation_points_sequence

- **Keywords Area**
- **method**
- **bayes_calibration**
- **dream**
- **emulator**
- **mf_pce**
- **orthogonal_least_interpolation**
- **collocation_points_sequence**

Sequence of collocation point counts used in a multi-stage expansion

## Specification

- **Alias:** none
- **Argument(s):** INTEGERLIST
Description

Each level entry of the collocation_points_sequence applies to one expansion within a multi-stage expansion. Current multi-stage expansions that support collocation point sequences include multilevel and multifidelity polynomial chaos and multilevel and multifidelity function train expansions.

If adaptive refinement is active, then this sequence specifies the starting point for each level within either an individual or integrated refinement approach.

A corresponding scalar specification is documented at, e.g., collocation_points

- collocation_points

7.2.68.4.8.252 tensor_grid

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- mf_pce
- orthogonal_least_interpolation
- tensor_grid

Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.

Specification

Alias: none

Argument(s): INTEGERLIST

Default: regression with LHS sample set (point collocation)

Description

The collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.
• emulator
• mf_pce
• orthogonal_least_interpolation
• reuse_points

This describes the behavior of reuse of points in constructing polynomial chaos expansion models.

Specification

Alias: reuse_samples
Argument(s): none
Default: no sample reuse in coefficient estimation

Description

The `reuse_points` option controls the reuse behavior of points for various types of polynomial chaos expansions, including: `collocation_points`, `collocation_ratio`, `expansion_samples`, or `orthogonal_least_interpolation`. If any of these approaches are specified to create a set of points for the polynomial chaos expansion, one can specify `reuse_points` so that any points that have been previously generated (for example, from the `import_points_file`) can be reused.

7.2.68.4.8.254  import_build_points_file

• Keywords Area
• method
• bayes_calibration
• dream
• emulator
• mf_pce

</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>freeform</td>
<td>Selects freeform file format</td>
</tr>
</tbody>
</table>

Optional active_only Import only active variables from tabular data file

Description

The `import_build_points_file` allows the user to specify a file that contains a list of points and truth model responses used to construct a surrogate model. These can be used by all methods that (explicitly, e.g. surrogate-based optimization, or implicitly, e.g. efficient global optimization) operate on a surrogate. In particular, these points and responses are used in place of truth model evaluations to construct the initial surrogate. When used to construct surrogate models or emulators these are often called build points or training data.

Default Behavior

By default, methods do not import points from a file.

Usage Tips

Dakota parses input files without regard to whitespace, but the `import_build_points_file` must be in one of three formats:

- annotated (default)
- custom_annotated
- freeform

Examples

```plaintext
method polynomial_chaos
  expansion_order = 4
  import_build_points_file = 'dakota_uq_rosenbrock_pce_import.annot.pts.dat'
```

```
7.2.68.4.8.255 custom_annotated

</tr>
<tr>
<td>Optional</td>
<td>interface_id</td>
<td>interface_id</td>
<td>Enable interface ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

Usage Tips

• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.
Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id

Resulting tabular file:

%eval_id x1   x2   obj_fn  nln_ineq_con_1  nln_ineq_con_2
1  0.9   1.1   0.0002  0.26    0.76

Selects annotated tabular file format

Topics
This keyword is related to the topics:

• file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format

Description
An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior
By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

• To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id

• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.
Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```environment
tabular_data
  tabular_data_file = 'dakota_summary.dat'
  annotated

- **Keywords Area**
- **method**
- **bayes_calibration**
- **dream**
- **emulator**
- **mf_pce**
- **askey**

Select the standardized random variables (and associated basis polynomials) from the Askey family that best match the user-specified random variables.

Specification

**Alias:** none

**Argument(s):** none

**Default:** extended (Askey + numerically-generated)

Description

The Askey option employs standard normal, standard uniform, standard exponential, standard beta, and standard gamma random variables in a transformed probability space. These selections correspond to Hermite, Legendre, Laguerre, Jacobi, and generalized Laguerre orthogonal polynomials, respectively.

Specific mappings for the basis polynomials are based on a closest match criterion, and include Hermite for normal (optimal) as well as bounded normal, lognormal, bounded lognormal, gumbel, frechet, and weibull (sub-optimal); Legendre for uniform (optimal) as well as loguniform, triangular, and bin-based histogram (sub-optimal); Laguerre for exponential (optimal); Jacobi for beta (optimal); and generalized Laguerre for gamma (optimal).

See Also

These keywords may also be of interest:

- **polynomial_chaos**
- **wiener**
Use standard normal random variables (along with Hermite orthogonal basis polynomials) when transforming to a standardized probability space.

**Specification**

*Alias*: none

*Argument(s)*: none

*Default*: extended (Askey + numerically-generated)

**Description**

The Wiener option employs standard normal random variables in a transformed probability space, corresponding to a Hermite orthogonal polynomial basis. This is the same nonlinear variable transformation used by local and global reliability methods (and therefore has the same variable support).

**See Also**

These keywords may also be of interest:

- polynomial_chaos
- askey

The normalized specification requests output of PCE coefficients that correspond to normalized orthogonal basis polynomials.
Specification

Alias: none
Argument(s): none
Default: PCE coefficients correspond to unnormalized basis polynomials

Description

The normalized specification requests output of PCE coefficients that correspond to normalized orthogonal basis polynomials.

7.2.68.4.8.265 export_expansion_file

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- mf_pce
- export_expansion_file

Export the coefficients and multi-index of a Polynomial Chaos Expansion (PCE) to a file.

Specification

Alias: none
Argument(s): STRING

Description

Export the coefficients and multi-index of a Polynomial Chaos Expansion (PCE) to a file. The multi-index written will be sparse. Specifically the expansion will consists only of the indices corresponding to the non-zero coefficients of the PCE.

7.2.68.4.8.266 diagonal_covariance

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- mf_pce
- diagonal_covariance

Display only the diagonal terms of the covariance matrix.
7.2 method

Specification

Alias: none
Argument(s): none
Default: diagonal_covariance for response vector > 10; else full_covariance

Description

With a large number of responses, the covariance matrix can be very large. diagonal_covariance is used to suppress the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

7.2.68.4.8.267  full_covariance

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- mf_pce
- full_covariance

Display the full covariance matrix

Specification

Alias: none
Argument(s): none

Description

With a large number of responses, the covariance matrix can be very large. full_covariance is used to force Dakota to output the full covariance matrix.

7.2.68.4.8.268  sc

Automatic polynomial order refinement
Description

The `p_refinement` keyword specifies the usage of automated polynomial order refinement, which can be either `uniform` or `dimension_adaptive`.

The `dimension_adaptive` option is supported for the tensor-product quadrature and Smolyak sparse grid options and `uniform` is supported for tensor and sparse grids as well as regression approaches (collocation_points or collocation_ratio).

Each of these refinement cases makes use of the `max_iterations` and `convergence_tolerance` method independent controls. The former control limits the number of refinement iterations, and the latter control terminates refinement when the two-norm of the change in the response covariance matrix (or, in goal-oriented approaches, the two-norm of change in the statistical quantities of interest (QOI)) falls below the tolerance.

The `dimension_adaptive` case can be further specified to utilize `sobol`, `decay`, or `generalized` refinement controls. The former two cases employ anisotropic tensor/sparse grids in which the anisotropic dimension preference (leading to anisotropic integrations/expansions with differing refinement levels for different random dimensions) is determined using either total Sobol' indices from variance-based decomposition (sobol case: high indices result in high dimension preference) or using spectral coefficient decay rates from a rate estimation technique similar to Richardson extrapolation (decay case: low decay rates result in high dimension preference). In these two cases as well as the `uniform` refinement case, the `quadrature_order` or `sparse_grid_level` are ramped by one on each refinement iteration until either of the two convergence controls is satisfied. For the `uniform` refinement case with regression approaches, the `expansion_order` is ramped by one on each iteration while the oversampling ratio (either defined by `collocation_ratio` or inferred from `collocation_points` based on the initial expansion) is held fixed. Finally, the generalized `dimension_adaptive` case is the default adaptive approach; it refers to the generalized sparse grid algorithm, a greedy approach in which candidate index sets are evaluated for their impact on the statistical QOI, the most influential sets are selected and used to generate additional candidates, and the index set frontier of a sparse grid is evolved in an unstructured and goal-oriented manner (refer to User’s Manual PCE descriptions for additional specifics).

For the case of `p_refinement` or the case of an explicit nested override, Gauss-Hermite rules are replaced with Genz-Keister nested rules and Gauss-Legendre rules are replaced with Gauss-Patterson nested rules, both of which exchange lower integrand precision for greater point reuse.

7.2.68.4.8.270 uniform

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- sc
- p_refinement
- uniform

Refine an expansion uniformly in all dimensions.
Specification

Alias: none
Argument(s): none

Description

The quadrature_order or sparse_grid_level are ramped by one on each refinement iteration until either of the two convergence controls is satisfied. For the uniform refinement case with regression approaches, the expansion_order is ramped by one on each iteration while the oversampling ratio (either defined by collocation_ratio or inferred from collocation_points based on the initial expansion) is held fixed.

7.2.68.4.8.271 dimension_adaptive

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- sc
- p_refinement
- dimension_adaptive

Perform anisotropic expansion refinement by preferentially adapting in dimensions that are detected to have higher ‘importance’.

Specification

Alias: none
Argument(s): none

Child Keywords:

<table>

<tbody>
<tr>
<td>Required (Choose One)</td>
<td>Dimension Adaptivity Estimation Approach (Group 1)</td>
<td>sobol</td>
<td>Estimate dimension preference for automated refinement of stochastic expansion using total Sobol’ sensitivity indices.</td>
</tr>
</tbody>
</table>
Use the generalized sparse grid dimension adaptive algorithm to refine a sparse grid approximation of stochastic expansion.

**Description**

Perform anisotropic expansion refinement by preferentially adapting in dimensions that are detected to hold higher ‘importance’ in resolving statistical quantities of interest.

Dimension importance must be estimated as part of the refinement process. Techniques include either sobol or generalized for stochastic collocation and either sobol, decay, or generalized for polynomial chaos. Each of these automated refinement approaches makes use of the max_iterations and convergence_tolerance iteration controls.

**7.2.68.4.8.272 sobol**

- **Keywords** Area
- **method**
- bayes_calibration
- dream
- emulator
- sc
- p_refinement
- dimension_adaptive
- sobol

Estimate dimension preference for automated refinement of stochastic expansion using total Sobol’ sensitivity indices.

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** generalized

**Description**

Determine dimension preference for refinement of a stochastic expansion from the total Sobol’ sensitivity indices obtained from global sensitivity analysis. High indices indicate high importance for resolving statistical quantities of interest and therefore result in high dimension preference.
Examples

```
method, polynomial_chaos
  sparse_grid_level = 3
  dimension_adaptive p_refinement sobol
  max_iterations = 20
  convergence_tol = 1.e-4
```

7.2.68.4.8.273 generalized

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- sc
- p_refinement
- dimension_adaptive
- generalized

Use the generalized sparse grid dimension adaptive algorithm to refine a sparse grid approximation of stochastic expansion.

**Argument(s):** none

Description

The generalized sparse grid algorithm is a greedy approach in which candidate index sets are evaluated for their impact on the statistical QOI, the most influential sets are selected and used to generate additional candidates, and the index set frontier of a sparse grid is evolved in an unstructured and goal-oriented manner (refer to User’s Manual PCE descriptions for additional specifics).

Examples

```
method,
  polynomial_chaos
  sparse_grid_level = 3
  dimension_adaptive p_refinement generalized
  max_iterations = 20
  convergence_tol = 1.e-4
```

7.2.68.4.8.274 h_refinement

- Keywords Area
- method
- bayes_calibration
Employ h-refinement to refine the grid

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** no refinement

**Child Keywords:**

</tr>
</tbody>
</table>

**Description**

Automated expansion refinement can be selected as either p_refinement or h_refinement, and either refinement specification can be either uniform or dimension_adaptive. The dimension_adaptive case can be further specified as either sobol or generalized (decay not supported). Each of these automated refinement approaches makes use of the max_iterations and convergence_tolerance iteration controls. The h_refinement specification involves use of the same piecewise interpolants (linear or cubic Hermite splines) described above for the piecewise specification option (it is not necessary to redundantly specify piecewise in the case of h_refinement). In future releases, the hierarchical interpolation approach will enable local refinement in addition to the current uniform and dimension_-adaptive options.
Refine an expansion uniformly in all dimensions.

Specification

Alias: none

Argument(s): none

Description

The quadrature_order or sparse_grid_level are ramped by one on each refinement iteration until either of the two convergence controls is satisfied. For the uniform refinement case with regression approaches, the expansion_order is ramped by one on each iteration while the oversampling ratio (either defined by collocation_ratio or inferred from collocation_points based on the initial expansion) is held fixed.

Perform anisotropic expansion refinement by preferentially adapting in dimensions that are detected to have higher ‘importance’.

**Description**

Perform anisotropic expansion refinement by preferentially adapting in dimensions that are detected to hold higher 'importance' in resolving statistical quantities of interest.

Dimension importance must be estimated as part of the refinement process. Techniques include either sobol or generalized for stochastic collocation and either sobol, decay, or generalized for polynomial chaos. Each of these automated refinement approaches makes use of the max_iterations and convergence_tolerance iteration controls.

7.2.68.4.8.277 sobol

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- sc
- h_refinement
- dimension_adaptive
- sobol

Estimate dimension preference for automated refinement of stochastic expansion using total Sobol' sensitivity indices.

**Specification**

Alias: none

Argument(s): none

Default: generalized
Description

Determine dimension preference for refinement of a stochastic expansion from the total Sobol' sensitivity indices obtained from global sensitivity analysis. High indices indicate high importance for resolving statistical quantities of interest and therefore result in high dimension preference.

Examples

method,
  polynomial_chaos
  sparse_grid_level = 3
  dimension_adaptive p_refinement sobol
  max_iterations = 20
  convergence_tol = 1.e-4

7.2.68.4.8.278 generalized

- Keywords Area
- method
  - bayes_calibration
  - dream
  - emulator
  - sc
  - h_refinement
  - dimension_adaptive
  - generalized

Use the generalized sparse grid dimension adaptive algorithm to refine a sparse grid approximation of stochastic expansion.

Specification

Alias: none

Argument(s): none

Description

The generalized sparse grid algorithm is a greedy approach in which candidate index sets are evaluated for their impact on the statistical QOI, the most influential sets are selected and used to generate additional candidates, and the index set frontier of a sparse grid is evolved in an unstructured and goal-oriented manner (refer to User's Manual PCE descriptions for additional specifics).

Examples

method,
  polynomial_chaos
  sparse_grid_level = 3
  dimension_adaptive p_refinement generalized
  max_iterations = 20
  convergence_tol = 1.e-4
7.2.68.4.8.279  local_adaptive

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- sc
- h_refinement
- local_adaptive

Planned future capability for local pointwise refinement within a generalized sparse grid.

Specification

Alias: none
Argument(s): none

Description

Sparse grid interpolation admits approaches for pointwise local refinement within the general framework of generalized sparse grids. This algorithmic capability is currently in a partial prototype stage.

7.2.68.4.8.280  max_refinement_iterations

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- sc
- max_refinement_iterations

Maximum number of expansion refinement iterations

Specification

Alias: none
Argument(s): INTEGER
Default: 100

Description

Limits the number of times the expansion can be refined under various refinement strategies.
Examples

```plaintext
method, polynomial_chaos
dimension_adaptive generalized
p_refinement
  max_refinement_iterations = 20
  convergence_tol = 1.e-4
  sparse_grid_level = 1
```

7.2.68.4.8.281 quadrature_order

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- sc
- quadrature_order

Order for tensor-products of Gaussian quadrature rules

Specification

**Alias:** none

<table>
<thead>
<tr>
<th>Optional</th>
<th>Quadrature Rule Nesting (Group 1)</th>
<th>non_nested</th>
<th>Enforce use of non-nested quadrature rules</th>
</tr>
</thead>
</table>

Description

Multidimensional integration by a tensor-product of Gaussian quadrature rules (specified with `quadrature_order`, and, optionally, `dimension_preference`). The default rule selection is to employ `non_nested` Gauss rules including Gauss-Hermite (for normals or transformed normals), Gauss-Legendre (for uniforms or transformed uniforms), Gauss-Jacobi (for betas), Gauss-Laguerre (for exponentials), generalized Gauss-Laguerre (for gammas), and numerically-generated Gauss rules (for other distributions when using an Extended basis). For the case of `p_refinement` or the case of an explicit `nested` override, Gauss-Hermite rules are replaced with Genz-Keister nested rules and Gauss-Legendre rules are replaced with Gauss-Patterson nested rules, both of which exchange lower integrand precision for greater point reuse. By specifying a `dimension_preference`,
where higher preference leads to higher order polynomial resolution, the tensor grid may be rendered anisotropic. The dimension specified to have highest preference will be set to the specified quadrature_order and all other dimensions will be reduced in proportion to their reduced preference; any non-integral portion is truncated. To synchronize with tensor-product integration, a tensor-product expansion is used, where the order $p_i$ of the expansion in each dimension is selected to be half of the integrand precision available from the rule in use, rounded down. In the case of non-nested Gauss rules with integrand precision $2m_i - 1$, $p_i$ is one less than the quadrature order $m_i$ in each dimension (a one-dimensional expansion contains the same number of terms, $p + 1$, as the number of Gauss points). The total number of terms, $N$, in a tensor-product expansion involving $n$ uncertain input variables is

$$N = 1 + P = \prod_{i=1}^{n} (p_i + 1)$$

In some advanced use cases (e.g., multifidelity UQ), multiple grid resolutions can be employed; for this reason, the quadrature_order specification supports an array input.

A corresponding sequence specification is documented at, e.g., quadrature_order_sequence and quadrature_order_sequence

### Description

Multi-dimensional integration by the Smolyak sparse grid method (specified with sparse_grid_level and, optionally, dimension_preference). The underlying one-dimensional integration rules are the same as for the tensor-product quadrature case; however, the default rule selection is nested for sparse grids (Genz-Keister for normals/transformed normals and Gauss-Patterson for uniforms/transformed uniforms). This default can be overridden with an explicit non_nested specification (resulting in Gauss-Hermite for normals/transformed normals and Gauss-Legendre for uniforms/transformed uniforms). As for tensor quadrature, the dimension_preference specification enables the use of anisotropic sparse grids (refer to the PCE description in the User’s Manual for the anisotropic index set constraint definition). Similar to anisotropic tensor grids, the dimension with greatest preference will have resolution at the full sparse_grid_level and all other dimension resolutions will be reduced in proportion to their reduced preference. For PCE with either isotropic or anisotropic sparse grids, a summation of tensor-product expansions is used, where each anisotropic tensor-product quadrature rule underlying the sparse grid construction results in its own anisotropic tensor-product expansion as described in case 1. These anisotropic tensor-product expansions are summed into a sparse PCE using the standard Smolyak summation (again, refer to the User’s Manual for additional details). As for quadrature_order, the sparse_grid_level specification admits an array input for enabling specification of multiple grid resolutions used by certain advanced solution methodologies.

A corresponding sequence specification is documented at, e.g., sparse_grid_level_sequence and sparse_grid_level_sequence

### Notes

7.2.68.4.8.286 dimension_preference

- Keywords Area
- method
A set of weights specifying the relative importance of each uncertain variable (dimension)

**Specification**

**Alias:** none  
**Argument(s):** REALLIST  
**Default:** isotropic grids

**Description**

A set of weights specifying the relative importance of each uncertain variable (dimension). Using this specification leads to anisotropic integrations with differing refinement levels for different random dimensions.

**See Also**

These keywords may also be of interest:

- sobol  
- decay

Employ a nodal sparse grid construction in stochastic collocation

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** nodal
Description

Stochastic collocation with sparse grids can employ either a nodal or hierarchical formulation. The nodal formulation does not require nested interpolation rules and is therefore more generally applicable. However, in the context of adaptive refinement, it can suffer from loss of precision due to subtractive cancellation.

7.2.68.4.8.288 hierarchical

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- sc
- sparse_grid_level
- hierarchical

Employ a hierarchical sparse grid construction

Specification

Alias: none
Argument(s): none

Description

Stochastic collocation with sparse grids can employ either a nodal or hierarchical formulation. The hierarchical formulation requires nested interpolation rules as it utilizes increments in collocation points along with hierarchical weights defined from a hierarchical basis formulation.

This keyword requests the hierarchical formulation, which has benefits for adaptive refinement by supporting direct computation of increments in targeted statistics (e.g. mean, covariance, reliability indices), avoiding loss of precision from subtractive cancellation.

7.2.68.4.8.289 restricted

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- sc
- sparse_grid_level
- restricted

Restrict the growth rates for nested and non-nested rules can be synchronized for consistency.
Specification

**Alias:** none

**Argument(s):** none

**Default:** restricted (except for generalized sparse grids)

**Description**

In the quadrature and sparse grid cases, growth rates for nested and non-nested rules can be synchronized for consistency. For a non-nested Gauss rule used within a sparse grid, linear one-dimensional growth rules of \( m = 2l + 1 \) are used to enforce odd quadrature orders, where \( l \) is the grid level and \( m \) is the number of points in the rule. The precision of this Gauss rule is then \( i = 2m - 1 = 4l + 1 \). For nested rules, order growth with level is typically exponential; however, the default behavior is to restrict the number of points to be the lowest order rule that is available that meets the one-dimensional precision requirement implied by either a level \( l \) for a sparse grid (\( i = 4l + 1 \)) or an order \( m \) for a tensor grid (\( i = 2m - 1 \)). This behavior is known as "restricted growth" or "delayed sequences." To override this default behavior in the case of sparse grids, the unrestricted keyword can be used; it cannot be overridden for tensor grids using nested rules since it also provides a mapping to the available nested rule quadrature orders. An exception to the default usage of restricted growth is the dimension_adaptive p_refinement generalized sparse grid case described previously, since the ability to evolve the index sets of a sparse grid in an unstructured manner eliminates the motivation for restricting the exponential growth of nested rules.

7.2.68.4.8.290 unrestricted

**Specification**

**Alias:** none

**Argument(s):** none
### Description

Enforce use of non-nested quadrature rules if available. For instance if the aleatory variables are Gaussian use the non-nested Gauss-Hermite rule.

#### 7.2.68.4.8.293 piecewise

- **Keywords Area**
- **method**
- **bayes_calibration**
- **dream**
- **emulator**
- **sc**
- **piecewise**

Use piecewise local basis functions.

### Specification

**Alias:** none  
**Argument(s):** none  
**Default:** extended (Askey + numerically-generated)

### Description

SC also supports the option of piecewise local basis functions. These are piecewise linear splines, or in the case of gradient-enhanced interpolation via the use_derivatives specification, piecewise cubic Hermite splines. Both of these basis selections provide local support only over the range from the interpolated point to its nearest 1D neighbors (within a tensor grid or within each of the tensor grids underlying a sparse grid), which exchanges the fast convergence of global bases for smooth functions for robustness in the representation of nonsmooth response functions (that can induce Gibbs oscillations when using high-order global basis functions). When local basis functions are used, the usage of nonequidistant collocation points (e.g., the Gauss point selections described above) is not well motivated, so equidistant Newton-Cotes points are employed in this case, and all random variable types are transformed to standard uniform probability space.

#### 7.2.68.4.8.294 askey

- **Keywords Area**
- **method**
- **bayes_calibration**
- **dream**
- **emulator**
- **sc**
- **askey**

Select the standardized random variables (and associated basis polynomials) from the Askey family that best match the user-specified random variables.
Specification

Alias: none
Argument(s): none
Default: extended (Askey + numerically-generated)

Description

The Askey option employs standard normal, standard uniform, standard exponential, standard beta, and standard gamma random variables in a transformed probability space. These selections correspond to Hermite, Legendre, Laguerre, Jacobi, and generalized Laguerre orthogonal polynomials, respectively.

Specific mappings for the basis polynomials are based on a closest match criterion, and include Hermite for normal (optimal) as well as bounded normal, lognormal, bounded lognormal, gumbel, frechet, and weibull (sub-optimal); Legendre for uniform (optimal) as well as loguniform, triangular, and bin-based histogram (sub-optimal); Laguerre for exponential (optimal); Jacobi for beta (optimal); and generalized Laguerre for gamma (optimal).

7.2.68.4.8.296 use_derivatives

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- sc
- use_derivatives

Use derivative data to construct surrogate models

Specification

Alias: none

Argument(s): none

Default: use function values only

Description

The use_derivatives flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, its use with Surfpack Gaussian process is not recommended.

7.2.68.4.8.297 diagonal_covariance

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- sc
- diagonal_covariance

Display only the diagonal terms of the covariance matrix
Specification

Alias: none
Argument(s): none
Default: diagonal_covariance for response vector > 10; else full_covariance

Description

With a large number of responses, the covariance matrix can be very large. diagonal_covariance is used to suppress the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

7.2.68.4.298 full_covariance

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- sc
- full_covariance

Display the full covariance matrix

Specification

Alias: none
Argument(s): none

Description

With a large number of responses, the covariance matrix can be very large. full_covariance is used to force Dakota to output the full covariance matrix.

Automatic polynomial order refinement

**Specification**

- **Alias:** none
- **Argument(s):** none
- **Default:** no refinement
- **Child Keywords:**
### Description

The `p_refinement` keyword specifies the usage of automated polynomial order refinement, which can be either `uniform` or `dimension_adaptive`.

The `dimension_adaptive` option is supported for the tensor-product quadrature and Smolyak sparse grid options, and `uniform` is supported for tensor and sparse grids as well as regression approaches (`collocation_points` or `collocation_ratio`).

Each of these refinement cases makes use of the `max_iterations` and `convergence_tolerance` method independent controls. The former control limits the number of refinement iterations, and the latter control terminates refinement when the two-norm of the change in the response covariance matrix (or, in goal-oriented approaches, the two-norm of change in the statistical quantities of interest (QOI)) falls below the tolerance.

The `dimension_adaptive` case can be further specified to utilize `sobol`, `decay`, or `generalized` refinement controls. The former two cases employ anisotropic tensor/sparse grids in which the anisotropic dimension preference (leading to anisotropic integrations/expansions with differing refinement levels for different random dimensions) is determined using either total Sobol’ indices from variance-based decomposition (sobol case: high indices result in high dimension preference) or using spectral coefficient decay rates from a rate estimation technique similar to Richardson extrapolation (decay case: low decay rates result in high dimension preference). In these two cases as well as the uniform refinement case, the `quadrature_order` or `sparse_grid_level` are ramped by one on each refinement iteration until either of the two convergence controls is satisfied. For the uniform refinement case with regression approaches, the `expansion_order` is ramped by one on each iteration while the oversampling ratio (either defined by `collocation_ratio` or inferred from `collocation_points` based on the initial expansion) is held fixed. Finally, the generalized dimension_adaptive case is the default adaptive approach; it refers to the generalized sparse grid algorithm, a greedy approach in which candidate index sets are evaluated for their impact on the statistical QOI, the most influential sets are selected and used to generate additional candidates, and the index set frontier of a sparse grid is evolved in an unstructured and goal-oriented manner (refer to User’s Manual PCE descriptions for additional specifics).

For the case of `p_refinement` or the case of an explicit nested override, Gauss-Hermite rules are replaced with Genz-Keister nested rules and Gauss-Legendre rules are replaced with Gauss-Patterson nested rules, both of which exchange lower integrand precision for greater point reuse.

**Description**

Perform anisotropic expansion refinement by preferentially adapting in dimensions that are detected to hold higher 'importance' in resolving statistical quantities of interest.

Dimension importance must be estimated as part of the refinement process. Techniques include either sobol or generalized for stochastic collocation and either sobol, decay, or generalized for polynomial chaos. Each of these automated refinement approaches makes use of the max_iterations and convergence_tolerance iteration controls.

7.2.68.4.8.303 sobol

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- mf_sc
- p_refinement
- dimension_adaptive
- sobol

Estimate dimension preference for automated refinement of stochastic expansion using total Sobol' sensitivity indices.

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** generalized
7.2 method

Description
Determine dimension preference for refinement of a stochastic expansion from the total Sobol’ sensitivity indices obtained from global sensitivity analysis. High indices indicate high importance for resolving statistical quantities of interest and therefore result in high dimension preference.

Examples

```
method, polynomial_chaos
  sparse_grid_level = 3
  dimension_adaptive p_refinement sobol
  max_iterations = 20
  convergence_tol = 1.e-4
```

7.2.68.4.8.304 generalized

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- mf_sc
- p_refinement
- dimension_adaptive
- generalized

Use the generalized sparse grid dimension adaptive algorithm to refine a sparse grid approximation of stochastic expansion.

Specification

**Alias**: none

**Argument(s)**: none

Description
The generalized sparse grid algorithm is a greedy approach in which candidate index sets are evaluated for their impact on the statistical QOI, the most influential sets are selected and used to generate additional candidates, and the index set frontier of a sparse grid is evolved in an unstructured and goal-oriented manner (refer to User’s Manual PCE descriptions for additional specifics).

Examples

```
method, polynomial_chaos
  sparse_grid_level = 3
  dimension_adaptive p_refinement generalized
  max_iterations = 20
  convergence_tol = 1.e-4
```
Employ h-refinement to refine the grid

Specification

**Alias:** none

**Argument(s):** none

**Default:** no refinement

**Child Keywords:**

</tbody>
</table>

**Description**

Automated expansion refinement can be selected as either p_refinement or h_refinement, and either refinement specification can be either uniform or dimension_adaptive. The dimension_adaptive case can be further specified as either sobol or generalized (decay not supported). Each of these automated refinement approaches makes use of the max_iterations and convergence_tolerance iteration controls. The h_refinement specification involves use of the same piecewise interpolants (linear or cubic Hermite splines) described above for the piecewise specification option (it is not necessary to redundantly specify piecewise in the case of h_refinement). In future releases, the hierarchical interpolation approach will enable local refinement in addition to the current uniform and dimension_adaptive options.
7.2.6.4.8.306 uniform

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- mf_sc
- h_refinement
- uniform

Refine an expansion uniformly in all dimensions.

Specification

Alias: none
Argument(s): none

Description

The quadrature_order or sparse_grid_level are ramped by one on each refinement iteration until either of the two convergence controls is satisfied. For the uniform refinement case with regression approaches, the expansion_order is ramped by one on each iteration while the oversampling ratio (either defined by collocation_ratio or inferred from collocation_points based on the initial expansion) is held fixed.

Dakota Keyword Description
Sample allocation based on greedy refinement within multifidelity stochastic collocation

Description

Multifidelity surrogate approaches, including polynomial chaos, stochastic collocation, and function train, can optionally employ a integrated greedy competition across the model sequence, where each model index can supply one or more refinement candidates which are competed to determine the candidate with the greatest impact on the QoI statistics per unit cost. This greedy competition implicitly determines the optimal sample allocation across model indices.

Default Behavior

The default, when allocation_control is not specified, is to compute or adapt separately for each model index (individual instead of integrated refinement).
Sample allocation based on greedy refinement within multifidelity stochastic collocation

### Specification

**Alias:** none  
**Argument(s):** none

### Description

Multifidelity stochastic collocation supports greedy refinement strategies using tensor and sparse grids for both nodal and hierarchical collocation approaches. The key idea is that each level of the model hierarchy being approximated can generate one or more candidates for refinement. These candidates are competed against each other within an integrated competition, and the candidate that induces the largest change in the statistical QoI (response covariance by default, or results of any level mappings when specified), normalized by relative cost of evaluating the candidate, is selected and then used to generate additional candidates for consideration at its model level.

### Examples

The following example of greedy multifidelity stochastic collocation using nodal interpolation starts from a zeroth-order expansion (a constant) for each level, and generates uniform candidate refinements for each level that are competed in a greedy competition. The number of new samples for the incremented candidate expansion order is determined from the quadrature rules of the new sparse grid level. In this case, the number of candidates for each level is limited to one uniform refinement of the current sparse grid level.

```plaintext
method,  
  model_pointer = 'HIERARCH'  
  multifidelity_stoch_collocation  
  nodal  
  allocation_control greedy  
  p_refinement uniform  
  sparse_grid_level_sequence = 0 unrestricted  
  convergence_tolerance 1.e-3
```

The next example employs generalized sparse grids and hierarchical interpolation. Each level starts from a level 0 reference grid (a single point) and generates multiple admissible index set candidates. The full set of candidates across all levels is competed within a unified greedy competition, where the greedy selection metric is the induced change in the statistical QoI, normalized by the aggregate simulation cost of the index set candidate. In this case, there are multiple candidates for each level and the number of candidates grows rapidly with random dimension and grid level.
method,
    model_pointer = 'HIERARCH'
    multifidelity_stoch_collocation
    hierarchical
    allocation_control greedy
    p_refinement dimension_adaptive generalized
    sparse_grid_level_sequence = 0 unrestricted
    convergence_tolerance 1.e-8

7.2.68.4.8.314 discrepancy_emulation

• Keywords Area
• method
• bayes_calibration
• dream
• emulator
• mf_sc
• discrepancy_emulation

Formulation for emulation of model discrepancies.

Specification

Alias: none
Argument(s): none
Default: distinct

<td></td>
<td>recursive</td>
<td>Recursive formulation for emulation of model discrepancies.</td>
</tr>
</tbody>
</table>

Description

In many uncertainty quantification approaches, model discrepancies are emulated using, e.g., polynomial chaos, stochastic collocation, or Gaussian process models. Two formulations are available for this emulation:

1. distinct emulation (default), in which we directly approximate the difference or ratio between the evaluations of two models or solution levels.

2. recursive emulation (experimental option), in which we approximate a difference or ratio among the new model evaluation and the emulator approximation of the previous model.
The latter approach is a form of hierarchical emulation in which we emulate the surplus between the previous emulator and the new modeling level. This approach has a few advantages: (i) it reduces bias by correcting for emulation errors that occur at previous levels, and (ii) it does not require paired model evaluations for each discrepancy level, which reduces cost, allows for disparate sample points, and simplifies data imports.

On the other hand, its primary disadvantage is that the aggregate emulation is only as good as its weakest link, in that a poor emulator recovery can create difficulty in accurately resolving discrepancies that are recursively dependent on it. Thus, the distinct approach may tend to be more expensive in exchange for greater robustness.

Examples

```
method,
    multilevel_polynomial_chaos
    expansion_order_sequence = 2
    collocation_ratio = .9
    orthogonal_matching_pursuit
    discrepancy_emulation recursive
```

7.2.68.4.8.323 nodal

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- mf_sc
- sparse_grid_level_sequence
- nodal

Employ a nodal sparse grid construction in stochastic collocation

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** nodal

**Description**

Stochastic collocation with sparse grids can employ either a nodal or hierarchical formulation. The nodal formulation does not require nested interpolation rules and is therefore more generally applicable. However, in the context of adaptive refinement, it can suffer from loss of precision due to subtractive cancellation.
7.2.68.4.8.324 hierarchical

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- mf_sc
- sparse_grid_level_sequence
- hierarchical

Employ a hierarchical sparse grid construction

Specification

Alias: none

Argument(s): none

Description

Stochastic collocation with sparse grids can employ either a nodal or hierarchical formulation. The hierarchical formulation requires nested interpolation rules as it utilizes increments in collocation points along with hierarchical weights defined from a hierarchical basis formulation.

This keyword requests the hierarchical formulation, which has benefits for adaptive refinement by supporting direct computation of increments in targeted statistics (e.g. mean, covariance, reliability indices), avoiding loss of precision from subtractive cancellation.

7.2.68.4.8.325 restricted

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- mf_sc
- sparse_grid_level_sequence
- restricted

Restrict the growth rates for nested and non-nested rules can be synchronized for consistency.

Specification

Alias: none

Argument(s): none

Default: restricted (except for generalized sparse grids)
Description

In the quadrature and sparse grid cases, growth rates for nested and non-nested rules can be synchronized for consistency. For a non-nested Gauss rule used within a sparse grid, linear one-dimensional growth rules of \( m = 2l + 1 \) are used to enforce odd quadrature orders, where \( l \) is the grid level and \( m \) is the number of points in the rule. The precision of this Gauss rule is then \( i = 2m - 1 = 4l + 1 \). For nested rules, order growth with level is typically exponential; however, the default behavior is to restrict the number of points to be the lowest order rule that is available that meets the one-dimensional precision requirement implied by either a level \( l \) for a sparse grid (\( i = 4l + 1 \)) or an order \( m \) for a tensor grid (\( i = 2m - 1 \)). This behavior is known as "restricted growth" or "delayed sequences." To override this default behavior in the case of sparse grids, the unrestricted keyword can be used; it cannot be overridden for tensor grids using nested rules since it also provides a mapping to the available nested rule quadrature orders. An exception to the default usage of restricted growth is the dimension_adaptive p_refinement generalized sparse grid case described previously, since the ability to evolve the index sets of a sparse grid in an unstructured manner eliminates the motivation for restricting the exponential growth of nested rules.

7.2.68.4.8.326 unrestricted

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- mf_sc
- sparse_grid_level_sequence
- unrestricted

Override the default restriction of growth rates for nested and non-nested rules that are by defualt synchronized for consistency.

Specification

Alias: none

Argument(s): none

Description

In the quadrature and sparse grid cases, growth rates for nested and non-nested rules can be synchronized for consistency. For a non-nested Gauss rule used within a sparse grid, linear one-dimensional growth rules of \( m = 2l + 1 \) are used to enforce odd quadrature orders, where \( l \) is the grid level and \( m \) is the number of points in the rule. The precision of this Gauss rule is then \( i = 2m - 1 = 4l + 1 \). For nested rules, order growth with level is typically exponential; however, the default behavior is to restrict the number of points to be the lowest order rule that is available that meets the one-dimensional precision requirement implied by either a level \( l \) for a sparse grid (\( i = 4l + 1 \)) or an order \( m \) for a tensor grid (\( i = 2m - 1 \)). This behavior is known as "restricted growth" or "delayed sequences." To override this default behavior in the case of sparse grids, the unrestricted keyword can be used; it cannot be overridden for tensor grids using nested rules since it also provides a mapping to the available nested rule quadrature orders. An exception to the default usage of restricted growth is the dimension_adaptive p_refinement generalized sparse grid case described previously, since the ability to evolve the index sets of a sparse grid in an unstructured manner eliminates the motivation for restricting the exponential growth of nested rules.
Enforce use of nested quadrature rules if available

**Specification**

Enforce use of nested quadrature rules if available. For instance if the aleatory variables are Gaussian use the Nested Genz-Keister rule instead of the default non-nested Gauss-Hermite rule variables are

**non_nested**

*Alias:* none

*Argument(s):* none

**Description**

Enforce use of non-nested quadrature rules
Description

Enforce use of non-nested quadrature rules if available. For instance if the aleatory variables are Gaussian use the non-nested Gauss-Hermite rule

7.2.68.4.8.329 piecewise

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- mf_sc
- piecewise

Use piecewise local basis functions

Specification

Alias: none
Argument(s): none
Default: extended (Askey + numerically-generated)

Description

SC also supports the option of piecewise local basis functions. These are piecewise linear splines, or in the case of gradient-enhanced interpolation via the use_derivatives specification, piecewise cubic Hermite splines. Both of these basis selections provide local support only over the range from the interpolated point to its nearest 1D neighbors (within a tensor grid or within each of the tensor grids underlying a sparse grid), which exchanges the fast convergence of global bases for smooth functions for robustness in the representation of nonsmooth response functions (that can induce Gibbs oscillations when using high-order global basis functions). When local basis functions are used, the usage of nonequidistant collocation points (e.g., the Gauss point selections described above) is not well motivated, so equidistant Newton-Cotes points are employed in this case, and all random variable types are transformed to standard uniform probability space.

7.2.68.4.8.330 askey

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- mf_sc
- askey

Select the standardized random variables (and associated basis polynomials) from the Askey family that best match the user-specified random variables.
Specification

**Alias:** none

**Argument(s):** none

**Default:** extended (Askey + numerically-generated)

**Description**

The Askey option employs standard normal, standard uniform, standard exponential, standard beta, and standard gamma random variables in a transformed probability space. These selections correspond to Hermite, Legendre, Laguerre, Jacobi, and generalized Laguerre orthogonal polynomials, respectively.

Specific mappings for the basis polynomials are based on a closest match criterion, and include Hermite for normal (optimal) as well as bounded normal, lognormal, bounded lognormal, gumbel, frechet, and weibull (sub-optimal); Legendre for uniform (optimal) as well as loguniform, triangular, and bin-based histogram (sub-optimal); Laguerre for exponential (optimal); Jacobi for beta (optimal); and generalized Laguerre for gamma (optimal).

**See Also**

These keywords may also be of interest:

- `polynomial_chaos`
- `wiener`

Use standard normal random variables (along with Hermite orthogonal basis polynomials) when transforming to a standardized probability space.

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** extended (Askey + numerically-generated)

**Description**

The Wiener option employs standard normal random variables in a transformed probability space, corresponding to a Hermite orthogonal polynomial basis. This is the same nonlinear variable transformation used by local and global reliability methods (and therefore has the same variable support).
See Also

These keywords may also be of interest:

- polynomial_chaos
- askey

7.2.68.4.8.332 use_derivatives

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- mf_sc
- use_derivatives

Use derivative data to construct surrogate models

Specification

**Alias:** none

**Argument(s):** none

**Default:** use function values only

Description

The `use_derivatives` flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, its use with Surfpack Gaussian process is not recommended.

7.2.68.4.8.333 diagonal_covariance

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- mf_sc
- diagonal_covariance

Display only the diagonal terms of the covariance matrix
7.2 method

Specification

Alias: none
Argument(s): none
Default: diagonal_covariance for response vector > 10; else full_covariance

Description

With a large number of responses, the covariance matrix can be very large. diagonal_covariance is used to suppress the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

7.2.68.4.8.334 full_covariance

- Keywords Area
- method
- bayes_calibration
- dream
- emulator
- mf_sc
- full_covariance

Display the full covariance matrix

Specification

Alias: none
Argument(s): none

Description

With a large number of responses, the covariance matrix can be very large. full_covariance is used to force Dakota to output the full covariance matrix.

7.2.68.4.9 standardized_space

- Keywords Area
- method
- bayes_calibration
- dream
- standardized_space

Perform Bayesian inference in standardized probability space

Specification

Alias: none
Argument(s): none
Keywords Area

Description

This option transforms the inference process (MCMC sampling and any emulator model management) into a standardized probability space.

The variable transformations performed are as described in `askey`.

Default Behavior

The default for the Gaussian process and no emulator options is to perform inference in the original probability space (no transformation). Polynomial chaos and stochastic collocation emulators, on the other hand, are always formed in standardized probability space, such that the inference process is also performed in this standardized space.

Expected Output

The user will see the truth model evaluations performed in the original space, whereas any method diagnostics relating to the MCMC samples (e.g., QUESO data in the outputData directory) will report points and response data (response gradients and Hessians, if present, will differ but response values will not) that correspond to the transformed space.

Usage Tips

Selecting `standardized_space` generally has the effect of scaling the random variables to be of comparable magnitude, which can improve the efficiency of the Bayesian inference process.

Examples

```dakota
method,
  bayes_calibration queso
  samples = 2000 seed = 348
dram
  standardized_space

7.2.68.4.10  export_chain_points_file

  • Keywords Area
  • method
  • bayes_calibration

<th>Dakota Keyword Description</th>
</tr>
</thead>
</table>
Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```plaintext
environment
tabular_data
  tabular_data_file = 'dakota_summary.dat'
custom_annotated header eval_id
```

Resulting tabular file:

```plaintext
%eval_id x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 0.9 1.1 0.0002 0.26 0.76
2 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...
```

Selects annotated tabular file format

**Topics**

This keyword is related to the topics:

- file_formats

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** annotated

**Description**

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

**Default Behavior**

By default, Dakota imports and exports tabular files in annotated format. The `annotated` keyword can be used to explicitly specify this.

**Usage Tips**
• To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify `custom_annotated` header eval_id.

• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```plaintext
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
annotated
```

Resulting tabular file:

```
%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 NO_ID 0.9 1.1 0.0002 0.26 0.76
2 NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 NO_ID 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...
```

7.2.6.4.10.6 freeform

• Keywords Area
  • method
  • bayes_calibration
  • dream
  • export_chain_points_file
  • freeform

Selects freeform file format.

Topics

This keyword is related to the topics:

• file_formats

Specification

Alias: none

Argument(s): none

Default: annotated
Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```dakota
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    freeform

Resulting tabular file:

<p>| | | | | |</p>

### Description

The muq method supports the following MCMC algorithms: adaptive metropolis (AM), Metropolis Hasting (MH), delayed rejection (DR), or delayed-rejection adaptive metropolis (DRAM).

The muq method is currently an experimental method that relies on algorithms from MIT’s MUQ code documented at: [https://bitbucket.org/mituq/muq2/src/master/](https://bitbucket.org/mituq/muq2/src/master/)

We anticipate using more advanced features of MUQ such as Hamiltonian Monte Carlo and Langevin methods in future releases of Dakota.

### 7.2.68.5.1 chain_samples

- **Keywords Area**
- **method**
- **bayes_calibration**
3034 Keywords Area

- muq
- chain_samples

Number of Markov Chain Monte Carlo posterior samples

**Specification**

**Alias:** samples

**Argument(s):** INTEGER

**Default:** method-dependent

**Description**

The `chain_samples` keyword indicates the number of draws from the posterior distribution to perform. When an emulator is active, this will be the number of samples on the constructed surrogate model.

**Default Behavior**

The default number of chain samples is method-dependent. QUESO and MUQ methods use 1000. DREAM uses (number of generations) x (number of chains), resulting in chain_samples close to that specified.

**Usage Tips**

MCMC methods typically require a large number of chain samples to converge, often thousands to millions.

**Examples**

```
method bayes_calibration queso
  chain_samples = 20000
```

7.2.68.5.2 seed

- Keywords Area
- method
- bayes_calibration
- muq
- seed

Seed of the random number generator

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** system-generated (non-repeatable)
Description

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior
If not specified, the seed is randomly generated.

Expected Output
If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips
If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

7.2.68.5.3 rng

- Keywords Area
- method
- bayes_calibration
- muq
- rng

Selection of a random number generator

Specification

- **Alias:** none
- **Argument(s):** none
- **Default:** Mersenne twister (mt19937)

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional Required (Choose One)</th>
<th>Description of Group RNG Algorithm (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>mt19937</td>
<td>Generates random numbers using the Mersenne twister</td>
</tr>
</tbody>
</table>
**Description**

The `rng` keyword is used to indicate a choice of random number generator.

**Default Behavior**

If specified, the `rng` keyword must be accompanied by either `rnum2` (pseudo-random numbers) or `mt19937` (random numbers generated by the Mersenne twister). Otherwise, `mt19937`, the Mersenne twister is used by default.

**Usage Tips**

The default is recommended, as the Mersenne twister is a higher quality random number generator.

**Examples**

```plaintext
method	sampling
  sample_type lhs
  samples = 10
  seed = 98765
  rng rnum2
```

**7.2.68.5.3.1 mt19937**

- Keywords Area
- method
- bayes_calibration
- muq
- rng
- mt19937

Generates random numbers using the Mersenne twister

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The `mt19937` keyword directs Dakota to use the Mersenne twister to generate random numbers. Additional information can be found on wikipedia: [http://en.wikipedia.org/wiki/Mersenne_twister](http://en.wikipedia.org/wiki/Mersenne_twister).

**Default Behavior**

`mt19937` is the default random number generator. To specify it explicitly in the Dakota input file, however, it must be specified in conjunction with the `rng` keyword.

**Usage Tips**

Use of the Mersenne twister random number generator (`mt19937`) is recommended.
Examples

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng mt19937
```

7.2.68.5.3.2  rnum2

- Keywords Area
- method
- bayes_calibration
- muq
- rng
- rnum2

Generates pseudo-random numbers using the Pecos package

Specification

**Alias:** none

**Argument(s):** none

Description

The `rnum2` keyword directs Dakota to use pseudo-random numbers generated by the Pecos package.

**Default Behavior**

`rnum2` is not used by default. To change this behavior, it must be specified in conjunction with the `rng` keyword.

**Usage Tips**

Use of the Mersenne twister random number generator (`mt19937`) is recommended over `rnum2`.

Examples

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2
```

7.2.68.5.4  dram

- Keywords Area
- method
- bayes_calibration
- muq
- dram

Use the DRAM MCMC algorithm
This keyword is related to the topics:

- bayesian_calibration

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** dram

**Description**

The type of Markov Chain Monte Carlo used. This keyword specifies the use of DRAM, (Delayed Rejection Adaptive Metropolis) [40].

**Default Behavior**

Five MCMC algorithm variants are supported: dram, delayed_rejection, adaptive_metropolis, metropolis_hastings, and multilevel. The default is dram.

**Usage Tips**

If the user knows very little about the proposal covariance, using dram is a recommended strategy. The proposal covariance is adaptively updated, and the delayed rejection may help improve low acceptance rates.

**Examples**

```plaintext
method, bayes_calibration queso
dram
samples = 10000 seed = 348
```

**7.2.68.5.5 delayed_rejection**

- **Keywords Area**

- **method**

- **bayes_calibration**

- **muq**

- **delayed_rejection**

Use the Delayed Rejection MCMC algorithm

**Topics**

This keyword is related to the topics:

- bayesian_calibration
Specification

**Alias:** none  
**Argument(s):** none  
**Default:** dram

**Description**

This keyword specifies the use of the Delayed Rejection algorithm in which there can be a delay in rejecting samples from the chain. That is, the "DR" part of DRAM is used but the "AM" part is not, rather a regular Metropolis-Hastings algorithm is used.

**Default Behavior**

Five MCMC algorithm variants are supported: dram, delayed_rejection, adaptive_metropolis, metropolis_hastings, and multilevel. The **default** is dram.

**Usage Tips**

If the user knows something about the proposal covariance or the proposal covariance is informed through derivative information, using delayed_rejection is preferred over dram: the proposal covariance is already being informed by derivative information and the adaptive metropolis is not necessary.

**Examples**

```plaintext
method,  
bayes_calibration queso  
delayed_rejection  
samples = 10000 seed = 348
```

**See Also**

These keywords may also be of interest:

- proposal_covariance

7.2.68.5.6 adaptive_metropolis

- Keywords Area
- method
- bayes_calibration
- muq
- adaptive_metropolis

Use the Adaptive Metropolis MCMC algorithm

**Topics**

This keyword is related to the topics:

- bayesian_calibration
Specification

Alias: none
Argument(s): none
Default: dram

Description

This keyword specifies the use of the Adaptive Metropolis algorithm. That is, the "AM" part of DRAM is used but the "DR" part is not: specifying this keyword activates only the Adaptive Metropolis part of the MCMC algorithm, in which the covariance of the proposal density is updated adaptively.

Default Behavior

Five MCMC algorithm variants are supported in QUESO: dram, delayed_rejection, adaptive_metropolis, metropolis_hastings, and multilevel. The default is dram.

Four MCMC variants are currently supported in MUQ: dram, delayed_rejection, metropolis_hastings and adaptive_metropolis.

Usage Tips

If the user knows very little about the proposal covariance, but doesn’t want to incur the cost of using full dram with both delayed rejection and adaptive metropolis, specifying only adaptive_metropolis offers a good strategy.

Examples

```python
method,
    bayes_calibration queso
    adaptive_metropolis
    samples = 10000 seed = 348
```

7.2.68.5.7 metropolis_hastings

- Keywords Area
- method
- bayes_calibration
- muq
- metropolis_hastings

Use the Metropolis-Hastings MCMC algorithm

Topics

This keyword is related to the topics:

- bayesian_calibration

Specification

Alias: none
Argument(s): none
Default: dram
Description

This keyword specifies the use of a Metropolis-Hastings algorithm for the MCMC chain generation. This means there is no delayed rejection and no adaptive proposal covariance updating as in DRAM.

Default Behavior

Five MCMC algorithm variants are supported currently in QUESO: dram, delayed_rejection, adaptive_metropolis, metropolis_hastings, and multilevel. The default is dram.

Four MCMC algorithm variants are currently supported in MUQ: dram, delayed_rejection, metropolis_hastings and adaptive_metropolis.

Usage Tips

If the user wants to use Metropolis-Hastings, possibly as a comparison to the other methods which involve more chain adaptation, this is the MCMC type to use.

Examples

```
method,
   bayes_calibration queso
   metropolis_hastings
   samples = 10000 seed = 348
```

7.2.68.5.8 proposal_covariance

- Keywords Area
- method
- bayes_calibration
- muq
- proposal_covariance

Defines the technique used to generate the MCMC proposal covariance.

Topics

This keyword is related to the topics:

- bayesian_calibration

Specification

Alias: none
Argument(s): none
Child Keywords:
### Description

The proposal covariance is used to define a multivariate normal (MVN) jumping distribution used to create new points within a Markov chain. That is, a new point in the chain is determined by sampling within a MVN probability density with prescribed covariance that is centered at the current chain point. The accuracy of the proposal covariance has a significant effect on rejection rates and the efficiency of chain mixing.

#### Default Behavior

The default proposal covariance is `prior` when no emulator is present; `derivatives` when an emulator is present.

#### Expected Output

The effect of the proposal covariance is reflected in the MCMC chain values and the rejection rates, which can be seen in the diagnostic outputs from the QUESO solver within the `QuesoDiagnostics` directory.

#### Usage Tips

When derivative information is available inexpensively (e.g., from an emulator model), the derived-based proposal covariance forms a more accurate proposal distribution, resulting in lower rejection rates and faster chain mixing.

7.2.68.5.8.1 `prior`

- **Keywords Area**
- **method**
- **bayes_calibration**
- **muq**
- **proposal_covariance**
- **prior**

Uses the covariance of the prior distributions to define the MCMC proposal covariance.
7.2 method 3043

Topics

This keyword is related to the topics:

- bayesian_calibration

Specification

Alias: none

Argument(s): none

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>multiplier</td>
<td>Multiplier to scale prior variance</td>
</tr>
</tbody>
</table>

Description

This keyword selection results in definition of the MCMC proposal covariance from the covariance of the prior distributions. This covariance is currently assumed to be diagonal without correlation.

Default Behavior

This is the default proposal_covariance option.

Usage Tips

Since this proposal covariance is defined globally, the chain does not need to be periodically restarted using local updates to this proposal. However, it is usually effective to adapt the proposal using one of the adaptive metropolis MCMC options.

Examples

```
method,
    bayes_calibration queso
    samples = 2000  seed = 348
    dram
    proposal_covariance prior
```

7.2.68.5.8.2 multiplier

- Keywords Area
- method
- bayes_calibration
- muq
- proposal_covariance
- prior
- multiplier

Multiplier to scale prior variance
Specification

**Alias:** none

**Argument(s):** REAL

**Default:** 1.0

**Description**

The initial proposal covariance will be given by the prior variance times the multiplier.

**Default Behavior**

When using prior-based proposal covariance, the default is to use the prior variance for the proposal (multiplier = 1.0)

**Usage Tips**

The prior variance may result in too tight or narrow a proposal covariance. The multiplier can be used to scale all entries of the prior variance in determining the initial proposal covariance.

**Examples**

```
method
  bayes_calibration queso
    samples = 2000 seed = 348
    dram
    proposal_covariance prior
    multiplier 0.1
```

**7.2.68.5.8.3 derivatives**

- **Keywords Area**
- **method**
- **bayes_calibration**
- **muq**
- **proposal_covariance**
- **derivatives**

Use derivatives to inform the MCMC proposal covariance.

**Topics**

This keyword is related to the topics:

- **bayesian_calibration**

**Specification**

**Alias:** none

**Argument(s):** none

**Child Keywords:**
### Description

This keyword selection results in definition of the MCMC proposal covariance from the Hessian of the misfit function (negative log likelihood), where this Hessian is defined from either a Gauss-Newton approximation (using only first derivatives of the calibration terms) or a full Hessian (using values, first derivatives, and second derivatives of the calibration terms). If this Hessian is indeterminate, it will be corrected as described in [16].

**Default Behavior** The default is prior based proposal covariance. This is a more advanced option that exploits structure in the form of the likelihood.

### Expected Output

When derivatives are specified for defining the proposal covariance, the misfit Hessian and its inverse (the MVN proposal covariance) will be output to the standard output stream.

### Usage Tips

The full Hessian of the misfit is used when either supported by the emulator in use (for PCE and surfpack GP, but not SC or dakota GP) or by the user's response specification (Hessian type is not "no_hessians"), in the case of no emulator. When this full Hessian is indefinite and cannot be inverted to form the proposal covariance, fallback to the positive semi-definite Gauss-Newton Hessian is employed.

Since this proposal covariance is locally accurate, it should be updated periodically using the `update_period` option. While the adaptive metropolis option can be used in combination with derivative-based preconditioning, it is generally preferable to instead decrease the proposal update period due to the improved local accuracy of this approach.

### Examples

Generate a 2000 sample posterior chain, using derivatives to initialize the proposal covariance at the start of the chain.

```bash
method,
  bayes_calibration queso
  samples = 2000 seed = 348
  delayed_rejection
  emulator pce sparse_grid_level = 2
  proposal_covariance derivatives
```

#### 7.2.68.5.8.4 `update_period`

- **Keywords Area**
  - method
  - bayes_calibration
  - muq
  - proposal_covariance
  - derivatives
  - update_period

Period at which to update derivative-based proposal covariance
### Specification

**Alias:** none  
**Argument(s):** INTEGER

### Description

For derivative-based proposal covariance, this specifies the period (number of accepted MCMC samples) after which the proposal covariance is updated using derivative values at the current chain point.

#### Default Behavior

When `update_period` is not specified, derivatives will inform the proposal covariance at the start of the chain, but not updated further.

#### Usage Tips

The `update_period` should be tailored to the size of the total chain, accounting for the relative expense of derivative-based proposal updates.

### Examples

```plaintext
method, bayes_calibration queso
  samples = 2000 seed = 348
  delayed_rejection
  emulator pce sparse_grid_level = 2
  proposal_covariance derivatives
    update_period = 40  # update proposal covariance every 40 points
```

### 7.2.68.5.8.5 values

- Keywords Area
- method
- bayes_calibration
- muq
- proposal_covariance
- values

Specifies matrix values to use as the MCMC proposal covariance.

### Specification

**Alias:** none  
**Argument(s):** REALIST

**Child Keywords:**
### Description

This keyword selection results in definition of the MCMC proposal covariance from user-specified matrix values. The matrix input format must be declared as either a full matrix or a matrix diagonal.

### Default Behavior

This option is not the default, and generally implies special a priori knowledge from the user.

### Usage Tips

This option is not supported for the case of transformations to standardized probability space.

### Examples

```plaintext
method,
  bayes_calibration queso
    samples = 1000 seed = 348
    dram
    proposal_covariance
      values ... # See leaf nodes for required format option
```

### 7.2.68.5.8.6 diagonal

- Keywords Area
- method
- bayes_calibration
- muq
- proposal_covariance
- values
- diagonal

Specifies the diagonal matrix format when specifying a user-specified proposal covariance.

### Specification

**Alias:** none

**Argument(s):** none
Description

When specifying the MCMC proposal covariance in an input file, this keyword declares the use of a diagonal matrix format, i.e., the user only provides the (positive) values along the diagonal.

Examples

```plaintext
method,
   bayes_calibration queso
   samples = 1000 seed = 348
   dram
   proposal_covariance
      diagonal values 1.0e6 1.0e-1
```

7.2.68.5.8.7  matrix

- Keywords Area
- method
- bayes_calibration
- muq
- proposal_covariance
- values
- matrix

Specifies the full matrix format when specifying a user-specified proposal covariance.

Specification

**Alias:** none

**Argument(s):** none

Description

When specifying the MCMC proposal covariance in an input file, this keyword declares the use of a full matrix format, i.e., the user provides all values of the matrix, not just the diagonal. The matrix must be symmetric, positive-definite.

Examples

```plaintext
method,
   bayes_calibration queso
   samples = 1000 seed = 348
   dram
   proposal_covariance
      matrix values 1.0 0.1
                  0.1 2.0
```

7.2.68.5.8.8  filename

- Keywords Area
- method
- bayes_calibration
• muq
• proposal_covariance
• filename

Uses a file to import a user-specified MCMC proposal covariance.

**Specification**

**Alias:** none

**Argument(s):** STRING

**Child Keywords:**

<table>

<td>matrix</td>
<td>matrix</td>
<td>Specifies the full matrix format when importing a user-specified proposal covariance.</td>
</tr>
</tbody>
</table>

**Description**

This keyword selection results in definition of the MCMC proposal covariance from importing data a user-specified filename. This import must be declared as either a full matrix or a matrix diagonal.

**Default Behavior**

This option is not the default, and generally implies special a priori knowledge from the user.

**Usage Tips**

This option is not supported for the case of transformations to standardized probability space.

**Examples**

```plaintext
method,
    bayes_calibration queso
    samples = 1000 seed = 348
    dram
    proposal_covariance
    filename ... # See leaf nodes for required format option
```

7.2.68.5.8.9 diagonal

• **Keywords Area**
  • method
• bayes_calibration
• muq
• proposal_covariance
• filename
• diagonal

Specifies the diagonal matrix format when importing a user-specified proposal covariance.

Specification

Alias: none
Argument(s): none

Description

When importing the MCMC proposal covariance from a user-specified filename, this keyword declares the use of a diagonal matrix format, i.e., the user only provides the (positive) values along the diagonal.

Examples

method,
    bayes_calibration queso
    samples = 1000 seed = 348
dram
    proposal_covariance
        diagonal filename 'dakota_cantilever_queso.diag.dat'

7.2.68.5.8.10 matrix

• Keywords Area
• method
• bayes_calibration
• muq
• proposal_covariance
• filename
• matrix

Specifies the full matrix format when importing a user-specified proposal covariance.

Specification

Alias: none
Argument(s): none

Description

When importing the MCMC proposal covariance from a user-specified filename, this keyword declares the use of a full matrix format, i.e., the user provides all values of the matrix, not just the diagonal. The matrix must be symmetric, positive-definite.
Examples

```
method, bayes_calibration queso
    samples = 1000 seed = 348
dram
    proposal_covariance
        matrix filename 'dakota_cantilever_queso.matrix.dat'
```

</tbody>
</table>
Description

This “experimental design” algorithm uses responses produced by a high-fidelity model as data to update the parameters of a low-fidelity model using Bayes’ Rule. It is a capability that is under active development and is currently compatible only with queso. The user-specified high-fidelity model should depend only on configuration variables (i.e. design conditions), such as temperature or spatial location, while the user-specified low-fidelity model should depend on both configuration variables and its own model parameters to be calibrated.

The algorithm starts with a preliminary Bayesian calibration using the number of data points specified in initial_samples. These data points can be read in through the calibration_data_file command in the responses block. If num_experiments is less than initial_samples or if no such data file is provided, Latin Hypercube Samples of the design space (specified in the variables block) will be run through the user-specified high-fidelity code to supplement the initial data. Once this first calibration is complete, a set of possible experimental design conditions, specified using the configuration variables, is proposed. The user specifies the size of this set using num_candidates. The set of candidates itself may be explicitly given through the import_candidate_points_file command. If the number of candidates in this file is less than num_candidates, or if this file is omitted, the set of candidate designs will again be supplemented with a Latin Hypercube Sample of the design space.

For each candidate design \( \xi_i \) in the set of possible design conditions, the mutual information (MI) between the low-fidelity model parameters \( \theta \) and the high-fidelity model response \( y(\xi_i) \),

\[
MI = \int \int f(\theta, y(\xi)) \log \frac{f(\theta, y(\xi))}{f(\theta) f(y(\xi))} d\theta dy,
\]

is approximated. The high-fidelity model is replaced by the low-fidelity model and a \( k \)-nearest neighbor approximation is used in the calculation. The design point \( \xi^* \) for which MI is the largest is selected and run through the high-fidelity model to yield a new observation \( y(\xi^*) \). This new observation is added to the calibration data, and a subsequent Bayesian calibration is performed. A new MI for each remaining candidate design is computed, and the process repeats until one of three stopping criteria are met. Multiple optimal designs may be selected concurrently by specifying batch_size.

Of the three stopping criteria, two are automatically checked by Dakota. If the relative change in the MI from one iteration to the next is sufficiently small or if the set of candidate design conditions has been exhausted, the algorithm terminates. The user may specify the third stopping criteria using max_hifi_evaluations. This limits the number of high-fidelity model evaluations that will be performed during this algorithm. It therefore limits the number of iterations through the algorithm that will be performed. Any high-fidelity model runs needed to produce the data set for the initial calibration are not included in this allocation.

In the case that the high-fidelity model must be run independently of Dakota, the user may set max_hifi_evaluations to zero. The optimal experimental design point will be calculated and reported, but the high-fidelity model will not be run. For more details, see the User’s Manual.

Expected Output

Information regarding the progress and termination condition of the experimental design algorithm is output to the screen with varying levels of verbosity. Further details can be found, regardless of verbosity, in the output file experimental_design_output.txt

Usage Tips

Due to the optional file read-ins and the supplemental sampling, it is important for the user to check consistency within the input file specifications. For example, if num_experiments is less than the number of experiments in the calibration_data_file, only the first lines of the file will be used and the rest will be discarded. The same holds true for the import_candidate_points_file and num_candidates.
Examples

The input file below illustrates the use of experimental_design and its options

```plaintext
bayes_calibration
  queso
dram
  chain_samples = 1000 seed = 348
experimental_design
  initial_samples = 5
  num_candidates = 10
  import_candidate_points_file = "bayes_experimental_design.cand.dat"
  freeform
  max_hifi_evaluations = 3
```

7.2.68.6.1 initial_samples

- Keywords Area
- method
- bayes_calibration
- experimental_design
- initial_samples

Number of data points used during initial Bayesian calibration

Specification

Alias: samples
Argument(s): INTEGER
Default: method-dependent

Description

The experimental design algorithm starts with a preliminary Bayesian calibration. The keyword initial_samples specifies the number of data points used during this initial calibration. These data points may come from external data sources through calibration_data_file, from an LHS sample of the design space, or both.

7.2.68.6.2 num_candidates

- Keywords Area
- method
- bayes_calibration
- experimental_design
- num_candidates

Number of candidate design points considered
Specification

Alias: none
Argument(s): INTEGER
Default: 1

Description

After the initial Bayesian calibration, a set of candidate design points is created, from which the optimal design(s) will be chosen. This set is of size num_candidates. These candidate points may be specified by the user through import_candidate_points_file, from an LHS sample of the design space, or both.

7.2.68.6.3 max_hifi_evaluations

- Keywords Area
- method
- bayes_calibration
- experimental_design
- max_hifi_evaluations

Maximum number of high-fidelity model runs to be used

Specification

Alias: none
Argument(s): INTEGER

Description

There are three stopping criteria by which the Bayesian experimental design algorithm will be terminated:

- The high-fidelity model has been run max_hifi_evaluations times
- The set of candidate design points have been exhausted
- The relative change in the mutual information from one iteration to the next is sufficiently small The first criterion is controlled by this keyword specification

Default Behavior

If no maximum number of high-fidelity model runs is specified, only the last two stopping criteria listed above will be evaluated.

Usage Tips

Be wary that max_hifi_evaluations does not include any high-fidelity model evaluations that need to be run to produce the data set for the initial Bayesian calibration. This number only includes those evaluations performed on the sequentially chosen optimal design points

If max_hifi_evaluations is set to zero, the a single optimal experimental design point will be selected, and Dakota will exit without running the high-fidelity model.
7.2.68.6.4  batch_size

- Keywords Area

- method

- bayes_calibration

- experimental_design

- batch_size

Number of optimal designs selected concurrently

Specification

Alias: none

Argument(s): INTEGER

Description

Each iteration of the experimental_design algorithm yields batch_size optimal designs. If max_hifi is set to zero, these values will merely be reported in Dakota output and the file experimental_design_output.txt. Otherwise, the high-fidelity model will be run at all optimal designs, and the responses will be added to the list of experiment data before the Bayesian calibration is performed in the next iteration of the algorithm.

Default Behavior

By default, optimal designs will be selected one at a time.

7.2.68.6.5  import_candidate_points_file

- Keywords Area

- method

- bayes_calibration

- experimental_design

- import_candidate_points_file

Specify text file containing candidate design points

Specification

Alias: none

Argument(s): STRING

Default: no point import from a file

Child Keywords:
### Description
Enables text file import of user-specified design points (i.e. configuration variables). No model responses should be included. Each row should correspond to a single design or configuration.

### Default Behavior
By default, methods do not import points from a file.

### Usage Tips
Dakota parses input files without regard to whitespace, but the `import_build_points_file` must be in one of three formats:

- annotated (default)
- custom_annotated
- freeform

#### 7.2.68.6.5.1 custom_annotated

Dakota Version 6.16 Reference Manual generated on May 12, 2022
### Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

### Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

### Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

### Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
  tabular_data_file = 'dakota_summary.dat'
  custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id   x1   x2   obj_fn  nln_ineq_con_1  nln_ineq_con_2
1          0.9  1.1  0.0002  0.26          0.76
2          0.90009 1.1  0.0001996404857 0.2601620081 0.759955
3          0.89991 1.1  0.0002003604863 0.2598380081 0.760045
...```

7.2.68.6.5.5  annotated

- Keywords Area
- method
- bayes_calibration
- experimental_design
- import_candidate_points_file
- annotated

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none
Default: annotated
Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id
- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```environment
tabular_data
  tabular_data_file = 'dakota_summary.dat'
annotated
```

Resulting tabular file:

```%
%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 NO_ID 0.9 1.1 0.0002 0.26 0.76
2 NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 NO_ID 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...```

7.2.68.6.5.6 freeform

- Keywords Area
- method
- bayes_calibration
- experimental_design
- import_candidate_points_file
- freeform

Selects freeform file format

Topics

This keyword is related to the topics:

- file_formats
7.2 method

Specification

**Alias:** none

**Argument(s):** none

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
  tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

```
  0.9  1.1  0.0002  0.26  0.76
  0.90009  1.1  0.0001996404857  0.2601620081  0.759955
  0.89991  1.1  0.0002003604863  0.2598380081  0.760045
  ...
```

7.2.68.6.6 ksg2

- **Keywords Area**
- **method**
- **bayes_calibration**
- **experimental_design**
- **ksg2**

Use second Kraskov algorithm to compute mutual information
This algorithm is derived in [58]. The mutual information between \( m \) random variables is approximated by

\[
I_2(\mathbf{X}) = \psi(k) + (m - 1)\psi(N) - (m - 1)/k - \langle \psi(n_{x_1}) + \psi(n_{x_2}) + \ldots + \psi(n_{x_m}) \rangle,
\]

where \( \psi \) is the digamma function, \( k \) is the number of nearest neighbors being used, and \( N \) is the number of samples available for the joint distribution of the random variables. For each point \( z_i = (x_{1i}, x_{2i}, \ldots, x_{mi}) \) in the joint distribution, \( z_i \) and its \( k \) nearest neighbors are projected into each marginal subspace. For each subspace \( j = 1, \ldots, m \), \( \epsilon_j \) is defined as the radius of the \( l_\infty \)-ball containing all \( k + 1 \) points. Then, \( n_{x_ji} \) is the number of points in the \( j \)-th subspace within a distance of \( \epsilon_{ji} \) from the point \( x_{ji} \). The angular brackets denote that the average of \( \psi(n_{x_{ji}}) \) is taken over all points \( i = 1, \ldots, N \).

**Examples**

```plaintext
method bayes_calibration
dram
seed = 34785
chain_samples = 1000
posterior_stats mutual_info
ksg2
```

```plaintext
method bayes_calibration
queso
dram
chain_samples = 1000 seed = 348
experimental_design
initial_samples = 5
num_candidates = 10
max_hifi_evaluations = 3
ksg2
```

7.2.68.7 calibrate_error_multipliers

- Keywords Area
- method
- bayes_calibration
- calibrate_error_multipliers

Calibrate hyper-parameter multipliers on the observation error covariance

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** none

**Child Keywords:**
### Description

Calibrate one or more multipliers on the user-provided observation error covariance (\texttt{experiment_variance_\text{-type})}. Options include one multiplier on the whole block-diagonal covariance structure, one multiplier \texttt{per\text{-experiment}} covariance block, one multiplier \texttt{per\_response} covariance block, or separate multipliers for each response/experiment pair (for a total of number experiments X number response groups).

**Default Behavior:** No hyper-parameter calibration. When hyper-parameter calibration is enabled, the default prior on the multiplier is a diffuse inverse gamma, with mean and mode approximately 1.0.

**Expected Output:** Final calibration results will include both inference parameters and one or more calibrated hyper-parameters.

**Usage Tips:** The \texttt{per\_response} option can be useful when each response has its own measurement error process, but all experiments were gathered with the same equipment and conditions. The \texttt{per\_experiment} option might be used when working with data from multiple independent laboratories.

### Examples

Perform Bayesian calibration with 2 calibration variables and two hyper-parameter multipliers, one per each of two responses. The multipliers are assumed the same across the 10 experiments. The priors on the multipliers are specified using the \texttt{hyperprior\_alphas} and \texttt{hyperprior\_betas} keywords.

```bash
bayes_calibration queso
  samples = 1000  seed = 348
  dram
  calibrate_error_multipliers per_response
    hyperprior_alphas = 27.0
```
hyperprior_betas = 26.0

variables
uniform_uncertain 2
upper_bounds 1e8 10.0

Argument(s): REALLIST

Description

Scale of the prior distribution for calibrated error multipliers. Either a single value or number of hyper-parameters values may be specified.

Defaults to 103.0 (with alpha = 102.0) so mean and mode are approximately 1.0 and standard deviation is about 0.1.
7.2.68.8 burn_in_samples

- Keywords Area
- method
- bayes_calibration
- burn_in_samples

Manually specify the burn in period for the MCMC chain.

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 0

**Description**

The burn in period is the number of samples at the beginning of the MCMC chain that are discarded. The resulting chain is less dependent on the starting point of the chain.

**Default Behavior**

If not specified, no MCMC samples are discarded

**Expected Output**

If `burn_in_samples` is specified, an additional tabular output file containing the final MCMC chain is generated.

**Examples**

Generate a chain of length 1000 and discard the first 100 points, resulting in a chain of length 900.

```plaintext
method, bayes_calibration queso
  chain_samples = 1000 seed = 348
dram
  proposal_covariance
    diagonal values 1.0e6 1.0e-1
burn_in_samples 100
```

7.2.68.9 posterior_stats

- Keywords Area
- method
- bayes_calibration
- posterior_stats

Compute information-theoretic metrics on posterior parameter distribution
Specification

Alias: none
Argument(s): none

<tr>
<td>Optional</td>
<td>mutual_info</td>
<td>Calculate the mutual information between prior and posterior</td>
</tr>
<tr>
<td>Optional</td>
<td>kde</td>
<td>Calculate the Kernel Density Estimate of the posterior distribution</td>
</tr>
</tbody>
</table>

**Description**

Information theory allows for the calculation and quantification of the information contained within a distribution. It is particularly useful for distributions which are not Gaussian, such as those which are bimodal or highly skewed. The `posterior_stats` command calculates information metrics relating to the posterior distribution of the model parameters. These metrics are approximated by making use of the MCMC chain produced during the Bayesian update. This capability can be used with any Bayesian method.

7.2.68.9.1 kl_divergence

- **Keywords Area**
  - method
  - bayes_calibration
  - posterior_stats
  - kl_divergence

Calculate the Kullback-Leibler Divergence between prior and posterior

**Specification**

**Alias**: none

**Argument(s)**: none

**Description**

The Kullback-Leibler (KL) Divergence, also called the relative entropy, provides a measure of the difference between two probability distributions. By specifying `kl_divergence`, the KL Divergence between the posterior \( f(\theta | y_{\text{Data}}) \) and the prior \( f(\theta) \) parameter distributions is calculated such that

\[
D_{KL} = \int f(\theta | y_{\text{Data}}) \log \frac{f(\theta | y_{\text{Data}})}{f(\theta)} d\theta
\]
This quantity can be interpreted as the amount of information gained about the parameters during the Bayesian update.

**Expected Output**

If `kl_divergence` is specified, the calculated value will be reported to the screen at the end of the calibration, following the sample statistics of the response functions. Example output is given below.

**Additional Discussion**

The quantity calculated is a $k$-nearest neighbor approximation of the possibly multi-dimensional integral given above. Therefore, some applications whose true KL Divergence is quite close to zero may report a negative KL Divergence.

**Examples**

Below is a method block of a Dakota input file that indicates the calculation of the KL Divergence

```plaintext
method,
   bayes_calibration queso
dram
   seed = 34785
   chain_samples = 1000
   posterior_stats kl_divergence
```

- method
- bayes_calibration
- posterior_stats
- mutual_info

Calculate the mutual information between prior and posterior

**Specification**

**Alias:** none

**Argument(s):** none

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
</table>

Dakota Version 6.16 Reference Manual generated on May 12, 2022
**Description**

The mutual information quantifies how much information two random variables contain about each other. It is a measure of the mutual dependence of two random variables. The mutual information is a non-negative measure, with zero representing complete independence of the two random variables. For continuous random variables \( X \) and \( Y \), the mutual information is

\[
I(X,Y) = \int \int p(x,y) \log \frac{p(x,y)}{p(x)p(y)} \, dx \, dy.
\]

The mutual information can also be interpreted as the reduction in uncertainty of one random variable due to the knowledge of another. By specifying, `mutual_info`, the mutual information between the posterior parameters and the prior parameters is calculated.

The mutual information is calculated using a \( k \)-nearest neighbor approximation algorithm. As of Dakota 6.6, there are two such algorithms available, both of which are derived in [58]. By default, Dakota uses the first such algorithm; the second may be selected by specifying the keyword `ksg2`. Further details can be found in the Dakota Theory Manual [16].

**Expected Output**

If `mutual_information` is specified, the calculated value will be reported to the screen at the end of the calibration.

**Additional Discussion**

Due to the necessary approximation of the multidimensional integral above, a negative mutual information may be reported for applications whose true value is close to or equal to zero. As of Dakota 6.6, mutual information calculations are primarily used in the implementation of the `experimental_design` algorithm.

**Examples**

```plaintext
method
  bayes_calibration queso
dram
  seed = 34785
  chain_samples = 1000
  posterior_stats mutual_info

7.2.68.9.2.1 ksg2
  • Keywords Area
  • method
  • bayes_calibration
  • posterior_stats
  • mutual_info
  • ksg2

Use second Kraskov algorithm to compute mutual information
```

Dakota Version 6.16 Reference Manual generated on May 12, 2022
This algorithm is derived in [58]. The mutual information between $m$ random variables is approximated by

$$I_2(X_1, X_2, \ldots, X_m) = \psi(k) + (m - 1)\psi(N) - (m - 1)/k - \langle \psi(n_{x_1}) + \psi(n_{x_2}) + \ldots + \psi(n_{x_m}) \rangle,$$

where $\psi$ is the digamma function, $k$ is the number of nearest neighbors being used, and $N$ is the number of samples available for the joint distribution of the random variables. For each point $z_i = (x_{i,1}, x_{i,2}, \ldots, x_{i,m})$ in the joint distribution, $z_i$ and its $k$ nearest neighbors are projected into each marginal subspace. For each subspace $j = 1, \ldots, m$, $\varepsilon_{j,i}$ is defined as the radius of the $l_\infty$-ball containing all $k + 1$ points. Then, $n_{x_j,i}$ is the number of points in the $j$-th subspace within a distance of $\varepsilon_{j,i}$ from the point $x_{j,i}$. The angular brackets denote that the average of $\psi(n_{x_j,i})$ is taken over all points $i = 1, \ldots, N$.

Examples

7.2.68.9.3 kde

- Keywords Area
- method
- bayes_calibration
- posterior_stats
- kde

Calculate the Kernel Density Estimate of the posterior distribution
A kernel density estimate (KDE) is a non-parametric, smooth approximation of the probability density function of a random variable. It is calculated using a set of samples of the random variable. If $X$ is a univariate random variable with unknown density $f$ and independent and identically distributed samples $x_1, x_2, \ldots, x_n$, the KDE is given by

$$ \hat{f} = \frac{1}{nh} \sum_{i=1}^{n} K \left( \frac{x - x_i}{h} \right). $$

The kernel $K$ is a non-negative function which integrates to one. Although the kernel can take many forms, such as uniform or triangular, Dakota uses a normal kernel. The bandwidth $h$ is a smoothing parameter that should be optimized. Choosing a large value of $h$ yields a wide KDE with large variance, while choosing a small value of $h$ yields a choppy KDE with large bias. Dakota approximates the bandwidth using Silverman’s rule of thumb,

$$ h = \hat{\sigma} \left( \frac{4}{3n} \right)^{1/5}, $$

where $\hat{\sigma}$ is the standard deviation of the sample set $\{x_i\}$.

For multivariate cases, the random variables are treated as independent, and a separate KDE is calculated for each.

**Expected Output**

If `kde` is specified, calculated values of $\hat{f}$ will be output to the file `kde_posterior.dat`. Example output is given below.

**Examples**

Below is a `method` block of a Dakota input file that indicates the calculation of the KDE

```plaintext
method,
   bayes_calibration queso
dram
   seed = 34785
   chain_samples = 1000
   posterior_stats kde
```

The calculated KDE values are output to the file `kde_posterior.dat`, as shown below

<table>

<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>confidence_intervals</td>
<td>Calculate the confidence intervals on estimates of first and second moments</td>
</tr>
</tbody>
</table>

Description

While a Markov chain produced via Monte Carlo sampling eventually converges to a set of samples representative of an underlying probability distribution, the first set of samples may not accurately capture the target distribution. Chain diagnostic metrics provide measures of this convergence, and are intended to help users decide whether samples should be increased in Bayesian calibration exercises.

7.2.68.10.1 confidence_intervals

• Keywords Area
• method
• bayes_calibration
• chain_diagnostics
• confidence_intervals

Calculate the confidence intervals on estimates of first and second moments

Specification

Alias: none
Argument(s): none

Description

During Bayesian calibration, a chain of samples is produced, which represents the underlying posterior distribution of model parameters. For each parameter sample, the corresponding model response is computed. The confidence_intervals keyword indicates the calculation of a 95% confidence interval on the estimated mean and variance of each parameter and each response.

As of Dakota 6.10, these confidence intervals are calculated using the asymptotically valid interval estimator,

\[ \hat{g}_n \pm t_\alpha \frac{\hat{\sigma}_n}{\sqrt{n}} \]

where \( \hat{g}_n \) is the moment (i.e. mean or variance), \( t_\alpha \) is the Student’s \( t \)-value for the 95th quantile, \( n \) is the sample size, and \( \hat{\sigma}_n \) is an estimate of the standard error whose square is obtained using batch means estimation. The Markov
chain produced during calibration is broken up into “batches,” the sample moment is calculated for each batch, and \( \hat{\sigma}_n \) is an unbiased estimate of the standard deviation in these batch moment calculations.

**Expected Output**

If `confidence_intervals` is specified, the 95% confidence interval for the mean and variance for each parameter and for each response will be output to the screen. If `output` is set to `debug`, the mean of the moment calculated for each batch will also be output to the screen.

**Additional Discussion**

Confidence intervals may be used to indicate to the user whether samples needs to be increased during the Bayesian calibration. For example, if the width of the intervals (one, many, or all) is below some threshold value, that may indicate that enough samples have been drawn.

**Examples**

Below is a method block of a Dakota input file that indicates the calculation of confidence intervals

```plaintext
method,
  bayes_calibration queso
dram
    seed = 34785
chain_samples = 1000
  chain_diagnostics
    confidence_intervals
```

The calculated confidence intervals are output to the screen under “Chain diagnostics”:

```

**7.2.68.11 model_evidence**

- **Keywords Area**
- **method**
- **bayes_calibration**
- **model_evidence**

Calculate model evidence (marginal likelihood of model) when using Bayesian methods
Model evidence is used in Bayesian model selection and model averaging. It is defined as the probability of the data given the model, and is calculated by averaging the likelihood of the model parameters over all values of the model parameters according to their prior distributions. In Dakota, one must calculate the model evidence separately for each model and perform the normalization to obtain the posterior model plausibility for each model.

Default Behavior
When specifying `model_evidence`, there are two methods of calculating it. One or both may be specified. They include the Monte Carlo approximation, given by `mc_approx` and the Laplace approximation, given by `laplace_approx`. `mc_approx` is the default approach.

Expected Output Currently, the model evidence will be printed in the screen output with prefacing text indicating if it is calculated by Monte Carlo sampling or the Laplace approximation.

Usage Tips

7.2.68.11.1 mc_approx

- Keywords Area
- method
- bayes_calibration
- model_evidence
- mc_approx

Calculate model evidence using a Monte Carlo sampling approach
**Argument(s):** none

**Description**

The `mc_approx` keyword for model evidence indicates that sample values will be generated from the prior distribution, and then the simulation model will be evaluated at these sample values to obtain corresponding likelihood values. The average of the likelihood weighted by the prior is the model evidence. The accuracy of this approximation depends on the number of samples taken, which is specified by the `evidence_samples` keyword.

**Default Behavior**

If `evidence_samples` is not specified with `mc_approx`, Dakota uses the number of chain samples from the MCMC (`chain_samples`) as the number of samples to use for calculating the model evidence.

**Expected Output**

Currently, the model evidence will be printed in the screen output with prefacing text indicating if it is calculated by Monte Carlo sampling.

**Usage Tips**

### 7.2.68.11.2 evidence_samples

- **Keywords Area**
- **method**
- **bayes_calibration**
- **model_evidence**
- **evidence_samples**

The number of samples used in Monte Carlo approximation of the model evidence.

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Description**

The `mc_approx` keyword for model evidence indicates that sample values will be generated from the prior distribution, and then the simulation model will be evaluated at these sample values to obtain corresponding likelihood values. The average of the likelihood weighted by the prior is the model evidence. The accuracy of this approximation depends on the number of samples taken, which is specified by the `evidence_samples` keyword. Note that each sample specified by the `evidence_samples` keyword will require an evaluation of the simulation model to compute the corresponding likelihood. So, this may become costly for expensive simulations. Additionally, many prior samples will have very low (near zero) likelihood, so millions of samples may be required for accurate computation of the integral which defines model evidence.

**Default Behavior**

If `evidence_samples` is not specified with `mc_approx`, Dakota uses the number of chain samples from the MCMC (`chain_samples`) as the number of samples to use for calculating the model evidence.

**Expected Output**

Currently, the model evidence will be printed in the screen output with prefacing text indicating if it is calculated by Monte Carlo sampling.

**Usage Tips**
7.2.68.11.3 laplace_approx

- Keywords Area
- method
- bayes_calibration
- model_evidence
- laplace_approx

Calculate model evidence using the Laplace approximation

Specification

Alias: none
Argument(s): none

Description

The `laplace_approx` keyword for model evidence indicates that a pre-solve will be used prior to the Bayesian MCMC sampling to estimate the Maximum A Posteriori (MAP) point. The Laplace approximation assumes the posterior density is nearly Gaussian and is given by a formula which involves the likelihood at the MAP point, the prior density at the MAP point, and the Hessian of the log-posterior at the MAP point. The formula is given in the Dakota User's manual. This method is efficient at estimating the model evidence for posterior densities with weak non-Gaussian characteristics but it does require a MAP solve (so pre-solve should be specified) and it does require gradient and Hessians of the response to be on.

Default Behavior

Expected Output Currently, the model evidence will be printed in the screen output with prefacing text indicating if it is calculated by the Laplace approximation.

Usage Tips

**Description**

The goal of parameter calibration is to minimize the difference between experimental data, \( d(x) \), and model observations, \( M(\theta, x) \), where \( \theta \) are the model parameters and \( x \) is a configuration variable, such as temperature or pressure. However, it is not uncommon that, at the conclusion of parameter calibration, the agreement between experimental data and the calibrated model is not "close enough." This is often due to model form or structural error. In this case, the canonical equation

\[
d(x) = M(\theta, x) + \varepsilon
\]

is replaced by one that also includes model discrepancy \( \delta(x) \),

\[
d(x) = M(\theta, x) + \delta(x) + \varepsilon.
\]

In the Dakota implementation, the calculation of \( \delta(x) \) is performed after the model parameters \( \theta \) are calibrated. For each observable \( d_i \), the discrepancy

\[
\delta_i(x_j) = d_i(x_j) - M_i(\theta^*, x_j)
\]

is calculated for each value \( x_j \) of the configuration variable, where \( \theta^* \) is the optimal parameter value obtained during the calibration. For scalar responses, the model discrepancy is only a function of the configuration variables, and
there is one discrepancy regression model for each observable $d_i$. This set of discrepancy models may be specified to be either Gaussian process or polynomial regression models of constant, linear, or quadratic order, and each model is fit to the calculated discrepancy values. See the `discrepancy_type` command for more details regarding these options. For field responses, the model discrepancy is a function of the configuration variables as well as the independent field coordinates (such as time or space), and there is one discrepancy regression model for each field. In this case, the discrepancy models are Gaussian process models. The calculation of model discrepancy has not been tested for cases in which responses are mixed scalar and field responses.

The user may then specify new or “prediction” configurations at which the corrected model $M(\theta^*,x_{\text{new}}) + \delta(x_{\text{new}})$ should be calculated, using one of the `num_prediction_configs`, `prediction_configs`, or `import_prediction_configs` keywords. If none of these keywords is specified, the number of prediction configurations is set to 10 for scalar responses. The corresponding prediction variances are also calculated, according to

$$\Sigma_{\text{total}}(x) = \Sigma_{\delta}(x) + \sigma^2_{\text{exp}} I.$$  

Here, $\Sigma_{\delta}(x)$ is the (co)variance calculated from the Gaussian process or polynomial regression model, and $\sigma^2_{\text{exp}}$ is the maximum variance, taken over all configuration variables for that observation. In the case of field responses, the default prediction configurations are set equal to the input configurations, and the variance information contains only the variance calculated from the Gaussian process correction model. Further details can be found in the Dakota User’s and Theory Manuals.

### Usage Tips

For field responses, the keyword `read_field_coordinates` must be specified when computing the model discrepancy. See `field_calibration_terms` for more information regarding options for calibration with field responses.

### Expected Output

The resulting values of $\delta(x_{\text{new}})$ will be exported to the file specified using `export_discrepancy_file` or to the default file `dakota_discrepancy_tabular.dat`. The values of the corrected model at the specified prediction configurations will be exported to the file specified using `export_corrected_model_file` or to the default file `dakota_corrected_model_tabular.dat`, and the corresponding prediction variances will be exported to `dakota_discrepancy_variance_tabular.dat` or the file specified with `export_corrected_variance_file`.

### Examples

Extensive examples can be found in the Dakota User’s and Theory Manuals. The input files below illustrate the options available to `model_discrepancy`:

```plaintext

</tbody>
</table>

Description

After the model parameters are calibrated, the difference between the data and the calibrated model, i.e. the model discrepancy, is calculated

\[
\delta_i(x_j) = d_i(x_j) - M_i(\theta^*, x_j).
\]

Each \(\delta_i\) corresponds to a different regression model. These regression models must all be either Gaussian process or polynomial models, and they are functions of the configuration variable \(x\). The order of the trend function may be selected using the `correction_order` command by specifying `constant`, `linear`, or `quadratic`.

Note that for Dakota 6.9 and earlier, this keyword only applies to discrepancy calculations for scalar responses. For field responses, a Gaussian process model with a quadratic function is used by default.

7.2.68.12.1.1 gaussian_process

- Keywords Area
  - method
  - bayes_calibration
  - model_discrepancy
  - discrepancy_type
  - gaussian_process

Use the Surfpack version of Gaussian process as the discrepancy model
Specification

</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>trend_order</td>
<td>Trend function order of the model discrepancy</td>
</tr>
</tbody>
</table>

Description

This keyword specifies a generic version of the Gaussian process implemented in the surface-fitting library called Surfpack. With the exception of the correction_order specification, all default options are used in the approximation of the model discrepancy function. That is, DIRECT is used as the optimization method for finding the maximum likelihood estimates of the hyper-parameters that govern the trend and correlation functions, the correlation lengths are optimized by Surfpack, and ill-conditioning is handled internally; gradient-enhanced kriging is not provided as an option in this application.

By selecting this option, each discrepancy function will take the form of a Gaussian process.

7.2.68.12.1.2 trend_order

- Keywords Area
- method
- bayes_calibration
- model_discrepancy
- discrepancy_type
- gaussian_process
- trend_order

Trend function order of the model discrepancy

Specification

Alias: none

Argument(s): INTEGER

Default: 2

Description

The order of the trend function may be specified using the trend_order command, followed by either 0, for which a constant trend function will be used, 1, for which a linear trend function will be used, or 2, for which a quadratic trend function will be used.

Default Behavior

By default, a quadratic trend function is used.
Use a polynomial surrogate as the discrepancy model

**Specification**

<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>basis_order</td>
<td>Basis function order of the model discrepancy</td>
</tr>
</tbody>
</table>

**Description**

For the purposes of model discrepancy, constant, linear, and quadratic polynomial surrogate models are available. These models are less expensive to calculate than Gaussian process models but are consequently less flexible to discrepancy trends that are not constant, linear, or quadratic in nature. For more information, see the Dakota User’s and Theory Manuals.

By specifying this command, each discrepancy function will take the form of a polynomial regression. They will all have the same order.
Specification

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** 2  

**Description**

The order of the polynomial for the model discrepancy may be specified using the `basis_order` command, followed by either 0, for which a constant polynomial will be used, 1, for which a linear polynomial will be used, or 2, for which a quadratic polynomial will be used.

**Default Behavior**

By default, a quadratic polynomial is used.

7.2.68.12.2  num_prediction_configs

- **Keywords Area**
- **method**
- **bayes_calibration**
- **model_discrepancy**
- **num_prediction_configs**

Specify number of prediction locations for model discrepancy

**Specification**

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** 0  

**Description**

Following the calculation of the model discrepancy functions, $\delta_i$, and the corrected model $M_i + \delta_i$ may be calculated at new or “prediction” configurations. Using the `num_prediction_configurations` command, the user may specify the number of prediction configurations they wish to be computed. The new configuration locations will be spread uniformly in the configuration variable domain specified in the `variables` block of the input file.

**Usage Tips**

If none of `num_prediction_configs`, `prediction_configs`, or `import_prediction_configs` is specified, the number of prediction configurations is set to 10 for scalar responses. For field responses, the corrected model will be output at the input values of the configuration variables.

7.2.68.12.3  prediction_configs

- **Keywords Area**

List prediction locations for model discrepancy

Specification

Alias: none

Argument(s): REALLIST

Description

Following the calculation of the model discrepancy functions, $\delta_i$, and the corrected model $M_i + \delta_i$ may be calculated at new or "prediction" configurations. Using the `prediction_configs` command, the user may explicitly list the locations of the prediction configurations they wish to be computed. See parent command for an example.

Usage Tips

If none of `num_prediction_configs`, `prediction_configs`, or `import_prediction_configs` is specified, the number of prediction configurations is set to 10 for scalar responses. For field responses, the corrected model will be output at the input values of the configuration variables.

7.2.68.12.4 import_prediction_configs

- Keywords Area
  - method
  - bayes_calibration
  - model_discrepancy
  - import_prediction_configs

Specify text file containing prediction configurations for model discrepancy

Specification

<th>Required/Optional</th>
<th>Description of Group Tabular Format (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional (Choose One)</td>
<td>annotated</td>
<td>selected</td>
<td>custom_annotated</td>
</tr>
</tbody>
</table>

Selects custom-annotated tabular file format

Selects annotated tabular file format
Keywords Area

| freeform | Selects freeform file format |

Description

Enables text file import of user-specified prediction configurations at which to calculate the corrected model $M_i + \delta_i$.

Usage Tips

Dakota parses input files without regard to whitespace, but the `import_prediction_configs` file must be in one of three formats:

- annotated (default)
- custom_annotated
- freeform

7.2.68.12.4.1 custom_annotated

Specification

**Alias:** none

**Argument(s):** none

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>header</td>
<td></td>
<td>Enable header row in custom-annotated tabular file</td>
</tr>
</tbody>
</table>
Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```plaintext
environment
tabular_data
tabular_data_file = ’dakota_summary.dat’
custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id  x1     x2     obj_fn  nln_ineq_con_1  nln_ineq_con_2
1  0.9    1.1  0.0002    0.26    0.76
2  0.90009 1.1  0.0001996404857 0.2601620081 0.759955
3  0.89991 1.1  0.0002003604863 0.2598380081 0.760045
...

• import_prediction_configs
• annotated

Selects annotated tabular file format

Topics
This keyword is related to the topics:

• file_formats

Specification
Alias: none
Argument(s): none
Default: annotated

Description
An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior
By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

• To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id

• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
annotated

Resulting tabular file:

\begin{verbatim}
%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 NO_ID 0.9 1.1 0.0002 0.26 0.76
2 NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955

Selects freeform file format

Topics

This keyword is related to the topics:

• file_formats

Specification

Aliasing: none

Argument(s): none

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior
The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    freeform

Resulting tabular file:
```

<p>| | | | | |</p>

<tbody>
<tr>
<td>Optional (Choose One)</td>
<td>Tabular Format (Group 1)</td>
<td>custom_annotated</td>
<td>Selects custom-annotated tabular file format</td>
</tr>
</tbody>
</table>

**Description**

Enables the user to specify the name and format of the file to which corrected model variance information is output. The file will contain the values of the variances computed at those points specified with `num_predictions`, `prediction_configs`, or `import_prediction_configs`.

For scalar responses, the prediction variance for each observable $d_i$ is calculated according to

$$\Sigma_{total}(x) = \Sigma_{d}(x) + \sigma_{exp}^2.$$  

Here, $\Sigma_{d}(x)$ is the (co)variance calculated from the Gaussian process or polynomial regression model, details of which can be found in the Dakota User’s and Theory Manuals. If experimental variance information is provided for the calibration, the maximum variance found for the observable $d_i$ is used as $\sigma_{exp}^2$. For more details, see the Dakota User’s and Theory Manuals. For field responses, the variance of the discrepancy model alone is output to this file.

**Default Behavior**

If `export_corrected_variance_file` is not specified, information will be automatically output to `dakota_discrepancy_variance_tabular.dat`.

**Usage Tips**

Dakota exports tabular data in one of three formats:

- annotated (default)
- custom_annotated
- freeform

7.2.68.12.7.1 custom_annotated

- Keywords Area
- method
- bayes_calibration
- model_discrepancy
- export_corrected_variance_file
• custom_annotated

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

• file_formats

Specification

Alias: none

Argument(s): none

Child Keywords:

<table>
<thead>

</tr>
<tr>
<td>Optional</td>
<td>interface_id</td>
<td>interface_id</td>
<td>Enable interface ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

Usage Tips

• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.
Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```environment
  tabular_data
  tabular_data_file = 'dakota_summary.dat'
custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id  x1   x2  obj_fn  nln_ineq_con_1  nln_ineq_con_2
1  0.9  1.1  0.0002  0.26  0.76

- export_corrected_variance_file
- annotated

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- file_formats
Specification

Alias: none
Argument(s): none
Default: annotated

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated

Resulting tabular file:

%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1   NO_ID  0.9  1.1  0.0002  0.26  0.76
2   NO_ID  0.90009  1.1  0.0001996404857  0.2601620081  0.759955
3   NO_ID  0.89991  1.1  0.0002003604863  0.2598380081  0.760045
...
```

7.2.68.12.7.6 freeform

- Keywords Area
- method
- bayes_calibration
- model_discrepancy
- export_corrected_variance_file
- freeform

Selects freeform file format
Topics
This keyword is related to the topics:

- file_formats

Specification
Alias: none
Argument(s): none
Default: annotated

Description
A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior
The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples
Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```plaintext
evironment
  tabular_data
  tabular_data_file = 'dakota_summary.dat'
  freeform

Resulting tabular file:

  0.9     1.1    0.0002    0.26    0.76
  0.90009 1.1  0.0001996404857 0.2601620081 0.759955
  0.89991 1.1  0.0002003604863 0.2598380081 0.760045
  ...
```

7.2.68.13 sub_sampling_period

- Keywords Area
Specify a sub-sampling of the MCMC chain

**Specification**

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** 0

**Description**

If a `sub_sampling_period` is specified, the MCMC chain is filtered such that only the sample at the beginning of each period is in the final MCMC chain. The `sub_sampling_period` should therefore be greater than or equal to the correlation length of the samples.

**Default Behavior**

If not specified, all MCMC samples are included in the final chain.

**Expected Output**

If specified, an additional tabular output file containing the final (sub-sampled) MCMC chain is generated.

**Examples**

Generate and then filter a 1000 sample MCMC chain, retaining the first accepted sample and every 100th sample thereafter.

An example method block of a Dakota input file is given below

```dakota
method,
    bayes_calibration queso
    chain_samples = 1000 seed = 348
    dram
    proposal_covariance
diagonal_values 1.0e6 1.0e-1
sub_sampling_period 100
```

**7.2.68.14  probability_levels**

- **Keywords Area**
- **method**
- **bayes_calibration**
- **probability_levels**

Specify probability levels at which to compute credible and prediction intervals
Specification

**Alias:** none

**Argument(s):** REALLIST

**Default:** No CDF/CCDF response levels to compute

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>num_probability_levels</td>
<td>This capability is currently inactive</td>
<td></td>
</tr>
</tbody>
</table>

Description

Credible and prediction intervals of model responses are computed for specified probabilities. Credible intervals are calculated from the response function values corresponding to the final MCMC chain. Calculation of prediction intervals consider these response values as well as the experimental uncertainty, which is specified by the user via the `experiment_variance_type` command.

**Expected Output**

If `probability_levels` is specified, Dakota will create a table containing the credible intervals for each response function. The corresponding table containing the prediction intervals will also be created if a `experiment_variance_type` has been specified. This information is output to the screen and to a file. In addition, the output file contains the means and standard deviations of each response function and Gaussian approximations of the 5/95 credible and prediction intervals, in which the lower bound is two standard deviations below the mean and the upper bound is two standard deviations above the mean.

**Usage Tips**

Only one probability level needs to be specified for each desired interval. Both corresponding end points of the intervals are automatically calculated. For example, if 0.05 is specified, both the 0.05 and 0.95 probability levels are output to the screen and output file.

**Additional Discussion**

Credible intervals propagate uncertainties in parameter density information to the quantity of interest and quantify how well the model fits the provided data. Prediction intervals propagate both parameter and experimental measurement uncertainties and contain the next experimental or simulated observation with the specified probability.

**Examples**

Below is a Dakota input file specifying the calculation of credible and prediction intervals

```dakota
method,
  bayes_calibration queso
  chain_samples = 1000 seed = 348
  dram
  proposal_covariance
diagonal values 1.0e6 1.0e-1
  probability_levels 0.05 0.1
  0.075 0.1
variables,
  uniform_uncertain 2
    upper_bounds 1.e8 10.0
    lower_bounds 1.e6 0.1
    initial_point 2.85e7 2.5
descriptors 'E' 'w'
  continuous_state 4
    initial_state 3 40000 500 1000
descriptors 't' 'R' 'X' 'Y'
```

Dakota Version 6.16 Reference Manual generated on May 12, 2022
interface,
    direct
        analysis_driver = 'mod_cantilever'

responses,
    calibration_terms = 2
    calibration_data_file = 'dakota_cantilever_queso.withsigma.dat'
    freeform
        num_experiments = 10
        experiment_variance_type = 'scalar'
        descriptors = 'stress' 'displacement'
        no_gradients
        no_hessians

The resulting screen output below shows the table of credible and prediction intervals.

7.2.68.14.1 num_probability_levels

- Keywords Area
- method
- bayes_calibration
- probability_levels
- num_probability_levels

This capability is currently inactive

Specification

Alias: none

Argument(s): INTEGERLIST

Default: probability_levels evenly distributed among response functions
7.2.68.15  convergence_tolerance

- Keywords Area
- method
- bayes_calibration
- convergence_tolerance

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The convergence_tolerance specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by convergence_tolerance, then this convergence criterion is satisfied on the current iteration. Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See nl2sol
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

7.2.68.16  max_iterations

- Keywords Area
- method
Number of iterations allowed for optimizers and adaptive UQ methods

**Topics**

This keyword is related to the topics:

- method.independent.controls

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 100 (exceptions: fsu_cvt, local.reliability: 25; global.reliability, interval_est, evidence) / efficient_global: 25*n)

**Description**

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max.iterations` iterations. In cases where there are multiple nested iterations to be controlled, `max.iterations` generally controls the outer-most context.

**Default Behavior**

Default value is 100.

**See Also**

These keywords may also be of interest:

- max.function.evaluations

7.2.68.17  model_pointer

- Keywords Area
- method
- bayes_calibration
- model_pointer

Identifier for model block to be used by a method

**Topics**

This keyword is related to the topics:

- block.pointer
7.2 method

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

Examples

```
environment
    tabular_data
    method_pointer = 'UQ'

method
    id_method = 'UQ'
    model_pointer = 'SURR'
    sampling,
        samples = 10
        seed = 98765 rng rnum2
        response_levels = 0.1 0.2 0.6
            0.1 0.2 0.6
            0.1 0.2 0.6
        sample_type lhs
    distribution cumulative

model
    id_model = 'SURR'
    surrogate global,
        dace_method_pointer = 'DACE'
        polynomial quadratic

method
    id_method = 'DACE'
    model_pointer = 'DACE_M'
    sampling sample_type lhs
        samples = 121 seed = 5034 rng rnum2

model
    id_model = 'DACE_M'
    single
    interface_pointer = 'I1'

variables
    uniform_uncertain = 2
        lower_bounds = 0. 0.
        upper_bounds = 1. 1.
        descriptors = 'x1' 'x2'

interface
    id_interface = 'I1'
    system asynch evaluation_concurrency = 5
```
Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the scaling keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords scale_types and/or *scales in the variables and responses blocks. When the scaling keyword is omitted from method, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

- a *scales keyword, which gives characteristic values (divisors)

- a *scale_types keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in responses for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are three scale types:
1. **value** - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.

2. **auto** - automatic scaling
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   - two-sided bounds scaled into the interval [0,1];
   - one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
   - no bounds or targets: no automatic scaling possible, therefore no scaling for this component

   Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

3. **log** - logarithmic scaling
   First, any characteristic values from the optional *scales specification are applied. Then logarithm base 10 scaling is applied.
   Logarithmic scaling is not available for linear constraints.
   When continuous design variables are log scaled, linear constraints are not allowed.

**Scales**

The *scales keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding *scale_types, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- **auto, log** - optional
- **value** - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10*DBL_MIN$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

**Examples**

The two examples below are equivalent:

```plaintext
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100

responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

### Description

The Distributed Design and Analysis of Computer Experiments (DDACE) library provides the following DACE techniques:

1. **grid sampling** *(grid)*
2. **pure random sampling** *(random)*
3. **orthogonal array sampling** *(oas)*
4. **latin hypercube sampling** *(lhs)*
5. **orthogonal array latin hypercube sampling** *(oa_lhs)*
6. **Box-Behnken** *(box_behnken)*
7. **central composite design** *(central_composite)*

These methods all generate point sets that may be used to drive a set of computer experiments. Note that all of the DACE methods generated randomized designs, except for Box-Behnken and Central composite which are classical designs. That is, the grid sampling will generate a randomized grid, not what one typically thinks of as a grid of uniformly spaced points over a rectangular grid. Similar, the orthogonal array is a randomized version of an orthogonal array: it does not generate discrete, fixed levels.

In addition to the selection of the method, there are keywords that affect the method outputs:

1. **main_effects**
2. **quality_metrics**
3. **variance_based_decomp**

And keywords that affect the sampling:

1. **fixed_seed**
2. **symbols**
3. **samples**
4. **seed**

These keywords may also be of interest:

- fsu_cv
- fsu_quasi_mc
- psuade_moat

7.2.69.1 grid

- Keywords Area
- method
- dace
- grid

Grid Sampling

Specification

Alias: none
Argument(s): none

Description

The grid option in DACE will produce a randomized grid of points. If you are interested in a regular grid of points, use the multidimensional parameter study (under Parameter Studies) instead. Grid Sampling

7.2.69.2 random

- Keywords Area
- method
- dace
- random

Uses purely random Monte Carlo sampling to sample variables

Specification

Alias: none
Argument(s): none
Description

The `random` keyword invokes Monte Carlo sampling as the means of drawing samples of uncertain variables according to their probability distributions.

Default Behavior

In most contexts, Monte Carlo sampling is not the default sampling mode (exception: multilevel_sampling). To change this behavior, the `random` keyword must be specified in conjunction with the `sample_type` keyword.

Usage Tips

Monte Carlo sampling is more computationally expensive than Latin Hypercube Sampling as it requires a larger number of samples to accurately estimate statistics.

Examples

```plaintext
method sampling
   sample_type random
   samples = 200
```

7.2.69.3 oas

- dace
- oas

Orthogonal Array Sampling

Specification

Alias: none
Argument(s): none

Description

Orthogonal array sampling (OAS) is a widely used technique for running experiments and systematically testing factor effects. An orthogonal array sample can be described as a 4-tuple \((m; n; s; r)\), where \(m\) is the number of sample points, \(n\) is the number of input variables, \(s\) is the number of symbols, and \(r\) is the strength of the orthogonal array. The number of sample points, \(m\), must be a multiple of the number of symbols, \(s\). The number of symbols refers to the number of levels per input variable. The strength refers to the number of columns where we are guaranteed to see all the possibilities an equal number of times. Note that the DACE OAS capability produces a randomized orthogonal array: the samples for a particular level are randomized within that level.

If one examines the sample sets in an orthogonal array by looking at the rows as individual samples and columns as the variables sampled, one sees that the columns are orthogonal to each other in an orthogonal array. This feature is important in main effects analysis, which is a sensitivity analysis technique that identifies which variables have the most influence on the output.
Uses Latin Hypercube Sampling (LHS) to sample variables

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The `lhs` keyword invokes Latin Hypercube Sampling as the means of drawing samples of uncertain variables according to their probability distributions. This is a stratified, space-filling approach that selects variable values from a set of equi-probable bins.

**Default Behavior**

Latin Hypercube Sampling is the default sampling mode in most contexts (exception: multilevel_sampling). To explicitly specify LHS in the Dakota input file, the `lhs` keyword must appear in conjunction with the `sample_type` keyword.

**Usage Tips**

Latin Hypercube Sampling is very robust and can be applied to any problem. It is fairly effective at estimating the mean of model responses and linear correlations with a reasonably small number of samples relative to the number of variables.

**Examples**

```dakota
method
  sampling
    sample_type lhs
    samples = 20
```

7.2.69.5 **oa_lhs**

- **oa_lhs**

Orthogonal Array Latin Hypercube Sampling

**Specification**

**Alias:** none

**Argument(s):** none
The Orthogonal Array Latin Hypercube Sampling option in DACE produces a "latinized" version of an orthogonal array. That is, after the orthogonal array is generated, the samples go through a stratification process to produce samples that have been both orthogonalized and stratified.

These keywords may also be of interest:

- oas

Box-Behnken Design

Specification

**Alias**: none

**Argument(s)**: none

**Description**

The Box-Behnken design is similar to a Central Composite design, with some differences. The Box-Behnken design is a quadratic design in that it does not contain an embedded factorial or fractional factorial design. In this design the treatment combinations are at the midpoints of edges of the process space and at the center, as compared with CCD designs where the extra points are placed at 'star points' on a circle outside of the process space. Box-Behnken designs are rotatable (or near rotatable) and require 3 levels of each factor.

Central Composite Design

Specification

**Alias**: none

**Argument(s)**: none
Description

A central composite design (CCD), contains an embedded factorial or fractional factorial design with a center points that is augmented with a group of "star points" that allow estimation of curvature.

Examples

See the User's Manual for an example.

7.2.69.8 samples

- Keywords Area
- method
- dace
- samples

Number of samples for sampling-based methods

Specification

Alias: none
Argument(s): INTEGER
Default: 0

Description

The samples keyword is used to define the number of samples (i.e., randomly chosen sets of variable values) at which to execute a model.

Default Behavior

By default, Dakota will use the minimum number of samples required by the chosen method.

Usage Tips

To obtain linear sensitivities or to construct a linear response surface, at least dim+1 samples should be used, where "dim" is the number of variables. For sensitivities to quadratic terms or quadratic response surfaces, at least (dim+1)(dim+2)/2 samples are needed. For uncertainty quantification, we recommend at least 10+dim samples. For variance_based_decomp, we recommend hundreds to thousands of samples. Note that for variance_based_decomp, the number of simulations performed will be N*(dim+2).

Examples

method sampling
   sample_type lhs
   samples = 20

7.2.69.9 seed

- Keywords Area
- method
Seed of the random number generator

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** system-generated (non-repeatable)

**Description**

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

**Default Behavior**

If not specified, the seed is randomly generated.

**Expected Output**

If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

**Usage Tips**

If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

**Examples**

```dakota
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

**7.2.69.10 fixed_seed**

- **Keywords Area**
- **method**
- **dace**
- **fixed_seed**

Reuses the same seed value for multiple random sampling sets

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** not fixed; pattern varies run-to-run
Description

The fixed_seed flag is relevant if multiple sampling sets will be generated over the course of a Dakota analysis. This occurs when using advance methods (e.g., surrogate-based optimization, optimization under uncertainty). The same seed value is reused for each of these multiple sampling sets, which can be important for reducing variability in the sampling results.

Default Behavior

The default behavior is to not use a fixed seed, as the repetition of the same sampling pattern can result in a modeling weakness that an optimizer could potentially exploit (resulting in actual reliabilities that are lower than the estimated reliabilities). For repeatable studies, the seed must also be specified.

Examples

```dakota
method
  sampling
    sample_type lhs
    samples = 10
    fixed_seed
```

7.2.69.11 main_effects

- Keywords Area
- method
- dace
- main_effects

ANOVA

Specification

Alias: none
Argument(s): none
Default: No main_effects

Description

The main_effects control prints Analysis-of-Variance main effects results (e.g. ANOVA tables with p-values per variable). The main_effects control is only operational with the orthogonal arrays or Latin Hypercube designs, not for Box Behnken or Central Composite designs.

Main effects is a sensitivity analysis method which identifies the input variables that have the most influence on the output. In main effects, the idea is to look at the mean of the response function when variable A (for example) is at level 1 vs. when variable A is at level 2 or level 3. If these mean responses of the output are statistically significantly different at different levels of variable A, this is an indication that variable A has a significant effect on the response. The orthogonality of the columns is critical in performing main effects analysis, since the column orthogonality means that the effects of the other variables "cancel out" when looking at the overall effect from one variable at its different levels.

7.2.69.12 quality_metrics

- Keywords Area
Calculate metrics to assess the quality of quasi-Monte Carlo samples

Topics

This keyword is related to the topics:

- package_fsudace

Specification

Alias: none
Argument(s): none
Default: No quality_metrics

Description

quality_metrics calculates four quality metrics relating to the volumetric spacing of the samples. The four quality metrics measure different aspects relating to the uniformity of point samples in hypercubes. Desirable properties of such point samples are:

- are the points equally spaced
- do the points cover the region
- and are they isotropically distributed
- with no directional bias in the spacing

The four quality metrics we report are:

- h: the point distribution norm, which is a measure of uniformity of the point distribution
- chi: a regularity measure, and provides a measure of local uniformity of a set of points
- tau: the second moment trace measure
- d: the second moment determinant measure

All of these values are scaled so that smaller is better (the smaller the metric, the better the uniformity of the point distribution).

Examples

Complete explanation of these measures can be found in [39].
7.2.69.13  variance_based_decomp

- Keywords Area
- method
- dace
- variance_based_decomp

Activates global sensitivity analysis based on decomposition of response variance into contributions from variables

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** no variance-based decomposition

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>drop_tolerance</td>
<td>Suppresses output of sensitivity indices with values lower than this tolerance</td>
</tr>
</tbody>
</table>

**Description**

Dakota can calculate sensitivity indices through variance based decomposition using the keyword `variance_based_decomp`. These indicate how important the uncertainty in each input variable is in contributing to the output variance.

**Default Behavior**

Because of the computational cost, `variance_based_decomp` is turned off as a default.

If the user specified a number of samples, N, and a number of nondeterministic variables, M, variance-based decomposition requires the evaluation of $N(M+2)$ samples. **Note that specifying this keyword will increase the number of function evaluations above the number requested with the `samples` keyword since replicated sets of sample values are evaluated.**

**Expected Outputs**

When `variance_based_decomp` is specified, sensitivity indices for main effects and total effects will be reported. Main effects (roughly) represent the percent contribution of each individual variable to the variance in the model response. Total effects represent the percent contribution of each individual variable in combination with all other variables to the variance in the model response.

**Usage Tips**

To obtain sensitivity indices that are reasonably accurate, we recommend that N, the number of samples, be at least one hundred and preferably several hundred or thousands.

**Examples**

```
method,
sampling
  sample_type lhs
```
7.2 method

samples = 100
variance_based_decomp

Theory

In this context, we take sensitivity analysis to be global, not local as when calculating derivatives of output variables with respect to input variables. Our definition is similar to that of [76]: "The study of how uncertainty in the output of a model can be apportioned to different sources of uncertainty in the model input."

Variance based decomposition is a way of using sets of samples to understand how the variance of the output behaves, with respect to each input variable. A larger value of the sensitivity index, $S_i$, means that the uncertainty in the input variable $i$ has a larger effect on the variance of the output. More details on the calculations and interpretation of the sensitivity indices can be found in [76] and [90].

7.2.69.13.1 drop_tolerance

- Keywords Area
- method
- dace
- variance_based_decomp
- drop_tolerance

Suppresses output of sensitivity indices with values lower than this tolerance

Specification

Alias: none
Argument(s): REAL
Default: All VBD indices displayed

Description

The drop_tolerance keyword allows the user to specify a value below which sensitivity indices generated by variance_based_decomp are not displayed.

Default Behavior

By default, all sensitivity indices generated by variance_based_decomp are displayed.

Usage Tips

For polynomial_chaos, which outputs main, interaction, and total effects by default, the univariate_effects may be a more appropriate option. It allows suppression of the interaction effects since the output volume of these results can be prohibitive for high dimensional problems. Similar to suppression of these interactions is the covariance control, which can be selected to be diagonal_covariance or full_covariance, with the former supporting suppression of the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

Examples

method,
sampling
  sample_type lhs
  samples = 100
  variance_based_decomp
  drop_tolerance = 0.001
7.2.69.14 symbols

- Keywords Area
- method
- dace
- symbols

Number of replications in the sample set

Specification

Alias: none

Argument(s): INTEGER

Default: default for sampling algorithm

Description

symbols is related to the number of levels per variable in the sample set (a larger number of symbols equates to more stratification and fewer replications). For example, if symbols = 7, each variable would be divided into seven levels.

7.2.69.15 model_pointer

- Keywords Area
- method
- dace
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)
Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.

See block_pointer for details about pointers.

Examples

```plaintext
environment
    tabular_data
    method_pointer = 'UQ'

method
    id_method = 'UQ'
    model_pointer = 'SURR'
    sampling,
        samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
        0.1 0.2 0.6
        0.1 0.2 0.6
        sample_type lhs
    distribution cumulative

model
    id_model = 'SURR'
    surrogate global,
    dace_method_pointer = 'DACE'
    polynomial quadratic

method
    id_method = 'DACE'
    model_pointer = 'DACE_M'
    sampling sample_type lhs

### Description

The FSU Centroidal Voronoi Tessellation method (fsu_cvt) produces a set of sample points that are (approximately) a Centroidal Voronoi Tessellation. The primary feature of such a set of points is that they have good volumetric spacing; the points tend to arrange themselves in a pattern of cells that are roughly the same shape.

To produce this set of points, an almost arbitrary set of initial points is chosen, and then an internal set of iterations is carried out. These iterations repeatedly replace the current set of sample points by an estimate of the centroids of the corresponding Voronoi subregions. [18].

The user may generally ignore the details of this internal iteration. If control is desired, however, there are a few variables with which the user can influence the iteration. The user may specify:

- `max_iterations`, the number of iterations carried out
- `num_trials`, the number of secondary sample points generated to adjust the location of the primary sample points
- `trial_type`, which controls how these secondary sample points are generated

This method generates sets of uniform random variables on the interval [0,1]. If the user specifies lower and upper bounds for a variable, the [0,1] samples are mapped to the [lower, upper] interval.

### Theory

This method is designed to generate samples with the goal of low discrepancy. Discrepancy refers to the nonuniformity of the sample points within the hypercube.

Discrepancy is defined as the difference between the actual number and the expected number of points one would expect in a particular set B (such as a hyper-rectangle within the unit hypercube), maximized over all such sets. Low discrepancy sequences tend to cover the unit hypercube reasonably uniformly.
Centroidal Voronoi Tessellation does very well volumetrically: it spaces the points fairly equally throughout the space, so that the points cover the region and are isotropically distributed with no directional bias in the point placement. There are various measures of volumetric uniformity which take into account the distances between pairs of points, regularity measures, etc. Note that Centroidal Voronoi Tessellation does not produce low-discrepancy sequences in lower dimensions. The lower-dimension (such as 1-D) projections of Centroidal Voronoi Tessellation can have high discrepancy.

  samples = 20
```
7.2.70.2 seed

- Keywords Area
- method
- fsu_cvt
- seed

Seed of the random number generator

Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** system-generated (non-repeatable)

Description

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

**Default Behavior**

If not specified, the seed is randomly generated.

**Expected Output**

If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

**Usage Tips**

If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

**Examples**

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

7.2.70.3 fixed_seed

- Keywords Area
- method
- fsu_cvt
- fixed_seed

Reuses the same seed value for multiple random sampling sets
Specification

Alias: none
Argument(s): none
Default: not fixed; pattern varies run-to-run

Description

The fixed_seed flag is relevant if multiple sampling sets will be generated over the course of a Dakota analysis. This occurs when using advance methods (e.g., surrogate-based optimization, optimization under uncertainty). The same seed value is reused for each of these multiple sampling sets, which can be important for reducing variability in the sampling results.

Default Behavior

The default behavior is to not use a fixed seed, as the repetition of the same sampling pattern can result in a modeling weakness that an optimizer could potentially exploit (resulting in actual reliabilities that are lower than the estimated reliabilities). For repeatable studies, the seed must also be specified.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    fixed_seed
```

Adjust samples to improve the discrepancy of the marginal distributions

Specification

Alias: none
Argument(s): none
Default: No latinization

Description

The latinize control takes the samples and "latinizes" them, meaning that each original sample is moved so that it falls into one strata or bin in each dimension as in Latin Hypercube sampling. The default setting is NOT to latinize. However, one may be interested in doing this in situations where one wants better discrepancy of the 1-dimensional projections (the marginal distributions).
7.2.70.5  quality_metrics

- Keywords Area
- method
- fsu_cvt
- quality_metrics

Calculate metrics to assess the quality of quasi-Monte Carlo samples

Topics

This keyword is related to the topics:

- package_fsudace

Specification

Alias: none
Argument(s): none
Default: No quality_metrics

Description

quality_metrics calculates four quality metrics relating to the volumetric spacing of the samples. The four quality metrics measure different aspects relating to the uniformity of point samples in hypercubes. Desirable properties of such point samples are:

- are the points equally spaced
- do the points cover the region
- and are they isotropically distributed
- with no directional bias in the spacing

The four quality metrics we report are:

- h: the point distribution norm, which is a measure of uniformity of the point distribution
- chi: a regularity measure, and provides a measure of local uniformity of a set of points
- tau: the second moment trace measure
- d: the second moment determinant measure

All of these values are scaled so that smaller is better (the smaller the metric, the better the uniformity of the point distribution).

Examples

Complete explanation of these measures can be found in [39].

Description

Dakota can calculate sensitivity indices through variance based decomposition using the keyword variance_based_decomp. These indicate how important the uncertainty in each input variable is in contributing to the output variance.

Default Behavior

Because of the computational cost, variance_based_decomp is turned off as a default.

If the user specified a number of samples, N, and a number of nondeterministic variables, M, variance-based decomposition requires the evaluation of N*(M+2) samples. Note that specifying this keyword will increase the number of function evaluations above the number requested with the samples keyword since replicated sets of sample values are evaluated.

Expected Outputs

When variance_based_decomp is specified, sensitivity indices for main effects and total effects will be reported. Main effects (roughly) represent the percent contribution of each individual variable to the variance in the model response. Total effects represent the percent contribution of each individual variable in combination with all other variables to the variance in the model response.

Usage Tips

To obtain sensitivity indices that are reasonably accurate, we recommend that N, the number of samples, be at least one hundred and preferably several hundred or thousands.

Examples

```dakota
method,
  sampling
    sample_type lhs
```
Theory

In this context, we take sensitivity analysis to be global, not local as when calculating derivatives of output variables with respect to input variables. Our definition is similar to that of [76] : "The study of how uncertainty in the output of a model can be apportioned to different sources of uncertainty in the model input."

Variance based decomposition is a way of using sets of samples to understand how the variance of the output behaves, with respect to each input variable. A larger value of the sensitivity index, $S_i$, means that the uncertainty in the input variable $i$ has a larger effect on the variance of the output. More details on the calculations and interpretation of the sensitivity indices can be found in [76] and [90].

7.2.70.6.1 drop_tolerance

- Keywords Area
- method
- fsu_cvt
- variance_based_decomp
- drop_tolerance

Suppresses output of sensitivity indices with values lower than this tolerance

Specification

Alias: none

Argument(s): REAL

Default: All VBD indices displayed

Description

The drop_tolerance keyword allows the user to specify a value below which sensitivity indices generated by variance_based_decomp are not displayed.

Default Behavior

By default, all sensitivity indices generated by variance_based_decomp are displayed.

Usage Tips

For polynomial_chaos, which outputs main, interaction, and total effects by default, the univariate_effects may be a more appropriate option. It allows suppression of the interaction effects since the output volume of these results can be prohibitive for high dimensional problems. Similar to suppression of these interactions is the covariance control, which can be selected to be diagonal_covariance or full_covariance, with the former supporting suppression of the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

- trial_type

7.2.70.7.2 halton

- Keywords Area
- method
- fsu_cvt
- trial_type
- halton

Generate samples from a Halton sequence

Topics

This keyword is related to the topics:

- package_fsudace

Specification

Alias: none
Argument(s): none

Description

The quasi-Monte Carlo sequences of Halton are deterministic sequences determined by a set of prime bases. These sequences generate random numbers with the goal of filling a unit hypercube uniformly.

Generally, we recommend that the user leave the default setting for the bases, which are the lowest primes. Thus, if one wants to generate a sample set for 3 random variables, the default bases used are 2, 3, and 5 in the Halton sequence. To give an example of how these sequences look, the Halton sequence in base 2 starts with points 0.5, 0.25, 0.75, 0.125, 0.625, etc. The first few points in a Halton base 3 sequence are 0.33333, 0.66667, 0.11111, 0.44444, 0.77777, etc. Notice that the Halton sequence tends to alternate back and forth, generating a point closer to zero then a point closer to one. An individual sequence is based on a radix inverse function defined on a prime base. The prime base determines how quickly the [0,1] interval is filled in.
Theory

For more information about these sequences, see [44], [45], and [1].

7.2.70.7.3 random

- Keywords Area
- method
- fsu_cvt
- trial_type
- random

Uses purely random Monte Carlo sampling to sample variables

Specification

Alias: none
Argument(s): none

Description

The random keyword invokes Monte Carlo sampling as the means of drawing samples of uncertain variables according to their probability distributions.

Default Behavior

In most contexts, Monte Carlo sampling is not the default sampling mode (exception: multilevel_sampling). To change this behavior, the random keyword must be specified in conjunction with the sample_type keyword.

Usage Tips

Monte Carlo sampling is more computationally expensive than Latin Hypercube Sampling as it requires a larger number of samples to accurately estimate statistics.

Examples

method
sampling
  sample_type random
  samples = 200

7.2.70.8 num_trials

The number of secondary sample points generated to adjust the location of the primary sample points
7.2 method

Specification

Alias: none
Argument(s): INTEGER
Default: 10000

Description

In general, the variable with the most influence on the quality of the final sample set is \texttt{num\_trials}, which determines how well the Voronoi subregions are sampled. Generally, \texttt{num\_trials} should be "large", certainly much bigger than the number of sample points being requested; a reasonable value might be 10,000, but values of 100,000 or 1 million are not unusual.

7.2.70.9 max\_iterations

- Keywords Area
- method
- fsu\_cvt
- max\_iterations

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- method\_independent\_controls

Specification

Alias: none
Argument(s): INTEGER
Default: 100 (exceptions: fsu\_cvt, local\_reliability: 25; global\_\{reliability, interval\_est, evidence\} / efficient\_global: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed \texttt{max\_iterations} iterations. In cases where there are multiple nested iterations to be controlled, \texttt{max\_iterations} generally controls the outer-most context.

Default Behavior

Default value is 100.

See Also

These keywords may also be of interest:

- max\_function\_evaluations
7.2.70.10  model_pointer

- Keywords Area
- method
- fsu_cvt
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.

See block_pointer for details about pointers.

Examples

```plaintext
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'

Morris One-at-a-Time

Topics

This keyword is related to the topics:

- package_psuade

- design_and_analysis_of_computer_experiments

Specification

Alias: none

Argument(s): none

Child Keywords:
Description

The Morris One-At-A-Time (MOAT) method, originally proposed by Morris [64], is a screening method, designed to explore a computational model to distinguish between input variables that have negligible, linear and additive, or nonlinear or interaction effects on the output. The computer experiments performed consist of individually randomized designs which vary one input factor at a time to create a sample of its elementary effects.

The number of samples (samples) must be a positive integer multiple of (number of continuous design variable + 1) and will be automatically adjusted if misspecified.

The number of partitions (partitions) applies to each variable being studied and must be odd (the number of MOAT levels per variable is partitions + 1). This will also be adjusted at runtime as necessary.

For information on practical use of this method, see [76].

Theory

With MOAT, each dimension of a \( k \)-dimensional input space is uniformly partitioned into \( p \) levels, creating a grid of \( p^k \) points \( x \in \mathbb{R}^k \) at which evaluations of the model \( y(x) \) might take place. An elementary effect corresponding to input \( i \) is computed by a forward difference

\[
d_i(x) = \frac{y(x + \Delta e_i) - y(x)}{\Delta},
\]

where \( e_i \) is the \( i \)-th coordinate vector, and the step \( \Delta \) is typically taken to be large (this is not intended to be a local derivative approximation). In the present implementation of MOAT, for an input variable scaled to \([0,1]\), \( \Delta = \frac{p}{2(p-1)} \), so the step used to find elementary effects is slightly larger than half the input range.

The distribution of elementary effects \( d_i \) over the input space characterizes the effect of input \( i \) on the output of interest. After generating \( r \) samples from this distribution, their mean,

\[
\mu_i = \frac{1}{r} \sum_{j=1}^{r} d_i^{(j)}
\]

modified mean

\[
\mu_i^* = \frac{1}{r} \sum_{j=1}^{r} |d_i^{(j)}|,
\]

(using absolute value) and standard deviation

\[
\sigma_i = \sqrt{\frac{1}{r} \sum_{j=1}^{r} (d_i^{(j)} - \mu_i^*)^2}
\]
are computed for each input $i$. The mean and modified mean give an indication of the overall effect of an input on the output. Standard deviation indicates nonlinear effects or interactions, since it is an indicator of elementary effects varying throughout the input space.

7.2.71.1 partitions

- Keywords Area
- method
- psuade_moat
- partitions

Number of partitions of each variable

Specification

Alias: none
Argument(s): INTEGERLIST
Default: 3

Description

Described on the parent page, psuade_moat

7.2.71.2 samples

- Keywords Area
- method
- psuade_moat
- samples

Number of samples for sampling-based methods

Specification

Alias: none
Argument(s): INTEGER
Default: 0

Description

The samples keyword is used to define the number of samples (i.e., randomly chosen sets of variable values) at which to execute a model.

Default Behavior

By default, Dakota will use the minimum number of samples required by the chosen method.

Usage Tips
To obtain linear sensitivities or to construct a linear response surface, at least \( \text{dim} + 1 \) samples should be used, where "\( \text{dim} \)" is the number of variables. For sensitivities to quadratic terms or quadratic response surfaces, at least \( \frac{\text{dim} + 1 \times (\text{dim} + 2)}{2} \) samples are needed. For uncertainty quantification, we recommend at least \( 10 \times \text{dim} \) samples. For \texttt{variance-based_decomp}, we recommend hundreds to thousands of samples. Note that for \texttt{variance-based_decomp}, the number of simulations performed will be \( N \times (\text{dim} + 2) \).

**Examples**

```plaintext
method
  sampling
    sample_type lhs
    samples = 20

7.2.71.3 seed
  • Keywords Area
  • method
  • psuade_moat
  • seed

Seed of the random number generator

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** system-generated (non-repeatable)

**Description**

The random \texttt{seed} control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

**Default Behavior**

If not specified, the seed is randomly generated.

**Expected Output**

If \texttt{seed} is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

**Usage Tips**

If a stochastic study was run without \texttt{seed} specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

**Examples**

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

7.2.72.1 sqp

• Keywords Area

• method

• local_evidence

• sqp

Uses a sequential quadratic programming method for underlying optimization

Specification

**Alias**: none

**Argument(s)**: none

Description

Many uncertainty quantification methods solve a constrained optimization problem under the hood. The sqp keyword directs Dakota to use a sequential quadratic programming method to solve that problem. A sequential quadratic programming solves a sequence of linearly constrained quadratic optimization problems to arrive at the solution to the optimization problem.

7.2.72.2 nip

• Keywords Area

• method

• local_evidence

• nip

Uses a nonlinear interior point method for underlying optimization

Specification

**Alias**: none

**Argument(s)**: none

Description

Many uncertainty quantification methods solve a constrained optimization problem under the hood. The nip keyword directs Dakota to use a nonlinear interior point to solve that problem. A nonlinear interior point method traverses the interior of the feasible region to arrive at the solution to the optimization problem.
7.2.72.3 response_levels

- Keywords Area
  - method
  - local_evidence
  - response_levels

Values at which to estimate desired statistics for each response

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Default:** No CDF/CCDF probabilities/reliabilities to compute

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>num_response_levels</td>
<td></td>
<td>Number of values at which to estimate desired statistics for each response</td>
</tr>
<tr>
<td>Optional</td>
<td>compute</td>
<td></td>
<td>Selection of statistics to compute at each response level</td>
</tr>
</tbody>
</table>

**Description**

The `response_levels` specification provides the target response values for which to compute probabilities, reliabilities, or generalized reliabilities (forward mapping).

**Default Behavior**

If `response_levels` are not specified, no statistics will be computed. If they are, probabilities will be computed by default.

**Expected Outputs**

If `response_levels` are specified, Dakota will create two tables in the standard output: a Probability Density function (PDF) histogram and a Cumulative Distribution Function (CDF) table. The PDF histogram has the lower and upper endpoints of each bin and the corresponding density of that bin. Note that the PDF histogram has bins defined by the `probability_levels` and/or `response_levels` in the Dakota input file. If there are not very many levels, the histogram will be coarse. Dakota does not do anything to optimize the bin size or spacing. The CDF table has the list of response levels and the corresponding probability that the response value is less than or equal to each response level threshold.

**Usage Tips**

The `num_response_levels` is used to specify which arguments of the `response_level` correspond to which response.
Examples

For example, specifying a response_level of 52.3 followed with compute probabilities will result in the calculation of the probability that the response value is less than or equal to 52.3, given the uncertain distributions on the inputs.

For an example with multiple responses, the following specification

```
response_levels = 1. 2. .1 .2 .3 .4 10. 20. 30.
num_response_levels = 2 4 3
```

would assign the first two response levels (1., 2.) to response function 1, the next four response levels (.1, .2, .3, .4) to response function 2, and the final three response levels (10., 20., 30.) to response function 3. If the num_response_levels key were omitted from this example, then the response levels would be evenly distributed among the response functions (three levels each in this case).

The Dakota input file below specifies a sampling method with response levels of interest.

```
method,
  sampling,
    samples = 100 seed = 1
  complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
    6.0e+04 6.5e+04 7.0e+04
    3.5e+05 4.0e+05 4.5e+05
variables,
  normal_uncertain = 2
    means = 248.89, 593.33
    std_deviations = 12.4, 29.7
    descriptors = ’TF1n’ ’TF2n’
  uniform_uncertain = 2
    lower_bounds = 199.3, 474.63
    upper_bounds = 298.5, 712.
    descriptors = ’TF1u’ ’TF2u’
  weibull_uncertain = 2
    alphas = 12., 30.
    betas = 250., 590.
    descriptors = ’TF1w’ ’TF2w’
histogram_bin_uncertain = 2
  num_pairs = 3
  abscissas = 5 8 10 .1 .2 .3 .4
  counts = 17 21 0 12 24 12 0
  descriptors = ’TF1h’ ’TF2h’
histogram_point_uncertain
  real = 1
  num_pairs = 2
  abscissas = 3 4
  counts = 1 1
  descriptors = ’TF3h’
interface,
  system async evaluation_concurrency = 5
  analysis_driver = ’text_book’
responses,
  response_functions = 3
  no_gradients
  no_hessians
```

Given the above Dakota input file, the following excerpt from the output shows the PDF and CCDF generated. Note that the bounds on the bins of the PDF are the response values specified in the input file. The probability levels corresponding to those response values are shown in the CCDF.

```
Probability Density Function (PDF) histograms for each response function:
PDF for response_fn_1:
      Bin Lower       Bin Upper       Density Value
           ---------        ---------            --------------
  2.7604749078e+11  3.6000000000e+11  5.3601733194e-12
```

Dakota Version 6.16 Reference Manual generated on May 12, 2022
Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

A forward mapping involves computing the belief and plausibility probability level for a specified response level.

7.2.72.3.1 num_response_levels

- Keywords Area
- method
- local_evidence
- response_levels
- num_response_levels

Number of values at which to estimate desired statistics for each response

Specification

Alias: none
Argument(s): INTEGERLIST
**Default:** response_levels evenly distributed among response functions

**Description**

The `num_response_levels` keyword allows the user to specify the number of response values, for each response, at which estimated statistics are of interest. Statistics that can be computed are probabilities and reliabilities, both according to either a cumulative distribution function or a complementary cumulative distribution function.

**Default Behavior**

If `num_response_levels` is not specified, the response_levels will be evenly distributed among the responses.

**Expected Outputs**

The specific output will be determined by the type of statistics that are specified. In a general sense, the output will be a list of response level-statistic pairs that show the estimated value of the desired statistic for each response level specified.

**Examples**

```dakota
method
  sampling
    samples = 100
    seed = 34785
    num_response_levels = 1 1 1
    response_levels = 0.5 0.5 0.5

7.2.72.3.2 compute

  • Keywords Area
  • method
  • local_evidence
  • response_levels
  • compute
```

**Selection of statistics to compute at each response level**

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** probabilities

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group Statistics to Compute (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required (Choose One)</td>
<td>probabilities</td>
<td>probabilities</td>
<td>Computes probabilities associated with response levels</td>
</tr>
</tbody>
</table>
### Description

The `compute` keyword is used to select which forward statistical mapping is calculated at each response level.

### Default Behavior

If `response_levels` is not specified, no statistics are computed. If `response_levels` is specified but `compute` is not, probabilities will be computed by default. If both `response_levels` and `compute` are specified, then one of the following must be specified: `probabilities`, `reliabilities`, or `gen_reliabilities`.

### Expected Output

The type of statistics specified by `compute` will be reported for each response level.

### Usage Tips

CDF/CCDF probabilities are calculated for specified response levels using a simple binning approach.

CDF/CCDF reliabilities are calculated for specified response levels by computing the number of sample standard deviations separating the sample mean from the response level.

### Examples

```plaintext
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                     6.0e+04 6.5e+04 7.0e+04
                     3.5e+05 4.0e+05 4.5e+05
  compute reliabilities

7.2.72.3.2.1 probabilities
```

- Keywords Area
- method
- local_evidence
- response_levels
- compute
- probabilities

Computes probabilities associated with response levels
Specification

Alias: none
Argument(s): none

Description

The **probabilities** keyword directs Dakota to compute the probability that the model response will be below (cumulative) or above (complementary cumulative) a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the probabilities are computed by default. To explicitly specify it in the Dakota input file, though, the **probabilities** keyword should be specified in conjunction with the **compute** keyword.

Expected Outputs

The Dakota output is a set of response level-probability pairs that give the probability that the model response will be below or above the corresponding response level, depending on the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
  complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                      6.0e+04 6.5e+04 7.0e+04
                      3.5e+05 4.0e+05 4.5e+05
  compute probabilities
```

7.2.72.3.2.2  **gen_reliabilities**

- **Keywords Area**
- **method**
- **local_evidence**
- **response_levels**
- **compute**
- **gen_reliabilities**

Computes generalized reliabilities associated with response levels

Specification

Alias: none
Argument(s): none

Description

The **gen_reliabilities** keyword directs Dakota to compute generalized reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.
Default Behavior

If `response_levels` is specified, the generalized reliabilities are not computed by default. To change this behavior, the `gen_reliabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-generalized reliability pairs according to the distribution defined.

Examples

```bash
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary_distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
      6.0e+04 6.5e+04 7.0e+04
      3.5e+05 4.0e+05 4.5e+05
  compute gen_reliabilities
```

<td>series</td>
<td>Aggregate response statistics assuming a parallel system</td>
</tr>
<tr>
<td>parallel</td>
<td></td>
<td>Aggregate response statistics assuming a parallel system</td>
<td>parallel</td>
<td></td>
</tr>
</tbody>
</table>

Description

With the system probability/reliability option, statistics for specified `response_levels` are calculated and reported assuming the response functions combine either in series or parallel to produce a total system response.
For a series system, the system fails when any one component (response) fails. The probability of failure is the complement of the product of the individual response success probabilities.

For a parallel system, the system fails only when all components (responses) fail. The probability of failure is the product of the individual response failure probabilities.

Specify probability levels at which to estimate the corresponding response value

Specification

Alias: none
Argument(s): REALLIST
Default: No CDF/CCDF response levels to compute
Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>num_probability_levels</td>
<td>Specify which probability_levels correspond to which response</td>
</tr>
</tbody>
</table>

Description

Response levels are calculated for specified CDF/CCDF probabilities by indexing into a sorted samples array (the response levels computed are not interpolated and will correspond to one of the sampled values).

Expected Output

If probability_levels are specified, Dakota will create two tables in the standard output: a Probability Density function (PDF) histogram and a Cumulative Distribution Function (CDF) table. The PDF histogram has the lower and upper endpoints of each bin and the corresponding density of that bin. Note that the PDF histogram has bins defined by the probability_levels and/or response_levels in the Dakota input file. If there are not very many levels, the histogram will be coarse. Dakota does not do anything to optimize the bin size or spacing. The CDF table has the list of response levels and the corresponding probability that the response value is less than or equal to each response level threshold.

Examples

The Dakota input file below specifies a sampling method with probability levels of interest.

```plaintext
method,  
  sampling,  
  samples = 100 seed = 1  
  complementary distribution  
  probability_levels = 1. .66 .33 0.  
                      1.  .8 .5 0.  
                      1.  .3 .2 0.  

variables,  
  normal_uncertain = 2  
  means = 248.89, 593.33  
  std_deviations = 12.4, 29.7  
  descriptors = 'TF1n' 'TF2n'
```

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).

7.2.72.4.1 num_probability_levels

Specify which probability_levels correspond to which response

Specification

Alias: none

Argument(s): INTEGERLIST

Default: probability_levels evenly distributed among response functions

Description

See parent page

7.2.72.5 gen_reliability_levels

Specify generalized reliability levels at which to estimate the corresponding response value
Specification

Alias: none

Argument(s): REALLIST

Default: No CDF/CCDF response levels to compute

Child Keywords:

<table>
<thead>
<tr>
<th>Optional</th>

|                                        |                                                              | complementary  | Computes statistics according to complementary cumulative functions |

Description

The distribution keyword allows the user to select between a cumulative distribution/belief/plausibility function and a complementary cumulative distribution/belief/plausibility function. This choice affects how probabilities and reliability indices are reported.

Default Behavior

If the distribution keyword is present, it must be accompanied by either cumulative or complementary. Otherwise, a cumulative distribution will be used by default.

Expected Outputs

Output will be a set of model response-probability pairs determined according to the choice of distribution. The choice of distribution also defines the sign of the reliability or generalized reliability indices.

Examples

method
sampling
Computes statistics according to cumulative functions

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

Statistics on model responses will be computed according to a cumulative distribution/belief/plausibility function.

**Default Behavior**

By default, a cumulative distribution/belief/plausibility function will be used. To explicitly specify it in the Dakota input file, however, the `cumulative` keyword must appear in conjunction with the `distribution` keyword.

**Expected Outputs**

Output will be a set of model response-probability pairs determined according to a cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls below given response thresholds.

**Examples**

```plaintext
method
 sampling
  sample_type lhs
  samples = 10
  distribution cumulative
```

Computes statistics according to complementary cumulative functions
Specification

Alias: none
Argument(s): none

Description

Statistics on model responses will be computed according to a complementary cumulative distribution/belief/plausibility function.

Default Behavior

By default, a complementary cumulative distribution/belief/plausibility function will not be used. To change that behavior, the complementary keyword must be appear in conjunction with the distribution keyword.

Expected Outputs

Output will be a set of model response-probability pairs determined according to a complementary cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls above given response thresholds.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    distribution complementary
```

7.2.72.7 model_pointer

- Keywords Area
- method
- local_evidence
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none
Argument(s): STRING
Default: method use of last model parsed (or use of default model if none parsed)
Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

Examples

```plaintext
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
    0.1 0.2 0.6
    0.1 0.2 0.6
  sample_type lhs
  distribution cumulative

model
  id_model = 'SURR'
  surrogate global,
  dace_method_pointer = 'DACE'
  polynomial quadratic

method
  id_method = 'DACE'
  model_pointer = 'DACE_M'
  sampling sample_type lhs
  samples = 121 seed = 5034 rng rnum2

</tbody>
</table>
Optional

| model_pointer | Identifier for model block to be used by a method |

**Description**

Interval analysis using local methods (*local_interval_est*). If the problem is amenable to local optimization methods (e.g., can provide derivatives or use finite difference method to calculate derivatives), then one can use one of two local methods to calculate these bounds.

- sqp
- nip

**Additional Resources**

Refer to *variable_support* for information on supported variable types.

**Theory**

In interval analysis, one assumes that nothing is known about an epistemic uncertain variable except that its value lies somewhere within an interval. In this situation, it is NOT assumed that the value has a uniform probability of occurring within the interval. Instead, the interpretation is that any value within the interval is a possible value or a potential realization of that variable. In interval analysis, the uncertainty quantification problem is one of determining the resulting bounds on the output (defining the output interval) given interval bounds on the inputs. Again, any output response that falls within the output interval is a possible output with no frequency information assigned to it.

**7.2.73.1 sqp**

- Keywords Area
- method
- local_interval_est
- sqp

Uses a sequential quadratic programming method for underlying optimization

**Specification**

**Alias**: none

**Argument(s)**: none
Description

Many uncertainty quantification methods solve a constrained optimization problem under the hood. The sqp keyword directs Dakota to use a sequential quadratic programming method to solve that problem. A sequential quadratic programming solves a sequence of linearly constrained quadratic optimization problems to arrive at the solution to the optimization problem.

7.2.73.2 nip

- Keywords Area
- method
- local_interval_est
- nip

Uses a nonlinear interior point method for underlying optimization

Specification

Alias: none

Argument(s): none

Description

Many uncertainty quantification methods solve a constrained optimization problem under the hood. The nip keyword directs Dakota to use a nonlinear interior point to solve that problem. A nonlinear interior point method traverses the interior of the feasible region to arrive at the solution to the optimization problem.

7.2.73.3 convergence_tolerance

- Keywords Area
- method
- local_interval_est
- convergence_tolerance

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4
The convergence_tolerance specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by convergence_tolerance, then this convergence criterion is satisfied on the current iteration. Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See nl2sol
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

7.2.73.4 model_pointer

- Keywords Area
- method
- local_interval_est
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.
7.2 method

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.

See block_pointer for details about pointers.

**Description**

Local reliability methods compute approximate response function distribution statistics based on specified uncertain variable probability distributions. Each of the local reliability methods can compute forward and inverse mappings involving response, probability, reliability, and generalized reliability levels.

The forward reliability analysis algorithm of computing reliabilities/probabilities for specified response levels is called the Reliability Index Approach (RIA), and the inverse reliability analysis algorithm of computing response levels for specified probability levels is called the Performance Measure Approach (PMA).

The different RIA/PMA algorithm options are specified using the `mpp_search` specification which selects among different limit state approximations that can be used to reduce computational expense during the MPP searches.

**Theory**

The Mean Value method (MV, also known as MVFOSM in [43]) is the simplest, least-expensive method in that it estimates the response means, response standard deviations, and all CDF/CCDF forward/inverse mappings from a single evaluation of response functions and gradients at the uncertain variable means. This approximation can have acceptable accuracy when the response functions are nearly linear and their distributions are approximately Gaussian, but can have poor accuracy in other situations.

All other reliability methods perform an internal nonlinear optimization to compute a most probable point (MPP) of failure. A sign convention and the distance of the MPP from the origin in the transformed standard normal space (“u-space”) define the reliability index, as explained in the section on Reliability Methods in the Uncertainty Quantification chapter of the Users Manual [5]. Also refer to `variable_support` for additional information on supported variable types for transformations to standard normal space. The reliability can then be converted to a probability using either first- or second-order integration, may then be refined using importance sampling, and finally may be converted to a generalized reliability index.

</tbody>
</table>
The x_taylor_mean MPP search option performs a single Taylor series approximation in the space of the original uncertain variables ("x-space") centered at the uncertain variable means, searches for the MPP for each response/probability level using this approximation, and performs a validation response evaluation at each predicted MPP. This option is commonly known as the Advanced Mean Value (AMV) method. The u_taylor_mean option is identical to the x_taylor_mean option, except that the approximation is performed in u-space. The x_taylor_mpp approach starts with an x-space Taylor series at the uncertain variable means, but iteratively updates the Taylor series approximation at each MPP prediction until the MPP converges. This option is commonly
known as the AMV+ method. The \texttt{u_taylor_mpp} option is identical to the \texttt{x_taylor_mpp} option, except that all approximations are performed in u-space. The order of the Taylor-series approximation is determined by the corresponding responses specification and may be first or second-order. If second-order (methods named AMV$^2$ and AMV$^{2+}$ in [22]), the series may employ analytic, finite difference, or quasi Hessians (BFGS or SR1).

The \texttt{x_two_point} MPP search option uses an x-space Taylor series approximation at the uncertain variable means for the initial MPP prediction, then utilizes the Two-point Adaptive Nonlinear Approximation (TANA) outlined in [95] for all subsequent MPP predictions. The \texttt{u_two_point} approach is identical to \texttt{x_two_point}, but all the approximations are performed in u-space. The \texttt{x_taylor_mpp} and \texttt{u_taylor_mpp}, \texttt{x_two_point} and \texttt{u_two_point} approaches utilize the \texttt{max_iterations} and \texttt{convergence_tolerance} method independent controls to control the convergence of the MPP iterations (the maximum number of MPP iterations per level is limited by \texttt{max_iterations}, and the MPP iterations are considered converged when $\| \mathbf{u}^{(k+1)} - \mathbf{u}^{(k)} \|_2 < \texttt{convergence_tolerance}$). And, finally, the \texttt{no_approx} option performs the MPP search on the original response functions without the use of any approximations. The optimization algorithm used to perform these MPP searches can be selected to be either sequential quadratic programming (uses the \texttt{npsol_sqp} optimizer) or nonlinear interior point (uses the \texttt{optpp_q_newton} optimizer) algorithms using the \texttt{sqp} or \texttt{nip} keywords.

In addition to the MPP search specifications, one may select among different integration approaches for computing probabilities at the MPP by using the integration keyword followed by either \texttt{first_order} or \texttt{second_order}. Second-order integration employs the formulation of [51] (the approach of [12] and the correction of [52] are also implemented, but are not active). Combining the \texttt{no_approx} option of the MPP search with first- and second-order integrations results in the traditional first- and second-order reliability methods (FORM and SORM). These integration approximations may be subsequently refined using importance sampling. The refinement specification allows the selection of basic importance sampling (\texttt{import}), adaptive importance sampling (\texttt{adapImporter}), or multimodal adaptive importance sampling (\texttt{mm_adap_import}), along with the specification of number of samples (\texttt{samples}) and random seed (\texttt{seed}). Additional details on these methods are available in [24] and [22] and in the Uncertainty Quantification Capabilities chapter of the Users Manual [5].

Specification

Alias: none
Argument(s): none

Description
This mpp_search option performs a single Taylor series approximation in the transformed space of the uncertain variables ("u-space") centered at the uncertain variable means. This option is commonly known as the Advanced Mean Value (AMV) method, but is performed in u-space instead of x-space.

7.2.74.1.3 x_taylor_mpp

- Keywords Area
- method
- local_reliability
- mpp_search
- x_taylor_mpp

X-space Taylor series approximation with iterative updates

Topics
This keyword is related to the topics:

- reliability_methods

Specification

Alias: none
Argument(s): none
Description

This mpp_search option starts with an x-space Taylor series at the uncertain variable means, but iteratively updates the Taylor series approximation at each MPP prediction until the MPP converges. This option is commonly known as the AMV+ method.

7.2.74.1.4  u_taylor_mpp

- Keywords Area
- method
- local_reliability
- mpp_search
- u_taylor_mpp

U-space Taylor series approximation with iterative updates

Topics

This keyword is related to the topics:

- reliability_methods

Specification

Alias: none

Argument(s): none

Description

This mpp_search option starts with a u-space Taylor series at the uncertain variable means, and iteratively updates the Taylor series approximation at each MPP prediction until the MPP converges. This option is commonly known as the AMV+ method and is identify to x_taylor_mpp except that it is performed in u-space.

7.2.74.1.5  x_two_point

- Keywords Area
- method
- local_reliability
- mpp_search
- x_two_point

Predict MPP using Two-point Adaptive Nonlinear Approximation in "x-space"

Topics

This keyword is related to the topics:

- reliability_methods
7.2 method

Specification

**Alias**: none  
**Argument(s)**: none

**Description**

This mpp_search option uses an x-space Taylor series approximation at the uncertain variable means for the initial MPP prediction, then utilizes the Two-point Adaptive Nonlinear Approximation (TANA) outlined in [Xu98 “Xu and Grandhi, 1998”] for all subsequent MPP predictions.

7.2.74.1.6  **u_two_point**

- **Keywords Area**
- **method**

MPP search for local reliability based on QMEA multi-point approximation in u-space
Local reliability methods that search for the most probable point of failure (MPP) may use a surrogate-based optimization procedure. The \texttt{x\_multi\_point} surrogate option creates a QMEA approximation in the original random variable space ("x-space") from accumulating data from multiple expansion points.

This capability is \textbf{experimental}.

\textbf{7.2.74.1.8 \texttt{u\_multi\_point}}

- \textbf{mpp\_search}
- \textbf{no\_approx}

Perform MPP search on original response functions (use no approximation)

\textbf{Topics}

This keyword is related to the topics:

- \textbf{reliability\_methods}
7.2 method

Specification

Alias: none

Argument(s): none

Description

This mpp_search option performs the MPP search on the original response functions without the use of any approximations. Note that the use of the no_approx MPP search with first-order probability integration results in the traditional reliability method called FORM (First-Order Reliability Method). Similarly, the use of no_approx with second-order probability integration results in SORM (Second-Order Reliability Method).

7.2.74.1.10 sqp

• Keywords Area
• method
• local_reliability
• mpp_search
• sqp

Uses a sequential quadratic programming method for underlying optimization

Specification

Alias: none

Argument(s): none

Description

Many uncertainty quantification methods solve a constrained optimization problem under the hood. The sqp keyword directs Dakota to use a sequential quadratic programming method to solve that problem. A sequential quadratic programming solves a sequence of linearly constrained quadratic optimization problems to arrive at the solution to the optimization problem.

7.2.74.1.11 nip

• Keywords Area
• method
• local_reliability
• mpp_search
• nip

Uses a nonlinear interior point method for underlying optimization

Specification

Alias: none

Argument(s): none
Description

Many uncertainty quantification methods solve a constrained optimization problem under the hood. The nip keyword directs Dakota to use a nonlinear interior point to solve that problem. A nonlinear interior point method traverses the interior of the feasible region to arrive at the solution to the optimization problem.

7.2.74.1.12 integration

- Keywords Area
- method
- local_reliability
- mpp_search
- integration

Integration approach

Topics

This keyword is related to the topics:

- reliability_methods

Specification

Alias: none
Argument(s): none
Default: First-order integration

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>

<td>Allow refinement of probability and generalized reliability results using importance sampling</td>
</tr>
</tbody>
</table>

Description

This keyword controls how the probabilities at the MPP are computed: integration is followed by either first_order or second_order, indicating the order of the probability integration.

7.2.74.1.12.1 first_order

- Keywords Area
- method
First-order integration scheme

Topics
This keyword is related to the topics:

- reliability_methods

Specification

Alias: None
Argument(s): None

Description
First-order integration in local reliability methods uses the minimum Euclidean distance from the origin to the most probable point (MPP) in transformed space to compute the probability of failure. This distance, commonly called the reliability index Beta, is used to calculate the probability of failure by calculating the standard normal cumulative distribution function at -Beta.

Second-order integration scheme

Topics
This keyword is related to the topics:

- reliability_methods

Specification

Alias: None
Argument(s): None
Description

Second-order integration in local reliability methods modifies the first-order integration approach to apply a curvature correction. This correction is based on the formulation of [Hohenbichler and Rackwitz, 1988].

7.2.74.1.12.3 probability_refinement

</tr>
</tbody>
</table>
### Description

The **probability_refinement** allows refinement of probability and generalized reliability results using importance sampling. If one specifies **probability_refinement**, there are some additional options. One can specify which type of importance sampling to use (**import**, **adapt_import**, or **mm_adapt_import**). Additionally, one can specify the number of refinement samples to use with **refinement_samples** and the seed to use with **seed**.

The **probability_refinement** density reweighting accounts originally was developed based on Gaussian distributions. It now accounts for additional non-Gaussian cases.

#### 7.2.74.1.12.4 import

- **Keywords** Area
- **method**
- **local_reliability**
- **mpp_search**
- **integration**
- **probability_refinement**
- **import**

Importance sampling option for probability refinement

#### Specification

**Alias:** none

**Argument(s):** none

#### Description

**import** centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level).

#### 7.2.74.1.12.5 adapt_import

- **Keywords** Area
- **method**
- **local_reliability**
- **mpp_search**
- **integration**
- **probability_refinement**
- **adapt_import**

Importance sampling option for probability refinement
Specification

Alias: none
Argument(s): none

Description

adapt_import centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level). This continues iteratively until the failure probability estimate converges.

7.2.74.1.12.6 mm_adapt_import

- Keywords Area
- method
- local_reliability
- mpp_search
- integration
- probability_refinement
- mm_adapt_import

Importance sampling option for probability refinement

Specification

Alias: none
Argument(s): none

Description

mm_adapt_import starts with all of the samples located in the failure region to build a multimodal sampling density. First, it uses a small number of samples around each of the initial samples in the failure region. Note that these samples are allocated to the different points based on their relative probabilities of occurrence: more probable points get more samples. This early part of the approach is done to search for "representative" points. Once these are located, the multimodal sampling density is set and then mm_adapt_import proceeds similarly to adapt_import (sample until convergence).

7.2.74.1.12.7 refinement_samples

- Keywords Area
- method
- local_reliability
- mpp_search
- integration
- probability_refinement
- refinement_samples

Number of samples used to refine a probability estimate or sampling design.
7.2 method

Specification

**Alias:** none

**Argument(s):** INTEGERLIST

Description

Probability estimate: Specify the (scalar) number of samples used to improve a probability estimate. If using unimodal sampling all samples are assigned to the sampling center. If using multi-modal sampling the samples are split between multiple samples according to some internally computed weights.

Sampling design: Specify one or a sequence of refinement samples to augment the initial_samples in a sampling design.

7.2.74.1.12.8 seed

- Keywords
- Area
- method
- local_reliability
- mpp_search
- integration
- probability_refinement
- seed

Seed of the random number generator

Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** system-generated (non-repeatable)

Description

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

**Default Behavior**

If not specified, the seed is randomly generated.

**Expected Output**

If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

**Usage Tips**

If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.
Examples

```dakota
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

### 7.2.74.2 response_levels

- **Keywords Area**
- **method**
- **local_reliability**
- **response_levels**

Values at which to estimate desired statistics for each response

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Default:** No CDF/CCDF probabilities/reliabilities to compute

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>num_response_levels</td>
<td>Number of values at which to estimate desired statistics for each response</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>compute</td>
<td>Selection of statistics to compute at each response level</td>
</tr>
</tbody>
</table>

**Description**

The `response_levels` specification provides the target response values for which to compute probabilities, reliabilities, or generalized reliabilities (forward mapping).

**Default Behavior**

If `response_levels` are not specified, no statistics will be computed. If they are, probabilities will be computed by default.

**Expected Outputs**

If `response_levels` are specified, Dakota will create two tables in the standard output: a Probability Density function (PDF) histogram and a Cumulative Distribution Function (CDF) table. The PDF histogram has the lower and upper endpoints of each bin and the corresponding density of that bin. Note that the PDF histogram has bins defined by the `probability_levels` and/or `response_levels` in the Dakota input file. If there are not very many levels, the histogram will be coarse. Dakota does not do anything to optimize the bin size or spacing.
The CDF table has the list of response levels and the corresponding probability that the response value is less than or equal to each response level threshold.

**Usage Tips**

The `num_response_levels` is used to specify which arguments of the `response_level` correspond to which response.

**Examples**

For example, specifying a `response_level` of 52.3 followed with `compute probabilities` will result in the calculation of the probability that the response value is less than or equal to 52.3, given the uncertain distributions on the inputs.

For an example with multiple responses, the following specification

```plaintext
response_levels = 1. 2. .1 .2 .3 .4 10. 20. 30.
num_response_levels = 2 4 3
```

would assign the first two response levels (1., 2.) to response function 1, the next four response levels (.1, .2, .3, .4) to response function 2, and the final three response levels (10., 20., 30.) to response function 3. If the `num_response_levels` key were omitted from this example, then the response levels would be evenly distributed among the response functions (three levels each in this case).

The Dakota input file below specifies a sampling method with response levels of interest.

```plaintext
method, sampling,
samples = 100 seed = 1
complementary distribution
response_levels = 3.6e+11 4.0e+11 4.4e+11
                       6.0e+04 6.5e+04 7.0e+04
                       3.5e+05 4.0e+05 4.5e+05
variables,
    normal_uncertain = 2
        means = 248.89, 593.33
        std_deviations = 12.4, 29.7
        descriptors = ‘TF1n’ ‘TF2n’
    uniform_uncertain = 2
        lower_bounds = 199.3, 474.63
        upper_bounds = 298.5, 712.
        descriptors = ‘TF1u’ ‘TF2u’
    weibull_uncertain = 2
        alphas = 12., 30.
        betas = 250., 590.
        descriptors = ‘TF1w’ ‘TF2w’
histogram_bin_uncertain = 2
    num_pairs = 3 4
    abscissas = 5 8 10 .1 .2 .3 .4
    counts = 17 21 0 12 24 12 0
    descriptors = ‘TF1b’ ‘TF2b’
histogram_point_uncertain
    real = 1
    num_pairs = 2
    abscissas = 3 4
    counts = 1 1
    descriptors = ‘TF3h’
interface,
    system asynch evaluation_concurrency = 5
    analysis_driver = ‘text_book’
responses,
    response_functions = 3
    no_gradients
    no_hessians
```

Given the above Dakota input file, the following excerpt from the output shows the PDF and CCDF generated. Note
that the bounds on the bins of the PDF are the response values specified in the input file. The probability levels corresponding to those response values are shown in the CCDF.

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function. In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

A forward mapping involves computing the belief and plausibility probability level for a specified response level.

7.2.74.2.1 num_response_levels

- Keywords Area
- method
- local_reliability
- response_levels
- num_response_levels

Number of values at which to estimate desired statistics for each response.
7.2 method

Specification

**Alias:** none

**Argument(s):** INTEGERLIST

**Default:** response_levels evenly distributed among response functions

Description

The `num_response_levels` keyword allows the user to specify the number of response values, for each response, at which estimated statistics are of interest. Statistics that can be computed are probabilities and reliabilities, both according to either a cumulative distribution function or a complementary cumulative distribution function.

**Default Behavior**

If `num_response_levels` is not specified, the response_levels will be evenly distributed among the responses.

**Expected Outputs**

The specific output will be determined by the type of statistics that are specified. In a general sense, the output will be a list of response level-statistic pairs that show the estimated value of the desired statistic for each response level specified.

Examples

```dakota
method
  sampling
    samples = 100
    seed = 34785
    num_response_levels = 1 1 1
    response_levels = 0.5 0.5 0.5

7.2.74.2.2 compute
  • Keywords Area
  • method
  • local_reliability
  • response_levels
  • compute

Selection of statistics to compute at each response level
```

Specification

**Alias:** none

**Argument(s):** none

**Default:** probabilities

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
</table>
### Description
The `compute` keyword is used to select which forward statistical mapping is calculated at each response level.

### Default Behavior
If `response_levels` is not specified, no statistics are computed. If `response_levels` is specified but `compute` is not, probabilities will be computed by default. If both `response_levels` and `compute` are specified, then one of the following must be specified: `probabilities`, `reliabilities`, or `gen_reliabilities`.

### Expected Output
The type of statistics specified by `compute` will be reported for each response level.

### Usage Tips
CDF/CCDF probabilities are calculated for specified response levels using a simple binning approach. CDF/CCDF reliabilities are calculated for specified response levels by computing the number of sample standard deviations separating the sample mean from the response level.

### Examples
```plaintext
method
  sampling
    sample_type random
    samples = 100 seed = 1
  complementary_distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                    6.0e+04 6.5e+04 7.0e+04
                    3.5e+05 4.0e+05 4.5e+05
    compute reliabilities

7.2.74.2.2.1 probabilities
  
  • Keywords Area
  • method
  • local_reliability
  • response_levels
```
Computes probabilities associated with response levels

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

The `probabilities` keyword directs Dakota to compute the probability that the model response will be below (cumulative) or above (complementary cumulative) a specified response value. This is done for every response level designated for each response.

**Default Behavior**

If `response_levels` is specified, the probabilities are computed by default. To explicitly specify it in the Dakota input file, though, the `probabilities` keyword should be specified in conjunction with the `compute` keyword.

**Expected Outputs**

The Dakota output is a set of response level-probability pairs that give the probability that the model response will be below or above the corresponding response level, depending on the distribution defined.

**Examples**

```
method  
sampling  
    sample_type random  
    samples = 100  
    seed = 1  
    complementary distribution  
    response_levels = 3.6e+11 4.0e+11 4.4e+11  
                  6.0e+04 6.5e+04 7.0e+04  
                  3.5e+05 4.0e+05 4.5e+05  
    compute probabilities
```

**Computes reliabilities associated with response levels**

**Specification**

**Alias:** none  
**Argument(s):** none
Description

The `reliabilities` keyword directs Dakota to compute reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the reliabilities are not computed by default. To change this behavior, the `reliabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-reliability pairs according to the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
  complementary distribution

```

7.2.74.2.2.3  `gen_reliabilities`

- Keywords Area
- method
- local_reliability
- response_levels
- compute
- gen_reliabilities

Computes generalized reliabilities associated with response levels

Specification

**Alias:** none

**Argument(s):** none

Description

The `gen_reliabilities` keyword directs Dakota to compute generalized reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the generalized reliabilities are not computed by default. To change this behavior, the `gen_reliabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-generalized reliability pairs according to the distribution defined.
Examples

method
sampling
  sample_type random
  samples = 100 seed = 1
  complementary distribution
  response_levels = 3.6e+11 4.0e+11 4.4e+11
                  6.0e+04 6.5e+04 7.0e+04
                  3.5e+05 4.0e+05 4.5e+05
  compute gen_reliabilities

7.2.74.2.2.4 system

• Keywords Area
• method
• local_reliability
• response_levels
• compute
• system

Compute system reliability (series or parallel)

Specification

Alias: none
Argument(s): none
Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required (Choose One)</td>
<td>System Reliability Mode (Group 1)</td>
<td>series</td>
<td>Aggregate response statistics assuming a series system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>parallel</td>
<td>Aggregate response statistics assuming a parallel system</td>
</tr>
</tbody>
</table>

Description

With the system probability/reliability option, statistics for specified response_levels are calculated and reported assuming the response functions combine either in series or parallel to produce a total system response.

For a series system, the system fails when any one component (response) fails. The probability of failure is the complement of the product of the individual response success probabilities.

For a parallel system, the system fails only when all components (responses) fail. The probability of failure is the product of the individual response failure probabilities.
7.2.74.2.2.5 series

7.2.74.3 probability_levels

- Keywords Area
- method
- local_reliability
- probability_levels

Specify probability levels at which to estimate the corresponding response value

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Default:** No CDF/CCDF response levels to compute

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>num_probability_levels</td>
<td>Specify which probability_levels correspond to which response</td>
</tr>
</tbody>
</table>

**Description**

Response levels are calculated for specified CDF/CCDF probabilities by indexing into a sorted samples array (the response levels computed are not interpolated and will correspond to one of the sampled values).

**Expected Output**

If probability_levels are specified, Dakota will create two tables in the standard output: a Probability Density function (PDF) histogram and a Cumulative Distribution Function (CDF) table. The PDF histogram has the lower and upper endpoints of each bin and the corresponding density of that bin. Note that the PDF histogram has bins defined by the probability_levels and/or response_levels in the Dakota input file. If there are not very many levels, the histogram will be coarse. Dakota does not do anything to optimize the bin size or spacing. The CDF table has the list of response levels and the corresponding probability that the response value is less than or equal to each response level threshold.

**Examples**

The Dakota input file below specifies a sampling method with probability levels of interest.

```plaintext
method, sampling,
samples = 100 seed = 1
complementary distribution
probability_levels = 1. .66 .33 0.
  1.8 .5 0.
  1.3 .2 0.

variables,
normal_uncertain = 2
means = 248.89, 593.33
std_deviations = 12.4, 29.7
descriptors = ‘TF1n’ ‘TF2n’
```

Dakota Version 6.16 Reference Manual generated on May 12, 2022
uniform_uncertain = 2
lower_bounds = 199.3, 474.63
upper_bounds = 298.5, 712.
descriptors = 'TF1u' 'TF2u'
weibull_uncertain = 2
alphas = 12., 30.
betas = 250., 590.
descriptors = 'TF1w' 'TF2w'
histogram_bin_uncertain = 2
num_pairs = 3 4
abscissas = 5 8 10 .1 .2 .3 .4
counts = 17 21 0 .2 .4 .6 .8 .0

descriptors = 'TF1h' 'TF2h'
histogram_point_uncertain
real = 1
num_pairs = 2
abscissas = 3 4
counts = 1 1
descriptors = 'TF3h'

Given the above Dakota input file, the following excerpt from the output shows the PDF and CCDF generated. Note that the bounds on the bins of the PDF are the response values that correspond the probability levels specified in the input file. Those response values are also shown in the CCDF.

Probability Density Function (PDF) histograms for each response function:

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).

7.2.74.3.1 num_probability_levels

Specify which probability_levels correspond to which response

|                                        |                                                             | complementary   | Computes statistics according to complementary cumulative functions |

Description

The distribution keyword allows the user to select between a cumulative distribution/belief/plausibility function and a complementary cumulative distribution/belief/plausibility function. This choice affects how probabilities and reliability indices are reported.

Default Behavior

If the distribution keyword is present, it must be accompanied by either cumulative or complementary. Otherwise, a cumulative distribution will be used by default.

Expected Outputs
Output will be a set of model response-probability pairs determined according to the choice of distribution. The choice of distribution also defines the sign of the reliability or generalized reliability indices.

### Examples

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

#### 7.2.74.6.1 cumulative

- Keywords: Area
- method
- local_reliability
- distribution
- cumulative

Computes statistics according to cumulative functions

### Specification

**Alias:** none

**Argument(s):** none

### Description

Statistics on model responses will be computed according to a cumulative distribution/belief/plausibility function.

**Default Behavior**

By default, a cumulative distribution/belief/plausibility function will be used. To explicitly specify it in the Dakota input file, however, the `cumulative` keyword must appear in conjunction with the `distribution` keyword.

**Expected Outputs**

Output will be a set of model response-probability pairs determined according to a cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls below given response thresholds.

### Examples

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

#### 7.2.74.6.2 complementary

- Keywords: Area
- method
- local_reliability
Computes statistics according to complementary cumulative functions

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

Statistics on model responses will be computed according to a complementary cumulative distribution/belief/plausibility function.

**Default Behavior**

By default, a complementary cumulative distribution/belief/plausibility function will not be used. To change that behavior, the `complementary` keyword must appear in conjunction with the `distribution` keyword.

**Expected Outputs**

Output will be a set of model response-probability pairs determined according to a complementary cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls above given response thresholds.

**Examples**

```plaintext
method sampling
    sample_type lhs
    samples = 10
    distribution complementary
```

7.2.74.7 max_iterations

**Topics**

This keyword is related to the topics:

- `method_independent_controls`

---

Dakota Version 6.16 Reference Manual generated on May 12, 2022
7.2 method

Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** 100 (exceptions: fsu_cvt, local_reliability: 25; global_(reliability, interval_est, evidence) / efficient_global: 25*n)

**Description**

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_iterations` iterations. In cases where there are multiple nested iterations to be controlled, `max_iterations` generally controls the outer-most context.

**Default Behavior**

Default value is 100.

**See Also**

These keywords may also be of interest:

- `max_function_evaluations`

7.2.74.8 convergence_tolerance

- **Keywords Area**
- **method**
- **local_reliability**
- **convergence_tolerance**

Stopping criterion based on objective function or statistics convergence

**Topics**

This keyword is related to the topics:

- **method_independent_controls**

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 1.e-4

**Description**

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration.
For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by convergence_tolerance, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See nl2sol
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

7.2.74.9 final_moments

- Keywords Area
- method
- local_reliability
- final_moments

Output moments of the specified type and include them within the set of final statistics.

Specification

Alias: none

Argument(s): none

Default: standard

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required (Choose One)</td>
<td>Final moment type (Group 1)</td>
<td>none</td>
<td>Omit moments from the set of final statistics.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>standard</td>
<td>Output standardized moments and include them within the set of final statistics.</td>
</tr>
</tbody>
</table>
Description

When performing a nested study that may employ moment statistics on the inner loop, it can be desirable to control the type of these moments. The final_moments specification supports options of none, standard (default), or central, corresponding to omission of moments, standardized moments (mean, standard deviation, skewness, and excess kurtosis), or central moments (mean, variance, 3rd central, and 4th central).

The presence or omission of moment results in the final statistics influences the outer level mappings in the case of a nested study. For example, final_moments none can allow for a more compact specification of primary and/or secondary response mappings.

Examples

The following method specification overrides the default to print central moments and include them in the set of final statistics.

```
method,
sampling
  samples = 50 seed = 1234
  response_levels = 3.6e+11 1.2e+05 3.5e+05
  final_moments central
```

Overriding the default to none as follows:

```
method,
sampling
  samples = 50 seed = 1234
  response_levels = 3.6e+11 1.2e+05 3.5e+05
  final_moments none
```

allows associated nested model mappings to be simplified from:

```
model
  nested
    sub_method_pointer = 'UQ'
    primary_response_mapping = 0. 0. 1. 0. 0. 1. 0. 0. 0.
    secondary_response_mapping = 0. 0. 0. 0. 0. 0. 0. 0. 1.
```

to a more compact version focused only on the response level mappings (two leading zeros per response function for moment mappings have been removed):

```
model
  nested
    sub_method_pointer = 'UQ'
    primary_response_mapping = 1. 1. 0.
    secondary_response_mapping = 0. 0. 1.
```

7.2.74.9.1 none

- **Keywords Area**
- method
- local_reliability
- final_moments
• none

Omit moments from the set of final statistics.

Specification

Alias: none
Argument(s): none

Description

The omission of moment results from the final statistics can allow for a more compact definition of primary and/or secondary response mappings within a nested model specification.

Examples

```
method,
sampling
  samples = 50 seed = 1234
  response_levels = 3.6e+11 1.2e+05 3.5e+05
  final_moments none
```

```
7.2.74.9.2 standard

• Keywords Area
• method
• local_reliability
• final_moments
• standard
```

Output standardized moments and include them within the set of final statistics.

Specification

Alias: none
Argument(s): none

Description

Output standardized moments (mean, standard deviation, skewness, and excess kurtosis) and include the first two within the set of final statistics to be used at a higher level (e.g., optimization under uncertainty, mixed aleatory-epistemic UQ). This inclusion of moment results affects the primary and/or secondary response mappings in a nested model specification.

Examples

The following method specification overrides the default to print central moments and include them in the set of final statistics.
method,
sampling
    samples = 50  seed = 1234
    response_levels = 3.6e+11  1.2e+05  3.5e+05
    final_moments  standard

7.2.74.9.3  central

• Keywords  Area
• method
• local_reliability
• final_moments
• central

Output central moments and include them within the set of final statistics.

Specification

Alias: none
Argument(s): none

Description

Output central moments (mean, variance, 3rd central, and 4th central) and include the first two within the set of final statistics to be used at a higher level (e.g., optimization under uncertainty, mixed aleatory-epistemic U-Q). This inclusion of moment results affects the primary and/or secondary response mappings in a nested model specification.

Examples

The following method specification overrides the default to print central moments and include them in the set of final statistics.

method,
sampling
    samples = 50  seed = 1234
    response_levels = 3.6e+11  1.2e+05  3.5e+05
    final_moments  central

7.2.74.10  model_pointer

• Keywords  Area
• method
• local_reliability
• model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

• block_pointer
Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

Examples

```plaintext
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
  response_levels = 0.1 0.2 0.6
                    0.1 0.2 0.6
                    0.1 0.2 0.6
    sample_type lhs
    distribution cumulative

**Description**

These methods do not support forward/inverse mappings involving reliability_levels, since they never form a reliability index based on distance in u-space. Rather they use a Gaussian process model to form an approximation to the limit state (based either in x-space via the x_gaussian_process specification or in u-space via the u_gaussian_process specification), followed by probability estimation based on multimodal adaptive importance sampling (see [10]) and [11]). These probability estimates may then be transformed into generalized reliability levels if desired. At this time, inverse reliability analysis (mapping probability or generalized reliability levels into response levels) is not implemented.

The Gaussian process model approximation to the limit state is formed over the aleatory uncertain variables by default, but may be extended to also capture the effect of design, epistemic uncertain, and state variables. If this is desired, one must use the appropriate controls to specify the active variables in the variables specification block. Refer to variable_support for additional information on supported variable types.

7.2.75.1 initial_samples

- Keywords Area
- method
- global_reliability
- initial_samples

Initial number of samples for sampling-based methods
Specification

Alias: none
Argument(s): INTEGER
Default: \(\frac{(d+1)(d+2)}{2}\)

Description

The initial_samples keyword is used to define the number of initial samples (i.e., randomly chosen sets of variable values) at which to execute a model. The initial samples may later be augmented in an iterative process.

Default Behavior

By default, Dakota will use the minimum number of samples required by the chosen method.

Usage Tips

To obtain linear sensitivities or to construct a linear response surface, at least \(dim+1\) samples should be used, where \("dim"\) is the number of variables. For sensitivities to quadratic terms or quadratic response surfaces, at least \(\frac{(dim+1)(dim+2)}{2}\) samples are needed. For uncertainty quantification, we recommend at least \(10+dim\) samples. For variance_based_decomp, we recommend hundreds to thousands of samples. Note that for variance_-based_decomp, the number of simulations performed will be \(N\times(dim+2)\).

Examples

```
method
  sampling
    sample_type random
    initial_samples = 20
    refinement_samples = 5
```

<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>export_model</td>
<td>Exports surrogate model in user-specified format(s)</td>
</tr>
</tbody>
</table>

**Description**

This keyword specifies the use of the Gaussian process that is incorporated in our surface fitting library called Surfpack.

Several user options are available:
1. Optimization methods:

   Maximum Likelihood Estimation (MLE) is used to find the optimal values of the hyper-parameters governing the trend and correlation functions. By default the global optimization method DIRECT is used for MLE, but other options for the optimization method are available. See optimization_method.

   The total number of evaluations of the likelihood function can be controlled using the `max_trials` keyword followed by a positive integer. Note that the likelihood function does not require running the "truth" model, and is relatively inexpensive to compute.

2. Trend Function:

   The GP models incorporate a parametric trend function whose purpose is to capture large-scale variations. See trend.

3. Correlation Lengths:

   Correlation lengths are usually optimized by Surfpack, however, the user can specify the lengths manually. See correlation_lengths.

4. Ill-conditioning

   One of the major problems in determining the governing values for a Gaussian process or Kriging model is the fact that the correlation matrix can easily become ill-conditioned when there are too many input points close together. Since the predictions from the Gaussian process model involve inverting the correlation matrix, ill-conditioning can lead to poor predictive capability and should be avoided.

   Note that a sufficiently bad sample design could require correlation lengths to be so short that any interpolatory GP model would become inept at extrapolation and interpolation.

   The surfpack model handles ill-conditioning internally by default, but behavior can be modified using

5. Gradient Enhanced Kriging (GEK)

   The use_derivatives keyword will cause the Surfpack GP to be constructed from a combination of function value and gradient information (if available).

   See notes in the Theory section.

Theory

Gradient Enhanced Kriging

Incorporating gradient information will only be beneficial if accurate and inexpensive derivative information is available, and the derivatives are not infinite or nearly so. Here "inexpensive" means that the cost of evaluating a function value plus gradient is comparable to the cost of evaluating only the function value, for example gradients computed by analytical, automatic differentiation, or continuous adjoint techniques. It is not cost effective to use derivatives computed by finite differences. In tests, GEK models built from finite difference derivatives were also significantly less accurate than those built from analytical derivatives. Note that GEK's correlation matrix tends to have a significantly worse condition number than Kriging for the same sample design.

This issue was addressed by using a pivoted Cholesky factorization of Kriging's correlation matrix (which is a small sub-matrix within GEK's correlation matrix) to rank points by how much unique information they contain. This reordering is then applied to whole points (the function value at a point immediately followed by gradient information at the same point) in GEK's correlation matrix. A standard non-pivoted Cholesky is then applied to the reordered GEK correlation matrix and a bisection search is used to find the last equation that meets the constraint on the (estimate of) condition number. The cost of performing pivoted Cholesky on Kriging's correlation matrix is usually negligible compared to the cost of the non-pivoted Cholesky factorization of GEK's correlation matrix. In tests, it also resulted in more accurate GEK models than when pivoted Cholesky or whole-point-block pivoted Cholesky was performed on GEK's correlation matrix.
Exports surrogate model in user-specified format(s)

This keyword is related to the topics:

- surrogate_models

**Specification**

**Alias:** none

**Argument(s):** none

<tr>
<td>Required</td>
<td>formats</td>
<td></td>
<td>Formats for surrogate model export</td>
</tr>
</tbody>
</table>

**Description**

Export the surrogate for later re-import to Dakota or evaluation using the surfpack executable (`bin/surfpack`) or a user-developed tool. Export format is controlled using the `formats` specification. Four formats are available in Dakota; however, not all have been enabled for all surrogates.

The four formats are:

- `text_archive` - Plain-text, machine-readable archive for re-import or use with the surfpack executable
- `binary_archive` - Binary, machine-readable archive for re-import or use with the surfpack executable
- `algebraic_file` - Plain-text, human-readable file intended for use with user-created tools; not compatible with Dakota or the surfpack executable
- `algebraic_console` - Print the model in algebraic format to the screen; not compatible with Dakota or the surfpack executable

These global surrogates can be exported in all four formats:

- Gaussian process (keyword `gaussian_process surfpack`)
- Artificial neural network (keyword `neural_network`)
- Radial basis Functions (keyword `radial_basis`)
• Polynomial (keyword polynomial)

However, for experimental Gaussian Process and polynomial models as well as Multivariate Adaptive Regression Spline (keyword mars) and moving least squares (keyword moving_least_squares) models, only text_archive and binary_archive formats may be used.

Currently, no other surrogate models can be exported.

Default Behavior
No export.

Expected Output
Output depends on selected format; see the formats specification.

Additional Discussion
The Dakota examples include a demonstration of using the surfpack executable with an exported model file.

7.2.75.4.1.1 filename_prefix

• Keywords Area

• method

• global_reliability

• surfpack

• export_model

• filename_prefix

User-customizable portion of exported/imported surrogate model filenames

Topics

This keyword is related to the topics:

• surrogate_models

Specification

Alias: none

Argument(s): STRING

Default: exported_surrogate

Description

Dakota surrogate model files are exported and imported using one file per response, per requested format. The files are named using the pattern `{prefix}.{response_descriptor}.{extension}`. This filename_prefix keyword is used to supply the prefix portion of the pattern.

The response_descriptor portion of the pattern is filled in using the response descriptors provided by the user (or, if none are specified, descriptors automatically generated by Dakota). Extension is a three or four letter string that depends on the format.
Examples

This input snippet directs Dakota to write one algebraic format file and one binary archive file for each response. The names of the files will follow the patterns my_surrogate.{response_descriptor}.alg (for the algebraic files) and my_surrogate.{response_descriptor}.bsps (for the binary files).

```plaintext
surrogate global gaussian_process surfpack
  export_model
    filename_prefix = 'my_surrogate'
    formats
      algebraic_file
      binary_archive
```

Surrogate model binary archive file format
7.2 method

Topics

This keyword is related to the topics:

- surrogate_models

Specification

Alias: none

Argument(s): none

Description

When specified, the surrogate model will be exported (or imported) using a binary archive format.

Experimental surrogates will export to (import from) binary archives named {prefix}.{response_descriptor}.bin.

Other (Surfpack) surrogates will export/import using files named {prefix}.{response_descriptor}.bsps, in which 'bsps' stands for binary Surfpack surrogate.

See filename_prefix for further information about surrogate file naming.

Examples

The Dakota examples include a demonstration of using the surfpack executable with an exported model file.

7.2.75.5 dakota

- Keywords Area
- method
- global_reliability
- dakota

Select the built in Gaussian Process surrogate

Specification

Alias: none

Argument(s): none

Description

A second version of GP surrogates was available in prior versions of Dakota. For now, both versions are supported but the dakota version is deprecated and intended to be removed in a future release.

Historically these models were drastically different, but in Dakota 5.1, they became quite similar. They now differ in that the Surfpack GP has a richer set of features/options and tends to be more accurate than the Dakota version. Due to how the Surfpack GP handles ill-conditioned correlation matrices (which significantly contributes to its greater accuracy), the Surfpack GP can be a factor of two or three slower than Dakota's. As of Dakota 5.2, the Surfpack implementation is the default in all contexts except Bayesian calibration.

More details on the gaussian_process dakota model can be found in [60].
Dakota’s GP deals with ill-conditioning in two ways. First, when it encounters a non-invertible correlation matrix it iteratively increases the size of a “nugget,” but in such cases the resulting approximation smooths rather than interpolates the data. Second, it has a point_selection option (default off) that uses a greedy algorithm to select a well-spaced subset of points prior to the construction of the GP. In this case, the GP will only interpolate the selected subset. Typically, one should not need point selection in trust-region methods because a small number of points are used to develop a surrogate within each trust region. Point selection is most beneficial when constructing with a large number of points, typically more than order one hundred, though this depends on the number of variables and spacing of the sample points.

This differs from the point_selection option of the Dakota GP which initially chooses a well-spaced subset of points and finds the correlation parameters that are most likely for that one subset.

7.2.75.6 experimental

Surrogate model plain-text archive file format

Topics

This keyword is related to the topics:

• surrogate_models

Specification

**Alias:** none

**Argument(s):** none

**Description**

When specified, the surrogate model will be exported (or imported) using a plain-text archive format. Experimental surrogates will export (import from) text archives named \{prefix\}.{response_descriptor}.txt. Other (Surfpack) surrogates will export/import using files named \{prefix\}.{response_descriptor}.sps, in which ‘sps’ stands for Surfpack surrogate.

See [filename_prefix](#) for further information about surrogate file naming.

**Examples**

The Dakota examples include a demonstration of using the surfpack executable with an exported model file.

7.2 method

Topics

This keyword is related to the topics:

- surrogate_models

Specification

Alias: none

Argument(s): none

Description

When specified, the surrogate model will be exported (or imported) using a binary archive format.

Experimental surrogates will export to (import from) binary archives named \( \text{prefix}.\text{responseDescriptor}.bin \).

Other (Surfpack) surrogates will export/import using files named \( \text{prefix}.\text{responseDescriptor}.bsps \), in which 'bsps' stands for binary Surfpack surrogate.

See filename_prefix for further information about surrogate file naming.

Examples

The Dakota examples include a demonstration of using the surfpack executable with an exported model file.

7.2.75.6.2 options_file

- Keywords Area
- method
- global_reliability
- experimental
- options_file

Filename for a YAML file that specifies Gaussian process options

Specification

Alias: none

Argument(s): STRING

Default: no advanced options file

Description

The YAML file contains configuration options that are used to populate a Teuchos ParameterList used by the Gaussian process that will override other keyword-specified parameters. Missing options in the YAML file are set to default values.
Examples

# FILE: gp_options.yaml

GP Parameters:
Sigma Bounds:
   lower bound: 1.0e-2
   upper bound: 1.0e2
scaler name: standardization
num restarts: 20
Nugget:
   fixed nugget: 0.0
   estimate nugget: true
   Bounds:
      lower bound: 3.17e-8
      upper bound: 1.0e-2
gp seed: 42
standardize response: false
Trend:
   estimate trend: true
Options:
   max degree: 2
   reduced basis: false
   p-norm: 1.0
   scaler type: none
   regression solver type: SVD
   verbosity: 1
kernel type: squared exponential
Length-scale Bounds:
   lower bound: 1.0e-2
   upper bound: 1.0e2
   verbosity: 1

7.2.75.7 import_build_points_file

* Keywords Area

* method

* global_reliability

* import_build_points_file

File containing points you wish to use to build a surrogate

Specification

Alias: import_points_file

Argument(s): STRING

Default: no point import from a file

Child Keywords:
The `import_build_points_file` allows the user to specify a file that contains a list of points and truth model responses used to construct a surrogate model. These can be used by all methods that (explicitly, e.g. surrogate-based optimization, or implicitly, e.g. efficient global optimization) operate on a surrogate. In particular, these points and responses are used in place of truth model evaluations to construct the initial surrogate. When used to construct surrogate models or emulators these are often called build points or training data.

**Default Behavior**

By default, methods do not import points from a file.

**Usage Tips**

Dakota parses input files without regard to whitespace, but the `import_build_points_file` must be in one of three formats:

- annotated (default)
- custom_annotated
- freeform

**Examples**

```dakota
method
    polynomial_chaos
    expansion_order = 4
    import_build_points_file = 'dakota_uq_rosenbrock_pce_import.annot.pts.dat'
```

**7.2.75.7.1 custom_annotated**

- **Keywords Area**
  - method
  - global_reliability
  - import_build_points_file
  - custom_annotated

Selects custom-annotated tabular file format
Keywords Area

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>header</td>
<td>header</td>
<td>Enable header row in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td>eval_id</td>
<td>eval_id</td>
<td>Enable evaluation ID column in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td>interface_id</td>
<td>interface_id</td>
<td>Enable interface ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:
7.2 method

environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id

Resulting tabular file:

7.2.75.7.2 annotated

- Keywords Area
- method
- global_reliability
- import_build_points_file
- annotated

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none
Default: annotated format
Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
  tabular_data_file = 'dakota_summary.dat'
  annotated
```

Resulting tabular file:

```
%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 NO_ID 0.9 1.1 0.0002 0.26 0.76
2 NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 NO_ID 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...```

7.2.75.7.3 freeform

- Keywords Area

- method

- global_reliability

- import_build_points_file

- freeform

Selects freeform file format

Topics

This keyword is related to the topics:

- fileFormats
Specification

**Alias:** none

**Argument(s):** none

**Default:** annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

**Default Behavior**

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

**Usage Tips**

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

**Examples**

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
  tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

```
0.9 1.1 0.0002 0.26 0.76
0.90009 1.1 0.0001996404857 0.2601620081 0.759955
0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...```

7.2.75.7.4 active_only

- **Keywords Area**
- **method**
- **global_reliability**
- **import_build_points_file**
- **active_only**

Import only active variables from tabular data file
7.2 method

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword active_only indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

7.2.75.8 export_approx_points_file

- Keywords Area
- method
- global_reliability
- export_approx_points_file

Output file for surrogate model value evaluations

Specification

Alias: export_points_file
Argument(s): STRING
Default: no point export to a file

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional (Choose One)</td>
<td>Tabular Format (Group 1)</td>
<td>custom_annotated</td>
<td>Selects custom-annotated tabular file format</td>
</tr>
<tr>
<td>annotated</td>
<td>annotated</td>
<td>Selects annotated tabular file format</td>
<td></td>
</tr>
</tbody>
</table>
Description

Specifies a file in which the points (input variable values) at which the surrogate model is evaluated and corresponding response values computed by the surrogate model will be written. The response values are the surrogate’s predicted approximation to the truth model responses at those points.

Usage Tips

Dakota exports tabular data in one of three formats:

- annotated (default)
- custom_annotated
- freeform

7.2.75.8.1 custom_annotated

- Keywords Area
- method
- global_reliability

Dakota Version 6.16 Reference Manual generated on May 12, 2022
### Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

### Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

### Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

### Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
tabular_data_file = 'dakota_summary.dat'
custom_annotated header eval_id
```

Resulting tabular file:

```plaintext
@eval_id  x1  x2  obj_fn  nlneq_con_1  nlneq_con_2
1  0.9  1.1  0.0002  0.26  0.76
2  0.90009  1.1  0.0001996404857  0.2601620081  0.759955
3  0.89991  1.1  0.0002003604863  0.2598380081  0.760045
...
```

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none
Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom.annotated header eval_id

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```plaintext
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
annotated
```

Resulting tabular file:

```
%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2

```

7.2.75.8.3 freeform

• Keywords Area

• method

• global_reliability

• export_approx_points_file

• freeform

Selects freeform file format

Topics

This keyword is related to the topics:

• file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.
The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    freeform

Resulting tabular file:

0.9 1.1 0.0002 0.26 0.76
0.90009 1.1 0.0001996404857 0.2601620081 0.759955
0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...```

7.2.75.9 use_derivatives

- Keywords Area
- method
- global_reliability
- use_derivatives

Use derivative data to construct surrogate models

Specification

Alias: none

Argument(s): none

Default: use function values only

Description

The use_derivatives flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, its use with Surfpack Gaussian process is not recommended.
7.2.75.10 seed

• Keywords Area
• method
• global_reliability
• seed

Seed of the random number generator

Specification

Alias: none
Argument(s): INTEGER
Default: system-generated (non-repeatable)

Description

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior
If not specified, the seed is randomly generated.

Expected Output
If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips
If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```dakota
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

7.2.75.11 rng

• Keywords Area
• method
• global_reliability
• rng

Selection of a random number generator
Specification

**Alias:** none
**Argument(s):** none
**Default:** Mersenne twister (mt19937)

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group RNG Algorithm (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required (Choose One)</td>
<td></td>
<td>mt19937</td>
<td>Generates random numbers using the Mersenne twister</td>
</tr>
<tr>
<td></td>
<td></td>
<td>rnum2</td>
<td>Generates pseudo-random numbers using the Pecos package</td>
</tr>
</tbody>
</table>

**Description**

The `rng` keyword is used to indicate a choice of random number generator.

**Default Behavior**

If specified, the `rng` keyword must be accompanied by either `rnum2` (pseudo-random numbers) or `mt19937` (random numbers generated by the Mersenne twister). Otherwise, `mt19937`, the Mersenne twister is used by default.

**Usage Tips**

The default is recommended, as the Mersenne twister is a higher quality random number generator.

**Examples**

```
method sampling
  sample_type lhs
  samples = 10
  seed = 98765
  rng rnum2
```

**7.2.75.11.1 mt19937**

- **Keywords Area**
- **method**
- **global_reliability**
- **rng**
- **mt19937**

Generates random numbers using the Mersenne twister

**Specification**

**Alias:** none
**Argument(s):** none
Description

The mt19937 keyword directs Dakota to use the Mersenne twister to generate random numbers. Additional information can be found on wikipedia: http://en.wikipedia.org/wiki/Mersenne_twister.

Default Behavior

mt19937 is the default random number generator. To specify it explicitly in the Dakota input file, however, it must be specified in conjunction with the rng keyword.

Usage Tips

Use of the Mersenne twister random number generator (mt19937) is recommended.

Examples

method	sampling
  sample_type lhs
  samples = 10
  seed = 98765
  rng mt19937

7.2.75.11.2 rnum2

- Keywords Area
- method
- global_reliability
- rng
- rnum2

Generates pseudo-random numbers using the Pecos package

Specification

Alias: none
Argument(s): none

Description

The rnum2 keyword directs Dakota to use pseudo-random numbers generated by the Pecos package.

Default Behavior

rnum2 is not used by default. To change this behavior, it must be specified in conjunction with the rng keyword.

Usage Tips

Use of the Mersenne twister random number generator (mt19937) is recommended over rnum2.

Examples

method	sampling
  sample_type lhs
  samples = 10
  seed = 98765
  rng rnum2
7.2.75.12 response_levels

- Keywords Area
  - method
  - global_reliability
  - response_levels

Values at which to estimate desired statistics for each response

### Specification

**Alias:** none

**Argument(s):** REALLIST

**Default:** No CDF/CCDF probabilities/reliabilities to compute

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>num_response_levels</td>
<td></td>
<td>Number of values at which to estimate desired statistics for each response</td>
</tr>
<tr>
<td>Optional</td>
<td>compute</td>
<td></td>
<td>Selection of statistics to compute at each response level</td>
</tr>
</tbody>
</table>

### Description

The `response_levels` specification provides the target response values for which to compute probabilities, reliabilities, or generalized reliabilities (forward mapping).

### Default Behavior

If `response_levels` are not specified, no statistics will be computed. If they are, probabilities will be computed by default.

### Expected Outputs

If `response_levels` are specified, Dakota will create two tables in the standard output: a Probability Density function (PDF) histogram and a Cumulative Distribution Function (CDF) table. The PDF histogram has the lower and upper endpoints of each bin and the corresponding density of that bin. Note that the PDF histogram has bins defined by the `probability_levels` and/or `response_levels` in the Dakota input file. If there are not very many levels, the histogram will be coarse. Dakota does not do anything to optimize the bin size or spacing. The CDF table has the list of response levels and the corresponding probability that the response value is less than or equal to each response level threshold.

### Usage Tips

The `num_response_levels` is used to specify which arguments of the `response_level` correspond to which response.
Examples

For example, specifying a `response_level` of 52.3 followed with `compute probabilities` will result in the calculation of the probability that the response value is less than or equal to 52.3, given the uncertain distributions on the inputs.

For an example with multiple responses, the following specification

```plaintext
response_levels = 1. 2. .1 .2 .3 .4 10. 20. 30.
num_response_levels = 2 4 3
```

would assign the first two response levels (1., 2.) to response function 1, the next four response levels (.1, .2, .3, .4) to response function 2, and the final three response levels (10., 20., 30.) to response function 3. If the `num_response_levels` key were omitted from this example, then the response levels would be evenly distributed among the response functions (three levels each in this case).

The Dakota input file below specifies a sampling method with response levels of interest.

```plaintext
method,
    sampling,
        samples = 100 seed = 1
    complementary distribution
        response_levels = 3.6e+11 4.0e+11 4.4e+11
        6.0e+04 6.5e+04 7.0e+04
        3.5e+05 4.0e+05 4.5e+05
variables,
    normal_uncertain = 2
        means = 248.89, 593.33
        descriptors = ’TF1n’ ’TF2n’
    uniform_uncertain = 2
        lower_bounds = 199.3, 474.63
        upper_bounds = 298.5, 712.
        descriptors = ’TF1u’ ’TF2u’
    weibull_uncertain = 2
        alphas = 12., 30.
        betas = 250., 590.
        descriptors = ’TF1w’ ’TF2w’
    histogram_bin_uncertain = 2
        num_pairs = 3 4
        abscissas = 5 8 10 .1 .2 .3 .4
        counts = 17 21 0 12 24 12 0
        descriptors = ’TF1h’ ’TF2h’
    histogram_point_uncertain
        real = 1
        num_pairs = 2
        abscissas = 3 4
        counts = 1 1
        descriptors = ’TF3h’
interface,
    system async evaluation_concurrency = 5
    analysis_driver = ’text_book’
responses,
    response_functions = 3
        no_gradients
        no_hessians
```

Given the above Dakota input file, the following excerpt from the output shows the PDF and CCDF generated. Note that the bounds on the bins of the PDF are the response values specified in the input file. The probability levels corresponding to those response values are shown in the CCDF.

Probability Density Function (PDF) histograms for each response function:

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

A forward mapping involves computing the belief and plausibility probability level for a specified response level.

7.2.75.12.1 num_response_levels

- Keywords Area
- method
- global_reliability
- response_levels
- num_response_levels

Number of values at which to estimate desired statistics for each response

Specification

Alias: none

Argument(s): INTEGERLIST
Default: response_levels evenly distributed among response functions

Description

The num_response_levels keyword allows the user to specify the number of response values, for each response, at which estimated statistics are of interest. Statistics that can be computed are probabilities and reliabilities, both according to either a cumulative distribution function or a complementary cumulative distribution function.

Default Behavior

If num_response_levels is not specified, the response_levels will be evenly distributed among the responses.

Expected Outputs

The specific output will be determined by the type of statistics that are specified. In a general sense, the output will be a list of response level-statistic pairs that show the estimated value of the desired statistic for each response level specified.

Examples

```
method
  sampling
    samples = 100
    seed = 34785
  num_response_levels = 1 1 1
    response_levels = 0.5 0.5 0.5

7.2.75.12.2 compute

  • Keywords Area
  • method
  • global_reliability
  • response_levels
  • compute
```

Selection of statistics to compute at each response level

Specification

Alias: none

Argument(s): none

Default: probabilities

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional Required (Choose One)</th>
<th>Description of Group Statistics to Compute (Group 1)</th>
<th>Dakota Keyword probabilities</th>
<th>Dakota Keyword Description Computes probabilities associated with response levels</th>
</tr>
</thead>
</table>
### Description

The `compute` keyword is used to select which forward statistical mapping is calculated at each response level.

### Default Behavior

If `response_levels` is not specified, no statistics are computed. If `response_levels` is specified but `compute` is not, probabilities will be computed by default. If both `response_levels` and `compute` are specified, then on of the following must be specified: `probabilities`, `reliabilities`, or `gen_reliabilities`.

### Expected Output

The type of statistics specified by `compute` will be reported for each response level.

### Usage Tips

CDF/CCDF probabilities are calculated for specified response levels using a simple binning approach.

CDF/CCDF reliabilities are calculated for specified response levels by computing the number of sample standard deviations separating the sample mean from the response level.

### Examples

```plaintext
method sampling
  sample_type random
  samples = 100 seed = 1
  complementary distribution
  response_levels = 3.6e+11 4.0e+11 4.4e+11
                   6.0e+04 6.5e+04 7.0e+04
                   3.5e+05 4.0e+05 4.5e+05
  compute reliabilities
```

#### 7.2.75.12.2.1 probabilities

- Keywords Area
  - method
  - global_reliability
  - response_levels
  - compute
  - probabilities

Computes probabilities associated with response levels
Specification

**Alias:** none  
**Argument(s):** none

Description

The `probabilities` keyword directs Dakota to compute the probability that the model response will be below (cumulative) or above (complementary cumulative) a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the probabilities are computed by default. To explicitly specify it in the Dakota input file, though, the `probabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-probability pairs that give the probability that the model response will be below or above the corresponding response level, depending on the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
  complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                     6.0e+04 6.5e+04 7.0e+04
                     3.5e+05 4.0e+05 4.5e+05
  compute probabilities

7.2.7.5.12.2.2 gen_reliabilities

  • Keywords Area
  • method
  • global_reliability
  • response_levels
  • compute
  • gen_reliabilities

Computes generalized reliabilities associated with response levels
```

Specification

**Alias:** none  
**Argument(s):** none

Description

The `gen_reliabilities` keyword directs Dakota to compute generalized reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.
Default Behavior

If `response_levels` is specified, the generalized reliabilities are not computed by default. To change this behavior, the `gen_reliabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-generalized reliability pairs according to the distribution defined.

Examples

```
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary_distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                       6.0e+04 6.5e+04 7.0e+04
                       3.5e+05 4.0e+05 4.5e+05
    compute gen_reliabilities
```

7.2.75.12.2.3 system

- Keywords Area
- method
- global_reliability
- response_levels
- compute
- system

Compute system reliability (series or parallel)

Specification

Alias: none
Argument(s): none
Child Keywords:

<table>
<thead>

<th>Description of Group System Reliability Mode (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>series</td>
<td>Aggregate response statistics assuming a series system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>parallel</td>
<td>Aggregate response statistics assuming a parallel system</td>
</tr>
</tbody>
</table>
Description

With the system probability/reliability option, statistics for specified response_levels are calculated and reported assuming the response functions combine either in series or parallel to produce a total system response.

For a series system, the system fails when any one component (response) fails. The probability of failure is the complement of the product of the individual response success probabilities.

For a parallel system, the system fails only when all components (responses) fail. The probability of failure is the product of the individual response failure probabilities.

7.2.75.12.2.4 series

Description

See parent keyword system for description.

7.2.75.13 probability_levels

• Keywords Area
  • method
  • global_reliability
  • probability_levels

Specify probability levels at which to estimate the corresponding response value

Specification

Alias: none
Argument(s): REALLIST
Default: No CDF/CCDF response levels to compute

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>num_probability_levels</td>
<td></td>
<td>Specify which probability_levels correspond to which response</td>
</tr>
</tbody>
</table>

Description

Response levels are calculated for specified CDF/CCDF probabilities by indexing into a sorted samples array (the response levels computed are not interpolated and will correspond to one of the sampled values).

Expected Output

If probability_levels are specified, Dakota will create two tables in the standard output: a Probability Density function (PDF) histogram and a Cumulative Distribution Function (CDF) table. The PDF histogram has the lower and upper endpoints of each bin and the corresponding density of that bin. Note that the PDF histogram has bins defined by the probability_levels and/or response_levels in the Dakota input file. If there are not very many levels, the histogram will be coarse. Dakota does not do anything to optimize the bin size or spacing. The CDF table has the list of response levels and the corresponding probability that the response value is less than or equal to each response level threshold.

Examples

The Dakota input file below specifies a sampling method with probability levels of interest.
Given the above Dakota input file, the following excerpt from the output shows the PDF and CCDF generated. Note that the bounds on the bins of the PDF are the response values that correspond to the probability levels specified in the input file. Those response values are also shown in the CCDF.

### Probability Density Function (PDF) histograms for each response function:

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).

7.2.75.15 distribution

• Keywords Area
• method
• global_reliability
• distribution

Selection of cumulative or complementary cumulative functions

Specification

Alias: none
Argument(s): none
Default: cumulative (CDF)

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional Required (Choose One)</th>
<th>Description of Group Distribution Type (CDF/CCDF) (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>cumulative</td>
<td>Computes statistics according to cumulative functions</td>
</tr>
<tr>
<td></td>
<td></td>
<td>complementary</td>
<td>Computes statistics according to complementary cumulative functions</td>
</tr>
</tbody>
</table>

Description

The distribution keyword allows the user to select between a cumulative distribution/belief/plausibility function and a complementary cumulative distribution/belief/plausibility function. This choice affects how probabilities and reliability indices are reported.

Default Behavior

If the distribution keyword is present, it must be accompanied by either cumulative or complementary. Otherwise, a cumulative distribution will be used by default.

Expected Outputs
Output will be a set of model response-probability pairs determined according to the choice of distribution. The choice of distribution also defines the sign of the reliability or generalized reliability indices.

**Examples**

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

7.2.75.15.1 cumulative

- Keywords Area
- method
- global_reliability
- distribution
- cumulative

Computes statistics according to cumulative functions

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

Statistics on model responses will be computed according to a cumulative distribution/belief/plausibility function.

**Default Behavior**

By default, a cumulative distribution/belief/plausibility function will be used. To explicitly specify it in the Dakota input file, however, the `cumulative` keyword must appear in conjunction with the `distribution` keyword.

**Expected Outputs**

Output will be a set of model response-probability pairs determined according to a cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls below given response thresholds.

**Examples**

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

7.2.75.15.2 complementary

- Keywords Area
- method
- global_reliability
7.2 method

- distribution
- complementary

Computes statistics according to complementary cumulative functions

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

Statistics on model responses will be computed according to a complementary cumulative distribution/belief/plausibility function.

**Default Behavior**

By default, a complementary cumulative distribution/belief/plausibility function will not be used. To change that behavior, the **complementary** keyword must be appear in conjunction with the **distribution** keyword.

**Expected Outputs**

Output will be a set of model response-probability pairs determined according to a complementary cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls above given response thresholds.

**Examples**

```plaintext
method sampling
    sample_type lhs
    samples = 10
    distribution complementary
```

7.2.75.16 max_iterations

- Keywords Area
- method
- global_reliability
- max_iterations

Number of iterations allowed for optimizers and adaptive UQ methods

**Topics**

This keyword is related to the topics:

- method_independent_controls
Specification

Alias: none
Argument(s): INTEGER
Default: 100 (exceptions: fsu_cvt, local_reliability: 25; global_(reliability, interval_est, evidence) / efficient_global: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed $\text{max\_iterations}$ iterations. In cases where there are multiple nested iterations to be controlled, $\text{max\_iterations}$ generally controls the outer-most context.

Default Behavior

Default value is 100.

See Also

These keywords may also be of interest:

- $\text{max\_function\_evaluations}$

7.2.75.17 convergence_tolerance

- Keywords Area
- method
- global_reliability
- convergence_tolerance

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- $\text{method\_independent\_controls}$

Specification

Alias: none
Argument(s): REAL
Default: 1.e-4

Description

The $\text{convergence\_tolerance}$ specification provides a real value for controlling the termination of iteration.
For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by convergence_tolerance, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

**Behavior Varies by Package/Library**

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See nl2sol
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

### 7.2.75.18 model_pointer

- **Keywords Area**
- method
- global_reliability
- model_pointer

Identifier for model block to be used by a method

**Topics**

This keyword is related to the topics:

- block_pointer

**Specification**

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)

**Description**

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.
Usage Tips
When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.

See block_pointer for details about pointers.

Examples

```plaintext
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
     samples = 10
     seed = 98765 rng rnum2
     response_levels = 0.1 0.2 0.6
       0.1 0.2 0.6
       0.1 0.2 0.6
     sample_type lhs
     distribution cumulative

model
  id_model = 'SURR'
  surrogate global,
  dace_method_pointer = 'DACE'
  polynomial quadratic

method
  id_method = 'DACE'
  model_pointer = 'DACE_M'
  sampling sample_type lhs
     samples = 121 seed = 5034 rng rnum2

model
  id_model = 'DACE_M'
  single
  interface_pointer = 'I1'

</tbody>
</table>
Description

Quasi-Monte Carlo methods produce low discrepancy sequences, especially if one is interested in the uniformity of projections of the point sets onto lower dimensional faces of the hypercube (usually 1-D: how well do the marginal distributions approximate a uniform?)

This method generates sets of uniform random variables on the interval [0,1]. If the user specifies lower and upper bounds for a variable, the [0,1] samples are mapped to the [lower, upper] interval.

The user must first choose the sequence type:

• halton or
• hammersley

Then three keywords are used to define the sequence and how it is sampled:

• prime_base
• sequence_start
• sequence_leap

Each of these has defaults, so specification is optional.

Theory

The quasi-Monte Carlo sequences of Halton and Hammersley are deterministic sequences determined by a set of prime bases. Generally, we recommend that the user leave the default setting for the bases, which are the lowest primes. Thus, if one wants to generate a sample set for 3 random variables, the default bases used are 2, 3, and 5 in the Halton sequence. To give an example of how these sequences look, the Halton sequence in base 2 starts with points 0.5, 0.25, 0.75, 0.125, 0.625, etc. The first few points in a Halton base 3 sequence are 0.33333, 0.66667, 0.11111, 0.44444, 0.77777, etc. Notice that the Halton sequence tends to alternate back and forth, generating a point closer to zero then a point closer to one. An individual sequence is based on a radix inverse function defined on a prime base. The prime base determines how quickly the [0,1] interval is filled in. Generally, the lowest primes are recommended.

The Hammersley sequence is the same as the Halton sequence, except the values for the first random variable are equal to 1/N, where N is the number of samples. Thus, if one wants to generate a sample set of 100 samples for 3
random variables, the first random variable has values 1/100, 2/100, 3/100, etc. and the second and third variables are generated according to a Halton sequence with bases 2 and 3, respectively.

For more information about these sequences, see [44], [45], and [1].

7.2.76.1 halton

- Keywords Area
- method
- fsu_quasi_mc
- halton

Generate samples from a Halton sequence

Topics

This keyword is related to the topics:

- package_fsudace

Specification

Alias: none

Argument(s): none

Description

The quasi-Monte Carlo sequences of Halton are deterministic sequences determined by a set of prime bases. These sequences generate random numbers with the goal of filling a unit hypercube uniformly.

Generally, we recommend that the user leave the default setting for the bases, which are the lowest primes. Thus, if one wants to generate a sample set for 3 random variables, the default bases used are 2, 3, and 5 in the Halton sequence. To give an example of how these sequences look, the Halton sequence in base 2 starts with points 0.5, 0.25, 0.75, 0.125, 0.625, etc. The first few points in a Halton base 3 sequence are 0.33333, 0.66667, 0.11111, 0.44444, 0.77777, etc. Notice that the Halton sequence tends to alternate back and forth, generating a point closer to zero then a point closer to one. An individual sequence is based on a radix inverse function defined on a prime base. The prime base determines how quickly the [0,1] interval is filled in.

Theory

For more information about these sequences, see [44], [45], and [1].
7.2.76.2 hammersley

• Keywords Area
• method
• fsu_quasi_mc
• hammersley

Use Hammersley sequences

Topics

This keyword is related to the topics:

• package_fsudace
• design_and_analysis_of_computer_experiments

Specification

Alias: none
Argument(s): none

Description

The Hammersley sequence is the same as the Halton sequence, except the values for the first random variable are equal to 1/N, where N is the number of samples. Thus, if one wants to generate a sample set of 100 samples for 3 random variables, the first random variable has values 1/100, 2/100, 3/100, etc. and the second and third variables are generated according to a Halton sequence with bases 2 and 3, respectively.

7.2.76.3 latinize

• Keywords Area
• method
• fsu_quasi_mc
• latinize

Adjust samples to improve the discrepancy of the marginal distributions

Specification

Alias: none
Argument(s): none
Default: No latinization
Description

The `latinize` control takes the samples and "latinizes" them, meaning that each original sample is moved so that it falls into one strata or bin in each dimension as in Latin Hypercube sampling. The default setting is NOT to latinize. However, one may be interested in doing this in situations where one wants better discrepancy of the 1-dimensional projections (the marginal distributions).

7.2.76.4 quality_metrics

- Keywords Area
- method
- fsu_quasi_mc
- quality_metrics

Calculate metrics to assess the quality of quasi-Monte Carlo samples

Topics

This keyword is related to the topics:

- package_fsudace

Specification

Alias: none

Argument(s): none

Default: No quality_metrics

Description

`quality_metrics` calculates four quality metrics relating to the volumetric spacing of the samples. The four quality metrics measure different aspects relating to the uniformity of point samples in hypercubes. Desirable properties of such point samples are:

- are the points equally spaced
- do the points cover the region
- and are they isotropically distributed
- with no directional bias in the spacing

The four quality metrics we report are:

- h: the point distribution norm, which is a measure of uniformity of the point distribution
- chi: a regularity measure, and provides a measure of local uniformity of a set of points
- tau: the second moment trace measure
- d: the second moment determinant measure

All of these values are scaled so that smaller is better (the smaller the metric, the better the uniformity of the point distribution).
Examples

Complete explanation of these measures can be found in [39].

7.2.76.5 variance_based_decomp

- Keywords Area
- method
- fsu_quasi_mc
- variance_based_decomp

Activates global sensitivity analysis based on decomposition of response variance into contributions from variables.

Specification

Alias: none

Argument(s): none

Default: no variance-based decomposition

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>drop_tolerance</td>
<td>Suppresses output of sensitivity indices with values lower than this tolerance</td>
</tr>
</tbody>
</table>

Description

Dakota can calculate sensitivity indices through variance based decomposition using the keyword variance_based_decomp. These indicate how important the uncertainty in each input variable is in contributing to the output variance.

Default Behavior

Because of the computational cost, variance_based_decomp is turned off as a default.

If the user specified a number of samples, N, and a number of nondeterministic variables, M, variance-based decomposition requires the evaluation of N x (M+2) samples. Note that specifying this keyword will increase the number of function evaluations above the number requested with the samples keyword since replicated sets of sample values are evaluated.

Expected Outputs

When variance_based_decomp is specified, sensitivity indices for main effects and total effects will be reported. Main effects (roughly) represent the percent contribution of each individual variable to the variance in the model response. Total effects represent the percent contribution of each individual variable in combination with all other variables to the variance in the model response.

Usage Tips

To obtain sensitivity indices that are reasonably accurate, we recommend that N, the number of samples, be at least one hundred and preferably several hundred or thousands.
Examples

method, sampling
    sample_type lhs
    samples = 100
    variance_based_decomp

Theory

In this context, we take sensitivity analysis to be global, not local as when calculating derivatives of output variables with respect to input variables. Our definition is similar to that of [76]: "The study of how uncertainty in the output of a model can be apportioned to different sources of uncertainty in the model input."

Variance based decomposition is a way of using sets of samples to understand how the variance of the output behaves, with respect to each input variable. A larger value of the sensitivity index, $S_i$, means that the uncertainty in the input variable $i$ has a larger effect on the variance of the output. More details on the calculations and interpretation of the sensitivity indices can be found in [76] and [90].

7.2.76.5.1 drop_tolerance

- Keywords Area
- method
- fsu_quasi_mc
- variance_based_decomp
- drop_tolerance

Suppresses output of sensitivity indices with values lower than this tolerance

Specification

Alias: none

Argument(s): REAL

Default: All VBD indices displayed

Description

The drop_tolerance keyword allows the user to specify a value below which sensitivity indices generated by variance_based_decomp are not displayed.

Default Behavior

By default, all sensitivity indices generated by variance_based_decomp are displayed.

Usage Tips

For polynomial_chaos, which outputs main, interaction, and total effects by default, the univariate_effects may be a more appropriate option. It allows suppression of the interaction effects since the output volume of these results can be prohibitive for high dimensional problems. Similar to suppression of these interactions is the covariance control, which can be selected to be diagonal_covariance or full_covariance, with the former supporting suppression of the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).
Examples

method,
sampling
  sample_type lhs
  samples = 100
  variance_based_decomp
  drop_tolerance = 0.001

7.2.76.6 samples

- Keywords Area
- method
- fsu_quasi_mc
- samples

Number of samples for sampling-based methods

Specification

Alias: none
Argument(s): INTEGER
Default: 0

Description

The samples keyword is used to define the number of samples (i.e., randomly chosen sets of variable values) at which to execute a model.

Default Behavior

By default, Dakota will use the minimum number of samples required by the chosen method.

Usage Tips

To obtain linear sensitivities or to construct a linear response surface, at least dim+1 samples should be used, where "dim" is the number of variables. For sensitivities to quadratic terms or quadratic response surfaces, at least (dim+1)(dim+2)/2 samples are needed. For uncertainty quantification, we recommend at least 10×dim samples. For variance_based_decomp, we recommend hundreds to thousands of samples. Note that for variance_based_decomp, the number of simulations performed will be N×(dim+2).

Examples

method
  sampling
    sample_type lhs
    samples = 20

7.2.76.7 fixed_sequence

- Keywords Area
- method
- fsu_quasi_mc
7.2 method

- fixed_sequence

Reuse the same sequence and samples for multiple sampling sets

Specification

Alias: none
Argument(s): none
Default: sequence not fixed: sampling patterns are variable among multiple QMC runs

Description

The fixed_sequence control is similar to fixed_seed for other sampling methods. If fixed_sequence is specified, the user will get the same sequence (meaning the same set of samples) for subsequent calls of the QMC sampling method (for example, this might be used in a surrogate based optimization method or a parameter study where one wants to fix the uncertain variables).

7.2.76.8 sequence_start

- Keywords Area
- method
- fsu_quasi_mc
- sequence_start

Choose where to start sampling the sequence

Specification

Alias: none
Argument(s): INTEGERLIST
Default: Vector of zeroes

Description

sequence_start determines where in the sequence the samples will start.

The default sequence_start is a vector with 0 for each variable, specifying that each sequence start with the first term.

Examples

For example, for the Halton sequence in base 2, if the user specifies sequence_start = 2, the sequence would not include 0.5 and 0.25, but instead would start at 0.75.

7.2.76.9 sequence_leap

- Keywords Area
- method
Specify how often the sequence is sampled

**Specification**

**Alias:** none  
**Argument(s):** INTEGERLIST  
**Default:** Vector of ones

**Description**

`sequence_leap` controls the "leaping" of terms in the sequence. The default is 1 for each variable, meaning that each term in the sequence be returned.

**Examples**

If the user specifies a `sequence_leap` of 2 for a variable, the points returned would be every other term from the QMC sequence.

**Theory**

The advantage to using a leap value greater than one is mainly for high-dimensional sets of random deviates. In this case, setting a leap value to the next prime number larger than the largest prime base can help maintain uniformity when generating sample sets for high dimensions. For more information about the efficacy of leaped Halton sequences, see [74].

7.2.76.10  prime_base

**Specification**

**Alias:** none  
**Argument(s):** INTEGERLIST  
**Default:** Vector of the first s primes for s-dimensions in Halton, First (s-1) primes for Hammersley

The prime numbers used to generate the sequence
Description

It is recommended that the user not specify this and use the default values.

- For the Halton sequence, the default bases are primes in increasing order, starting with 2, 3, 5, etc.
- For the Hammersley sequence, the user specifies (s-1) primes if one is generating an s-dimensional set of random variables.

7.2.76.11 max_iterations

- Keywords Area
- method
- fsu_quasi_mc
- max_iterations

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: fsu_cvt, local_reliability: 25; global_(reliability, interval_est, evidence) / efficient_global: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed max_iterations iterations. In cases where there are multiple nested iterations to be controlled, max_iterations generally controls the outer-most context.

Default Behavior

Default value is 100.

See Also

These keywords may also be of interest:

- max_function_evaluations
7.2.76.12  model_pointer

- Keywords Area
- method
- fsu_quasi_mc
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

**Usage Tips**

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

**Examples**

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10

7.2.77  vector_parameter_study

  • Keywords Area

  • method

  • vector_parameter_study

Samples variables along a user-defined vector

Topics

This keyword is related to the topics:

  • parameter_studies

Specification

Alias: none

Argument(s): none

Child Keywords:
### Description

Dakota’s vector parameter study computes response data sets at selected intervals along a vector in parameter space. It is often used for single-coordinate parameter studies (to study the effect of a single variable on a response set), but it can be used more generally for multiple coordinate vector studies (to investigate the response variations along some n-dimensional vector such as an optimizer search direction).

### Default Behavior

By default, the vector parameter study operates over all types of variables.

### Expected Outputs

A vector parameter study produces a set of responses for each parameter set that is generated.

### Expected HDF5 Output

If Dakota was built with HDF5 support and run with the `hdf5` keyword, this method writes the following results to HDF5:

- Parameter Sets

### Usage Tips

**Group 1** is used to define the vector along which the parameters are varied. Both cases also rely on the variables specification of an initial value, through:

- the `initial_point` keyword
- the `initial_state` keyword
- relying on the default initial value, based on the rest of the variables specification

From the initial value, the vector can be defined using one of the two keyword choices. Once the vector is defined, the samples are then fully specified by `num_steps`.

### Examples

The following example is a good comparison to the examples on `multidim_parameter_study` and `centered_parameter_study`.

7.2.77.1 final_point

- Keywords Area
- method
- vector_parameter_study
- final_point

Final variable values defining vector in vector parameter study

Specification

Alias: none
Argument(s): REALLIST

Description

The final_point keyword is used to define the final values for each variable on the vector to be used in the vector parameter study. The vector's direction and magnitude are determined by the initial value from the variables specification, and the final_point.
The user is required to specify either `final_point` or `step_vector`. There is no default definition for the vector.

**Usage Tips**

The actual points are determined based on this vector and the number of points chosen is given in `num_points`.

**Examples**

```plaintext
method
  vector_parameter_study
  num_steps = 10
  final_point =  2.0  2.0
```

7.2.77.2 step_vector

- Keywords Area
- method
- vector_parameter_study
- step_vector

Size of step for each variable

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Description**

The `step_vector` keyword specifies how much each variable will be incremented in a single step. `step_vector` works in conjunction with `num_steps`, which determines the number of steps taken during the `vector_parameter_study`. If instead of `step_vector`, `final_point` is specified with `num_steps`, Dakota will infer the step sizes.

Entries in the `step_vector` are the actual amounts by which continuous and range variables are incremented. For set variables, `step_vector` entries are interpreted as indexes into the underlying set.

**Default Behavior**

The user is required to specify either `final_point` or `step_vector`. There is no default definition for the vector.

**Examples**

```plaintext
variables
  continuous_design 1
  initial_point 1.0
  descriptors 'x1'
  discrete_design_set
  string 1
  elements 'bar' 'baz' 'foo' 'fuzz'
  initial_point 'bar'
  descriptors 'x1'

method
```
vector_parameter_study

num_steps = 3
  # Add 2.0 to x1 and increment s1 by 1 element in each step
  step_vector = 2.0 1

7.2.77.3 num_steps

  • Keywords Area
  • method
  • vector_parameter_study
  • num_steps

Number of sampling steps along the vector in a vector parameter study

Specification

Alias: none

Argument(s): INTEGER

Description

num_steps defines the number of steps that are taken in the direction of the vector. The magnitude of each step is determined in conjunction with the rest of the method specification.

Default Behavior

The user is required to specify num_steps for a vector parameter study. There is no default value.

This study performs function evaluations at both ends, making the total number of evaluations equal to num_steps+1.

Usage Tips

The study has stringent requirements on performing appropriate steps with any discrete range and discrete set variables. A num_steps specification must result in discrete range and set index steps that are integers: no remainder is currently permitted in the integer step calculation and no rounding to integer steps will occur.

Examples

method
  vector_parameter_study
    num_steps = 10
    final_point = 2.0 2.0

7.2.77.4 model_pointer

  • Keywords Area
  • method
  • vector_parameter_study
  • model_pointer

Identifier for model block to be used by a method
Topics

This keyword is related to the topics:

• block_pointer

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.

See block_pointer for details about pointers.

7.2.78 list_parameter_study

• Keywords Area
• method
• list_parameter_study

Samples variables as a specified values

Topics

This keyword is related to the topics:

• parameter_studies

Specification

Alias: none
Argument(s): none
Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group Points Source (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required (Choose One)</td>
<td></td>
<td>list_of_points</td>
<td>List of variable values to evaluate in a list parameter study</td>
</tr>
<tr>
<td></td>
<td></td>
<td>import_points_file</td>
<td>File containing list of variable values to evaluate in a list parameter study</td>
</tr>
</tbody>
</table>
Description

Dakota’s list parameter study allows for evaluations at user selected points of interest.

Default Behavior

By default, the list parameter study operates over all types of variables.

The number of real values in the list_of_points specification or file referenced by import_points_file must be a multiple of the total number of variables (including continuous and discrete types) contained in the variables specification.

Expected Outputs

A list parameter study produces a set of responses for each parameter set that is specified.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the hdf5 keyword, this method writes the following results to HDF5:

- Parameter Sets

Usage Tips

- This parameter study simply performs simulations for the first parameter set (the first \( n \) entries in the list), followed by the next parameter set (the next \( n \) entries), and so on, until the list of points has been exhausted.

- Since the initial values from the variables specification will not be used, they need not be specified.

- When the points are specified in the Dakota input file using the list_of_points keyword, discrete set values must be referred to using 0-based indexes, and not the values themselves. However, when using import_points_file, refer to discrete set values directly, not by index.

- For both list_of_points and import_points_file, Dakota expects the values for each evaluation to be ordered by type. The type ordering matches that of the variables section of this Reference Manual and of the listing in the Parameters file format section of the Dakota User’s Manual [5]. When multiple variables are present for a single type, the ordering within that type must match the order specified by the user in the variables section of her input file.

Examples

This shows the method and variables block of a Dakota input file that runs a list_parameter_study.

```plaintext
method
  list_parameter_study
  list_of_points =
    3.1e6   0.0029   0.31
    3.2e6   0.0028   0.32
    3.3e6   0.0027   0.34
    3.3e6   0.0026   0.36

variables
  continuous_design = 3
  descriptors = ‘E’ ‘MASS’ ‘DENSITY’
```

Note that because of the way Dakota treats whitespace, the above example is equivalent to:
method
  list_parameter_study
  list_of_points =
  \[\begin{array}{llllll}
  3.1e6 & 0.0029 & 0.31 & 3.2e6 & 0.0028 \\
  0.32 & 3.3e6 & 0.0027 \\
  0.34 & 3.3e6 & 0.0026 & 0.36
  \end{array}\]

variables
  continuous_design = 3
  descriptors = ‘E’ ‘MASS’ ‘DENSITY’

Although the first example is much more readable.

And here’s a full input file:

```plaintext
# tested on Dakota 6.0 on 140501
environment
  tabular_data
    tabular_data_file ‘List_param_study.dat’

method
  list_parameter_study
  list_of_points =
  \[\begin{array}{llllll}
  0.1 & 0.1 \\
  0.2 & 0.1 \\
  0.3 & 0.0 \\
  0.3 & 1.0
  \end{array}\]

model
  single

variables
  active design
  continuous_design = 2
    descriptors ‘x1’ ‘x2’
  continuous_state = 1
    descriptors = ‘constant1’
    initial_state = 100

interface
  analysis_drivers ‘text_book’
    fork
      asynchronous
        evaluation_concurrency 2

responses
  response_functions = 1
  no_gradients
  no_hessians
```

This example illustrates the list_parameter_study.

- The function evaluations are independent, so any level of evaluation_concurrency can be used
- Default behavior for parameter studies is to iterate on all variables. However, because active design is specified, this study will only iterate on the continuous_design variables.

See Also

These keywords may also be of interest:

- centered_parameter_study
- multidim_parameter_study
- vector_parameter_study
List of variable values to evaluate in a list parameter study

**Specification**

*Alias*: none

*Argument(s)*: REALLIST

**Description**

The `list_of_points` keyword allows the user to specify, in a freeform format, a list of variable values at which to compute a model response.

**Default Behavior**

The user is required to provide a list of points for a list parameter study either by specifying it with `list_of_points` or by providing a file from which such a list can be read via `import_points_file`. There is no default list of points.

**Usage Tips**

The number of values in the list must be an integer multiple of the number of variables. Dakota will verify that this condition is met.

**Examples**

```
method
list_parameter_study
  list_of_points =
  3.1e6  0.0029  0.31
  3.2e6  0.0028  0.32
  3.3e6  0.0027  0.34
  3.3e6  0.0026  0.36
```

---

7.2.78.2 import_points_file

*Keywords Area*

*method*

*list_parameter_study*

*import_points_file*

File containing list of variable values to evaluate in a list parameter study
Specification

Alias: none

Argument(s): STRING

Default: no point import from a file

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Optional</strong> <em>(Choose One)</em></td>

<td></td>
<td>freeform</td>
<td>Selects freeform file format</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>active_only</td>
<td>Import only active variables from tabular data file</td>
</tr>
</tbody>
</table>

Description

The `import_points_file` specifies a file containing a list of variable values at which to compute a model response.

Default Behavior

By default, methods do not import points from a file.

Usage Tips

Dakota parses input files without regard to whitespace, but the `import_points_file` must be in one of three formats:

- `annotated` (default)
- `custom_annotated`
- `freeform`

Examples

```
method
  list_parameter_study
    import_points_file = 'dakota_pstudy.3.dat'
```

7.2.78.2.1 custom_annotated

- Keywords Area
- method
- list_parameter_study
- import_points_file
- custom_annotated

Selects custom-annotated tabular file format
Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>header</td>
<td>header</td>
<td>Enable header row in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td>eval_id</td>
<td>eval_id</td>
<td>Enable evaluation ID column in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td>interface_id</td>
<td>interface_id</td>
<td>Enable interface ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
custom_annotated header eval_id

Resulting tabular file:

<table>
<thead>
<tr>
<th>@eval_id</th>
<th>x1</th>
<th>x2</th>
<th>obj_fn</th>
<th>nln_ineq_con_1</th>
<th>nln_ineq_con_2</th>

Description

See description of parent \texttt{custom\_annotated}

7.2.78.2.2 \texttt{annotated}

- Keywords Area
- method
- \texttt{list\_parameter\_study}
- \texttt{import\_points\_file}
- \texttt{annotated}

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- \texttt{file\_formats}

Specification

\textbf{Alias}: none

\textbf{Argument(s)}: none

\textbf{Default}: annotated
Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
  tabular_data_file = 'dakota_summary.dat'
  annotated
```

Resulting tabular file:

```
%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 NO_ID 0.9 1.1 0.0002 0.26 0.76
2 NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 NO_ID 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...```

7.2.78.2.3 freeform

- Keywords Area
- method
- list_parameter_study
- import_points_file
- freeform

Selects freeform file format

Topics

This keyword is related to the topics:

- file_formats
Specification

Alias: none
Argument(s): none

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```python
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    freeform
```

Resulting tabular file:

```
  0.9  1.1  0.0002  0.26  0.76
  0.90009 1.1  0.001996404857  0.2601620081  0.759955
  0.89991 1.1  0.0002003604863  0.2598380081  0.760045
...```

```
7.2.78.2.4  active_only

- Keywords Area
- method
- list_parameter_study
- import_points_file
- active_only

Import only active variables from tabular data file
Topics

This keyword is related to the topics:

- file_formats

Specification

**Alias:** none

**Argument(s):** none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

7.2.78.3 model_pointer

- Keywords Area
- Method
- list_parameter_study
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)

Description

The `model Pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.
Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

Examples

```dakota
environment
tabular_data
method_pointer = 'UQ'

method
id_method = 'UQ'
model_pointer = 'SURR'
sampling,
samples = 10
seed = 98765 rng rnum2
response_levels = 0.1 0.2 0.6
sample_type lhs
distribution cumulative

model
id_model = 'SURR'
surrogate global,
dace_method_pointer = 'DACE'
polynomial quadratic

method
id_method = 'DACE'
model_pointer = 'DACE_M'
sampling sample_type lhs
samples = 121 seed = 5034 rng rnum2

model
id_model = 'DACE_M'
single
interface_pointer = 'I1'

variables
uniform_uncertain = 2
lower_bounds = 0. 0.
upper_bounds = 1. 1.
descriptors = 'x1' 'x2'

interface
id_interface = 'I1'
system asynch evaluation_concurrency = 5
analysis_driver = 'text_book'

responses
response_functions = 3
no_gradients
no_hessians
```

7.2.79 `centered_parameter_study`

- Keywords Area
- method
- `centered_parameter_study`

Samples variables along points moving out from a center point
Topics

This keyword is related to the topics:

- parameter_studies

Specification

Alias: none

Argument(s): none

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required</td>
<td>step_vector</td>
<td></td>
<td>Size of steps to be taken in each dimension of a centered parameter study</td>
</tr>
<tr>
<td>Required</td>
<td>steps_per_variable</td>
<td></td>
<td>Number of steps to take in each dimension of a centered parameter study</td>
</tr>
<tr>
<td>Optional</td>
<td>model_pointer</td>
<td></td>
<td>Identifier for model block to be used by a method</td>
</tr>
</tbody>
</table>

Description

Dakota’s centered parameter study computes response data sets along multiple coordinate-based vectors, one per parameter, centered about the initial values from the variables specification. This is useful for investigation of function contours with respect to each parameter individually in the vicinity of a specific point (e.g., post-optimality analysis for verification of a minimum), thereby avoiding the cost associated with a multidimensional grid.

Default Behavior

By default, the centered parameter study operates over all types of variables.

The centered_parameter_study takes steps along each orthogonal dimension. Each dimension is treated independently. The number of steps are taken in each direction, so that the total number of points in the parameter study is \(1 + 2\sum n\).

Expected Outputs

A centered parameter study produces a set of responses for each parameter set that is generated.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the hdf5 keyword, this method writes the following results to HDF5:

- Parameter Sets
- Variable Slices
Examples

The following example is a good comparison to the examples on `multidim_parameter_study` and `vector_parameter_study`.

```dakota
# tested on Dakota 6.0 on 140501
environment
tabular_data
tabular_data_file = 'rosen_centered.dat'
method
centered_parameter_study
steps_per_variable = 5 4
step_vector = 0.4 0.5
model
single
variables
continuous_design = 2
initial_point = 0 0
descriptors = 'x1' "x2"

7.2.79.1 step_vector

- Keywords Area
- method
- centered_parameter_study
- step_vector

Size of steps to be taken in each dimension of a centered parameter study

Specification

**Alias:** none

**Argument(s):** REALLIST
Description

The `step_vector` keyword defines the individual step size in each dimension, treated separately.

Default Behavior

The user is required to define the number of step sizes for a centered parameter study. There are no default values.

Steps are taken in the plus and minus directions, and are defined in either actual values (continuous and discrete range) or index offsets (discrete set).

Examples

```
method
centered_parameter_study
    steps_per_variable = 5 4
    step_vector = 0.4 0.5
```

7.2.79.2 steps_per_variable

- Keywords Area
- method
- centered_parameter_study
- steps_per_variable

Number of steps to take in each dimension of a centered parameter study

Specification

Alias: `deltas_per_variable`

Argument(s): `INTEGERLIST`

Description

The `steps_per_variable` keyword allows the user to define the number of steps in each dimension of a centered parameter study. Because they are taken independently, the number of steps can be specified for each.

Default Behavior

The user is required to define the number of steps per variable for a centered parameter study. There are no default values.

Steps are taken in the plus and minus directions, and are defined in either actual values (continuous and discrete range) or index offsets (discrete set).

Examples

```
method
centered_parameter_study
    steps_per_variable = 5 4
    step_vector = 0.4 0.5
```
7.2.79.3 model_pointer

- Keywords Area
- method
- centered_parameter_study
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

Examples

```plaintext
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
      samples = 10
      seed = 98765 rng rnum2
      response_levels = 0.1 0.2 0.6
          0.1 0.2 0.6
          0.1 0.2 0.6
  sample_type lhs
  distribution cumulative

model
  id_model = 'SURR'
```
surrogate global,
dace_method_pointer = 'DACE'

method
  id_method = 'DACE'

7.2.80 multidim_parameter_study

• Keywords Area
• method
• multidim_parameter_study

Samples variables on full factorial grid of study points

Topics

This keyword is related to the topics:

• parameter_studies

Specification

Alias: none
Argument(s): none

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword partitions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required</td>
<td></td>
<td>Samples variables on full factorial grid of study points</td>
</tr>
</tbody>
</table>
Description

Dakota’s multidimensional parameter study computes response data sets for an n-dimensional grid of points. Each continuous and discrete range variable is partitioned into equally spaced intervals between its upper and lower bounds, each discrete set variable is partitioned into equally spaced index intervals. The partition boundaries in n-dimensional space define a grid of points, and every point is evaluated.

Default Behavior

By default, the multidimensional parameter study operates over all types of variables.

Expected Outputs

A multidimensional parameter study produces a set of responses for each parameter set that is generated.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the hdf5 keyword, this method writes the following results to HDF5:

- Parameter Sets
- Correlations

Usage Tips

Since the initial values from the variables specification will not be used, they need not be specified.

Examples

This example is taken from the Users Manual and is a good comparison to the examples on centered_parameter_study and vector_parameter_study.

```bash
# tested on Dakota 6.0 on 140501
environment
  tabular_data
  tabular_data_file = 'rosen_multidim.dat'

method
  multidim_parameter_study
  partitions = 10 8

model
  single

variables
  continuous_design = 2
  lower_bounds -2.0 -2.0
  upper_bounds 2.0 2.0
  descriptors 'x1' "x2"

interface
  analysis_driver = 'rosenbrock'
  fork

responses
  response_functions = 1
  no_gradients
  no_hessians
```
This example illustrates the full factorial combinations of parameter values created by the multidim_parameter_study. With 10 and 8 partitions, there are actually 11 and 9 values for each variable. This means that $11 \times 9 = 99$ function evaluations will be required.

7.2 method

| Optional | model_pointer | Identifier for model block to be used by a method |

Description

Solution verification procedures estimate the order of convergence of the simulation response data during the course of a refinement study. This branch of methods is new and currently only contains one algorithm: Richardson extrapolation.

Refinement of the model

The model fidelity must be parameterized by one or more continuous state variable(s).

The refinement path is determined from the initial_state of the continuous_state variables specification in combination with the refinement_rate, where each of the state variables is treated as an independent refinement factor and each of the initial state values is repeatedly divided by the refinement rate value to define new discretization states.

Results

Three algorithm options are currently provided:

1. estimate_order
2. converge_order
3. converge_qoi

Stopping Criteria

The method employs the max_iterations and convergence_tolerance method independent controls as stopping criteria.

Theory

In each of these cases, convergence order for a response quantity of interest (QoI) is estimated from

\[ p = \frac{\ln(QoI_3 - QoI_2)}{\ln(QoI_2 - QoI_1)} / \ln(r) \]

where \( r \) is the uniform refinement rate specified by refinement_rate.

7.2.81.1 estimate_order

- Keywords Area
- method
- richardson_extrap
- estimate_order

Compute the best estimate of the convergence order from three points

Specification

Alias: none
Argument(s): none
Description

The estimate_order option is the simplest option. For each of the refinement factors, it evaluates three points along the refinement path and uses these results to perform an estimate of the convergence order for each response function.

7.2.81.2 converge_order

- Keywords Area
- method
- richardson_extrap
- converge_order

Refine until the estimated coverage order converges

Specification

Alias: none

Argument(s): none

Description

The converge_order option is initialized using the estimate_order approach, and additional refinements are performed along the refinement path until the convergence order estimates converge (two-norm of the change in response orders is less than the convergence tolerance).

7.2.81.3 converge_qoi

- Keywords Area
- method
- richardson_extrap
- converge_qoi

Refine until the response converges

Specification

Alias: none

Argument(s): none

Description

The converge_qoi option is similar to the converge_order option, except that the convergence criterion is that the two-norm of the response discretization errors (computed from extrapolation) must be less than the convergence tolerance.
7.2.81.4  refinement_rate

- Keywords Area
- method
- richardson_extrap
- refinement_rate

Rate at which the state variables are refined

Specification

Alias: none
Argument(s): REAL
Default: 2.

Description

Described on parent page

7.2.81.5  convergence_tolerance

- Keywords Area
- method
- richardson_extrap
- convergence_tolerance

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none
Argument(s): REAL
Default: 1.e-4

Description

The convergence_tolerance specification provides a real value for controlling the termination of iteration.
For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by convergence_tolerance, then this convergence criterion is satisfied on the current iteration.
Therefore, permissible values are between 0 and 1, non-inclusive.

**Behavior Varies by Package/Library**

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See nl2sol
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

### 7.2.81.6 max_iterations

- **Keywords Area**
- **method**
- **richardson_extrap**
- **max_iterations**

Number of iterations allowed for optimizers and adaptive UQ methods

**Topics**

This keyword is related to the topics:

- **method_independent_controls**

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 100 (exceptions: fsu_cvt, local_reliability: 25; global_reliability, interval_est, evidence) / efficient_global: 25*n)

**Description**

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed max_iterations iterations. In cases where there are multiple nested iterations to be controlled, max_iterations generally controls the outer-most context.

**Default Behavior**

Default value is 100.

These keywords may also be of interest:

- max_function_evaluations

7.2.81.7 model_pointer

- Keywords Area
  - method
  - richardson_extrap
  - model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.

See block_pointer for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
```
seed = 98765 rng rnum2
response_levels = 0.1 0.2 0.6
    0.1 0.2 0.6
    0.1 0.2 0.6
sample_type lhs
distribution cumulative

model
    id_model = 'SURR'
surrogate global,
dace_method_pointer = 'DACE'
polynomial quadratic

method
    id_method = 'DACE'
    model_pointer = 'DACE_M'
sampling sample_type lhs
    samples = 121 seed = 5034 rng rnum2

model
    id_model = 'DACE_M'
single
    interface_pointer = 'I1'

variables
    uniform_uncertain = 2
    lower_bounds = 0. 0.
    upper_bounds = 1. 1.
    descriptors = 'x1' 'x2'

interface
    id_interface = 'I1'
system asynch evaluation_concurrency = 5
    analysis_driver = 'text_book'

responses
    response_functions = 3
    no_gradients
    no_hessians

7.3 model
    • Keywords Area
    • model

Specifies how variables are mapped into a set of responses

Topics

This keyword is related to the topics:
    • block

Specification

Alias: none
Argument(s): none

</tr>
</tbody>
</table>
Description

A model is comprised of a mapping from variables, through an interface, to responses.

Model Group 1  The type of model can be:

1. single (default)
2. surrogate
3. nested
4. subspace
5. random_field

The input file must specify one of these types. If the type is not specified, Dakota will assume a single model.

Block Pointers and ID

Each of these model types supports variables_pointer and responses_pointer strings for identifying the variables and responses specifications used in constructing the model by cross-referencing with id_variables and id_responses strings from particular variables and responses keyword specifications.

These pointers are valid for each model type since each model contains a set of variables that is mapped into a set of responses – only the specifics of the mapping differ.

Additional pointers are used for each model type for constructing the components of the variable to response mapping. As an environment specification identifies a top-level method and a method specification identifies a model, a model specification identifies variables, responses, and (for some types) interface specifications. This top-down flow specifies all of the object interrelationships.

Examples

The first example shows a minimal specification for a single model, which is the default model when no models are explicitly specified by the user.

```dakota
model
  single
```

The next example displays a surrogate model specification which selects a quadratic polynomial from among the global approximation methods. It uses a pointer to a design of experiments method for generating the data needed for building the global approximation, reuses any old data available for the current approximation region, and employs the first-order multiplicative approach to correcting the approximation each time correction is requested.

```dakota
model,
  id_model = 'M1'
  variables_pointer = 'V1'
  responses_pointer = 'R1'
```
This example demonstrates the use of identifiers and pointers. It provides the optional model independent specifications for model identifier, variables pointer, and responses pointer as well as model dependent specifications for global surrogates (see global).

Finally, an advanced nested model example would be

```
model
  id_model = 'M1'
  variables_pointer = 'V1'
  responses_pointer = 'R1'
  nested
    optional_interface_pointer = 'OI1'
    optional_interface_responses_pointer = 'OIR1'
    sub_method_pointer = 'SM1'
    primary_variable_mapping = ' ' 'X' 'Y'
    secondary_variable_mapping = ' ' 'mean' 'mean'
    primary_response_mapping = 1.0 0.0 0.0 0.0 0.0 0.0 0.0 0.0 0.0
    secondary_response_mapping = 0.0 0.0 0.0 1.0 3.0 0.0 0.0 0.0 0.0
```

This example illustrates controls for model identifier, variables pointer, and responses pointer and for specifying details of the nested mapping.

### 7.3.1 id_model

- **Keywords Area**
- **model**
- **id_model**

Give the model block an identifying name, in case of multiple model blocks

**Topics**

This keyword is related to the topics:

- **block_identifier**

**Specification**

*Alias:* none

*Argument(s):* STRING

*Default:* method use of last model parsed

**Description**

The model identifier string is supplied with `id_model` and is used to provide a unique identifier string for use within method specifications (refer to the keyword `model_pointer` in any of the methods in the `method` block, for example: `model_pointer`) This is used to determine which model the method will run.
See Also

These keywords may also be of interest:

- `model_pointer`

7.3.2 single

- Keywords Area
- `model`
- `single`

A model with one of each block: variable, interface, and response

Specification

**Alias:** simulation

**Argument(s):** none

**Default:** N/A (single if no model specification)

**Child Keywords:**

</tr>
</tbody>
</table>

**Description**

The single model is the simplest model type. It uses a single interface instance to map variables into responses. There is no recursion in this case.

The optional `interface_pointer` specification identifies the interface block by cross-referencing with the `id_-interface` string input from a particular interface keyword specification. This is only necessary when the input file has multiple interface blocks, and you wish to explicitly point to the desired block. The same logic follows for responses and variables blocks and pointers.
Examples

The example shows a minimal specification for a single model, which is the default model when no models are specified by the user.

```
model
  single
```

This example does not provide any pointer strings and therefore relies on the default behavior of constructing the model with the last variables, interface, and responses specifications parsed.

These keywords may also be of interest:

- surrogate
- nested

7.3.2.1 interface_pointer

- Keywords Area
- model
- single
- interface_pointer

Interface block pointer for the single model type

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none

Argument(s): STRING

Default: model use of last interface parsed

Description

In the single model case, a single interface is used to map the variables into responses. The optional interface_pointer specification identifies this interface by cross-referencing with the id_interface string input from a particular interface keyword specification.

See block_pointer for details about pointers.

When an interface pointer is not specified, the model will use the last interface block parsed from the input file.
7.3.2.2  solution_level_control

- Keywords Area
- model
- single
- solution_level_control

Cost estimates associated with a set of solution control values.

Specification

Alias: none
Argument(s): STRING
Default: use of single default solution level

Description

Simulation-based models may have an associated solution_level_control, which identifies a hierarchy of solution states, such as a set of mesh discretizations from coarse to fine, a set of solver tolerances from loose to tight, etc. The string specified as the solution_level_control identifies a discrete variable label that parameterizes the hierarchy of solution states.

Note: If the discrete variable identified is a discrete set variable, then it is important to note that the variable’s set values will be ordered (lexicographically in the case of string variables), and the ordering of values provided in solution_level_cost should correspond to this set ordering. A common error is to provide a listing of set values that is out of order and then providing a set of costs corresponding to this misordered list – in this case, the solution level costs will be associated with the re-ordered set values.

Examples

In this example, integer solution control values and solution costs are naturally well ordered.

model,
  simulation
    solution_level_control = 'mesh_size'
    solution_level_cost = 1. 8. 64. 512. 4096.
variables,
  uniform_uncertain = 9
  lower_bounds = 9*-1.
  upper_bounds = 9*1.
  discrete_state_set
    integer = 1
    set_values = 4 8 16 32 64
    descriptors = 'mesh_size'

In this example, string solution control values are lexicographically ordered, and care must be taken to align the solution cost estimates.

model,
  simulation
    solution_level_control = 'mesh_size'
    solution_level_cost = 1. 64. 8. # match set ordering
variables,
  uniform_uncertain = 9
  lower_bounds = 9*-1.
  upper_bounds = 9*1.
7.3.2.3 solution_level_cost

- **Keywords Area**
- **model**
- **single**
- **solution_level_cost**

Cost estimates associated with a set of solution control values.

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Description**

Simulation-based models may have an associated *solution_level_control*, which identifies a hierarchy of solution states, such as a set of mesh discretizations from coarse to fine, a set of solver tolerances from loose to tight, etc. In algorithms that manage such a hierarchy and perform optimal resource allocation among the solution states (e.g., multilevel Monte Carlo), it is important to estimate a set of costs associated with each state. These cost estimates can be relative, such as in the example below (lowest cost normalized to 1.)

**Note:** a scalar solution cost can be specified without an associated solution level control. This is useful when employing a hierarchy of model forms (each model has a scalar solution cost and no solution level control) instead of a hierarchy of discretization levels (one model has a vector-valued solution cost associated with multiple solution levels).

**Examples**

```dakota
model, 
  simulation 
    solution_level_control = 'mesh_size'
    solution_level_cost = 1. 8. 64. 512. 4096.
variables, 
  uniform_uncertain = 9
  lower_bounds = 9*1.
  upper_bounds = 9*1.
  discrete_state_set 
    integer = 1
    set_values = 4 8 16 32 64
    descriptors = 'mesh_size'
```

7.3.2.4 cost_recovery_metadata

- **Keywords Area**
- **model**
- **single**
• cost_recovery_metadata

Identify metadata by label for capturing online cost estimates

Specification

Alias: none

Argument(s): STRING

Description

Metadata can be used for a variety of response annotation purposes, including the online recovery of simulation cost (using facilities either implemented in a user’s analysis driver or codified in an embedded test driver). This information can then be used by certain algorithms that allocate resources based on relative cost, e.g. multifidelity UQ methods.

Cost estimates may be provided a priori, e.g. using solution_level_cost, in cases where they can be assumed fixed for each model form and/or resolution. In cases such as model tuning over a set of hyper-parameters, costs will generally be a function of these hyper-parameters and need to be captured online during initialization of the algorithm (e.g. during evaluation of the pilot sample).

Default Behavior  No recovery of cost estimates from the response metadata.

Usage Tips It is common to employ total CPU time, aggregated across all computing cores involved in a (parallel) simulation instance. Wall time, even when the number of cores is fixed, can be subject to additional variability due to system load.

Examples

```yaml
model,
    id_model = 'TUNABLE_LF'
  simulation
    cost_recovery_metadata = 'core_time'

responses,
  response_functions = 1
  descriptors = 'Q'
  no_gradients
  no_hessians
  metadata 'core_time'
```

**Description**

Surrogate models are inexpensive approximate models that are intended to capture the salient features of an expensive high-fidelity model. They can be used to explore the variations in response quantities over regions of the parameter space, or they can serve as inexpensive stand-ins for optimization or uncertainty quantification studies (see, for example, the surrogate-based optimization methods, surrogate_based_global and surrogate_based_local).

Surrogate models supported in Dakota are categorized as Data Fitting or Hierarchical, as shown below. Each of these surrogate types provides an approximate representation of a "truth" model which is used to perform the parameter to response mappings. This approximation is built and updated using results from the truth model, called the "training data".

- Data fits:
**Known Issue**: When using discrete variables, there have been sometimes significant differences in surrogate behavior observed across computing platforms in some cases. The cause has not yet been fully diagnosed and is currently under investigation. In addition, guidance on appropriate construction and use of surrogates with discrete variables is under development. In the meantime, users should therefore be aware that there is a risk of inaccurate results when using surrogates with discrete variables.

Data fitting methods involve construction of an approximation or surrogate model using data (response values, gradients, and Hessians) generated from the original truth model. Data fit methods can be further categorized as local, multipoint, and global approximation techniques, based on the number of points used in generating the data fit.

1. **Local**: built from response data from a single point in parameter space
   - Taylor series expansion: `taylor_series`
   - Training data consists of a single point, plus gradient and Hessian information.

2. **Multipoint**: built from two or more points in parameter space, often involving the current and previous iterates of a minimization algorithm.
   - TANA-3: `tana`
   - Training Data comes from a few previously evaluated points

3. **Global full space response surface methods**:
   - Polynomial regression: `polynomial`
   - Gaussian process (Kriging): `gaussian_process`
   - Artificial neutral network: `neural_network`
   - MARS: `mars`
   - Radial Basis Functions: `radial_basis`
   - Orthogonal polynomials (only supported in PCE/SC for now): `polynomial_chaos` and `stoch_-collocation`

   Training data is generated using either a design of experiments method applied to the truth model (specified by `dace_method_pointer`), or from saved data (specified by `reuse_points`) in a restart database, or an import file.

   - **Multifidelity/hierarchical**:
     Multifidelity modeling involves the use of a low-fidelity physics-based model as a surrogate for the original high-fidelity model. The low-fidelity model typically involves a coarser mesh, looser convergence tolerances, reduced element order, or omitted physics.

     See `hierarchical`.

The global and hierarchal surrogates have a correction feature in order to improve the local accuracy of the surrogate models. The correction factors force the surrogate models to match the true function values and possibly true function derivatives at the center point of each trust region. Details can be found on global `correction` or hierarchical `correction`.

**Theory**

Surrogate models are used extensively in the surrogate-based optimization and least squares methods, in which the goals are to reduce expense by minimizing the number of truth function evaluations and to smooth out noisy data with a global data fit. However, the use of surrogate models is not restricted to optimization techniques; uncertainty quantification and optimization under uncertainty methods are other primary users.

**Data Fit Surrogate Models**

A surrogate of the `{data fit}` type is a non-physics-based approximation typically involving interpolation or regression of a set of data generated from the original model. Data fit surrogates can be further characterized by the number of data points used in the fit, where a local approximation (e.g., first or second-order Taylor series) uses data from a single point, a multipoint approximation (e.g., two-point exponential approximations (TPEA) or two-point adaptive nonlinearity approximations (TANA)) uses a small number of data points often drawn from the previous iterates of a particular algorithm, and a global approximation (e.g., polynomial response surfaces, kriging/gaussian_process,
neural networks, radial basis functions, splines) uses a set of data points distributed over the domain of interest, often generated using a design of computer experiments.

Dakota contains several types of surface fitting methods that can be used with optimization and uncertainty quantification methods and strategies such as surrogate-based optimization and optimization under uncertainty. These are: polynomial models (linear, quadratic, and cubic), first-order Taylor series expansion, kriging spatial interpolation, artificial neural networks, multivariate adaptive regression splines, radial basis functions, and moving least squares. With the exception of Taylor series methods, all of the above methods listed in the previous sentence are accessed in Dakota through the Surfpack library. All of these surface fitting methods can be applied to problems having an arbitrary number of design parameters. However, surface fitting methods usually are practical only for problems where there are a small number of parameters (e.g., a maximum of somewhere in the range of 30-50 design parameters). The mathematical models created by surface fitting methods have a variety of names in the engineering community. These include surrogate models, meta-models, approximation models, and response surfaces. For this manual, the terms surface fit model and surrogate model are used.

The data fitting methods in Dakota include software developed by Sandia researchers and by various researchers in the academic community.

Multifidelity Surrogate Models

A second type of surrogate is the \{model hierarchy\} type (also called multifidelity, variable fidelity, variable complexity, etc.). In this case, a model that is still physics-based but is of lower fidelity (e.g., coarser discretization, reduced element order, looser convergence tolerances, omitted physics) is used as the surrogate in place of the high-fidelity model. For example, an inviscid, incompressible Euler CFD model on a coarse discretization could be used as a low-fidelity surrogate for a high-fidelity Navier-Stokes model on a fine discretization.

Surrogate Model Selection

This section offers some guidance on choosing from among the available surrogate model types.

- For Surrogate Based Local Optimization, using the surrogate_based_local method with a trust region:
  using the keywords:
  1. surrogate local taylor_series or
  2. surrogate multipoint tana
  will probably work best.
  If for some reason you wish or need to use a global surrogate (not recommended) then the best of these options is likely to be either:
  1. surrogate global gaussian_process surfpack or
  2. surrogate global moving_least_squares.

- For Efficient Global Optimization (EGO), the efficient_global method:
  the default surrogate is: gaussian_process surfpack which is likely to find a more optimal value and/or require fewer true function evaluations than the alternative, gaussian_process dakota. However, the surfpack will likely take more time to build than the dakota version. Note that currently the use_derivatives keyword is not recommended for use with EGO based methods.

- For EGO based global interval estimation, the global_interval_est ego method:
  the default gaussian_process surfpack will likely work better than the alternative gaussian_process dakota.

- For Efficient Global Reliability Analysis (EGRA), the global_reliability method:
  the surfpack and dakota versions of the gaussian process tend to give similar answers with the dakota version tending to use fewer true function evaluations. Since this is based on EGO, it is likely that the default surfpack is more accurate, although this has not been rigorously demonstrated.

- For EGO based Dempster-Shafer Theory of Evidence, i.e. the global_evidence ego method, the default gaussian_process surfpack often use significantly fewer true function evaluations than the alternative gaussian_process dakota.

- When using a global surrogate to extrapolate, any of the surrogates:
- `gaussian_process surfpack`
- `polynomial quadratic`
- `polynomial cubic`

are recommended.

- When there is over roughly two or three thousand data points and you wish to interpolate (or approximately interpolate) then a Taylor series, Radial Basis Function Network, or Moving Least Squares fit is recommended. The only reason that the `gaussian_process surfpack` is not recommended is that it can take a considerable amount of time to construct when the number of data points is very large. Use of the third party MARS package included in Dakota is generally discouraged.

- In other situations that call for a global surrogate, the `gaussian_process surfpack` is generally recommended. The `use_derivatives` keyword will only be useful if accurate and inexpensive derivatives are available. Finite difference derivatives are disqualified on both counts. However, derivatives generated by analytical, automatic differentiation, or continuous adjoint techniques can be appropriate. Currently, first order derivatives, i.e. gradients, are the highest order derivatives that can be used to construct the `gaussian_process surfpack` model; Hessians will not be used even if they are available.

7.3.3.1 `id_surrogates`

- Keywords Area
- `model`
- `surrogate`
- `id_surrogates`

Identifies the subset of the response functions by number that are to be approximated (the default is all functions).

Specification

**Alias:** none

**Argument(s):** INTEGERLIST

**Default:** All response functions are approximated

Description

In the surrogate model case, the specification first allows a mixture of surrogate and actual response mappings through the use of the optional `id_surrogates` specification. This identifies the subset of the response functions by number that are to be approximated (the default is all functions). The valid response function identifiers range from 1 through the total number of response functions (see `response_functions`).
Select a surrogate model with global support

### Description

The global surrogate model requires specification of one of the following approximation types:

1. Polynomial
2. Gaussian process (Kriging interpolation)
3. Layered perceptron artificial neural network approximation
4. MARS
5. Moving least squares
6. Radial basis function
7. Voronoi Piecewise Surrogate (VPS)

All these approximations are implemented in SurfPack [36], except for VPS. In addition, a second version of Gaussian process is implemented directly in Dakota.

### Training Data

Training data can be taken from prior runs, stored in a datafile, or by running a Design of Experiments method. The keywords listed below are used to determine how to collect training data:

- `dace_method_pointer`
- `reuse_points`
- `import_points_file`
- `use_derivatives` The source of training data is determined by the contents of a provided `import_points_file`, whether `reuse_points` and `use_derivatives` are specified, and the contents of the method block specified by `dace_method_pointer`. `use_derivatives` is a special case, the other keywords are discussed below.

The number of training data points used in building a global approximation is determined by specifying one of three point counts:

1. `minimum_points`: minimum required or minimum "reasonable" amount of training data. Defaults to \(d+1\) for \(d\) input dimensions for most models, e.g., polynomials override to the number of coefficients required to estimate the requested order.
2. `recommended_points`: recommended number of training data. (this is the default option, if none of the keywords is specified). Defaults to \(5+d\), except for polynomials where it’s equal to the minimum.
3. **total_points**: specify the number of training data points. However, if the total_points value is less than the default minimum_points value, the minimum_points value is used.

The sources of training data depend on the number of training points, $N_{tp}$, the number of points in the import file, $N_{if}$, and the value of reuse_points.

- If there is no import file, all training data come from the DACE method
- If there is an import file, all $N_{if}$ points from the file are used, and the remaining $N_{tp} - N_{if}$ points come from the DACE method
- If there is an import file and reuse_points is:
  - **none** - all $N_{tp}$ points from DACE method
  - **region** - only the points within a trust region are taken from the import file, and all remaining points are from the DACE method.
  - **all** - (Default) all $N_{if}$ points from the file are used, and the remaining $N_{tp} - N_{if}$ points come from the DACE method

**Surrogate Correction**

A correction model can be added to the constructed surrogate in order to better match the training data. The specified correction method will be applied to the surrogate, and then the corrected surrogate model is used by the method.

Finally, the quality of the surrogate can be tested using the metrics and challenge_points_file keywords.

**Theory**

Global methods, also referred to as response surface methods, involve many points spread over the parameter ranges of interest. These surface fitting methods work in conjunction with the sampling methods and design of experiments methods.

**Procedures for Surface Fitting**

The surface fitting process consists of three steps:

1. selection of a set of design points
2. evaluation of the true response quantities (e.g., from a user-supplied simulation code) at these design points,
3. using the response data to solve for the unknown coefficients (e.g., polynomial coefficients, neural network weights, kriging correlation factors) in the surface fit model.

In cases where there is more than one response quantity (e.g., an objective function plus one or more constraints), then a separate surface is built for each response quantity. Currently, the surface fit models are built using only 0th-order information (function values only), although extensions to using higher-order information (gradients and Hessians) are possible.

Each surface fitting method employs a different numerical method for computing its internal coefficients. For example, the polynomial surface uses a least-squares approach that employs a singular value decomposition to compute the polynomial coefficients, whereas the kriging surface uses Maximum Likelihood Estimation to compute its correlation coefficients. More information on the numerical methods used in the surface fitting codes is provided in the Dakota Developers Manual.

7.3.3.2.1.7 num_restarts

- Keywords Area
- model
- surrogate
- global
- experimental_gaussian_process
- num_restarts

Number of optimization restarts for L-BFGS-B

Specification

Alias: none
Argument(s): INTEGER

Description

Number of optimization runs at random initial guesses for maximum likelihood estimation. Multiple restarts are used to increase the chance of finding the global minimum with a gradient-based (i.e. local) optimization method.

Default Behavior  Default value of 20 restarts.
7.3.3.2.1.8 nugget

- Keywords Area
- model
- surrogate
- global
- experimental_gaussian_process
- nugget

Value for the fixed nugget parameter

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** None

**Description**

This keyword is used to specify a value for the nugget parameter. Its presence will turn off nugget estimation.

**Default Behavior**  No nugget when this keyword is absent. Alternatively a nugget may be estimated as part of the regression procedure.

7.3.3.2.1.9 find_nugget

- Keywords Area
- model
- surrogate
- global
- experimental_gaussian_process
- find_nugget

Use regression to estimate the nugget.

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** None

**Description**

Estimate a nugget term in the Gaussian process Gram matrix.

**Default Behavior**  Off by default. The user may alternatively specify a fixed nugget.
7.3.3.2.1.10  options_file

- Keywords Area
- model
- surrogate
- global
- experimental_gaussian_process
- options_file

Filename for a YAML file that specifies Gaussian process options

Specification

Alias: none

Argument(s): STRING

Default: no advanced options file

Description

The YAML file contains configuration options that are used to populate a Teuchos ParameterList used by the Gaussian process that will override other keyword-specified parameters. Missing options in the YAML file are set to default values.

Examples

# FILE: gp_options.yaml

GP Parameters:
Sigma Bounds:
  lower bound: 1.0e-2
  upper bound: 1.0e2
scaler name: standardization
num restarts: 20
Nugget:
  fixed nugget: 0.0
  estimate nugget: true
Bounds:
  lower bound: 3.17e-8
  upper bound: 1.0e-2
gp seed: 42
standardize response: false
Trend:
  estimate trend: true
Options:
  max degree: 2
  reduced basis: false
  p-norm: 1.0
scaler type: none
regression solver type: SVD
verbosity: 1
kernel type: squared exponential
Length-scale Bounds:
  lower bound: 1.0e-2
  upper bound: 1.0e2

<td></td>
<td>annotated</td>
<td>Selects annotated tabular file format</td>
</tr>
<tr>
<td>freeform</td>
<td></td>
<td>freeform</td>
<td>Selects freeform file format</td>
</tr>
</tbody>
</table>

**Description**

Specifies a file in which the points (input variable values) at which the surrogate model is evaluated and corresponding response **variance** values computed by the surrogate model will be written. The response values are the surrogate's predicted approximation to the truth model responses at those points.

**Usage Tips**

Dakota exports tabular data in one of three formats:

- annotated (default)
- custom_annotated
- freeform

<td>Enable evaluation ID column in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td>interface_id</td>
<td>interface_id</td>
<td>Enable interface ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.
Usability Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```dakota
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id x1  x2  obj_fn nln_ineq_con_1 nln_ineq_con_2
1  0.9  1.1  0.0002  0.26  0.76
2  0.90009  1.1  0.0001996404857  0.2601620081  0.759955
3  0.89991  1.1  0.0002003604863  0.2598380081  0.760045
...```

7.3.3.2.1.16 annotated

- Keywords Area
- model
- surrogate
- global
- experimental_gaussian_process
- export_approx_variance_file
- annotated

Selects annotated tabular file format

Topics
This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none
Default: annotated

Description
An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior
By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.
Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```plaintext
evironment
tabular_data
tabular_data_file = 'dakota_summary.dat'
annotated

Resulting tabular file:

```%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 NO_ID 0.9 1.1 0.0002 0.26 0.76
2 NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 NO_ID 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...
```

7.3.3.2.17 freeform

- Keywords Area
- model
- surrogate
- global
- experimental_gaussian_process
- export_approx_variance_file
- freeform

Selects freeform file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none
Default: annotated

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips
• Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```plaintext
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
freeform

Resulting tabular file:

0.9 1.1 0.0002 0.26 0.76
0.90009 1.1 0.0001996404857 0.2601620081 0.759955
0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...
```

7.3.3.2.1.18 export_model

• Keywords Area
  • model
  • surrogate
  • global
  • experimental_gaussian_process
  • export_model

Exports surrogate model in user-specified format(s)

Topics

This keyword is related to the topics:

• surrogate_models

Specification

Alias: none
Argument(s): none
Child Keywords:
Description

Export the surrogate for later re-import to Dakota or evaluation using the surfpack executable (bin/surfpack) or a user-developed tool. Export format is controlled using the *formats* specification. Four formats are available in Dakota; however, not all have been enabled for all surrogates.

The four formats are:

- **text_archive** - Plain-text, machine-readable archive for re-import or use with the surfpack executable
- **binary_archive** - Binary, machine-readable archive for re-import or use with the surfpack executable
- **algebraic_file** - Plain-text, human-readable file intended for use with user-created tools; not compatible with Dakota or the surfpack executable
- **algebraic_console** - Print the model in algebraic format to the screen; not compatible with Dakota or the surfpack executable

These global surrogates can be exported in all four formats:

- Gaussian process (keyword *gaussian_process* surfpack)
- Artificial neural network (keyword *neural_network*)
- Radial basis Functions (keyword *radial_basis*)
- Polynomial (keyword *polynomial*)

However, for experimental Gaussian Process and polynomial models as well as Multivariate Adaptive Regression Spline (keyword *mars*) and moving least squares (keyword *moving_least_squares*) models, only *text_archive* and *binary_archive* formats may be used.

Currently, no other surrogate models can be exported.

**Default Behavior**

No export.

**Expected Output**

Output depends on selected format; see the *formats* specification.

**Additional Discussion**

The Dakota examples include a demonstration of using the surfpack executable with an exported model file.
- global
- experimental_gaussian_process
- export_model
- filename_prefix

User-customizable portion of exported/imported surrogate model filenames

Topics
This keyword is related to the topics:
- surrogate_models

Specification

**Alias:** none

**Argument(s):** STRING

**Default:** exported_surrogate

Description
Dakota surrogate model files are exported and imported using one file per response, per requested format. The files are named using the pattern `{prefix}.{response_descriptor}.{extension}`. This `filename_prefix` keyword is used to supply the prefix portion of the pattern.

The `response_descriptor` portion of the pattern is filled in using the response descriptors provided by the user (or, if none are specified, descriptors automatically generated by Dakota). Extension is a three or four letter string that depends on the format.

Examples
This input snippet directs Dakota to write one algebraic format file and one binary archive file for each response. The names of the files will follow the patterns `my_surrogate.{response_descriptor}.alg` (for the algebraic files) and `my_surrogate.{response_descriptor}.bsps` (for the binary files).

```
surrogate global gaussian_process surfpack
eexport_model
  filename_prefix = 'my_surrogate'
  formats
    algebraic_file
    binary_archive
```

<tr>
<td></td>
<td></td>
<td>binary_archive</td>
<td>Surrogate model binary archive file format</td>
</tr>
</tbody>
</table>

Description

Imports a surrogate model from a file in `binary_archive` or `text_archive` format, typically instead of constructing it from generated or imported data. Importing can result in significant time savings with some models, such as Gaussian processes. The file from which to import is further specified with the child keywords `filename_prefix` and `binary_archive` or `text_archive`.

Default Behavior
When used in the context of an iteratively adapted or rebuilt surrogate, the imported model will only replace the initial surrogate model. Subsequent surrogate model builds require imported build points or a design of experiments method specified through `dace_method_pointer`.

Usage Tips

When importing a surrogate model, it is crucial that the global surrogate model part of the Dakota input file be identical for export and import, except for changing `export_model` and its child keywords to those needed for `import_model`. Any other keywords such as specifying a dace_iterator or imported points must remain intact to satisfy internal surrogate constructor requirements.

All variables over which the surrogate model was built (typically the active variables) when exported must be present in the Dakota study that imports it. The variables in the importing study will be matched by descriptor to those in the surrogate model. This allows the order and type of variables to change between export and import, for example to fix unimportant parameters as state variables even if they were previously active design variables.

For example, suppose the original Dakota study for the surrogate build had active uniform uncertain variables: a, b, c, d, and inactive state variables s, t, and the surrogate gets built over a, b, c, d. The follow-on study could perform design optimization over active design variables b and d, with inactive state variables a, c, s, t, held at fixed `initial_state` values. In this case the values of a, b, c, d will get mapped to the surrogate and s, t dropped when evaluating it. So it is important the state values for s and t haven't changed in some way that invalidates the surrogate.

While it might be possible to import surrogates externally-generated using the `surfpack` binary or the experimental `dakota.surrogates` Python module, it is untested and not the primary use case for this capability.

Examples

The following model block exports a Gaussian process after it’s built:

```dakota
model
  id_model = 'SURR_M'
  surrogate global
    dace_method_pointer = 'DACE'
    experimental_gaussian_process
      metrics 'root_mean_squared'
      cross_validation folds 5
    export_model
      filename_prefix = 'gp_export'
      formats = binary_archive
      export_approx_points_file 'gp_values.dat'
      export_approx_variance_file 'gp_variance.dat'

And this model block imports it using a nearly identical model specification:

```dakota
model
  id_model = 'SURR_M'
  surrogate global
    dace_method_pointer = 'DACE'
    experimental_gaussian_process
      metrics 'root_mean_squared'
      cross_validation folds 5
    import_model
      filename_prefix = 'gp_export'
      binary_archive
      export_approx_points_file 'gp_values.dat'
      export_approx_variance_file 'gp_variance.dat'
```

7.3.3.2.1.24  filename_prefix

- model
- surrogate
### 7.3 model

- `global`
- `experimental_gaussian_process`
- `import_model`
- `filename_prefix`

User-customizable portion of exported/imported surrogate model filenames

#### Topics

This keyword is related to the topics:

- `surrogate_models`

#### Specification

**Alias:** none

**Argument(s):** STRING

**Default:** exported_surrogate

#### Description

Dakota surrogate model files are exported and imported using one file per response, per requested format. The files are named using the pattern `{prefix}.{response_descriptor}.{extension}`. This `filename_prefix` keyword is used to supply the prefix portion of the pattern.

The `response_descriptor` portion of the pattern is filled in using the response descriptors provided by the user (or, if none are specified, descriptors automatically generated by Dakota). Extension is a three or four letter string that depends on the format.

#### Examples

This input snippet directs Dakota to write one algebraic format file and one binary archive file for each response. The names of the files will follow the patterns `my_surrogate.{response_descriptor}.alg` (for the algebraic files) and `my_surrogate.{response_descriptor}.bsps` (for the binary files).

```dakota
surrogate global gaussian_process surfpack
export_model
    filename_prefix = 'my_surrogate'
    formats
        algebraic_file
        binary_archive
```

Dakota Version 6.16 Reference Manual generated on May 12, 2022
Surrogate model plain-text archive file format

Topics
This keyword is related to the topics:

- surrogate_models

Specification

**Alias:** none

**Argument(s):** none

Description

When specified, the surrogate model will be exported (or imported) using a plain-text archive format.

Experimental surrogates will export to (import from) text archives named `{prefix}.{response_descriptor}.txt`.

Other (Surfpack) surrogates will export/import using files named `{prefix}.{response_descriptor}.sps`, in which `sps` stands for Surfpack surrogate.

See [filename_prefix](#) for further information about surrogate file naming.

Examples

The Dakota examples include a demonstration of using the surfpack executable with an exported model file.

7.3.3.2.1.26  binary_archive

Use the Gaussian process (GP) surrogate from Surfpack, which is specified using the surfpack keyword. An alternate version of GP surrogates was available in prior versions of Dakota. For now, both versions are supported but the dakota version is deprecated and intended to be removed in a future release.

Known Issue: When using discrete variables, there have been sometimes significant differences in surrogate behavior observed across computing platforms in some cases. The cause has not yet been fully diagnosed and is currently under investigation. In addition, guidance on appropriate construction and use of surrogates with discrete variables is under development. In the meantime, users should therefore be aware that there is a risk of inaccurate results when using surrogates with discrete variables.

7.3.3.2.2.1 dakota

- model
- surrogate
- global
- gaussian_process
- dakota

Select the built in Gaussian Process surrogate

Description

A second version of GP surrogates was available in prior versions of Dakota. For now, both versions are supported but the dakota version is deprecated and intended to be removed in a future release.

Historically these models were drastically different, but in Dakota 5.1, they became quite similar. They now differ in that the Surfpack GP has a richer set of features/options and tends to be more accurate than the Dakota version. Due to how the Surfpack GP handles ill-conditioned correlation matrices (which significantly contributes to its greater accuracy), the Surfpack GP can be a factor of two or three slower than Dakota's. As of Dakota 5.2, the Surfpack implementation is the default in all contexts except Bayesian calibration.

More details on the gaussian_process dakota model can be found in [60].
Dakota’s GP deals with ill-conditioning in two ways. First, when it encounters a non-invertible correlation matrix it iteratively increases the size of a “nugget,” but in such cases the resulting approximation smooths rather than interpolates the data. Second, it has a `point_selection` option (default off) that uses a greedy algorithm to select a well-spaced subset of points prior to the construction of the GP. In this case, the GP will only interpolate the selected subset. Typically, one should not need point selection in trust-region methods because a small number of points are used to develop a surrogate within each trust region. Point selection is most beneficial when constructing with a large number of points, typically more than order one hundred, though this depends on the number of variables and spacing of the sample points.

This differs from the `point_selection` option of the Dakota GP which initially chooses a well-spaced subset of points and finds the correlation parameters that are most likely for that one subset.

```

Dakota Version 6.16 Reference Manual generated on May 12, 2022
Description

This keyword specifies the use of the Gaussian process that is incorporated in our surface fitting library called Surfpack.

Several user options are available:

1. Optimization methods:
   Maximum Likelihood Estimation (MLE) is used to find the optimal values of the hyper-parameters governing the trend and correlation functions. By default the global optimization method DIRECT is used for MLE, but other options for the optimization method are available. See optimization_method.
   The total number of evaluations of the likelihood function can be controlled using the max_trials keyword followed by a positive integer. Note that the likelihood function does not require running the “truth” model, and is relatively inexpensive to compute.

2. Trend Function:
   The GP models incorporate a parametric trend function whose purpose is to capture large-scale variations. See trend.

3. Correlation Lengths:
   Correlation lengths are usually optimized by Surfpack, however, the user can specify the lengths manually. See correlation_lengths.

4. Ill-conditioning
   One of the major problems in determining the governing values for a Gaussian process or Kriging model is the fact that the correlation matrix can easily become ill-conditioned when there are too many input points close together. Since the predictions from the Gaussian process model involve inverting the correlation matrix, ill-conditioning can lead to poor predictive capability and should be avoided.
   Note that a sufficiently bad sample design could require correlation lengths to be so short that any interpolatory GP model would become inept at extrapolation and interpolation.
   The surfpack model handles ill-conditioning internally by default, but behavior can be modified using

5. Gradient Enhanced Kriging (GEK).
   The use_derivatives keyword will cause the Surfpack GP to be constructed from a combination of function value and gradient information (if available).
   See notes in the Theory section.

Theory

Gradient Enhanced Kriging

Incorporating gradient information will only be beneficial if accurate and inexpensive derivative information is available, and the derivatives are not infinite or nearly so. Here "inexpensive" means that the cost of evaluating a
function value plus gradient is comparable to the cost of evaluating only the function value, for example gradients computed by analytical, automatic differentiation, or continuous adjoint techniques. It is not cost effective to use derivatives computed by finite differences. In tests, GEK models built from finite difference derivatives were also significantly less accurate than those built from analytical derivatives. Note that GEK’s correlation matrix tends to have a significantly worse condition number than Kriging for the same sample design.

This issue was addressed by using a pivoted Cholesky factorization of Kriging’s correlation matrix (which is a small sub-matrix within GEK’s correlation matrix) to rank points by how much unique information they contain. This reordering is then applied to whole points (the function value at a point immediately followed by gradient information at the same point) in GEK’s correlation matrix. A standard non-pivoted Cholesky is then applied to the reordered GEK correlation matrix and a bisection search is used to find the last equation that meets the constraint on the (estimate of) condition number. The cost of performing pivoted Cholesky on Kriging’s correlation matrix is usually negligible compared to the cost of the non-pivoted Cholesky factorization of GEK’s correlation matrix. In tests, it also resulted in more accurate GEK models than when pivoted Cholesky or whole-point-block pivoted Cholesky was performed on GEK’s correlation matrix.

7.3.3.2.2.13 optimization_method

• Keywords Area
• model
• surrogate
• global
• gaussian_process
• surfpack
• optimization_method

Change the optimization method used to compute hyperparameters

Specification

Alias: none
Argument(s): STRING
Default: global

Description

Select the optimization method to compute hyperparameters of the Gaussian Process by specifying one of these arguments:

• global (default) - DIRECT method
• local - CONMIN method
• sampling - generates several random guesses and picks the candidate with greatest likelihood
• none - no optimization, pick the center of the feasible region

The none option, and the starting location of the local optimization, default to the center, in log(correlation length) scale, of the of feasible region.

Surfpack picks a small feasible region of correlation parameters.

Note that we have found the global optimization method to be the most robust.

7.3.3.2.2.14 max_trials

7.3.3.2.2.15 nugget

• Keywords Area

• model

• surrogate

• global

• gaussian_process

• surfpack

• nugget

Specify a nugget to handle ill-conditioning

Specification

Alias: none

Argument(s): REAL

Default: None

Description

By default, the Surfpack GP handles ill-conditioning and does not use a nugget. If the user wishes to specify a nugget, there are two approaches.

• The user can specify the value of a nugget with nugget.

• Have Surfpack find the optimal value of the nugget. This is specified by find_nugget. There are two options for find_nugget.
  
  – find_nugget = 1: assume that the reciprocal condition number of the correlation matrix R, rcondR, is zero and calculate the nugget needed to make the worst case of R not ill-conditioned.

  – find_nugget = 2: calculate rcondR, which requires a Cholesky factorization. If rcondR indicates that R is not ill-conditioned, then kriging uses the Cholesky factorization. Otherwise, if rcondR says R is ill conditioned, then kriging will calculate the nugget needed to make the worst case of R not ill conditioned.

find_nugget = 1 and 2 are similar, the second option just takes more computation (the initial Cholesky factorization) for larger problems.

<td>Formats for surrogate model export</td>
</tr>
</tbody>
</table>
Description

Export the surrogate for later re-import to Dakota or evaluation using the surfpack executable (bin/surfpack) or a user-developed tool. Export format is controlled using the formats specification. Four formats are available in Dakota; however, not all have been enabled for all surrogates.

The four formats are:

- **text_archive**: Plain-text, machine-readable archive for re-import or use with the surfpack executable
- **binary_archive**: Binary, machine-readable archive for re-import or use with the surfpack executable
- **algebraic_file**: Plain-text, human-readable file intended for use with user-created tools; not compatible with Dakota or the surfpack executable
- **algebraic_console**: Print the model in algebraic format to the screen; not compatible with Dakota or the surfpack executable

These global surrogates can be exported in all four formats:

- Gaussian process (keyword `gaussian_process` surfpack)
- Artificial neural network (keyword `neural_network`)
- Radial basis Funtions (keyword `radial_basis`)
- Polynomial (keyword `polynomial`)

However, for experimental Gaussian Process and polynomial models as well as Multivariate Adaptive Regression Spline (keyword `mars`) and moving least squares (keyword `moving_least_squares`) models, only `text_archive` and `binary_archive` formats may be used.

Currently, no other surrogate models can be exported.

Default Behavior

No export.

Expected Output

Output depends on selected format; see the formats specification.

Additional Discussion

The Dakota examples include a demonstration of using the surfpack executable with an exported model file.
Topics

This keyword is related to the topics:

- surrogate_models

Specification

Alias: none

Argument(s): STRING

Default: exported_surrogate

Description

Dakota surrogate model files are exported and imported using one file per response, per requested format. The files are named using the pattern \{prefix\}.\{response_descriptor\}.\{extension\}. This filename_prefix keyword is used to supply the prefix portion of the pattern.

The response_descriptor portion of the pattern is filled in using the response descriptors provided by the user (or, if none are specified, descriptors automatically generated by Dakota). Extension is a three or four letter string that depends on the format.

Examples

This input snippet directs Dakota to write one algebraic format file and one binary archive file for each response. The names of the files will follow the patterns my_surrogate.\{response_descriptor\}.alg (for the algebraic files) and my_surrogate.\{response_descriptor\}.bsps (for the binary files).

```
surrogate global gaussian_process surfpack
export_model
  filename_prefix = 'my_surrogate'

- export_model
- formats
- algebraic_file

Export surrogate model in algebraic format to a file

Topics

This keyword is related to the topics:

- surrogate_models

Specification

Alias: none

Argument(s): none

Description

After the surrogate model has been built, Dakota will export it to a file in a human-readable "algebraic" format. The file is named using the pattern \{prefix\}.{response_descriptor}.alg. See filename_prefix for further information about exported surrogate file naming. The file contains sufficient information for the user to (re)construct and evaluate the model outside of Dakota.

Expected Output

The format depends on the type of surrogate model, but in general will include a LaTeX-like representation of the analytic form of the model to aid tool development, all needed model hyperparameters, and headers describing the shape or dimension of the provided data.
The output written to the file matches exactly the output written to the console when `algebraic_console` is specified.

Export surrogate model in algebraic format to the console

Topics

This keyword is related to the topics:

- surrogate_models

Specification

Alias: none

Argument(s): none

Description

After the surrogate model has been built, Dakota will export it to the console (screen, or output file if Dakota was run using the `-o` option) in a human-readable "algebraic" format. The output contains sufficient information for the user to (re)construct and evaluate the model outside of Dakota.

Expected Output

The format depends on the type of surrogate model, but in general will include a LaTeX-like representation of the analytic form of the model to aid tool development, all needed model hyperparameters, and headers describing the shape or dimension of the provided data.

The output written to the screen for the exported model matches exactly the output written to file when `algebraic_file` is specified. Use of `algebraic_file` is preferred over `algebraic_console`, which exists largely to provide a measure of backward compatibility.

</tr>
<tr>
<td></td>
<td></td>
<td>binary_archive</td>
<td>Surrogate model binary archive file format</td>
</tr>
</tbody>
</table>

**Description**

Imports a surrogate model from a file in `binary_archive` or `text_archive` format, typically instead of constructing it from generated or imported data. Importing can result in significant time savings with some models, such as Gaussian processes. The file from which to import is further specified with the child keywords `filename_prefix` and `binary_archive` or `text_archive`.

**Default Behavior**

When used in the context of an iteratively adapted or rebuilt surrogate, the imported model will only replace the initial surrogate model. Subsequent surrogate model builds require imported build points or a design of experiments method specified through `dace_method_pointer`.

**Usage Tips**

When importing a surrogate model, it is crucial that the `global` surrogate model part of the Dakota input file be identical for export and import, except for changing `export_model` and its child keywords to those needed for `import_model`. Any other keywords such as specifying a `dace_iterator` or imported points must remain intact to satisfy internal surrogate constructor requirements.

All variables over which the surrogate model was built (typically the active variables) when exported must be present in the Dakota study that imports it. The variables in the importing study will be matched by descriptor to those in the surrogate model. This allows the order and type of variables to change between export and import, for example to fix unimportant parameters as state variables even if they were previously active design variables.

For example, suppose the original Dakota study for the surrogate build had active uniform uncertain variables: a, b, c, d, and inactive state variables s, t, and the surrogate gets built over a, b, c, d. The follow-on study could perform design optimization over active design variables b and d, with inactive state variables a, c, s, t, held at fixed `initial_state` values. In this case the values of a, b, c, d will get mapped to the surrogate and s, t dropped...
when evaluating it. So it is important the state values for $s$ and $t$ haven’t changed in some way that invalidates the surrogate.

While it might be possible to import surrogates externally-generated using the surfpack binary or the experimental dakota.surrogates Python module, it is untested and not the primary use case for this capability.

Examples

The following model block exports a Gaussian process after it’s built:

```model
id_model = ‘SURR_M’
surrogate global
dace_method_pointer = ‘DACE’
experimental_gaussian_process
  metrics ‘root_mean_squared’
cross_validation folds 5
export_model
  filename_prefix = ‘gp_export’
  formats = binary_archive
export_approx_points_file ‘gp_values.dat’
export_approx_variance_file ‘gp_variance.dat’
```

And this model block imports it using a nearly identical model specification:

```model
id_model = ‘SURR_M’
surrogate global
dace_method_pointer = ‘DACE’
experimental_gaussian_process
  metrics ‘root_mean_squared’
cross_validation folds 5
import_model
  filename_prefix = ‘gp_export’
binary_archive
export_approx_points_file ‘gp_values.dat’
export_approx_variance_file ‘gp_variance.dat’
```

7.3.3.2.2.26 filename_prefix

User-customizable portion of exported/imported surrogate model filenames

Topics

This keyword is related to the topics:

- surrogate_models
Specification

**Alias:** none

**Argument(s):** STRING

**Default:** exported_surrogate

Description

Dakota surrogate model files are exported and imported using one file per response, per requested format. The files are named using the pattern `{prefix}.{response_descriptor}.{extension}`. This `filename_prefix` keyword is used to supply the prefix portion of the pattern.

The `response_descriptor` portion of the pattern is filled in using the response descriptors provided by the user (or, if none are specified, descriptors automatically generated by Dakota). Extension is a three or four letter string that depends on the format.

Examples

This input snippet directs Dakota to write one algebraic format file and one binary archive file for each response. The names of the files will follow the patterns `my_surrogate.{response_descriptor}.alg` (for the algebraic files) and `my_surrogate.{response_descriptor}.bsps` (for the binary files).

```plaintext
surrogate global gaussian_process surfpack
export_model
    filename_prefix = 'my_surrogate'
    formats
        algebraic_file
        binary_archive
```

Surrogate model plain-text archive file format

Topics

This keyword is related to the topics:

- surrogate_models

Specification

**Alias:** none

**Argument(s):** none
Description

When specified, the surrogate model will be exported (or imported) using a plain-text archive format. Experimental surrogates will export to (import from) text archives named `{prefix}.{response_descriptor}.txt`. Other (Surfpack) surrogates will export/import using files named `{prefix}.{response_descriptor}.sps`, in which 'sps' stands for Surfpack surrogate.

See `filename_prefix` for further information about surrogate file naming.

Examples

The Dakota examples include a demonstration of using the surfpack executable with an exported model file.

<td></td>
<td></td>
</tr>
</tbody>
</table>

Description

Specifies a file in which the points (input variable values) at which the surrogate model is evaluated and corresponding response variance values computed by the surrogate model will be written. The response values are the surrogate’s predicted approximation to the truth model responses at those points.

Usage Tips

Dakota exports tabular data in one of three formats:

- annotated (default)
- custom_annotated
- freeform

</tr>
<tr>
<td>Optional</td>
<td>interface_id</td>
<td>interface_id</td>
<td>Enable interface ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.
Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to
  annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra
  is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface-
_id), and data for variables and responses. Input file fragment:

```plaintext
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id  x1  x2  obj_fn  nln_ineq_con_1  nln_ineq_con_2
1  0.9  1.1  0.0002  0.26  0.76
2  0.90009  1.1  0.0001996404857  0.2601620081  0.759955

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none
Default: annotated

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.
Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```python
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated

Resulting tabular file:

```
%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 NO_ID 0.9 1.1 0.0002 0.26 0.76
2 NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 NO_ID 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...
```

7.3.3.2.2.35 freeform

- Keywords Area
- model
- surrogate
- global
- gaussian_process
- export_approx_variance_file
- freeform

Selects freeform file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none
Default: annotated

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips
Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```environment
tabular_data
  tabular_data_file = 'dakota_summary.dat'
freeform
```

Resulting tabular file:

```
 0.9  1.1  0.0002  0.26  0.76
 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...```

7.3.3.2.3 mars

Multivariate Adaptive Regression Spline (MARS)

Specification

Alias: none

Argument(s): none

Child Keywords:
### Description

This surface fitting method uses multivariate adaptive regression splines from the MARS3.5 package [27] developed at Stanford University.

The MARS reference material does not indicate the minimum number of data points that are needed to create a MARS surface model. However, in practice it has been found that at least $n_{\text{quad}}$, and sometimes as many as 2 to 4 times $n_{\text{quad}}$, data points are needed to keep the MARS software from terminating. Provided that sufficient data samples can be obtained, MARS surface models can be useful in SBO and OUU applications, as well as in the prediction of global trends throughout the parameter space.

*Known Issue:* When using discrete variables, there have been sometimes significant differences in surrogate behavior observed across computing platforms in some cases. The cause has not yet been fully diagnosed and is currently under investigation. In addition, guidance on appropriate construction and use of surrogates with discrete variables is under development. In the meantime, users should therefore be aware that there is a risk of inaccurate results when using surrogates with discrete variables.

### Theory

The form of the MARS model is based on the following expression:

$$\hat{f}(x) = \sum_{m=1}^{M} a_m B_m(x)$$

where the $a_m$ are the coefficients of the truncated power basis functions $B_m$, and $M$ is the number of basis functions. The MARS software partitions the parameter space into subregions, and then applies forward and backward regression methods to create a local surface model in each subregion. The result is that each subregion contains its own basis functions and coefficients, and the subregions are joined together to produce a smooth, $C^2$-continuous surface model.

MARS is a nonparametric surface fitting method and can represent complex multimodal data trends. The regression component of MARS generates a surface model that is not guaranteed to pass through all of the response data values. Thus, like the quadratic polynomial model, it provides some smoothing of the data.

<td>Formats for surrogate model export</td>
</tr>
</tbody>
</table>

Description

Export the surrogate for later re-import to Dakota or evaluation using the surfpack executable (bin/surfpack) or a user-developed tool. Export format is controlled using the formats specification. Four formats are available in Dakota; however, not all have been enabled for all surrogates.

The four formats are:

- text_archive: Plain-text, machine-readable archive for re-import or use with the surfpack executable
- binary_archive: Binary, machine-readable archive for re-import or use with the surfpack executable
- algebraic_file: Plain-text, human-readable file intended for use with user-created tools; not compatible with Dakota or the surfpack executable
- algebraic_console: Print the model in algebraic format to the screen; not compatible with Dakota or the surfpack executable

These global surrogates can be exported in all four formats:

- Gaussian process (keyword gaussian_process surfpack)
- Artificial neural network (keyword neural_network)
- Radial basis Funtions (keyword radial_basis)
- Polynomial (keyword polynomial)

However, for experimental Gaussian Process and polynomial models as well as Multivariate Adaptive Regression Spline (keyword mars) and moving least squares (keyword moving_least_squares) models, only text_archive and binary_archive formats may be used.

Currently, no other surrogate models can be exported.

Default Behavior
No export.

Expected Output

Output depends on selected format; see the \texttt{formats} specification.

Additional Discussion

The Dakota examples include a demonstration of using the surfpack executable with an exported model file.

User-customizable portion of exported/imported surrogate model filenames

Topics

This keyword is related to the topics:

\begin{itemize}
  \item surrogate\_models
\end{itemize}

Specification

\textbf{Alias:} none

\textbf{Argument(s):} STRING

\textbf{Default:} exported\_surrogate

Description

Dakota surrogate model files are exported and imported using one file per response, per requested format. The files are named using the pattern \texttt{\{prefix\}\{response\_descriptor\}\{extension\}}. This \texttt{filename\_prefix} keyword is used to supply the prefix portion of the pattern.

The \texttt{response\_descriptor} portion of the pattern is filled in using the response \texttt{descriptors} provided by the user (or, if none are specified, descriptors automatically generated by Dakota). Extension is a three or four letter string that depends on the format.

Examples

This input snippet directs Dakota to write one algebraic format file and one binary archive file for each response. The names of the files will follow the patterns \texttt{my\_surrogate\{response\_descriptor\}.alg} (for the algebraic files) and \texttt{my\_surrogate\{response\_descriptor\}.bsps} (for the binary files).

Surrogate model binary archive file format

Topics

This keyword is related to the topics:

- surrogate_models

Specification

Alias: none
Argument(s): none

Description

When specified, the surrogate model will be exported (or imported) using a binary archive format.

Experimental surrogates will export to (import from) binary archives named {prefix}.{response_descriptor}.bin.

Other (Surfpack) surrogates will export/import using files named {prefix}.{response_descriptor}.bsps, in which 'bsps' stands for binary Surfpack surrogate.

See filename_prefix for further information about surrogate file naming.

Examples

The Dakota examples include a demonstration of using the surfpack executable with an exported model file.

7.3.3.2.3.10 import_model

- Keywords Area
- model
- surrogate
- global
- mars
- import_model

Import surrogate model from archive file

Specification

Alias: none
Argument(s): none
Child Keywords:
Description

Imports a surrogate model from a file in `binary_archive` or `text_archive` format, typically instead of constructing it from generated or imported data. Importing can result in significant time savings with some models, such as Gaussian processes. The file from which to import is further specified with the child keywords `filename_prefix` and `binary_archive` or `text_archive`.

Default Behavior

When used in the context of an iteratively adapted or rebuilt surrogate, the imported model will only replace the initial surrogate model. Subsequent surrogate model builds require imported build points or a design of experiments method specified through `dace_method_pointer`.

Usage Tips

When importing a surrogate model, it is crucial that the `global` surrogate model part of the Dakota input file be identical for export and import, except for changing `export_model` and its child keywords to those needed for `import_model`. Any other keywords such as specifying a `dace_iterator` or imported points must remain intact to satisfy internal surrogate constructor requirements.

All variables over which the surrogate model was built (typically the active variables) when exported must be present in the Dakota study that imports it. The variables in the importing study will be matched by descriptor to those in the surrogate model. This allows the order and type of variables to change between export and import, for example to fix unimportant parameters as state variables even if they were previously active design variables.

For example, suppose the original Dakota study for the surrogate build had active uniform uncertain variables: a, b, c, d, and inactive state variables s, t, and the surrogate gets built over a, b, c, d. The follow-on study could perform design optimization over active design variables b and d, with inactive state variables a, c, s, t, held at fixed `initial_state` values. In this case the values of a, b, c, d will get mapped to the surrogate and s, t dropped when evaluating it. So it is important the state values for s and t haven’t changed in some way that invalidates the surrogate.

While it might be possible to import surrogates externally-generated using the `surfpack` binary or the experimental `dakota.surrogates` Python module, it is untested and not the primary use case for this capability.

Examples

The following model block exports a Gaussian process after it’s built:

```plaintext
model
  id_model = 'SURR_M'
  surrogate global
    dace_method_pointer = 'DACE'
    experimental_gaussian_process
```
metrics 'root_mean_squared'
cross_validation folds 5
export_model
  filename_prefix = 'gp_export'
  formats = binary_archive
export_approx_points_file 'gp_values.dat'
export_approx_variance_file 'gp_variance.dat'

And this model block imports it using a nearly identical model specification:

model
  id_model = 'SURR_M'
surrogate global
dace_method_pointer = 'DACE'
experimental_gaussian_process
  metrics 'root_mean_squared'
cross_validation folds 5
import_model
  filename_prefix = 'gp_export'
  binary_archive
export_approx_points_file 'gp_values.dat'
export_approx_variance_file 'gp_variance.dat'

7.3.3.2.3.11 filename_prefix

- mars
- import_model
- filename_prefix

User-customizable portion of exported/imported surrogate model filenames

Topics

This keyword is related to the topics:

- surrogate_models

Specification

Alias: none

Argument(s): STRING

Default: exported_surrogate

Description

Dakota surrogate model files are exported and imported using one file per response, per requested format. The files are named using the pattern {prefix}.{response_descriptor}.{extension}. This filename_prefix keyword is used to supply the prefix portion of the pattern.

The response_descriptor portion of the pattern is filled in using the response descriptors provided by the user (or, if none are specified, descriptors automatically generated by Dakota). Extension is a three or four letter string that depends on the format.
Examples

This input snippet directs Dakota to write one algebraic format file and one binary archive file for each response. The names of the files will follow the patterns `my_surrogate.{response_descriptor}.alg` (for the algebraic files) and `my_surrogate.{response_descriptor}.bsps` (for the binary files).

```
surrogate global gaussian_process surfpack
  export_model
    filename_prefix = 'my_surrogate'
    formats
      algebraic_file
      binary_archive
```

7.3.2.3.12 text_archive

- Keywords Area

- surrogate
- global
- mars
- import_model
- text_archive

Surrogate model plain-text archive file format

Topics

This keyword is related to the topics:

- surrogate_models

Specification

Alias: none
Argument(s): none

Description

When specified, the surrogate model will be exported (or imported) using a plain-text archive format. Experimental surrogates will export to (import from) text archives named `{prefix}.{response_descriptor}.txt`. Other (Surfpack) surrogates will export/import using files named `{prefix}.{response_descriptor}.sps`, in which ‘sps’ stands for Surfpack surrogate. See `filename_prefix` for further information about surrogate file naming.

Examples

The Dakota examples include a demonstration of using the surfpack executable with an exported model file.

<td>Import surrogate model from archive file</td>
</tr>
</tbody>
</table>

**Description**

Moving least squares is a further generalization of weighted least squares where the weighting is "moved" or recalculated for every new point where a prediction is desired [66].

**The implementation of moving least squares is still under development.** It tends to work well in trust region optimization methods where the surrogate model is constructed in a constrained region over a few points. The present implementation may not work as well globally.

*Known Issue: When using discrete variables, there have been sometimes significant differences in surrogate behavior observed across computing platforms in some cases. The cause has not yet been fully diagnosed and is currently under investigation. In addition, guidance on appropriate construction and use of surrogates with discrete variables is under development. In the meantime, users should therefore be aware that there is a risk of inaccurate results when using surrogates with discrete variables.*

**Theory**

Moving Least Squares can be considered a more specialized version of linear regression models. In linear regression, one usually attempts to minimize the sum of the squared residuals, where the residual is defined as the difference between the surrogate model and the true model at a fixed number of points.

In weighted least squares, the residual terms are weighted so the determination of the optimal coefficients governing the polynomial regression function, denoted by $\hat{f}(x)$, are obtained by minimizing the weighted sum of squares at N data points:

$$\sum_{n=1}^{N} w_n (\| \hat{f}(x_n) - f(x_n) \|)$$
7.3 model

- model
- surrogate
- global
- moving_least_squares
- basis_order

Polynomial order for the MLS bases

Specification

**Alias:** poly_order

**Argument(s):** INTEGER

**Description**

The polynomial order for the moving least squares basis function (default = 2).

7.3.3.2.4.2 weight_function

- Keywords Area
- model
- surrogate
- global
- moving_least_squares
- weight_function

Selects the weight function for the MLS model

Specification

**Alias:** none

**Argument(s):** INTEGER

**Description**

The weight function decays as a function of distance from the training data. Specify one of:

- 1 (default): exponential decay in weight function; once differentiable MLS model
- 2: twice differentiable MLS model
- 3: three times differentiable MLS model
7.3.3.2.4.3  export_model

- Keywords Area
- model
- surrogate
- global
- moving_least_squares
- export_model

Exports surrogate model in user-specified format(s)

Topics

This keyword is related to the topics:

- surrogate_models

Specification

Alias: none

Argument(s): none

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>

<td>User-customizable portion of exported/imported surrogate model filenames</td>
</tr>
</tbody>
</table>

Description

Export the surrogate for later re-import to Dakota or evaluation using the surfpack executable (bin/surfpack) or a user-developed tool. Export format is controlled using the formats specification. Four formats are available in Dakota; however, not all have been enabled for all surrogates.

The four formats are:

- text_archive - Plain-text, machine-readable archive for re-import or use with the surfpack executable
- binary_archive - Binary, machine-readable archive for re-import or use with the surfpack executable
- algebraic_file - Plain-text, human-readable file intended for use with user-created tools; not compatible with Dakota or the surfpack executable
- algebraic_console - Print the model in algebraic format to the screen; not compatible with Dakota or the surfpack executable
These global surrogates can be exported in all four formats:

- Gaussian process (keyword \texttt{gaussian\_process surfpack})
- Artificial neural network (keyword \texttt{neural\_network})
- Radial basis functions (keyword \texttt{radial\_basis})
- Polynomial (keyword \texttt{polynomial})

However, for experimental Gaussian Process and polynomial models as well as Multivariate Adaptive Regression Spline (keyword \texttt{mars}) and moving least squares (keyword \texttt{moving\_least\_squares}) models, only text-\texttt{-archive} and binary\texttt{-archive} formats may be used.

Currently, no other surrogate models can be exported.

**Default Behavior**

No export.

**Expected Output**

Output depends on selected format; see the \texttt{formats specification}.

**Additional Discussion**

The Dakota examples include a demonstration of using the \texttt{surfpack} executable with an exported model file.

7.3.3.2.4.4 \texttt{filename\_prefix}

<td>Surrogate model binary archive file format</td>
</tr>
</tbody>
</table>

Description

Imports a surrogate model from a file in binary_archive or text_archive format, typically instead of constructing it from generated or imported data. Importing can result in significant time savings with some models, such as Gaussian processes. The file from which to import is further specified with the child keywords filename_prefix and binary_archive or text_archive.

Default Behavior

When used in the context of an iteratively adapted or rebuilt surrogate, the imported model will only replace the initial surrogate model. Subsequent surrogate model builds require imported build points or a design of experiments method specified through dace_method_pointer.

Usage Tips

When importing a surrogate model, it is crucial that the global surrogate model part of the Dakota input file be identical for export and import, except for changing export_model and its child keywords to those needed for import_model. Any other keywords such as specifying a dace_iterator or imported points must remain intact to satisfy internal surrogate constructor requirements.

All variables over which the surrogate model was built (typically the active variables) when exported must be present in the Dakota study that imports it. The variables in the importing study will be matched by descriptor to those in the surrogate model. This allows the order and type of variables to change between export and import, for example to fix unimportant parameters as state variables even if they were previously active design variables.

For example, suppose the original Dakota study for the surrogate build had active uniform uncertain variables: a, b, c, d, and inactive state variables s, t, and the surrogate gets built over a, b, c, d. The follow-on study could perform design optimization over active design variables b and d, with inactive state variables a, c, s, t, held at fixed initial_state values. In this case the values of a, b, c, d will get mapped to the surrogate and s, t dropped when evaluating it. So it is important the state values for s and t haven’t changed in some way that invalidates the surrogate.
While it might be possible to import surrogates externally-generated using the surfpack binary or the experimental dakota.surrogates Python module, it is untested and not the primary use case for this capability.

Examples

The following model block exports a Gaussian process after it’s built:

```plaintext
model
id_model = 'SURR_M'
surrogate global
dace_method_pointer = 'DACE'
experimental_gaussian_process
metrics 'root_mean_squared'
cross_validation folds 5
export_model
  filename_prefix = 'gp_export'
  formats = binary_archive
  export_approx_points_file 'gp_values.dat'
  export_approx_variance_file 'gp_variance.dat'

And this model block imports it using a nearly identical model specification:

```plaintext
model
id_model = 'SURR_M'
surrogate global
dace_method_pointer = 'DACE'
experimental_gaussian_process
metrics 'root_mean_squared'
cross_validation folds 5
import_model
  filename_prefix = 'gp_export'
  binary_archive
  export_approx_points_file 'gp_values.dat'
  export_approx_variance_file 'gp_variance.dat'
```

</tbody>
</table>
### Description

Tensor train decompositions are approximations that exploit low rank structure in an input-output mapping. The form of the approximation can be written as a set of matrix valued products:

\[ f_r(x) = F_1(x_1)F_2(x_2)\ldots F_d(x_d) \]

Where the "cores" expand to

\[ F_k(x_k) = \begin{bmatrix} f_{k1}^{11}(x_k) & \cdots & f_{k1}^{r_1}(x_k) \\ \vdots & \ddots & \vdots \\ f_{k1}^{r_{k-1}}(x_k) & \cdots & f_{k1}^{r_k}(x_k) \end{bmatrix} \]

An example expansion over four random variables with rank vector \((1,7,5,3,1)\) is

\[ f_r(x) = \begin{bmatrix} f_{11}^{11}(x_1) & \cdots & f_{11}^{7}(x_1) \\ \vdots & \ddots & \vdots \\ f_{11}^{1}(x_2) & \cdots & f_{11}^{5}(x_2) \\ \vdots & \ddots & \vdots \\ f_{11}^{1}(x_3) & \cdots & f_{11}^{3}(x_3) \end{bmatrix} \begin{bmatrix} f_{11}^{4}(x_4) \end{bmatrix} \]

In the current implementation, orthogonal polynomial basis functions (Hermite and Legendre) are employed as the basis functions \(f_{jk}^{ij}(x_i)\), although the C3 library will enable additional options in the future.

The number of coefficients that must be computed by the regression solver can be inferred from the construction above. For each QoI, the regression size can be determined as follows:

- For \(v\) variables, orders \(o\) is a \(v\)-vector and ranks \(r\) is a \(v+1\)-vector
- the first core is a \(1 \times r_1\) row vector and contributes \((o_0 + 1)r_1\) terms
- the last core is a \(r_{v-1} \times 1\) col vector and contributes \((o_{v-1} + 1)r_{v-1}\) terms
- the middle \(v-2\) cores are \(r_i \times r_{i+1}\) matrices that contribute \(r_ir_{i+1}(o_i + 1)\) terms, \(i = 1,\ldots,v-2\)
- neighboring vec/mat dimensions must match, so there are \(v-1\) unique ranks

### Usage Tips

This new capability is stabilizing and beginning to be embedded in higher-level strategies such as multilevel-multifidelity algorithms. It is not included in the Dakota build by default, as some C3 library dependencies (CBLAS) can induce small differences in our regression suite.
This capability is also being used as a prototype to explore model-based versus method-based specification of stochastic expansions. While the model specification is stand-alone, it currently requires a corresponding method specification to exercise the model, which can be a generic UQ strategy such as `surrogate_based_uq` method or a `sampling` method. The intent is to migrate function train, polynomial chaos, and stochastic collocation toward model-only specifications that can then be employed in any surrogate/emulator context.

### Examples

```plaintext
model,
    id_model = 'FT'
    surrogate global function_train
        start_order = 2
        start_rank = 2 kick_rank = 2 max_rank = 10
        adapt_rank
        dace_method_pointer = 'SAMPLING'
```

</tr>
</tbody>
</table>

**Description**

RLS2 is a regularized least squares solver that applies an $L_2$ penalty to mitigate overfitting. It includes the option to specify a penalty parameter.

**See Also**

These keywords may also be of interest:

- l2_penalty

7.3.3.2.5.4 l2_penalty

- Keywords Area
- model
- surrogate
- global
- function_train
- regression_type
- rls2
- l2_penalty

Penalty value applied in regularized regression solver for function train approximations
Specification

**Alias:** none

**Argument(s):** REAL

**Description**

Regularized regression applies a penalty to aspects of the recovered solution (e.g., cardinality, higher-order oscillatory terms, et al.) to mitigate overfitting. This specification provides the scalar penalty parameter (its value is not currently adapted or cross-validated).

**Default Behavior**

If this penalty parameter is not specified, then we adopt the internal C3 default.

**See Also**

These keywords may also be of interest:

- *rls2*

7.3.3.2.5.5  **max_solver_iterations**

- **Keywords Area**
- **model**
- **surrogate**
- **global**
- **function_train**
- **max_solver_iterations**

Maximum iterations in determining polynomial coefficients

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 100

**Description**

When using an iterative polynomial coefficient estimation approach, e.g., cross-validation-based solvers, limits the maximum iterations in the coefficient solver.

7.3.3.2.5.6  **max_cross_iterations**

- **Keywords Area**
- **model**
- **surrogate**
- **global**
• function_train
• max_cross_iterations

Maximum number of iterations for cross-approximation during a rank adaptation.

Specification

Alias: none
Argument(s): INTEGER
Default: 1

Description

The number of iterations for the cross-approximation algorithm is limited within the adapt_rank procedure.

See Also

These keywords may also be of interest:

• adapt_rank

7.3.3.2.5.7 solver_tolerance

Convergence tolerance for the optimizer used during the regression solve.

Specification

Alias: none
Argument(s): REAL
Default: 1.0e-10

Description

Defines the function value and function gradient tolerance for optimizer used solving the regression problem for the functional tensor train coefficients.
7.3.3.2.5.8 response_scaling

- Keywords Area
- model
- surrogate
- global
- function_train
- response_scaling

Perform bounds-scaling on response values prior to surrogate emulation

Specification

Alias: none
Argument(s): none
Default: use original data

Description

Particularly in multifidelity methods based on regression solutions at each level of a model hierarchy, scaling can be
an issue since the magnitude of discrepancy data may decay rapidly and regression solvers may employ absolute
tolerances in places.

By activating response_scaling, the set of response data used for each recovery is scaled to \([0,1]\) based on
the minimum value and range of the data set. This prevents loss of accuracy due to imbalances in scale across
model levels.

See Also

These keywords may also be of interest:

- multifidelity_function_train

7.3.3.2.5.9 tensor_grid

- Keywords Area
- model
- surrogate
- global
- function_train
- tensor_grid

Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.
Specification

**Alias:** none

**Argument(s):** none

**Default:** regression with random sample set

Description

The collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

7.3.3.2.5.10 rounding_tolerance

- Keywords Area
- model
- surrogate
- global
- function_train
- rounding_tolerance

An accuracy tolerance that is used to guide rounding during rank adaptation.

Specification

**Alias:** none

**Argument(s):** REAL

**Default:** 1.e-10

Description

The rounding tolerance is used to measure how closely one can approximate a functional tensor train representation at a step of the optimization procedure using one of lower ranks. If this tolerance is small, then less compression is achieved but greater accuracy is obtained. If this tolerance is big, greater compression is achieved at the expense of accuracy.

**Default Behavior**

If this tolerance is not specified, then we adopt the internal C3 default.

- function_train
- arithmetic_tolerance

A secondary rounding tolerance used for post-processing

**Specification**

**Alias:** none  
**Argument(s):** REAL  
**Default:** 1.e-10

**Description**

After forming one or more function train approximations, this tolerance is used for rolling up final results, in particular, combining multilevel/multifidelity expansions and forming products for higher-order moment estimation. It is generally intended as a looser tolerance than `rounding_tolerance`.

**Default Behavior**

If this tolerance is not specified, then we adopt the internal C3 default.

**See Also**

These keywords may also be of interest:

- `rounding_tolerance`

7.3.3.2.5.12 start_order

- Keywords Area
- model
- surrogate
- global
- function_train
- start_order

(Initial) polynomial order of each univariate function within the functional tensor train.
Specification

**Alias:** order

**Argument(s):** INTEGER

**Default:** 2

**Child Keywords:**
### dimension_preference

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>dimension_preference</td>
<td>A set of weights specifying the relative importance of each uncertain variable (dimension)</td>
</tr>
</tbody>
</table>

#### Description

This specifies the initial polynomial order of each univariate function that makes up the functional tensor train decomposition. In the case of `adapt_order`, polynomial order starts from this value and is then advanced; its maximum value is limited by `max_order` and increments are controlled by `kick_order`.

#### Default Behavior

Default is 2.

#### See Also

These keywords may also be of interest:

- `adapt_order`
- `kick_order`
- `max_order`

#### Specification

- **Alias:** none
- **Argument(s):** REALLIST
- **Default:** isotropic grids

#### Description

A set of weights specifying the relative importance of each uncertain variable (dimension). Using this specification leads to anisotropic integrations with differing refinement levels for different random dimensions.

- sobol
- decay

7.3.3.2.5.14 adapt_order

Activate adaptive procedure for determining the best basis order

Specification

Alias: none
Argument(s): none
Default: false

Description

This option activates a cross validation procedure to select the best basis order for representing the current set of data. It searches from start_order to max_order in increments of kick_order.

Default Behavior

No cross validation for basis order.

Examples

This example shows specification of an order adaptation starting at order 2, incrementing by 2, and limited at order 6.

```
model,
    id_model = 'FT'
surrogate global function_train
    start_rank = 4
    adapt_order start_order = 2 kick_order = 2 max_order = 6
    solver_tolerance = 1e-12
    rounding_tolerance = 1e-12
dace_method_pointer = 'SAMPLING'
```

Note that adapt_rank and adapt_order can either be combined or used separately.
7.3 model

7.3.3.2.5.15 kick_order

- Keywords Area
- model
- surrogate
- global
- function_train
- kick_order

 increment used when adapting the basis order in function train methods

Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** 1

**Description**

Used in combination with \textit{adapt\_order}, \textit{kick\_order} defines the size of the increment that is used during the cross validation process, within the range of \textit{start\_order} and \textit{max\_order}.

**Default Behavior**

Default is 1.

See Also

These keywords may also be of interest:

- adapt\_order

7.3.3.2.5.16 max_order

- Keywords Area
- model
- surrogate
- global
- function\_train
- max\_order

Maximum polynomial order of each univariate function within the functional tensor train.
Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** 4

**Description**

This specification is inactive for current adaptation options.

In future adaptation options (i.e., cross-approximation adaptation), this will specify the maximum order that can be obtained during adaptation, where polynomial order will start from `start_order` and be limited by `max_order`.

**Default Behavior**

Max order is unbounded (adaptive sweep will stop when CV error increases).

**See Also**

These keywords may also be of interest:

- `start_order`

7.3.3.2.5.17 `max_cv_order_candidates`

- **Keywords Area**
- **model**
- **surrogate**
- **global**
- **function_train**
- **max_cv_order_candidates**

Limit the number of cross-validation candidates for basis order

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** ushort max

**Description**

When generating refinement candidates by advancing the upper bound used for a cross-validation range, the number of cross-validation can eventually become excessive and hamper algorithm progress. This control limits the maximum number of candidates, which when active, will increase the lower bound for this range as the upper bound is advanced.

7.3.3.2.5.18 start_rank

The initial rank used for the starting point during a rank adaptation.

Specification

Alias: rank

Argument(s): INTEGER

Default: 2

Description

The adapt_rank procedure increments the rank on each iteration, starting from the rank defined by start_rank.

Default Behavior

Default is 2.

See Also

These keywords may also be of interest:

- adapt_rank
Activate adaptive procedure for determining best rank representation

Specification

Alias: none
Argument(s): none
Default: false

Description

The adaptive algorithm proceeds as follows:

1. Start from rank \texttt{start\_rank} and form an approximation

2. Adapt the current approximation by searching for a solution with lower rank that achieves L2 accuracy within epsilon tolerance of the reference.

3. If a lower rank solution is found with comparable accuracy, then stop. If not, increase the rank by an amount specified by \texttt{kick\_rank}.

4. Return to step 2 and continue until either \texttt{max\_rank} is reached or a converged rank (rank less than current reference with comparable accuracy) is found.

Default Behavior

No cross validation for rank.

Examples

This example shows specification of a rank adaptation starting at rank 2, incrementing by 2, and limited at rank 10.

\begin{verbatim}
model,
id_model = 'FT'
surrogate global function_train
  start_order = 5
  adapt_rank start_rank = 2 kick_rank = 2 max_rank = 10
  solver_tolerance = 1e-12
  rounding_tolerance = 1e-12
dace_method_pointer = 'SAMPLING'
\end{verbatim}

Note that \texttt{adapt\_rank} and \texttt{adapt\_order} can either be combined or used separately.

- Keywords Area
- model
- surrogate
- global
- function_train
- kick_rank

The increment in rank employed during each iteration of the rank adaptation.

Specification

Alias: none

Argument(s): INTEGER

Default: 2

Description

The adapt_rank procedure increments the rank on each iteration, using an increment defined by kick_rank.

Default Behavior

Default is 1.

See Also

These keywords may also be of interest:

- adapt_rank

7.3.3.2.5.21 max_rank

- Keywords Area
- model
- surrogate
- global
- function_train
- max_rank

Limits the maximum rank that is explored during a rank adaptation.
Specification

Alias: none
Argument(s): INTEGER
Default: 3

Description

The `adapt_rank` procedure increments the rank on each iteration, and the maximum value is limited by `max_rank`.

Default Behavior

Max rank is unbounded (adaptive sweep will stop when CV error increases).

See Also

These keywords may also be of interest:

- adapt_rank

7.3.3.2.5.22 max_cv_rank_candidates

- Keywords Area
- model
- surrogate
- global
- function_train
- max_cv_rank_candidates

Limit the number of cross-validation candidates for rank

Specification

Alias: none
Argument(s): INTEGER
Default: `size_t max`

Description

When generating refinement candidates by advancing the upper bound used for a cross-validation range, the number of cross-validation can eventually become excessive and hamper algorithm progress. This control limits the maximum number of candidates, which when active, will increase the lower bound for this range as the upper bound is advanced.

Description

Dakota's artificial neural network surrogate is a stochastic layered perceptron network, with a single hidden layer. Weights for the input layer are chosen randomly, while those in the hidden layer are estimated from data using a variant of the Zimmerman direct training approach [96].
This typically yields lower training cost than traditional neural networks, yet good out-of-sample performance. This is helpful in surrogate-based optimization and optimization under uncertainty, where multiple surrogates may be repeatedly constructed during the optimization process, e.g., a surrogate per response function, and a new surrogate for each optimization iteration.

The neural network is a non-parametric surface fitting method. Thus, along with Kriging (Gaussian Process) and MARS, it can be used to model data trends that have slope discontinuities as well as multiple maxima and minima. However, unlike Kriging, the neural network surrogate is not guaranteed to interpolate the data from which it was constructed.

This surrogate can be constructed from fewer than $n_{\text{quad}}$ data points, however, it is a good rule of thumb to use at least $n_{\text{quad}}$ data points when possible.

**Known Issue:** When using discrete variables, there have been sometimes significant differences in surrogate behavior observed across computing platforms in some cases. The cause has not yet been fully diagnosed and is currently under investigation. In addition, guidance on appropriate construction and use of surrogates with discrete variables is under development. In the meantime, users should therefore be aware that there is a risk of inaccurate results when using surrogates with discrete variables.

**Theory**

The form of the neural network model is

$$\hat{f}(x) \approx \tanh \{ A_1 \tanh (A_0^T x + \theta_0^T) + \theta_1 \}$$

where $x$ is the evaluation point in $n$-dimensional parameter space; the terms $A_0$, $\theta_0$ are the random input layer weight matrix and bias vector, respectively; and $A_1$, $\theta_1$ are a weight vector and bias scalar, respectively, estimated from training data. These coefficients are analogous to the polynomial coefficients obtained from regression to training data. The neural network uses a cross validation-based orthogonal matching pursuit solver to determine the optimal number of nodes and to solve for the weights and offsets.

7.3.3.2.6.1 max_nodes

- **Keywords Area**
- model
- surrogate
- global
- neural_network
- max_nodes

Maximum number of hidden layer nodes

**Topics**

This keyword is related to the topics:

- surrogate_models

**Specification**

**Alias:** nodes

**Argument(s):** INTEGER

**Default:** numTrainingData - 1
Description

Limits the maximum number of hidden layer nodes in the neural network model. The default is to use one less node than the number of available training data points yielding a fully-determined linear least squares problem. However, reducing the number of nodes can help reduce overfitting and more importantly, can drastically reduce surrogate construction time when building from a large data set. (Historically, Dakota limited the number of nodes to 100.)

The keyword `max_nodes` provides an upper bound. Dakota’s orthogonal matching pursuit algorithm may further reduce the effective number of nodes in the final model to achieve better generalization to unseen points.

7.3.3.2.6.2 `range`

- **Keywords Area**
- **model**
- **surrogate**
- **global**
- **neural_network**

<td>filename_prefix</td>
<td></td>
<td>User-customizable portion of exported/imported surrogate model filenames</td>
</tr>
<tr>
<td>Required</td>
<td>formats</td>
<td></td>
<td>Formats for surrogate model export</td>
</tr>
</tbody>
</table>
Description

Export the surrogate for later re-import to Dakota or evaluation using the surfpack executable \((\text{bin/surfpack})\) or a user-developed tool. Export format is controlled using the \texttt{formats} specification. Four formats are available in Dakota; however, not all have been enabled for all surrogates.

The four formats are:

- \texttt{text_archive} • Plain-text, machine-readable archive for re-import or use with the surfpack executable
- \texttt{binary_archive} • Binary, machine-readable archive for re-import or use with the surfpack executable
- \texttt{algebraic_file} • Plain-text, human-readable file intended for use with user-created tools; not compatible with Dakota or the surfpack executable
- \texttt{algebraic_console} • Print the model in algebraic format to the screen; not compatible with Dakota or the surfpack executable

These global surrogates can be exported in all four formats:

- Gaussian process (keyword \texttt{gaussian_process surfpack})
- Artificial neural network (keyword \texttt{neural_network})
- Radial basis Functions (keyword \texttt{radial_basis})
- Polynomial (keyword \texttt{polynomial})

However, for experimental Gaussian Process and polynomial models as well as Multivariate Adaptive Regression Spline (keyword \texttt{mars}) and moving least squares (keyword \texttt{moving_least_squares}) models, only \texttt{text_archive} and \texttt{binary_archive} formats may be used.

Currently, no other surrogate models can be exported.

Default Behavior

No export.

Expected Output

Output depends on selected format; see the \texttt{formats} specification.

Additional Discussion

The Dakota examples include a demonstration of using the surfpack executable with an exported model file.
Topics

This keyword is related to the topics:

- surrogate_models

Specification

Alias: none

Argument(s): STRING

Default: exported_surrogate

Description

Dakota surrogate model files are exported and imported using one file per response, per requested format. The files are named using the pattern \{prefix\}.{response_descriptor}.{extension}. This filename_prefix keyword is used to supply the prefix portion of the pattern.

The response_descriptor portion of the pattern is filled in using the response descriptors provided by the user (or, if none are specified, descriptors automatically generated by Dakota). Extension is a three or four letter string that depends on the format.

Examples

This input snippet directs Dakota to write one algebraic format file and one binary archive file for each response. The names of the files will follow the patterns my_surrogate.{response_descriptor}.alg (for the algebraic files) and my_surrogate.{response_descriptor}.bsps (for the binary files).

```
surrogate global gaussian_process surfpack
    export_model
        filename_prefix = 'my_surrogate'
        formats
            algebraic_file
            binary_archive
```

Surrogate model binary archive file format

**Topics**

This keyword is related to the topics:

- surrogate_models

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

When specified, the surrogate model will be exported (or imported) using a binary archive format.

Experimental surrogates will export to (import from) binary archives named \{prefix\}.{response_descriptor}.bin.
Other (Surfpack) surrogates will export/import using files named \texttt{{prefix}.\{response\_descriptor\}.bsps}, in which 'bsps' stands for binary Surfpack surrogate.

See \texttt{filename\_prefix} for further information about surrogate file naming.

Examples

The Dakota examples include a demonstration of using the surfpack executable with an exported model file.

7.3.3.2.6.9 algebraic\_file

- Keywords Area
- model
- surrogate
- global
- neural\_network
- export\_model
- formats
- algebraic\_file

Export surrogate model in algebraic format to a file

Topics

This keyword is related to the topics:

- surrogate\_models

Specification

Alias: none

Argument(s): none

Description

After the surrogate model has been built, Dakota will export it to a file in a human-readable "algebraic" format. The file is named using the pattern \texttt{{prefix}.\{response\_descriptor\}.alg}. See \texttt{filename\_prefix} for further information about exported surrogate file naming. The file contains sufficient information for the user to (re)construct and evaluate the model outside of Dakota.

Expected Output

The format depends on the type of surrogate model, but in general will include a LaTeX-like representation of the analytic form of the model to aid tool development, all needed model hyperparameters, and headers describing the shape or dimension of the provided data.

The output written to the file matches exactly the output written to the console when algebraic\_console is specified.
7.3.3.2.6.10 algebraic_console

- model
- surrogate
- global
- neural_network
- export_model
- formats
- algebraic_console

Export surrogate model in algebraic format to the console

Topics

This keyword is related to the topics:

- surrogate_models

Specification

Alias: none

Argument(s): none

Description

After the surrogate model has been built, Dakota will export it to the console (screen, or output file if Dakota was run using the -o option) in a human-readable "algebraic" format. The output contains sufficient information for the user to (re)construct and evaluate the model outside of Dakota.

Expected Output

The format depends on the type of surrogate model, but in general will include a LaTeX-like representation of the analytic form of the model to aid tool development, all needed model hyperparameters, and headers describing the shape or dimension of the provided data.

The output written to the screen for the exported model matches exactly the output written to file when algebraic_file is specified. Use of algebraic_file is preferred over algebraic_console, which exists largely to provide a measure of backward compatibility.

7.3.3.2.6.11 import_model

- Keywords Area
- model
- surrogate
- global
- neural_network
- import_model

Import surrogate model from archive file
Specification

Alias: none
Argument(s): none
Child Keywords:

<table>

<td>text_archive</td>
<td>Surrogate model plain-text archive file format</td>
</tr>
<tr>
<td></td>
<td></td>
<td>binary_archive</td>
<td>Surrogate model binary archive file format</td>
</tr>
</tbody>
</table>

Description

Imports a surrogate model from a file in binary_archive or text_archive format, typically instead of constructing it from generated or imported data. Importing can result in significant time savings with some models, such as Gaussian processes. The file from which to import is further specified with the child keywords filename_prefix and binary_archive or text_archive.

Default Behavior

When used in the context of an iteratively adapted or rebuilt surrogate, the imported model will only replace the initial surrogate model. Subsequent surrogate model builds require imported build points or a design of experiments method specified through dace_method_pointer.

Usage Tips

When importing a surrogate model, it is crucial that the global surrogate model part of the Dakota input file be identical for export and import, except for changing export_model and its child keywords to those needed for import_model. Any other keywords such as specifying a dace_iterator or imported points must remain intact to satisfy internal surrogate constructor requirements.

All variables over which the surrogate model was built (typically the active variables) when exported must be present in the Dakota study that imports it. The variables in the importing study will be matched by descriptor to those in the surrogate model. This allows the order and type of variables to change between export and import, for example to fix unimportant parameters as state variables even if they were previously active design variables.

For example, suppose the original Dakota study for the surrogate build had active uniform uncertain variables: a, b, c, d, and inactive state variables s, t, and the surrogate gets built over a, b, c, d. The follow-on study could perform design optimization over active design variables b and d, with inactive state variables a, c, s, t, held at fixed initial_state values. In this case the values of a, b, c, d will get mapped to the surrogate and s, t dropped when evaluating it. So it is important the state values for s and t haven’t changed in some way that invalidates the surrogate.

While it might be possible to import surrogates externally-generated using the surfpack binary or the experimental dakota.surrogates Python module, it is untested and not the primary use case for this capability.
Examples

The following model block exports a Gaussian process after it's built:

```dakota
model
  id_model = 'SURR_M'
  surrogate global
    dace_method_pointer = 'DACE'
    experimental_gaussian_process
      metrics 'root_mean_squared'
      cross_validation folds 5
    export_model
      filename_prefix = 'gp_export'
      formats = binary_archive
      export_approx_points_file 'gp_values.dat'
      export_approx_variance_file 'gp_variance.dat'

And this model block imports it using a nearly identical model specification:

```dakota
model
  id_model = 'SURR_M'
  surrogate global
    dace_method_pointer = 'DACE'
    experimental_gaussian_process
      metrics 'root_mean_squared'
      cross_validation folds 5
    import_model
      filename_prefix = 'gp_export'
      binary_archive
      export_approx_points_file 'gp_values.dat'
      export_approx_variance_file 'gp_variance.dat'

Description

Radial basis functions $\phi$ are functions whose value typically depends on the distance from a center point, called the centroid, $c$.

The surrogate model approximation comprises a sum of $K$ weighted radial basis functions:

$$\hat{f}(x) = \sum_{k=1}^{K} w_k \phi(\| x - c_k \|)$$

These basis functions take many forms, but Gaussian kernels or splines are most common. The Dakota implementation uses a Gaussian radial basis function. The weights are determined via a linear least squares solution approach. See [70] for more details.
Known Issue: When using discrete variables, there have been sometimes significant differences in surrogate behavior observed across computing platforms in some cases. The cause has not yet been fully diagnosed and is currently under investigation. In addition, guidance on appropriate construction and use of surrogates with discrete variables is under development. In the meantime, users should therefore be aware that there is a risk of inaccurate results when using surrogates with discrete variables.

7.3.3.2.7.1 bases

- Keywords Area
- model
- surrogate
- global
- radial_basis
- bases

Initial number of radial basis functions

Topics

This keyword is related to the topics:

- surrogate_models

Specification

Alias: none

Argument(s): INTEGER

Description

Initial number of radial basis functions. The default value is the smaller of the number of training points and 100.

7.3.3.2.7.2 max_pts

- Keywords Area
- model
- surrogate
- global
- radial_basis
- max_pts

Maximum number of RBF CVT points

Topics

This keyword is related to the topics:

- surrogate_models
7.3 model

Specification

Alias: none

Argument(s): INTEGER

Description

Maximum number of CVT points to use in generating each RBF center. Basis computing centroid of each. Defaults to 10 * (bases). Reducing this will reduce model build time.

7.3.3.2.7.3  min_partition

- Keywords Area
- model
- surrogate
- global
- radial_basis
- min_partition

Inactive) Minimum RBF partition

Topics

This keyword is related to the topics:

- surrogate_models

Specification

Alias: none

Argument(s): INTEGER

Description

This option currently has no effect and will likely be removed.

7.3.3.2.7.4  max_subsets

- Keywords Area
- model
- surrogate
- global
- radial_basis
- max_subsets

Number of trial RBF subsets
Topics

This keyword is related to the topics:

- surrogate_models

Specification

Alias: none

Argument(s): INTEGER

Description

Number of passes to take to identify the best subset of basis functions to use. Defaults to the smaller of $3 \times (bases)$ and 100.

7.3.3.2.7.5 export_model

- Keywords Area
- model
- surrogate
- global
- radial_basis
- export_model

Exports surrogate model in user-specified format(s)

Topics

This keyword is related to the topics:

- surrogate_models

Specification

Alias: none

Argument(s): none

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>

<td>filename_prefix</td>
<td>User-customizable portion of exported/imported surrogate model filenames</td>
</tr>
<tr>
<td>Required</td>
<td></td>
<td>formats</td>
<td>Formats for surrogate model export</td>
</tr>
</tbody>
</table>
Description

Export the surrogate for later re-import to Dakota or evaluation using the surfpack executable (bin/surfpack) or a user-developed tool. Export format is controlled using the formats specification. Four formats are available in Dakota; however, not all have been enabled for all surrogates.

The four formats are:

- **text_archive**: Plain-text, machine-readable archive for re-import or use with the surfpack executable
- **binary_archive**: Binary, machine-readable archive for re-import or use with the surfpack executable
- **algebraic_file**: Plain-text, human-readable file intended for use with user-created tools; not compatible with Dakota or the surfpack executable
- **algebraic_console**: Print the model in algebraic format to the screen; not compatible with Dakota or the surfpack executable

These global surrogates can be exported in all four formats:

- Gaussian process (keyword `gaussian_process surfpack`)
- Artificial neural network (keyword `neural_network`)
- Radial basis Functions (keyword `radial_basis`)
- Polynomial (keyword `polynomial`)

However, for experimental Gaussian Process and polynomial models as well as Multivariate Adaptive Regression Spline (keyword `mars`) and moving least squares (keyword `moving_least_squares`) models, only text_archive and binary_archive formats may be used.

Currently, no other surrogate models can be exported.

**Default Behavior**

No export.

**Expected Output**

Output depends on selected format; see the formats specification.

**Additional Discussion**

The Dakota examples include a demonstration of using the surfpack executable with an exported model file.

7.3.3.2.7.6 filename_prefix

- Keywords Area
- model
- surrogate
- global
- radial_basis
- export_model
- filename_prefix

User-customizable portion of exported/imported surrogate model filenames
Topics

This keyword is related to the topics:

- surrogate_models

Specification

Alias: none

Argument(s): STRING

Default: exported_surrogate

Description

Dakota surrogate model files are exported and imported using one file per response, per requested format. The files are named using the pattern `{prefix}.{response_descriptor}.{extension}`. This `filename_prefix` keyword is used to supply the prefix portion of the pattern.

The `response_descriptor` portion of the pattern is filled in using the response descriptors provided by the user (or, if none are specified, descriptors automatically generated by Dakota). Extension is a three or four letter string that depends on the format.

Examples

This input snippet directs Dakota to write one algebraic format file and one binary archive file for each response. The names of the files will follow the patterns `my_surrogate.{response_descriptor}.alg` (for the algebraic files) and `my_surrogate.{response_descriptor}.bsps` (for the binary files).

```bash
surrogate global gaussian_process surfpack export_model
    filename_prefix = 'my_surrogate'
    formats
        algebraic_file
        binary_archive
```

  - surrogate
  - global
  - radial_basis
  - export_model
  - formats
  - text_archive

Surrogate model plain-text archive file format

**Topics**

This keyword is related to the topics:

- surrogate_models
Specification

**Alias:** none

**Argument(s):** none

**Description**

When specified, the surrogate model will be exported (or imported) using a plain-text archive format. Experimental surrogates will export to (import from) text archives named `{prefix}.{response_descriptor}.txt`. Other (Surfpack) surrogates will export/import using files named `{prefix}.{response_descriptor}.sps`, in which 'sps' stands for Surfpack surrogate. See `filename_prefix` for further information about surrogate file naming.

**Examples**

The Dakota examples include a demonstration of using the surfpack executable with an exported model file.

### 7.3.3.2.7.9 binary_archive

- **Keywords Area**

- **surrogate**
- **global**
- **radial_basis**
- **export_model**
- **formats**
- **binary_archive**

**Surrogate model binary archive file format**

**Topics**

This keyword is related to the topics:

- **surrogate_models**

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

When specified, the surrogate model will be exported (or imported) using a binary archive format. Experimental surrogates will export to (import from) binary archives named `{prefix}.{response_descriptor}.bin`. 
Other (Surfpack) surrogates will export/import using files named \texttt{\{prefix\}.\{response\_descriptor\}.bsps}, in which 'bsps' stands for binary Surfpack surrogate.

See \texttt{filename\_prefix} for further information about surrogate file naming.

**Examples**

The Dakota examples include a demonstration of using the surfpack executable with an exported model file.

7.3.3.2.7.10 \texttt{algebraic\_file}

- **Keywords** Area
- model
- surrogate
- global
- radial\_basis
- export\_model
- formats
- algebraic\_file

Export surrogate model in algebraic format to a file

**Topics**

This keyword is related to the topics:

- surrogate\_models

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

After the surrogate model has been built, Dakota will export it to a file in a human-readable "algebraic" format. The file is named using the pattern \texttt{\{prefix\}.\{response\_descriptor\}.alg}. See \texttt{filename\_prefix} for further information about exported surrogate file naming. The file contains sufficient information for the user to (re)construct and evaluate the model outside of Dakota.

**Expected Output**

The format depends on the type of surrogate model, but in general will include a LaTeX-like representation of the analytic form of the model to aid tool development, all needed model hyperparameters, and headers describing the shape or dimension of the provided data.

The output written to the file matches exactly the output written to the console when \texttt{algebraic\_console} is specified.
7.3.3.2.7.11 algebraic_console

- Keywords Area
- model
- surrogate
- global
- radial_basis
- export_model
- formats
- algebraic_console

Export surrogate model in algebraic format to the console

Topics

This keyword is related to the topics:

- surrogate_models

Specification

Alias: none

Argument(s): none

Description

After the surrogate model has been built, Dakota will export it to the console (screen, or output file if Dakota was run using the -o option) in a human-readable "algebraic" format. The output contains sufficient information for the user to (re)construct and evaluate the model outside of Dakota.

Expected Output

The format depends on the type of surrogate model, but in general will include a LaTeX-like representation of the analytic form of the model to aid tool development, all needed model hyperparameters, and headers describing the shape or dimension of the provided data.

The output written to the screen for the exported model matches exactly the output written to file when algebraic_file is specified. Use of algebraic_file is preferred over algebraic_console, which exists largely to provide a measure of backward compatibility.

7.3.3.2.7.12 import_model

- Keywords Area
- model
- surrogate
- global
- radial_basis
- import_model

Import surrogate model from archive file
Specification

**Alias:** none

**Argument(s):** none

<td>Surrogate model plain-text archive file format</td>
</tr>
<tr>
<td></td>
<td></td>
<td>binary_archive</td>
<td>Surrogate model binary archive file format</td>
</tr>
</tbody>
</table>

**Description**

Imports a surrogate model from a file in `binary_archive` or `text_archive` format, typically instead of constructing it from generated or imported data. Importing can result in significant time savings with some models, such as Gaussian processes. The file from which to import is further specified with the child keywords `filename_prefix` and `binary_archive` or `text_archive`.

**Default Behavior**

When used in the context of an iteratively adapted or rebuilt surrogate, the imported model will only replace the initial surrogate model. Subsequent surrogate model builds require imported build points or a design of experiments method specified through `dace_method_pointer`.

**Usage Tips**

When importing a surrogate model, *it is crucial* that the **global** surrogate model part of the Dakota input file be identical for export and import, except for changing `export_model` and its child keywords to those needed for `import_model`. Any other keywords such as specifying a `dace_iterator` or imported points must remain intact to satisfy internal surrogate constructor requirements.

All variables over which the surrogate model was built (typically the active variables) when exported must be present in the Dakota study that imports it. The variables in the importing study will be matched by descriptor to those in the surrogate model. This allows the order and type of variables to change between export and import, for example to fix unimportant parameters as state variables even if they were previously active design variables.

For example, suppose the original Dakota study for the surrogate build had active uniform uncertain variables: a, b, c, d, and inactive state variables s, t, and the surrogate gets built over a, b, c, d. The follow-on study could perform design optimization over active design variables b and d, with inactive state variables a, c, s, t, held at fixed `initial_state` values. In this case the values of a, b, c, d will get mapped to the surrogate and s, t dropped when evaluating it. So it is important the state values for s and t haven’t changed in some way that invalidates the surrogate.

While it might be possible to import surrogates externally-generated using the `surfpack` binary or the experimental `dakota.surrogates` Python module, it is untested and not the primary use case for this capability.
Examples

The following model block exports a Gaussian process after it's built:

```plaintext
model
  id_model = 'SURR_M'
surrogate global
dace_method_pointer = 'DACE'
experimental_gaussian_process
  metrics 'root_mean_squared'
cross_validation folds 5
export_model
  filename_prefix = 'gp_export'
  formats = binary_archive
  export_approx_points_file 'gp_values.dat'
  export_approx_variance_file 'gp_variance.dat'
```

And this model block imports it using a nearly identical model specification:

```plaintext
model
  id_model = 'SURR_M'
surrogate global
dace_method_pointer = 'DACE'
experimental_gaussian_process
  metrics 'root_mean_squared'
cross_validation folds 5
import_model
  filename_prefix = 'gp_export'
  binary_archive
  export_approx_points_file 'gp_values.dat'
  export_approx_variance_file 'gp_variance.dat'
```

</tbody>
</table>

**Description**

Linear, quadratic, and cubic polynomial surrogate models are available in Dakota. The utility of the simple polynomial models stems from two sources:

- over a small portion of the parameter space, a low-order polynomial model is often an accurate approximation to the true data trends
- the least-squares procedure provides a surface fit that smooths out noise in the data.

Local surrogate-based optimization methods (surrogate_based_local) are often successful when using polynomial models, particularly quadratic models. However, a polynomial surface fit may not be the best choice for modeling data trends globally over the entire parameter space, unless it is known a priori that the true data trends are close to linear, quadratic, or cubic. See [65] for more information on polynomial models.
Known Issue: When using discrete variables, there have been sometimes significant differences in surrogate behavior observed across computing platforms in some cases. The cause has not yet been fully diagnosed and is currently under investigation. In addition, guidance on appropriate construction and use of surrogates with discrete variables is under development. In the meantime, users should therefore be aware that there is a risk of inaccurate results when using surrogates with discrete variables.

Theory

The form of the linear polynomial model is

$$\hat{f}(x) \approx c_0 + \sum_{i=1}^{n} c_i x_i$$

the form of the quadratic polynomial model is:

$$\hat{f}(x) \approx c_0 + \sum_{i=1}^{n} c_i x_i + \sum_{i=1, j \geq i}^{n} c_{ij} x_i x_j$$

and the form of the cubic polynomial model is:

$$\hat{f}(x) \approx c_0 + \sum_{i=1}^{n} c_i x_i + \sum_{i=1, j \geq i}^{n} c_{ij} x_i x_j + \sum_{i=1, j \geq i, k \geq j}^{n} c_{ijk} x_i x_j x_k$$

In all of the polynomial models, $\hat{f}(x)$ is the response of the polynomial model; the $x_i, x_j, x_k$ terms are the components of the $n$-dimensional design parameter values; the $c_0, c_i, c_{ij}, c_{ijk}$ terms are the polynomial coefficients, and $n$ is the number of design parameters. The number of coefficients, $n_c$, depends on the order of polynomial model and the number of design parameters. For the linear polynomial:

$$n_{c\text{linear}} = n + 1$$

for the quadratic polynomial:

$$n_{c\text{quad}} = \frac{(n+1)(n+2)}{2}$$

and for the cubic polynomial:

$$n_{c\text{cubic}} = \frac{n^3 + 6n^2 + 11n + 6}{6}$$

There must be at least $n_c$ data samples in order to form a fully determined linear system and solve for the polynomial coefficients. In Dakota, a least-squares approach involving a singular value decomposition numerical method is applied to solve the linear system.
7.3 model

Specification

Expected Output

The format depends on the type of surrogate model, but in general will include a LaTeX-like representation of the analytic form of the model to aid tool development, all needed model hyperparameters, and headers describing the shape or dimension of the provided data.

The output written to the screen for the exported model matches exactly the output written to file when algebraic_file is specified. Use of algebraic_file is preferred over algebraic_console, which exists largely to provide a measure of backward compatibility.

7.3.3.2.8.12 import_model

- Keywords Area

<td>Surrogate model binary archive file format</td>
</tr>
</tbody>
</table>

**Description**

Imports a surrogate model from a file in `binary_archive` or `text_archive` format, typically instead of constructing it from generated or imported data. Importing can result in significant time savings with some models, such as Gaussian processes. The file from which to import is further specified with the child keywords `filename_prefix` and `binary_archive` or `text_archive`.

**Default Behavior**

When used in the context of an iteratively adapted or rebuilt surrogate, the imported model will only replace the initial surrogate model. Subsequent surrogate model builds require imported build points or a design of experiments method specified through `dace_method_pointer`.

**Usage Tips**

When importing a surrogate model, it is crucial that the global surrogate model part of the Dakota input file be identical for export and import, except for changing `export_model` and its child keywords to those needed for `import_model`. Any other keywords such as specifying a `dace_iterator` or imported points must remain intact to satisfy internal surrogate constructor requirements.

All variables over which the surrogate model was built (typically the active variables) when exported must be present in the Dakota study that imports it. The variables in the importing study will be matched by descriptor to those in the surrogate model. This allows the order and type of variables to change between export and import, for example to fix unimportant parameters as state variables even if they were previously active design variables.

For example, suppose the original Dakota study for the surrogate build had active uniform uncertain variables: a, b, c, d, and inactive state variables s, t, and the surrogate gets built over a, b, c, d. The follow-on study could perform design optimization over active design variables b and d, with inactive state variables a, c, s, t, held at fixed `initial_state` values. In this case the values of a, b, c, d will get mapped to the surrogate and s, t dropped when evaluating it. So it is important the state values for s and t haven’t changed in some way that invalidates the surrogate.

While it might be possible to import surrogates externally-generated using the `surfpack` binary or the experimental `dakota.surrogates` Python module, it is untested and not the primary use case for this capability.
Examples

The following model block exports a Gaussian process after it’s built:

```dakota
model
  id_model = 'SURR_M'
surrogate global
dace_method_pointer = 'DACE'
experimental_gaussian_process
  metrics 'root_mean_squared'
cross_validation folds 5
export_model
  filename_prefix = 'gp_export'
  formats = binary_archive
  export_approx_points_file 'gp_values.dat'
  export_approx_variance_file 'gp_variance.dat'
```

And this model block imports it using a nearly identical model specification:

```dakota
model
  id_model = 'SURR_M'
surrogate global
dace_method_pointer = 'DACE'
experimental_gaussian_process
  metrics 'root_mean_squared'
cross_validation folds 5
import_model
  filename_prefix = 'gp_export'
  binary_archive
  export_approx_points_file 'gp_values.dat'
  export_approx_variance_file 'gp_variance.dat'
```

7.3.3.2.8.13 filename_prefix

- Keywords Area
- model
- surrogate
- global
- polynomial
- import_model
- filename_prefix

User-customizable portion of exported/imported surrogate model filenames

Topics

This keyword is related to the topics:

- surrogate_models

Specification

Alias: none

Argument(s): STRING

Default: exported_surrogate
Description

Dakota surrogate model files are exported and imported using one file per response, per requested format. The files are named using the pattern `{prefix}.{response_descriptor}.{extension}`. This `filename_prefix` keyword is used to supply the prefix portion of the pattern.

The `response_descriptor` portion of the pattern is filled in using the response descriptors provided by the user (or, if none are specified, descriptors automatically generated by Dakota). Extension is a three or four letter string that depends on the format.

Examples

This input snippet directs Dakota to write one algebraic format file and one binary archive file for each response. The names of the files will follow the patterns `my_surrogate.{response_descriptor}.alg` (for the algebraic files) and `my_surrogate.{response_descriptor}.bsps` (for the binary files).

```
surrogate global gaussian_process surfpack
export_model
   filename_prefix = 'my_surrogate'
formats
   algebraic_file
   binary_archive
```

7.3.3.2.8.14 text_archive

- Keywords Area

Surrogate model plain-text archive file format

Topics

This keyword is related to the topics:

- surrogate_models

Specification

Alias: none

Argument(s): none

Description

When specified, the surrogate model will be exported (or imported) using a plain-text archive format. Experimental surrogates will export to (import from) text archives named `{prefix}.{response_descriptor}.txt`. 
Other (Surfacpk) surrogates will export/import using files named `{prefix}.response_descriptor.sps`, in which 'sps' stands for Surfpack surrogate.

See `filename_prefix` for further information about surrogate file naming.

Examples

The Dakota examples include a demonstration of using the surfpack executable with an exported model file.

Description

Compute a polynomial surrogate for a specified total order by least-squares regression. This model is implemented in Dakota's surrogates module and is considered experimental.

7.3.3.2.9.1 basis_order

- Keywords Area
- model
- surrogate
- global
- experimental_polynomial
- basis_order

Total degree of the polynomial basis
Specification

**Alias:** none

**Argument(s):** INTEGER

**Description**

This keyword’s argument specifies the terms in the polynomial according to a total order scheme.

7.3.3.2.9.2 options_file

- Keywords Area
- model
- surrogate
- global
- experimental_polynomial
- options_file

Filename for a YAML file that specifies polynomial surrogate options

**Specification**

**Alias:** none

**Argument(s):** STRING

**Default:** no advanced options file

**Description**

The YAML file contains configuration options that are used to populate a Teuchos ParameterList used by the polynomial that will override other keyword-specified parameters. Missing options in the YAML file are set to default values.

**Examples**

# FILE: polynomial_options.yaml

Polynomial Parameters:
  max degree: 3
  scaler type: none
  reduced basis: false
  p-norm: 1.0
  regression solver type: SVD
  standardize response: false
  verbosity: 1

7.3.3.2.9.3 export_model

- Keywords Area
- model
- surrogate
Exports surrogate model in user-specified format(s)

**Topics**

This keyword is related to the topics:

- surrogate_models

**Specification**

**Alias:** none

**Argument(s):** none

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>

<tr>
<td>Required</td>
<td></td>
<td></td>
<td>Formats for surrogate model export</td>
</tr>
</tbody>
</table>

**Description**

Export the surrogate for later re-import to Dakota or evaluation using the surfpack executable (`bin/surfpack`) or a user-developed tool. Export format is controlled using the `formats` specification. Four formats are available in Dakota; however, not all have been enabled for all surrogates.

The four formats are:

- **text_archive**: Plain-text, machine-readable archive for re-import or use with the surfpack executable
- **binary_archive**: Binary, machine-readable archive for re-import or use with the surfpack executable
- **algebraic_file**: Plain-text, human-readable file intended for use with user-created tools; not compatible with Dakota or the surfpack executable
- **algebraic_console**: Print the model in algebraic format to the screen; not compatible with Dakota or the surfpack executable

These global surrogates can be exported in all four formats:

- Gaussian process (keyword `gaussian_process surfpack`)
- Artificial neural network (keyword `neural_network`)
- Radial basis Functions (keyword `radial_basis`)
• Polynomial (keyword polynomial)

However, for experimental Gaussian Process and polynomial models as well as Multivariate Adaptive Regression Spline (keyword mars) and moving least squares (keyword moving_least_squares) models, only text-_archive and binary_archive formats may be used.

Currently, no other surrogate models can be exported.

Default Behavior
No export.

Expected Output
Output depends on selected format; see the formats specification.

Additional Discussion
The Dakota examples include a demonstration of using the surfpack executable with an exported model file.

7.3.3.2.9.7 binary_archive

• Keywords Area
  • model
  • surrogate
  • global
  • experimental_polynomial
  • export_model
When specified, the surrogate model will be exported (or imported) using a binary archive format.

Experimental surrogates will export to (import from) binary archives named `{prefix}.{response_descriptor}.bin`.

Other (Surfpack) surrogates will export/import using files named `{prefix}.{response_descriptor}.bsps`, in which ‘bsps’ stands for binary Surfpack surrogate.

See `filename_prefix` for further information about surrogate file naming.

**Examples**

The Dakota examples include a demonstration of using the surfpack executable with an exported model file.
Description

Imports a surrogate model from a file in binary_archive or text_archive format, typically instead of constructing it from generated or imported data. Importing can result in significant time savings with some models, such as Gaussian processes. The file from which to import is further specified with the child keywords filename_prefix and binary_archive or text_archive.

Default Behavior

When used in the context of an iteratively adapted or rebuilt surrogate, the imported model will only replace the initial surrogate model. Subsequent surrogate model builds require imported build points or a design of experiments method specified through dace_method_pointer.

Usage Tips

When importing a surrogate model, it is crucial that the global surrogate model part of the Dakota input file be identical for export and import, except for changing export_model and its child keywords to those needed for import_model. Any other keywords such as specifying a dace_iterator or imported points must remain intact to satisfy internal surrogate constructor requirements.

All variables over which the surrogate model was built (typically the active variables) when exported must be present in the Dakota study that imports it. The variables in the importing study will be matched by descriptor to those in the surrogate model. This allows the order and type of variables to change between export and import, for example to fix unimportant parameters as state variables even if they were previously active design variables.

For example, suppose the original Dakota study for the surrogate build had active uniform uncertain variables: a, b, c, d, and inactive state variables s, t, and the surrogate gets built over a, b, c, d. The follow-on study could perform design optimization over active design variables b and d, with inactive state variables a, c, s, t, held at fixed initial_state values. In this case the values of a, b, c, d will get mapped to the surrogate and s, t dropped when evaluating it. So it is important the state values for s and t haven’t changed in some way that invalidates the surrogate.

While it might be possible to import surrogates externally-generated using the surfpack binary or the experimental dakota.surrogates Python module, it is untested and not the primary use case for this capability.

Examples

The following model block exports a Gaussian process after it’s built:

```python
    model
    id_model = 'SURR_M'
    surrogate global
      dace_method_pointer = 'DACE'
      experimental_gaussian_process
```
7.3 model

metrics 'root_mean_squared'

<td>Optional Discontinuity Detection Capability for the Piecewise Decomposition Option of Global Surrogates</td>
</tr>
</tbody>
</table>

Description

Typical regression techniques use all available sample points to build continuous approximations the underlying function.

An alternative option is to use piecewise decomposition to locally approximate the function at some point using a few sample points from its neighborhood only. This option currently supports Polynomial Regression, Gaussian Process (GP) Interpolation, and Radial Basis Functions (RBF) Regression. It requires a decomposition cell type (currently set to be Voronoi cells). Optional parameters are: the number of layers of neighbors used to solve the regression problem (default is one layer), and an optional discontinuity detection capability (identified by a user-input jump or gradient threshold).

The method can also make use of the gradient and Hessian information, if available. The user needs to specify the keyword `user_derivatives`.

7.3.3.2.10.1 cell_type

- Keywords Area
- model
- surrogate
- global
- domain_decomposition
7.3 model

- cell_type

Type of the Geometric Cells Used for the Piecewise Decomposition Option of Global Surrogates

Specification

Alias: none
Argument(s): STRING

Description

The piecewise decomposition option for global surrogates is used to locally approximate a function at some point using a few sample points from its neighborhood.

This option requires a decomposition cell type that can vary from structured grid boxes, to polygonal Voronoi cells. Currently, this option only supports Voronoi cells.

7.3.3.2.10.2 support_layers

- Keywords Area
- model
- surrogate
- global
- domain_decomposition
- support_layers

Optional Number of Support Layers for the Piecewise Decomposition Option of Global Surrogates

Specification

Alias: none
Argument(s): INTEGER

Description

The piecewise decomposition option for global surrogates is used to locally approximate a function at some point using a few sample points from its neighborhood.

The neighborhood of a cell is parameterized via a number of (support layers). The default value is set to one layer of neighbors (cells that share direct edges with the cell under study). One more support layer would include the neighbors of that cell's neighbors, and so on.

7.3.3.2.10.3 discontinuity_detection

- Keywords Area
- model
- surrogate
- global
- domain_decomposition
Optional Discontinuity Detection Capability for the Piecewise Decomposition Option of Global Surrogates

Description

The piecewise decomposition option for global surrogates is used to locally approximate a function at some point using a few sample points from its neighborhood.

The domain decomposition algorithm supports an optional discontinuity detection capability where seeds across a user-input discontinuity threshold are not considered neighbors when building the approximate connectivity Delaunay graph. Alternatively, the domain is split into patches that trap discontinuities between them. This capability is specified by either jump or gradient threshold values in the input spec.

7.3.3.2.10.4 jump_threshold

- Keywords Area

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>auto_refinement</td>
<td>Experimental auto-refinement of surrogate model</td>
</tr>
</tbody>
</table>

Description

The number of training points and the sources are specified on global, as well as the number of new training points required.

New training points are gathered by running the "truth" model using the method specified by dace_method_pointer. The DACE method will only be invoked if it has new samples to perform, and if new samples are required and no DACE iterator has been provided, an error will result.

The dace_method_pointer points to design of experiments method block used to generate truth model data.

Permissible methods include: Monte Carlo (random) sampling, Latin hypercube sampling, orthogonal array sampling, central composite design sampling, and Box-Behnken sampling.
Note that the number of samples specified in the method block may be overwritten, if the requested number of samples is less than minimum_points.

<td>Number of function evaluations allowed for optimizers</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>convergence_tolerance</td>
<td>Cross-validation threshold for surrogate convergence</td>
</tr>
</tbody>
</table>
### Description

(Experimental option) Automatically refine the surrogate model until desired cross-validation quality is achieved. Refinement is accomplished by iteratively adding more data to the training set until the cross-validation convergence_tolerance is achieved, or max_function_evaluations or max_iterations is exceeded.

The amount of new training data that is incorporated each iteration is specified in the DACE method that is referred to by the model's dace_method_pointer. See refinement_samples for more information.

- **Default:** 100

#### Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed max_iterations iterations. In cases where there are multiple nested iterations to be controlled, max_iterations generally controls the outer-most context.

**Default Behavior**

Default value is 100.

- auto_refinement
- max_function_evaluations

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed max_function_evaluations evaluations. See also max_iterations.

Some optimizers (e.g. ncsu_direct) may run past this limit in the course of an iteration step that began before max_function_evaluations was exceeded.

Default Behavior

Default value is 1000.
7.3 model

- `auto_refinement`
- `convergence_tolerance`

Cross-validation threshold for surrogate convergence

**Specification**

**Alias:** none  
**Argument(s):** REAL  
**Default:** 1.0e-4

**Description**

The surrogate model will be refined until the selected `cross_validation_metric` falls below this convergence tolerance.

**Default Behavior**  The default is 1e-4.

7.3.3.2.14.5 soft_convergence_limit

- `Keywords Area`
- `model`
- `surrogate`
- `global`
- `dace_method_pointer`
- `auto_refinement`
- `soft_convergence_limit`

Maximum number of iterations without improvement in cross-validation

**Specification**

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** 0

**Description**

The purpose of this control is to cease auto-refinement when improvement in the cross-validation score appears to have stalled or occurs too slowly.

A rolling average of improvement in the cross-validation score is computed over `soft_convergence_limit` iterations. Auto-refinement is halted if the average becomes smaller than the `convergence_tolerance`. The average is computed but ignored until the number of iterations has exceeded `soft_convergence_limit`. The default setting of 0 disables soft convergence.
7.3.3.2.14.6  cross_validation_metric

- Keywords Area
- model
- surrogate
- global
- dace_method_pointer
- auto_refinement
- cross_validation_metric

Choice of error metric to satisfy

Specification

**Alias:** none

**Argument(s):** STRING

**Default:** root-mean-squared error

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>folds</td>
<td>Number of cross validation folds</td>
</tr>
</tbody>
</table>

**Description**

The cross-validation score that the auto-refinement routine seeks to satisfy is based on an error metric. Any of the surrogate diagnostic metrics may be used. These include:

- root_mean_squared
- mean_abs
- rsquared
- sum_squared
- mean_squared
- sum_abs
- max_abs

**Default Behavior** The default metric is the root mean squared error ("root_mean_squared").

7.3.3.2.14.7  folds

- Keywords Area
- model
- surrogate
- global
7.3 model

- dace_method_pointer
- auto_refinement
- cross_validation_metric
- folds

Number of cross validation folds

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 10

**Description**

Number of folds (partitions) of the training data to use in cross validation (default 10).

7.3.3.2.15 truth_model_pointer

- Keywords Area
- model
- surrogate
- global
- truth_model_pointer

A surrogate model pointer that guides a method to whether it should use a surrogate model or compute truth function evaluations

**Specification**

**Alias:** actual_model_pointer

**Argument(s):** STRING

**Description**

Dakota methods use global surrogate models to compute surrogate function approximations. They also need to know the true function evaluations. A global surrogate model now must have a truth_model_pointer keyword to decide for the method whether to evaluate the global surrogate model, or compute the true function evaluations if truth_model_pointer = 'TRUTH'.

7.3.3.2.16 reuse_points

- Keywords Area
- model
- surrogate
- global
- reuse_points

Surrogate model training data reuse control
Topics

This keyword is related to the topics:

- surrogate_models

Specification

**Alias:** reuse_samples

**Argument(s):** none

**Default:** all for import; none otherwise

**Child Keywords:**

<table>
<thead>
<tr>

<tr>
<td>region</td>
<td></td>
<td>region</td>
<td>Option for reuse_points</td>
</tr>
<tr>
<td>none</td>
<td></td>
<td>none</td>
<td>Option for reuse_points</td>
</tr>
</tbody>
</table>

Description

Dakota's global surrogate methods rely on training data, which can either come from evaluation of a “truth” model, which is generated by the method specified with dace_method_pointer, from a file of existing training data, identified by import_build_points_file, or both.

The `reuse_points` keyword controls the amount of training data used in building a surrogate model, either initially, or during iterative rebuild, as in surrogate-based optimization. If `import_build_points_file` is specified, `reuse_points` controls how the file contents are used. If used during iterative rebuild, it controls what data from previous surrogate builds is reused in building the current model.

- **all** (default for file import) - use all points in the file or available from previous builds
- **region** - use only the points falling in the current trust region (see surrogate_based_local)
- **none** (default when no import) - ignore the contents of the file or previous build points, and gather new training data using the specified DACE method

</tr>
<tr>
<td></td>
<td></td>
<td>active_only</td>
<td>Import only active variables from tabular data file</td>
</tr>
</tbody>
</table>

**Description**

The `import_build_points_file` allows the user to specify a file that contains a list of points and truth model responses used to construct a surrogate model. These can be used by all methods that (explicitly, e.g. surrogate-based optimization, or implicitly, e.g. efficient global optimization) operate on a surrogate. In particular, these points and responses are used in place of truth model evaluations to construct the initial surrogate. When used to construct surrogate models or emulators these are often called build points or training data.

**Default Behavior**

By default, methods do not import points from a file.

**Usage Tips**

Dakota parses input files without regard to whitespace, but the `import_build_points_file` must be in one of three formats:

- `annotated` (default)
7.3 model

- custom_annotated
- freeform

Examples

```python
method
polynomial_chaos
  expansion_order = 4
  import_build_points_file = 'dakota_uq_rosenbrock_pce_import.annot.pts.dat'
```

7.3.3.2.17.1 custom_annotated

- Keywords Area
- model
- surrogate
- global
- import_build_points_file
- custom_annotated

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- file_formats

Specification

**Alias**: none

**Argument(s)**: none

**Child Keywords**:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>header</td>
<td>Enable header row in custom-annotated tabular file</td>

<td>Enable evaluation ID column in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>interface_id</td>
<td>Enable interface ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>
Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```
environment
tabular_data
    tabular_data_file = 'dakota_summary.dat'
custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 0.9 1.1 0.0002 0.26 0.76
2 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...```

7.3.3.2.17.2 header

7.3.3.2.17.3 use_variable_labels

- Keywords Area
- model
- surrogate
- global
- import_build_points_file
- custom_annotated
- header
- use_variable_labels

Validate/use variable labels from tabular file header

Specification

Alias: none
Argument(s): none

Description

When importing global surrogate training data (or challenge evaluation points) from a tabular data file containing a header (annotated or custom_annotated header), this keyword toggles validation of variable labels present in the header row.

The labels are validated against the descriptors of the variables being imported to. If the tabular file labels can be rearranged to match the expected labels, the columns in the data file will be reordered on read to match the Dakota variable order. If the read labels are not a permutation of, nor equal to, the expected labels, an error will result.

Default Behavior

When not specified, variable labels will be read, but not strictly enforced or reordered. A warning will be issued if the variable labels are not as expected, and guidance offered if they can be permuted to match expectations.

Expected Output

Console output will be generated for any warnings, as well as to indicate whether any variable reordering is taking place.

Usage Tips

The use of this keyword is recommended when importing header-annotated tabular data files where the variables are appropriately labeled. Tabular files do not always contain response labels, so no attempt is made to disambiguate variable from response labels. The variable labels must appear contiguously in the header after any leading column IDs such as 'eval_id' or 'interface'.

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
  tabular_data_file = 'dakota_summary.dat'
  annotated

Resulting tabular file:

%eval_id  interface  x1   x2   obj_fn nln_ineq_con_1 nln_ineq_con_2

challenge_points_file = 'dakota_surrogate_import.dat'
  annotated use_variable_labels
```

7.3.3.2.17.8 freeform

- Keywords Area
- model
- surrogate
- global
- import_build_points_file
- freeform

Selects freeform file format

Topics
This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none
Default: annotated

Description
A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.
Default Behavior

The **annotated** format is the default for tabular export/import. To change this behavior, specify **freeform** in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to **annotated** format, though **freeform** remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In **freeform**, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the **freeform** option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```plaintext
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
freeform
```

Resulting tabular file:

```
0.9   1.1   0.0002  0.26   0.76
0.90009 1.1  0.0001996404857 0.2601620081 0.759955
0.89991 1.1  0.0002003604863 0.2598380081 0.760045
...

7.3.3.2.17.9  active_only

- **Keywords Area**
- **model**
- **surrogate**
- **global**
- **import_build_points_file**
- **active_only**

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- **file_formats**

Specification

**Alias**: none

**Argument(s)**: none
7.3 model

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

7.3.3.2.18 export_approx_points_file

- **Keywords Area**
  - model
  - surrogate
  - global
  - export_approx_points_file

Output file for surrogate model value evaluations

Specification

**Alias:** export_points_file

**Argument(s):** STRING

**Default:** no point export to a file

**Child Keywords:**

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none
Default: annotated

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.
Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated

Resulting tabular file:

%eval_id interface x1  x2  obj_fn nln_ineq_con_1 nln_ineq_con_2
1    NO_ID  0.9   1.1  0.0002  0.26      0.76

7.3.3.2.18.6 freeform

- Keywords Area
- model
- surrogate
- global
- export_approx_points_file
- freeform

Selects freeform file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none
Default: annotated

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips
• Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    freeform
```

Resulting tabular file:

```
0.9   1.1   0.0002  0.26   0.76
0.90009 1.1  0.0001996404857  0.2601620081  0.759955
0.89991 1.1  0.0002003604863  0.2598380081  0.760045
...```

7.3.3.2.19 use_derivatives

• Keywords Area
• model
• surrogate
• global
• use_derivatives

Use derivative data to construct surrogate models

Specification

Alias: none
Argument(s): none
Default: use function values only

Description

The use_derivatives flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, it’s use with Surfpack Gaussian process is not recommended.
Correction approaches for surrogate models

### Specification

**Alias:** none  
**Argument(s):** none  
**Default:** no surrogate correction

### Child Keywords:

</table>

| Required (Choose One) | Correction Type (Group 2) | additive | Additive correction factor for local surrogate accuracy |
| | | multiplicative | Multiplicative correction factor for local surrogate accuracy. |
| | | combined | Multipoint correction for a hierarchical surrogate |
Description

Some of the surrogate model types support the use of correction factors that improve the local accuracy of the surrogate models.

The correction specification specifies that the approximation will be corrected to match truth data, either matching truth values in the case of zeroth_order matching, matching truth values and gradients in the case of first_order matching, or matching truth values, gradients, and Hessians in the case of second_order matching. For additive and multiplicative corrections, the correction is local in that the truth data is matched at a single point, typically the center of the approximation region. The additive correction adds a scalar offset (zeroth_order), a linear function (first_order), or a quadratic function (second_order) to the approximation to match the truth data at the point, and the multiplicative correction multiplies the approximation by a scalar (zeroth_order), a linear function (first_order), or a quadratic function (second_order) to match the truth data at the point. The additive first_order case is due to [59] and the multiplicative first_order case is commonly known as beta correction [41]. For the combined correction, the use of both additive and multiplicative corrections allows the satisfaction of an additional matching condition, typically the truth function values at the previous correction point (e.g., the center of the previous trust region). The combined correction is then a multipoint correction, as opposed to the local additive and multiplicative corrections. Each of these correction capabilities is described in detail in [24].

The correction factors force the surrogate models to match the true function values and possibly true function derivatives at the center point of each trust region. Currently, Dakota supports either zeroth-, first-, or second-order accurate correction methods, each of which can be applied using either an additive, multiplicative, or combined correction function. For each of these correction approaches, the correction is applied to the surrogate model and the corrected model is then interfaced with whatever algorithm is being employed. The default behavior is that no correction factor is applied.

The simplest correction approaches are those that enforce consistency in function values between the surrogate and original models at a single point in parameter space through use of a simple scalar offset or scaling applied to the surrogate model. First-order corrections such as the first-order multiplicative correction (also known as beta correction [14]) and the first-order additive correction [59] also enforce consistency in the gradients and provide a much more substantial correction capability that is sufficient for ensuring provable convergence in SBO algorithms. SBO convergence rates can be further accelerated through the use of second-order corrections which also enforce consistency in the Hessians [24], where the second-order information may involve analytic, finite-difference, or quasi-Newton Hessians.

Correcting surrogate models with additive corrections involves

\[ f_{\text{hi}}(x) = f_{\text{lo}}(x) + \alpha(x) \]  \hspace{1cm} (7.1)

where multifidelity notation has been adopted for clarity. For multiplicative approaches, corrections take the form

\[ f_{\text{hi}}(x) = f_{\text{lo}}(x) \beta(x) \]  \hspace{1cm} (7.2)

where, for local corrections, \( \alpha(x) \) and \( \beta(x) \) are first or second-order Taylor series approximations to the exact correction functions:

\[ \alpha(x) = A(x_c) + \nabla A(x_c)^T(x - x_c) + \frac{1}{2}(x - x_c)^T \nabla^2 A(x_c)(x - x_c) \]  \hspace{1cm} (7.3)

\[ \beta(x) = B(x_c) + \nabla B(x_c)^T(x - x_c) + \frac{1}{2}(x - x_c)^T \nabla^2 B(x_c)(x - x_c) \]  \hspace{1cm} (7.4)

where the exact correction functions are

\[ A(x) = f_{\text{hi}}(x) - f_{\text{lo}}(x) \]  \hspace{1cm} (7.5)

\[ B(x) = \frac{f_{\text{hi}}(x)}{f_{\text{lo}}(x)} \]  \hspace{1cm} (7.6)
Refer to [24] for additional details on the derivations.

A combination of additive and multiplicative corrections can provide for additional flexibility in minimizing the impact of the correction away from the trust region center. In other words, both additive and multiplicative corrections can satisfy local consistency, but through the combination, global accuracy can be addressed as well. This involves a convex combination of the additive and multiplicative corrections:

\[
\hat{f}_{hi}(x) = \gamma \hat{f}_{hi}(x) + (1 - \gamma) \hat{f}_{i}(x)
\]

where \(\gamma\) is calculated to satisfy an additional matching condition, such as matching values at the previous design iterate.

It should be noted that in both first order correction methods, the function \(\hat{f}(x)\) matches the function value and gradients of \(f_t(x)\) at \(x = x_c\). This property is necessary in proving that the first order-corrected SBO algorithms are provably convergent to a local minimum of \(f_t(x)\). However, the first order correction methods are significantly more expensive than the zeroth order correction methods, since the first order methods require computing both \(\nabla f_t(x_c)\) and \(\nabla f_s(x_c)\). When the SBO strategy is used with either of the zeroth order correction methods, or with no correction method, convergence is not guaranteed to a local minimum of \(f_t(x)\). That is, the SBO strategy becomes a heuristic optimization algorithm. From a mathematical point of view this is undesirable, but as a practical matter, the heuristic variants of SBO are often effective in finding local minima.

**Usage guidelines**

- Both the additive zeroth_order and multiplicative zeroth_order correction methods are “free” since they use values of \(f_t(x_c)\) that are normally computed by the SBO strategy.

- The use of either the additive first_order method or the multiplicative first_order method does not necessarily improve the rate of convergence of the SBO algorithm.

- When using the first order correction methods, the gradient-related response keywords must be modified to allow either analytic or numerical gradients to be computed. This provides the gradient data needed to compute the correction function.

- For many computationally expensive engineering optimization problems, gradients often are too expensive to obtain or are discontinuous (or may not exist at all). In such cases the heuristic SBO algorithm has been an effective approach at identifying optimal designs [35].

7.3.3.2.20.1 zeroth_order

- Keywords Area
- model
- surrogate
- global
- correction
- zeroth_order

Specify that truth values must be matched.

**Specification**

**Alias:** none  
**Argument(s):** none
Description

The correction specification specifies that the approximation will be corrected to match truth data. The keyword zeroth_order matching ensures that truth values are matched.

7.3.3.2.20.2 first_order

- Keywords Area
- model
- surrogate
- global
- correction
- first_order

Specify that truth values and gradients must be matched.

Specification

Alias: none
Argument(s): none

Description

This correction specification specifies that the approximation will be corrected to match truth data. The keyword first_order matching ensures that truth values and gradients are matched.

7.3.3.2.20.3 second_order

- Keywords Area
- model
- surrogate
- global
- correction
- second_order

Specify that truth values, gradients and Hessians must be matched.

Specification

Alias: none
Argument(s): none

Description

The correction specification specifies that the approximation will be corrected to match truth data. The keyword second_order matching ensures that truth values, gradients and Hessians are matched.
7.3.3.2.20.4 additive

- Keywords Area
- model
- surrogate
- global
- correction
- additive

Additive correction factor for local surrogate accuracy

Specification

Alias: none
Argument(s): none

Description

Use an additive correction factor to improve the local accuracy of a surrogate.

7.3.3.2.20.5 multiplicative

- Keywords Area
- model
- surrogate
- global
- correction
- multiplicative

Multiplicative correction factor for local surrogate accuracy.

Specification

Alias: none
Argument(s): none

Description

Use a multiplicative correction factor to improve the local accuracy of a surrogate.

7.3.3.2.20.6 combined

- Keywords Area
- model
- surrogate
Multipoint correction for a hierarchical surrogate

**Specification**

**Alias**: none

**Argument(s)**: none

**Description**

For the combined correction, the use of both additive and multiplicative corrections allows the satisfaction of an additional matching condition, typically the truth function values at the previous correction point (e.g., the center of the previous trust region). The combined correction is then a multipoint correction, as opposed to the local additive and multiplicative corrections.

7.3.3.2.21 **metrics**

- **Keywords Area**
- **model**
- **surrogate**
- **global**
- **metrics**

Compute surrogate quality metrics

**Topics**

This keyword is related to the topics:

- **surrogate_models**

**Specification**

**Alias**: diagnostics

**Argument(s)**: STRINGLIST

**Default**: No diagnostics

**Child Keywords**:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>cross_validation</td>
<td>press</td>
<td>Leave-one-out cross validation</td>
</tr>
</tbody>
</table>
Description

Diagnostic metrics assess the goodness of fit of a global surrogate to its training data. The default diagnostics are:

- root_mean_squared
- mean_abs
- rsquared

Additional available diagnostics include

- sum_squared
- mean_squared
- sum_abs
- max_abs

The keywords press and cross_validation further specify leave-one-out or k-fold cross validation, respectively, for all of the active metrics from above.

Usage Tips When specified, the metrics keyword must be followed by a list of quoted strings, each of which activates a metric.

Examples

This example input fragment constructs a quadratic polynomial surrogate and computes four metrics on the fit, both with and without 5-fold cross validation. (Also see dakota/share/dakota/test/dakota_surrogate_import.in for additional examples.)

```plaintext
model surrogate global
  polynomial quadratic
  metrics = "root_mean_squared" "sum_abs" "mean_abs" "max_abs"
  cross_validation folds = 5
```

Theory

Most of these diagnostics refer to some operation on the residuals (the difference between the surrogate model and the truth model at the data points upon which the surrogate is built).

For example, sum_squared refers to the sum of the squared residuals, and mean_abs refers to the mean of the absolute value of the residuals. rsquared refers to the R-squared value typically used in regression analysis (the proportion of the variability in the response that can be accounted for by the surrogate model). Care should be taken when interpreting metrics, for example, errors may be near zero for interpolatory models or rsquared may not be applicable for non-polynomial models.

7.3.3.2.21.1 cross_validation

- Keywords Area
- model
- surrogate
- global
- metrics
Perform k-fold cross validation

Topics
This keyword is related to the topics:

- surrogate_models

Specification

Alias: none
Argument(s): none
Default: No cross validation
Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group Partition Control (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional/Choose One</td>
<td></td>
<td>percent</td>
<td>Percent data per cross validation fold</td>
</tr>
</tbody>
</table>

Description

General k-fold cross validation may be performed by specifying cross_validation. The cross-validation statistics will be calculated for all metrics.

Cross validation may further specify:

- folds, the number of folds into which to divide the build data (between 2 and number of data points) or
- percent, the fraction of data (between 0 and 0.5) to use in each fold.

These will be adjusted as needed based on the number of available training points. The default number of folds \( k = 10 \), or 0.1

7.3.3.2.21.2 folds

- Keywords Area
- model
- surrogate
- global
- metrics
- cross_validation
- folds

Number of cross validation folds
Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** 10

**Description**

Number of folds (partitions) of the training data to use in cross validation (default 10).

7.3.3.2.21.3 percent

- Keywords Area
- model
- surrogate
- global
- metrics
- cross_validation
- percent

Percent data per cross validation fold

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 0.1

**Description**

Percent of the training data to use in each cross validation fold (default 0.1).

7.3.3.2.21.4 press

- Keywords Area
- model
- surrogate
- global
- metrics
- press

Leave-one-out cross validation
7.3 model

Specification

**Alias:** none

**Argument(s):** none

**Default:** No PRESS cross validation

Description

Leave-one-out (PRESS) cross validation may be performed by specifying `press`. The cross-validation statistics will be calculated for all metrics.

7.3.3.2.22 import_challenge_points_file

- **Keywords Area**
  - model
  - surrogate
  - global
  - import_challenge_points_file

Datafile of points to assess surrogate quality

Specification

**Alias:** challenge_points_file

**Argument(s):** STRING

**Default:** no user challenge data

**Child Keywords:**

<table>
<thead>

<td>Selects freeform file format</td>
</tr>
<tr>
<td></td>
<td></td>
<td>active_only</td>
<td>Import only active variables from tabular data file</td>
</tr>
</tbody>
</table>

Description

Specifies a data file containing variable and response (truth) values, in one of three formats:

- annotated *(default)*
- custom_annotated
The surrogate is evaluated at the points in the file, and the surrogate (approximate) responses are compared against the truth results from the file. All metrics specified with metrics will be computed for the challenge data.

7.3.3.2.22.1 custom_annotated

- Keywords Area
- model
- surrogate
- global
- import_challenge_points_file
- custom_annotated

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none
Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>header</td>
<td>header</td>
<td>Enable header row in custom-annotated tabular file</td>

<td>eval_id</td>
<td>Enable evaluation ID column in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td>interface_id</td>
<td>interface_id</td>
<td>Enable interface ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.
Default Behavior

The *annotated* format is the default for tabular export/import. To control which header row and columns are in the input/output, specify `custom_annotated`, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to *annotated* format, though *freeform* remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the *freeform* option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id  x1   x2   obj_fn  nln_ineq_con_1  nln_ineq_con_2
1        0.9   1.1  0.0002  0.26          0.76
2      0.90009 1.1  0.0001996404857 0.2601620081 0.759955
3     0.89991  1.1  0.0002003604863 0.2598380081 0.760045
...
```

Enable header row in custom-annotated tabular file

**Specification**

**Alias:** none

**Argument(s):** none

**Child Keywords:**
### use_variable_labels

**Keywords Area**
- model
- surrogate
- global
- import_challenge_points_file
- custom_annotated
- header
- use_variable_labels

**Description**
When importing global surrogate training data (or challenge evaluation points) from a tabular data file containing a header (annotated or custom_annotated header), this keyword toggles validation of variable labels present in the header row.

The labels are validated against the descriptors of the variables being imported to. If the tabular file labels can be rearranged to match the expected labels, the columns in the data file will be reordered on read to match the Dakota variable order. If the read labels are not a permutation of, nor equal to, the expected labels, an error will result.

**Default Behavior**
When not specified, variable labels will be read, but not strictly enforced or reordered. A warning will be issued if the variable labels are not as expected, and guidance offered if they can be permuted to match expectations.

**Expected Output**
Console output will be generated for any warnings, as well as to indicate whether any variable reordering is taking place.

**Usage Tips**
The use of this keyword is recommended when importing header-annotated tabular data files where the variables are appropriately labeled. Tabular files do not always contain response labels, so no attempt is made to disambiguate variable from response labels. The variable labels must appear contiguously in the header after any leading column IDs such as 'eval_id' or 'interface'.

<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td><code>use_variable_-labels</code></td>
<td>Validate/use variable labels from tabular file header</td>
</tr>
</tbody>
</table>

**Description**

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

**Default Behavior**

By default, Dakota imports and exports tabular files in annotated format. The `annotated` keyword can be used to explicitly specify this.

**Usage Tips**

- To specify pre-Dakota 6.1 tabular format, which did not include `interface_id`, specify `custom_annotated header eval_id`

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```plaintext
evironment
    tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated

Resulting tabular file:

<table>
<thead>
<tr>
<th>eval_id</th>

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.
Default Behavior

The `annotated` format is the default for tabular export/import. To change this behavior, specify `freeform` in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to `annotated` format, though `freeform` remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In `freeform`, the `num_rows x num_cols` total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the `freeform` option.

Examples

Export a `freeform` tabular file containing only data for variables and responses. Input file fragment:

```
environment
  tabular_data
  tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

```
0.9 1.1 0.0002 0.26 0.76
0.90009 1.1 0.0001996404857 0.2601620081 0.759955
0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...
```

7.3.3.2.22.9 active_only

- Keywords Area
- model
- surrogate
- global
- import_challenge_points_file

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- `file_formats`

Specification

**Alias:** none

**Argument(s):** none
Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

7.3.3.3 `multipoint`

- **Keywords Area**
  - model
  - surrogate
  - multipoint

Construct a surrogate from multiple existing training points

**Specification**

**Alias:** none

**Argument(s):** none

**Child Keywords:**

</tr>
</tbody>
</table>

**Description**

Multipoint approximations use data from previous design points to improve the accuracy of local approximations. The data often comes from the current and previous iterates of a minimization algorithm.

Currently, only the Two-point Adaptive Nonlinearity Approximation (TANA-3) method of [95] is supported with the `tana` keyword.

The truth model to be used to generate the value/gradient data used in the approximation is identified through the **required** `truth_model_pointer` specification.

7.3.3.3.1 tana

- Keywords Area
- model
- surrogate
- multipoint
- tana

Local multi-point model via two-point nonlinear approximation

Specification

**Alias:** none

**Argument(s):** none

Description

**TANA** stands for Two Point Adaptive Nonlinearity Approximation.

The TANA-3 method [95] is a multipoint approximation method based on the two point exponential approximation [25]. This approach involves a Taylor series approximation in intermediate variables where the powers used for the intermediate variables are selected to match information at the current and previous expansion points.

**Known Issue:** When using discrete variables, there have been sometimes significant differences in surrogate behavior observed across computing platforms in some cases. The cause has not yet been fully diagnosed and is currently under investigation. In addition, guidance on appropriate construction and use of surrogates with discrete variables is under development. In the meantime, users should therefore be aware that there is a risk of inaccurate results when using surrogates with discrete variables.

Theory

The form of the TANA model is:

\[
\hat{f}(x) \approx f(x_2) + \sum_{i=1}^{n} \frac{\partial f}{\partial x_i}(x_2) \frac{x_1^{1-p_i}}{p_i} (x_i^{p_i} - x_i^{p_1}) + \frac{1}{2} \epsilon(x) \sum_{i=1}^{n} (x_i^{p_i} - x_i^{p_1})^2
\]

where \( n \) is the number of variables and:

\[
p_i = 1 + \ln \left[ \frac{\frac{\partial f}{\partial x_i}(x_1)}{\frac{\partial f}{\partial x_i}(x_2)} \right] / \ln \left[ \frac{x_{1,i}}{x_{2,i}} \right],
\]

\[
\epsilon(x) = \frac{H}{\sum_{i=1}^{n} (x_i^{p_i} - x_i^{p_1})^2 + \sum_{i=1}^{n} (x_i^{p_i} - x_i^{p_1})^2 H} = 2 \left[ f(x_1) - f(x_2) - \sum_{i=1}^{n} \frac{\partial f}{\partial x_i}(x_2) \frac{x_1^{1-p_i}}{p_i} (x_i^{p_i} - x_i^{p_1}) \right]
\]

and \( x_2 \) and \( x_1 \) are the current and previous expansion points. Prior to the availability of two expansion points, a first-order Taylor series is used.
7.3.3.2 qmea

- Keywords Area
- model
- surrogate
- multipoint
- qmea

Multi-point surrogate approximation based on QMEA algorithm

Specification

Alias: none

Argument(s): none

Description

The Quadratic Multipoint Exponential Approximation (QMEA) builds a multi-point approximation from values and gradients at multiple expansion points. It is a generalization of the two-point exponential approximation (TPEA). This capability is **experimental**.

7.3.3.3.3 truth_model_pointer

- Keywords Area
- model
- surrogate
- multipoint
- truth_model_pointer

Pointer to specify a "truth" model, from which to construct a surrogate

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: actual_model_pointer

Argument(s): STRING

Description

This must point to a model block, identified by id_model. That model will be run to generate training data, from which a surrogate model will be constructed.

See block_pointer for details about pointers.
7.3.3.4 local

- Keywords Area
  - model
  - surrogate
  - local

Build a locally accurate surrogate from data at a single point

**Specification**

Alias: none

Argument(s): none

</tr>
<tr>
<td>Required</td>
<td></td>
<td>truth_model_pointer</td>
<td>Pointer to specify a &quot;truth&quot; model, from which to construct a surrogate</td>
</tr>
</tbody>
</table>

**Description**

Local approximations use value, gradient, and possibly Hessian data from a single point to form a series expansion for approximating data in the vicinity of this point.

The currently available local approximation is the `taylor_series` selection.

The truth model to be used to generate the value/gradient/Hessian data used in the series expansion is identified through the required `truth_model_pointer` specification. The use of a model pointer (as opposed to an interface pointer) allows additional flexibility in defining the approximation. In particular, the derivative specification for the truth model may differ from the derivative specification for the approximation, and the truth model results being approximated may involve a model recursion (e.g., the values/gradients from a nested model).

**See Also**

These keywords may also be of interest:

- global
- hierarchical
- multipoint

7.3.3.4.1 taylor_series

- Keywords Area
  - model
  - surrogate
Construct a Taylor Series expansion around a point

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

The Taylor series model is purely a local approximation method. That is, it provides local trends in the vicinity of a single point in parameter space.

The order of the Taylor series may be either first-order or second-order, which is automatically determined from the gradient and Hessian specifications in the responses specification (see responses for info on how to specify gradients and Hessians) for the truth model.

Known Issue: When using discrete variables, there have been sometimes significant differences in surrogate behavior observed across computing platforms in some cases. The cause has not yet been fully diagnosed and is currently under investigation. In addition, guidance on appropriate construction and use of surrogates with discrete variables is under development. In the meantime, users should therefore be aware that there is a risk of inaccurate results when using surrogates with discrete variables.

**Theory**

The first-order Taylor series expansion is:

$$\hat{f}(x) \approx f(x_0) + \nabla_x f(x_0)^T (x - x_0)$$  (7.7)

and the second-order expansion is:

$$\hat{f}(x) \approx f(x_0) + \nabla_x f(x_0)^T (x - x_0) + \frac{1}{2} (x - x_0)^T \nabla^2_x f(x_0) (x - x_0)$$  (7.8)

where $x_0$ is the expansion point in $n$-dimensional parameter space and $f(x_0)$, $\nabla_x f(x_0)$, and $\nabla^2_x f(x_0)$ are the computed response value, gradient, and Hessian at the expansion point, respectively.

As dictated by the responses specification used in building the local surrogate, the gradient may be analytic or numerical and the Hessian may be analytic, numerical, or based on quasi-Newton secant updates.

In general, the Taylor series model is accurate only in the region of parameter space that is close to $x_0$. While the accuracy is limited, the first-order Taylor series model reproduces the correct value and gradient at the point $x_0$, and the second-order Taylor series model reproduces the correct value, gradient, and Hessian. This consistency is useful in provably-convergent surrogate-based optimization. The other surface fitting methods do not use gradient information directly in their models, and these methods rely on an external correction procedure in order to satisfy the consistency requirements of provably-convergent SBO.

</tr>
</tbody>
</table>
Multifidelity modeling involves the use of lower-fidelity physics-based models as surrogates for a high-fidelity "truth" model. These low-fidelity models can involve variations in model form, resolution, or both. Model form variations for reduced fidelity may involve omitted physics or solution of approximated or averaged physics. Resolution variations typically involve coarsened space-time discretizations (e.g., h-derefinement), reduced element order (e.g., p-derefinement), or loosened convergence tolerances. Unlike local, global, and multipoint surrogates, these approximations are not data-driven (no high-fidelity data required for construction) and are stand-alone simulation models in their own right. As an example from computational fluid dynamics (CFD), both model form and resolution are varied when an inviscid, incompressible Euler model on a coarse discretization is used as a low-fidelity surrogate for a high-fidelity large eddy simulation model on a fine discretization.

The required `ordered_model_fidelities` specification points to a sequence of model specifications of varying fidelity, ordered from lowest to highest fidelity. The highest fidelity model provides the "truth" model, and each of the lower fidelity alternatives provides different levels of approximation at different levels of cost. This specification defines the sequence of model forms, and each model specification identified in this ordered listing may identify a set of resolution controls. Either or both of these sequences may be specified, and this is referred to as a "multilevel hierarchy" in the case of a hierarchy of resolutions (one entry in `ordered_model_fidelities` that includes active resolution control), a "multifidelity hierarchy" in the case of a hierarchy of model forms (multiple entries in `ordered_model_fidelities` without active resolution control), or a "multilevel-multifidelity hierarchy" in the case of two-dimensional hierarchy including both model forms and resolutions (multiple entries in `ordered_model_fidelities` with one or more including active resolution control). Note that the multilevel-multifidelity case can be "ragged" in the sense that not all models need to provide the same number of (or any) resolution controls.

The `correction` specification identifies what type (additive, multiplicative, combined) and order (zeroth_order, first_order, second_order) of correction technique will be applied to the low fidelity results in order to match high fidelity results (value and potentially gradient and Hessian) at one or more points. As described below, this is essential in the optimization context.

Use cases
In multifidelity surrogate-based optimization (SBO), the search algorithm relies primarily on the lower fidelity models, which are corrected for consistency with higher fidelity models. The higher fidelity models are used primarily for verifying candidate steps based on solution of low fidelity approximate subproblems and for updating low fidelity corrections. In the hierarchical SBO case (as compared to SBO with data fits), the `correction` specification is required, since the omission of a correction technique would effectively eliminate the purpose of the high fidelity model (to use a low fidelity model without corrections, then a single model can be used rather than a hierarchical model). Refer to `global` for additional information on available correction approaches.

In multifidelity uncertainty quantification (UQ), response differences are tracked for purposes of decomposing variance across model/resolution levels or for constructing separate discrepancy emulators. In this context, correction specifications are still valid for defining discrepancy emulation details but they are optional with the most common cases used as defaults.

7.3.3.5.1 ordered_model_fidelities

- Keywords Area
- model
- surrogate
- hierarchical
- ordered_model_fidelities

Specification of an hierarchy of model fidelities, ordered from low to high.

**Specification**

*Alias*: model_fidelity_sequence

*Argument(s)*: STRINGLIST

**Description**

A hierarchical surrogate model manages an ordered set of model fidelities, each of which may in turn involve multiple discretization levels (in the case of a simulation model) or additional model recursions.

The ordering is assumed to be from lowest fidelity to highest fidelity, as dictated by an accuracy versus cost trade-off. Corresponding sequence specifications within methods (e.g., quadrature_order_sequence, sparse_grid_level_sequence, expansion_order_sequence, etc. within stochastic expansion methods) should be synchronized with this model order.

**Additional Discussion**

Internal to the model, only one low fidelity model instance and one high fidelity model instance are active at any given time, although various optimization and UQ algorithms can be used to traverse deep multilevel and multifidelity hierarchies by activating different model combinations and different response modes within the hierarchical model infrastructure.

**Examples**

```dakota
model,
  id_model = 'HIERARCH'
surrogate hierarchical
  ordered_model_fidelities = 'LF 'MF 'HF'
correction additive zeroth_order

model,
  id_model = 'LF'
simulation
  interface_pointer = 'LF_DRIVER'
```

Description

Some of the surrogate model types support the use of correction factors that improve the local accuracy of the surrogate models.

The correction specification specifies that the approximation will be corrected to match truth data, either matching truth values in the case of zeroth_order matching, matching truth values and gradients in the case of first_order matching, or matching truth values, gradients, and Hessians in the case of second_order matching. For additive and multiplicative corrections, the correction is local in that the truth data is matched at a single point, typically the center of the approximation region. The additive correction adds a scalar offset (zeroth_order), a linear function (first_order), or a quadratic function (second_order) to the approximation to match the truth data at the point, and the multiplicative correction multiplies the approximation by a scalar (zeroth_order), a linear function (first_order), or a quadratic function (second_order) to match the truth data at the point. The additive first_order case is due to [59] and the multiplicative first_order case is commonly known as beta correction [41]. For the combined correction, the use of both additive and multiplicative corrections allows the satisfaction of an additional matching condition, typically the truth function values at the previous correction point (e.g., the center of the previous trust region). The combined correction is then a multipoint correction, as opposed to the local additive and multiplicative corrections. Each of these correction capabilities is described in detail in [24].

The correction factors force the surrogate models to match the true function values and possibly true function derivatives at the center point of each trust region. Currently, Dakota supports either zeroth-, first-, or second-order accurate correction methods, each of which can be applied using either an additive, multiplicative, or combined correction function. For each of these correction approaches, the correction is applied to the surrogate model and the corrected model is then interfaced with whatever algorithm is being employed. The default behavior is that no correction factor is applied.

The simplest correction approaches are those that enforce consistency in function values between the surrogate and original models at a single point in parameter space through use of a simple scalar offset or scaling applied to the surrogate model. First-order corrections such as the first-order multiplicative correction (also known as beta correction [14]) and the first-order additive correction [59] also enforce consistency in the gradients and provide a much more substantial correction capability that is sufficient for ensuring provable convergence in SBO algorithms. SBO convergence rates can be further accelerated through the use of second-order corrections which also enforce consistency in the Hessians [24], where the second-order information may involve analytic, finite-difference, or quasi-Newton Hessians.

Correcting surrogate models with additive corrections involves

\[
\hat{f}_{\text{cor}}(x) = f_{\text{lo}}(x) + \alpha(x)
\]  

(7.9)
where multifidelity notation has been adopted for clarity. For multiplicative approaches, corrections take the form

\[ \hat{f}_{hi}(\mathbf{x}) = f_{lo}(\mathbf{x})\beta(\mathbf{x}) \]  

(7.10)

where, for local corrections, \( \alpha(\mathbf{x}) \) and \( \beta(\mathbf{x}) \) are first or second-order Taylor series approximations to the exact correction functions:

\[ \alpha(\mathbf{x}) = A(\mathbf{x}_c) + \nabla A(\mathbf{x}_c)^T(\mathbf{x} - \mathbf{x}_c) + \frac{1}{2}(\mathbf{x} - \mathbf{x}_c)^T \nabla^2 A(\mathbf{x}_c)(\mathbf{x} - \mathbf{x}_c) \]  

(7.11)

\[ \beta(\mathbf{x}) = B(\mathbf{x}_c) + \nabla B(\mathbf{x}_c)^T(\mathbf{x} - \mathbf{x}_c) + \frac{1}{2}(\mathbf{x} - \mathbf{x}_c)^T \nabla^2 B(\mathbf{x}_c)(\mathbf{x} - \mathbf{x}_c) \]  

(7.12)

where the exact correction functions are

\[ A(\mathbf{x}) = f_{hi}(\mathbf{x}) - f_{lo}(\mathbf{x}) \]  

(7.13)

\[ B(\mathbf{x}) = \frac{f_{hi}(\mathbf{x})}{f_{lo}(\mathbf{x})} \]  

(7.14)

Refer to [24] for additional details on the derivations.

A combination of additive and multiplicative corrections can provide for additional flexibility in minimizing the impact of the correction away from the trust region center. In other words, both additive and multiplicative corrections can satisfy local consistency, but through the combination, global accuracy can be addressed as well. This involves a convex combination of the additive and multiplicative corrections:

\[ \hat{f}_{hi}(\mathbf{x}) = \gamma\hat{f}_{hi\alpha}(\mathbf{x}) + (1 - \gamma)\hat{f}_{hi\beta}(\mathbf{x}) \]

where \( \gamma \) is calculated to satisfy an additional matching condition, such as matching values at the previous design iterate.

It should be noted that in both first order correction methods, the function \( \hat{f}(\mathbf{x}) \) matches the function value and gradients of \( f_i(\mathbf{x}) \) at \( x = x_c \). This property is necessary in proving that the first order-corrected SBO algorithms are provably convergent to a local minimum of \( f_i(\mathbf{x}) \). However, the first order correction methods are significantly more expensive than the zeroth order correction methods, since the first order methods require computing both \( \nabla f_i(x_c) \) and \( \nabla f_s(x_c) \). When the SBO strategy is used with either of the zeroth order correction methods, or with no correction method, convergence is not guaranteed to a local minimum of \( f_i(\mathbf{x}) \). That is, the SBO strategy becomes a heuristic optimization algorithm. From a mathematical point of view this is undesirable, but as a practical matter, the heuristic variants of SBO are often effective in finding local minima.

Usage guidelines

- Both the additive zeroth_order and multiplicative zeroth_order correction methods are “free” since they use values of \( f_i(x_c) \) that are normally computed by the SBO strategy.

- The use of either the additive first_order method or the multiplicative first_order method does not necessarily improve the rate of convergence of the SBO algorithm.

- When using the first order correction methods, the gradient-related response keywords must be modified to allow either analytic or numerical gradients to be computed. This provides the gradient data needed to compute the correction function.

- For many computationally expensive engineering optimization problems, gradients often are too expensive to obtain or are discontinuous (or may not exist at all). In such cases the heuristic SBO algorithm has been an effective approach at identifying optimal designs [35].

7.3.3.5.2.1 zeroth_order

- Keywords Area
Specify that truth values must be matched.

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The correction specification specifies that the approximation will be corrected to match truth data. The keyword `zeroth_order` matching ensures that truth values are matched.

<td>The sub_method-pointer specifies the method block for the sub-iterator</td>
</tr>
</tbody>
</table>

**Description**

Instead of appealing directly to a primary interface, a nested model maps variables to responses by executing a secondary iterator, or a "sub-iterator". In other words, a function evaluation of the primary study consists of a solution of an entire secondary study - potentially many secondary function evaluations.

The sub-iterator in turn operates on a sub-model. The sub-iterator responses may be combined with non-nested contributions from an optional interface specification.

A **sub_method_pointer** must be provided in order to specify the method block describing the sub-iterator. The remainder of the model is specified under that keyword.

A **optional_interface_pointer** points to the interface specification and **optional_interface-responses_pointer** points to a responses specification describing the data to be returned by this interface. This interface is used to provide non-nested data, which is then combined with data from the nested iterator using the **primary_response_mapping**. (See the discussions for the **sub_method_pointer** and **optional_interface_pointer** keywords.)

<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>optional_interface_respons_responses_pointer</td>
<td>Pointer to responses block that defines non-nested responses</td>
</tr>
</tbody>
</table>

Description

`optional_interface_pointer` is used to specify an optional interface (using that interface block’s id_interface label) to provide non-nested responses to the nested model.

To generate the complete set of primary responses (response functions, objective functions, and calibration terms) expected by the nested model, primary responses from the optional interface may be combined (by addition) with responses derived from sub-iterator results, or they may be presented unchanged to the nested model. The way that Dakota treats primary responses from these two sources depends on the number of rows of and entries in the primary_response_mapping matrix.

To understand how, it is helpful to consider the following expression. Nested model primary responses \( r \) are computed from the column vector of optional interface responses \( f \), the primary_response_mapping matrix \( W \), and the column vector of results from the sub-iterator \( s \).

\[
\{ r \} = \left\{ \begin{array}{c} f \\ 0 \end{array} \right\} + \left\{ \begin{array}{c} [W] \{ s \} \\ 0 \end{array} \right\}
\]

The number of rows in \( f \) is equal to the number of primary responses returned by the optional interface, and in \( r \), the number of primary responses expected by the nested model. In this expression, \( 0 \) represents “padding” that may be needed by either the optional interface vector or the sub-iterator vector to make them the same dimension as \( r \). One or the other of these quantities may be padded, but not both. In terms of the Dakota input, this means that the number of nested model primary responses must equal the larger of these two quantities: the number of optional interface responses or the number of rows in the primary_response_mapping.
The nested model’s secondary responses (nonlinear constraints) are the secondary responses from the optional interface augmented by the secondary responses constructed from sub-iterator results. Unlike primary responses from these two sources, which may be combined by adding, it is not possible presently to combine secondary responses. For this reason, the number of nested model’s secondary responses must equal the number of secondary responses provided by the optional interface, plus the number provided by the sub-iterator (i.e. the number of rows in the secondary_response_mapping). Secondary responses from the optional interface are inserted first into the nested model’s nonlinear constraints; those from the sub-iterator come after. If the nested model has secondary responses and an optional interface is used, it is necessary to specify a separate response block for the optional interface using the optional_interface_response_pointer. Targets and upper and lower bounds for the nonlinear constraints are taken from the nested model’s response block.

Examples

The first example illustrates the use of an optional interface and primary response mapping. No secondary responses are present. Assume that the inner method returns two results (suppose its the mean and standard deviation of a single response), so that the dimensions of primary_response_mapping will be interpreted by Dakota as 1x2, just as they are written here.

The nested model (nested) expects two primary responses (outer_resp block), and the optional interface returns two (opt_resp block).

```
model
  id_model 'nested'
  nested
    optional_interface_pointer 'opt_intf'
    optional_interface_response_pointer 'opt_resp'
    sub_method_pointer 'inner_method'
    primary_response_mapping 1.0 2.0
    responses_pointer 'outer_resp'
    variables_pointer 'outer_vars'

responses
  id_responses 'opt_resp'
  response_functions 2
    descriptors 'opt1' 'opt2'
    no_gradients
    no_hessians

responses
  id_responses 'outer_resp'
  response_functions 2
    descriptors 'out1' 'out2'
    no_gradients
    no_hessians
```

The first nested model response, \( \text{out\,1} \) will be computed \( \text{out\,1} = \text{opt\,1} + 1.0 \cdot \text{mean} + 2.0 \cdot \text{stddev} \), and the second response \( \text{out\,2} \) will be equal to simply \( \text{opt\,2} \). In the matrix form introduced above, including the implicit padding:

\[
\begin{pmatrix}
\text{out\,1} \\
\text{out\,2}
\end{pmatrix}
= \begin{pmatrix}
\text{opt\,1} \\
\text{opt\,2}
\end{pmatrix} + \begin{pmatrix}
1.0 \cdot \text{mean} + 2.0 \cdot \text{stddev} \\
0
\end{pmatrix}
\]

The optional_interface_response_pointer was not strictly needed. Because the number of responses returned by the optional interface and expected by the nested model is the same (and no secondary responses are present), the nested model’s response specification alone would have sufficed.

If it were desired to combine \( \text{opt\,2} \) with the sub-iterator’s results and set \( \text{out\,1} \) to \( \text{opt\,1} \) with no combination, then the primary_response_mapping matrix could be changed to:

```
primary_response_mapping 0.0 0.0
  1.0 2.0
```

Secondary responses will be demonstrated in the second example.
The nested model expects a total of two constraints. Because the `secondary_response_mapping` has one row, one of these constraints will be supplied from the sub-iterator. The other is provided by the optional interface. Secondary responses from the optional iterator come first, and so `optc` is placed in `outc1`. `outc2` takes the value computed from the sub-iterator results.

7.3.4.1.1 optional_interface_responses_pointer

- **Keywords** Area
- **model**
- **nested**
- **optional_interface_pointer**
- **optional_interface_responses_pointer**

Pointer to responses block that defines non-nested responses

**Topics**

This keyword is related to the topics:

- **block_pointer**

**Specification**

- **Alias:** none
- **Argument(s):** STRING
- **Default:** reuse of top-level responses specification
optional_interface_responses_pointer points to the responses block (specifically, its id_responses label) that defines the non-nested response to return to the nested model. The primary_response_mapping keywords control how these non-nested responses are combined with responses from the nested sub-iterator. See the entry for optional_interface_pointer for a full description. If optional_interface_responses_pointer is not provided, the top-level responses specification is reused.

7.3.4.2 sub_method_pointer

- Keywords Area

### Variable Mappings

In the variable mapping case, primary and secondary variable mapping specifications are used to map from the top-level variables into the sub-model variables. These mappings support three possibilities in any combination: (1) insertion of an active top-level variable value into an identified sub-model distribution parameter for an identified active sub-model variable, (2) insertion of an active top-level variable value into an identified active sub-model variable value, and (3) addition of an active top-level variable value as an inactive sub-model variable, augmenting the active sub-model variables.

For the variable mappings, the primary and secondary specifications are lists of strings that are used to target specific sub-model variables and their sub-parameters, respectively. The primary strings are matched to sub-model variable descriptors such as ‘cdv_1’ (either user-supplied or default labels). The secondary strings are matched to random variable distribution parameters such as ‘mean’ or ‘num_trials’ or design/state variable sub-parameters such as ‘lower_bound’ or ‘upper_bound’.

### Description

The `sub_method_pointer` specifies the method block for the sub-iterator. See `block_pointer` for details about pointers.

A nested model performs an evaluation (variables-to-responses mapping) by running a complete sub-iterator (i.e. method) to completion. The sub-iterator, which is specified using the `sub_method_pointer`, has its own model. This model, referred to here as the sub-model, possesses its own variables and responses. Prior to every execution of the sub-iterator, information about the nested model’s variables is injected into the sub-model’s variables. After the sub-iterator has completed, its results are passed back up to the nested model as responses.

Communication of variables information from a nested model to its sub-iterator, and in the opposite direction of sub-iterator results to nested model responses, is called mapping. (This mapping must not be confused with the variables-to-responses mapping that constitutes an evaluation.) Dakota allows considerable power and flexibility in how nested model mappings are performed. They are specified using four keywords: for the variables, `primary_variable_mapping` and `secondary_variable_mapping`; and for the responses, `primary_response_mapping` and `secondary_response_mapping`. They are described below.

### Variable Mappings

<table>
<thead>
<tr>
<th>Type</th>
<th>Specification</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td><code>primary_variable_mapping</code></td>
<td>Primary mapping of top-level variables to sub-model variables</td>

<tr>
<td>Optional</td>
<td><code>secondary_response_mapping</code></td>
<td>Mapping of sub-method results to top-level secondary responses</td>
</tr>
<tr>
<td>Optional</td>
<td><code>identity_response_mapping</code></td>
<td>Identity mapping of sub-method results to top-level responses</td>
</tr>
</tbody>
</table>
An important limitation is that real-valued top-level variables must map to real-valued sub-model variables or real-valued sub-parameters, and integer-valued top-level variables must map to either integer-valued sub-model variables or integer-valued sub-parameters. However, as long as these real versus integer constraints are satisfied, mappings are free to cross variable types (design, aleatory uncertain, epistemic uncertain, state) and domain types (continuous, discrete).

Both primary_variable_mapping and secondary_variable_mapping specifications are optional, which is designed to support the following three possibilities:

1. If both primary and secondary variable mappings are specified, then an active top-level variable value will be inserted into the identified sub-parameter (the secondary mapping) for the identified sub-model variable (the primary mapping).

2. If a primary mapping is specified but a secondary mapping is not, then an active top-level variable value will be inserted into the identified sub-model variable value (the primary mapping).

3. If a primary mapping is not specified (corresponding secondary mappings, if specified, are ignored), then an active top-level variable value will be inserted into a corresponding sub-model variable, based on matching of variable types (e.g., top-level and sub-model variable specifications both allocate a set of ‘continuous_design’ variables which are active at the top level). Multiple sub-model variable types may be updated in this manner, provided that they are all active in the top-level variables. Since there is a direct variable correspondence for these default insertions, sub-model bounds and descriptors are also updated from the top-level bounds and labels in order to eliminate the need for redundant input file specifications. Thus, it is typical for the sub-model variables specification to only contain the minimal required information, such as the number of variables of each type, for these insertion targets. The sub-model must allocate enough space for each of the types that will accept default insertions, and the leading set of matching sub-model variables are updated (i.e., the sub-model may allocate more than needed and the trailing set will be unmodified).

These different variable mapping possibilities may be used in any combination by employing empty strings ("") for particular omitted mappings (the number of strings in user-supplied primary and secondary variable mapping specifications must equal the total number of active top-level variables, including both continuous and discrete types). The ordering of the active variables is the same as shown in dakota.input.summary on Input Spec Summary and as presented in the variables section of this manual.

Inactive nested model variables are treated differently from those in the active view. If inactive variables are present at the outer level, then the default type 3 mapping is used for these variables; that is, outer loop inactive variables are inserted into inner loop variables (active or inactive) based on matching of variable types, top-level bounds and labels are also propagated, the inner loop must allocate sufficient space to receive the outer loop values, and the leading subset within this inner loop allocation is updated. This capability is important for allowing nesting beyond two levels, since an active variable at the outer-most loop may become inactive at the next lower level, but still needs to be further propagated down to lower levels in the recursion.

Response Mappings

For the response mappings, the primary and secondary specifications determine how results from the completed sub-iterator are mapped into nested model responses. The response mapping defines a matrix which scales and combines the results from the inner loop into outer loop responses. Each row of the mapping corresponds to one outer loop response, and each column of the mapping corresponds to a result from the inner loop. The results returned from the sub-model are best thought of as forming a column vector; the nested model responses are then the dot-product of the mapping matrix and results vector. The number and type of results that are available and must be accounted for in the response mapping depends on the sub-iterator type:

- optimization: the final objective function(s) and nonlinear constraints
- nonlinear least squares: the final least squares terms and nonlinear constraints
- aleatory uncertainty quantification (UQ): for each response function, a mean statistic, a standard deviation statistic, and all probability/reliability/generalized reliability/response level results for any user-specified response_ levels, probability_levels, reliability_levels, and/or gen_reliability_levels, in that order.
- epistemic and mixed aleatory/epistemic UQ using interval estimation methods: lower and upper interval bounds for each response function.
epistemic and mixed aleatory/epistemic UQ using evidence methods: for each response function, lower and up-
ner interval bounds (belief and plausibility) for all probability/reliability/generic reliability/response level results 
computed from any user-specified response_levels, probability_levels, reliability_levels, 
and/or gen_reliability_levels, in that order. parameter studies and design of experiments: for optimiza-
tion and least squares response data sets, the best solution found (lowest constraint violation if infeasible, lowest 
composite objective function if feasible). For generic response data sets, a best solution metric is not defined, so 
the sub-iterator response vector is empty in this case.

The primary_response_mapping matrix maps sub-iterator results into top-level objective functions, 
least squares terms, or generic response functions, depending on the declared top-level response set. The secondary_response_mapping matrix maps sub-iterator results into top-level nonlinear inequality and 
equality constraints. Alternately, if all the responses of the sub-iterator are to be mapped one-to-one to the top-level 
nested model responses identity_response_mapping may be specified instead.

Summary
The nested model constructs admit a wide variety of multi-iterator, multi-model solution approaches. For example, 
optimization within optimization (for hierarchical multidisciplinary optimization), uncertainty quantification within un-
certainty quantification (for second-order probability), uncertainty quantification within optimization (for optimization 
under uncertainty), and optimization within uncertainty quantification (for uncertainty of optima) are all supported, 
with and without surrogate model indirection. Several examples of nested model usage are provided in the Users 
Manual, most notably mixed epistemic-aleatory UQ, optimization under uncertainty (OUU), and surrogate-based 
UQ.

Examples
Two examples are provided to illustrate nested models. The first is a relatively simple case. Although it is somewhat 
contrived, it demonstrates several features of nested models. A step-by-step explanation is provided below.

```
environment
  method_pointer 'opt'

method
  id_method 'opt'
  async_pattern_search
  model_pointer 'outer_model'
  output verbose

model
  id_model 'outer_model'

  responses_pointer 'outer_resps'
  nested
    sub_method_pointer 'UQ_method'
    primary_variable_mapping 'x1' 'x2'
    secondary_variable_mapping 'mean' 'mean'
    primary_response_mapping 0 0 0.3 0 0 0.7

variables
  id_variables 'outer_vars'
  continuous_design 2
  descriptors 'x1_mean' 'x2_mean'
  lower_bounds -2.0 -2.0
  upper_bounds 2.0 2.0

responses
  id_responses 'outer_resps'
  objective_functions 1
  descriptors 'sum_p'
  no_gradients
  no_hessians

method
  id_method 'UQ_method'
  sampling samples 30
  seed 1234
  model_pointer 'UQ_model'
```
The example input is an ‘optimization under uncertainty’ or OUU. In an OUU, some statistic of the simulation response is optimized. In this case, a weighted sum of the 90th percentiles of two simulation responses from the text_book driver is being minimized. The uncertainty in these responses is driven by uncertainty in the input variables, which are normally distributed. The means of the uncertain variables are the design variables in the optimization.

In Dakota, this is accomplished by nesting an uncertainty quantification method (sampling), which computes the 90th percentiles, within an optimizer (method-asynch_pattern_search), which iteratively adjusts the variable means to minimize the objective. For every evaluation requested by the optimizer, the design variables (x1_mean and x2_mean in the example) are inserted into the means of the uncertain variables (x1 and x2), then the sampling study is run to completion, and finally the resulting statistics for the responses f1 and f2 are mapped into the responses sum_p.

It may be helpful to sketch out the relationships between blocks as indicated by their various pointers in order to understand the nested structure of the study. The top-level or outer method, ‘opt’, has a model named ‘outer_model’. This model refers to variables and responses blocks (‘outer_vars’ and ‘outer_resps’) that are used by the optimizer. The ‘outer_model’ block also refers to a sub-method, ‘UQ_method’ which defines the UQ study and has its own model, which in turn possess variables, an interface, and responses.

Next, note the primary and secondary variable mappings in ‘outer_model’, which specify that the values of the active design variables x1_mean and x2_mean are to be inserted into the means of the uncertain variables x1 and x2.

The response mapping in ‘outer_model’ is a matrix with a single row and six columns. The single row corresponds to the number of responses in the outer method. As described above, for each of our two sub-model responses, the sampling method returns a mean, a standard deviation, and a single probability level in that order to the nested model. There are a total of six results and accordingly six columns in the mapping matrix. The coefficients 0.3 and 0.7 in the matrix result in a weighted sum of the 90th percentiles:

\[ \text{sum}_p = 0.3 \times (\text{90th percentile of } f1) + 0.7 \times (\text{90th percentile of } f2) \]

The next example is a fragment of an input file, showing only the nested model itself. It illustrates more complex variable and response mappings.
The variable mappings correspond to 4 top-level variables, the first two of which employ the default mappings from active top-level variables to sub-model variables of the same type (option 3 above) and the latter two of which are inserted into the mean distribution parameters of sub-model variables ‘X’ and ‘Y’ (option 1 above).

The response mappings define a 3 by 9 matrix corresponding to 9 inner loop results and 3 outer loop response functions (one primary response function and 2 secondary functions, such as one objective and two constraints). Each row of the response mapping is a vector which is multiplied (i.e., with a dot-product) against the 9 sub-iterator results to determine the outer loop function.

Consider again a UQ example with 3 response functions, each providing a mean, a standard deviation, and one level mapping (if no level mappings are specified, the responses would only have a mean and standard deviation). The primary response mapping can be seen to extract the first result from the inner loop, which would correspond to the mean of the first response function. This mapped sub-iterator response becomes a single objective function, least squares term, or generic response function at the outer level, as dictated by the top-level response specification. The secondary response mapping maps the fourth sub-iterator result plus 3 times the fifth sub-iterator result (mean plus 3 standard deviations) into one top-level nonlinear constraint and the seventh sub-iterator result plus 3 times the eighth sub-iterator result (mean plus 3 standard deviations) into another top-level nonlinear constraint, where these top-level nonlinear constraints may be inequality or equality, as dictated by the top-level response specification.

Note that a common case is for each sub-iterator result to be mapped to a unique outer loop response (for example, in the nested UQ case where one wants to determine an interval on each inner loop statistic). In these simple cases, the response mapping would define an identity matrix and identity_response_mapping may instead be specified.

7.3.4.2.1 iterator_servers

- Keywords Area
- model
- nested
- sub_method_pointer
- iterator_servers

Specify the number of iterator servers when Dakota is run in parallel

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none

Argument(s): INTEGER

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional iterator_servers specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, hybrid, multi_start, and pareto_set component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [5] for additional information.
7.3.4.2.2 iterator_scheduling

• Keywords Area
• model
• nested
• sub_method_pointer
• iterator_scheduling

Specify the scheduling of concurrent iterators when Dakota is run in parallel

Topics

This keyword is related to the topics:

• concurrency_and_parallelism

Specification

Alias: none
Argument(s): none

<td>Specify a peer partition for parallel iterator scheduling</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional iterator_scheduling specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, hybrid, multi_start, and pareto_set component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [5] for additional information.

7.3.4.2.2.1 master

• Keywords Area
• model
• nested
• sub_method_pointer
• iterator_scheduling
• master

Specify a dedicated master partition for parallel iterator scheduling
Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none

Argument(s): none

Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a dedicated master partition. In a dedicated master partition, one processor (the "master") dynamically schedules work on the iterator servers. This reduces the number of processors available to create servers by 1.

7.3.4.2.2.2 peer

- Keywords Area
- model
- nested
- sub_method_pointer
- iterator_scheduling
- peer

Specify a peer partition for parallel iterator scheduling

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none

Argument(s): none

Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a peer partition. In a peer partition, all processors are available to be assigned to iterator servers. Note that unlike the case of evaluation_scheduling, it is not possible to specify static or dynamic.
7.3.4.2.3 processors_per_iterator

- Keywords Area
- model
- nested
- sub_method_pointer
- processors_per_iterator

Specify the number of processors per iterator server when Dakota is run in parallel.

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none

Argument(s): INTEGER

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional processors_per_iterator specification supports user override of the automatic parallel configuration for the number of processors in each iterator server. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired server size at the iterator parallelism level. Currently, hybrid, multi_start, and pareto_set component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [5] for additional information.

7.3.4.2.4 primary_variable_mapping

- Keywords Area
- model
- nested
- sub_method_pointer
- primary_variable_mapping

Primary mapping of top-level variables to sub-model variables

Specification

Alias: none

Argument(s): STRINGLIST

Default: default variable insertions based on variable type
Description

The `primary_variable_mapping`, `secondary_variable_mapping`, `primary_response_mapping`, and `secondary_response_mapping` keywords control how top-level variables and responses are mapped to variables and responses in the sub-model. Their usage is explained on the parent keyword `sub_method_pointer` page.

7.3.4.2.5 secondary_variable_mapping

- Keywords Area
- `model`
- `nested`
- `sub_method_pointer`
- `secondary_variable_mapping`

Secondary mapping of top-level variables to sub-model variables

Specification

Alias: none

Argument(s): STRINGLIST

Default: primary mappings into sub-model variables are value-based

Description

The `primary_variable_mapping`, `secondary_variable_mapping`, `primary_response_mapping`, and `secondary_response_mapping` keywords control how top-level variables and responses are mapped to variables and responses in the sub-model. Their usage is explained on the parent keyword `sub_method_pointer` page.

7.3.4.2.6 primary_response_mapping

- Keywords Area
- `model`
- `nested`
- `sub_method_pointer`
- `primary_response_mapping`

Mapping of sub-method results to top-level primary responses

Specification

Alias: none

Argument(s): REALLIST

Default: no sub-iterator contribution to primary functions
Description

Matrix that specifies how sub-method results (statistics, best parameters, etc.) map to top-level nested model primary responses (objectives, calibration terms, or response functions). Its usage is explained in detail on the parent keyword (sub_method_pointer) page.

7.3.4.2.7 secondary_response_mapping

- Keywords Area
- model
- nested
- sub_method_pointer
- secondary_response_mapping

Mapping of sub-method results to top-level secondary responses

Specification

Alias: none

Argument(s): REALLIST

Default: no sub-iterator contribution to secondary functions

Description

Matrix that specifies how sub-method results (statistics, best parameters, etc.) map to top-level nested model secondary responses (nonlinear inequality or equality constraints). Its usage is explained in detail on the parent keyword (sub_method_pointer) page.

7.3.4.2.8 identity_response_mapping

- Keywords Area
- model
- nested
- sub_method_pointer
- identity_response_mapping

Identity mapping of sub-method results to top-level responses

Specification

Alias: none

Argument(s): none

Default: no sub-iterator contribution to nested model functions
7.3 model

Description

Specifies that the list of sub-method results (statistics, best parameters, etc.) should map one-to-one to the list of
top-level nested model responses.

Usage Tips

To use an identity mapping, the number of top-level nested model responses (primary + secondary responses) must
equal the number of sub-method results. If receiving an error about this, set output verbose and re-run the
Dakota study to see a list of sub-method results responses.

The identity map may not be used in conjunction with optional_interface_pointer, nor with an explicit primary_-
response_mapping or secondary_response_mapping.

Examples

model
  id_model 'nested'
  nested
  sub_method_pointer 'aleat'
  identity_response_mapping

7.3.4.2.9 Input Spec Summary

This file is derived automatically from dakota.xml, which is used in the generation of parser system files that are com-
piled into the Dakota executable. Therefore, these files are the definitive source for input syntax, capability options,
and associated data inputs. Refer to the Developers Manual information on how to modify the input specification
and propagate the changes through the parsing system.

Key features of the input specification and the associated user input files include:

- In the input specification, required individual specifications simply appear, optional individual and group spec-
  ifications are enclosed in [], required group specifications are enclosed in (), and either-or relationships are
denoted by the | symbol. These symbols only appear in dakota.input.summary; they must not appear in
actual user input files.

- Keyword specifications (i.e., environment, method, model, variables, interface, and responses) begin with the keyword possibly preceded by white space (blanks, tabs, and newlines) both in the input specifications and in user input files. For readability, keyword specifications may be spread across several lines. Earlier versions of Dakota (prior to 4.1) required a backslash character (\) at the ends of
intermediate lines of a keyword. While such backslashes are still accepted, they are no longer required.

- Some of the keyword components within the input specification indicate that the user must supply INTEGER,
REAL, STRING, INTEGERLIST, REALLIST, or STRINGLIST data as part of the specification. In a user
input file, the "=" is optional, data in a LIST can be separated by commas or whitespace, and the STRING
data are enclosed in single or double quotes (e.g., ’text_book’ or "text_book").

- In user input files, input is largely order-independent (except for entries in lists of data), case insensitive, and
white-space insensitive. Although the order of input shown in the Sample Input Files generally follows the
order of options in the input specification, this is not required.

- In user input files, specifications may be abbreviated so long as the abbreviation is unique. For example,
the npsol_sqp specification within the method keyword could be abbreviated as npsol, but dot_sqp
should not be abbreviated as dot since this would be ambiguous with other DOT method specifications.

- In both the input specification and user input files, comments are preceded by #.

- ALIAS refers to synonymous keywords, which often exist for backwards compatability. Users are encouraged
to use the most current keyword.

### Description

A model that transforms the original model (given by `truth_model_pointer`) to one with a reduced set of variables. This reduced model is identified by iteratively sampling the gradient of the original model and performing a singular value decomposition of the gradient matrix.

### Expected Output

A subspace model will perform an initial sampling design to identify an active subspace using one of the truncation methods.

### Usage Tips

If the desired subspace size is not identified, consider using the explicit `dimension` truncation option or one of the other truncation methods.

### Examples

Perform an initial 100 gradient samples and use the `bing_li` truncation method to identify an active subspace. The truncation method uses 150 bootstrap samples to compute the Bing Li truncation metric.

```model
subspace
  id_model = 'SUBSPACE'
  truth_model_pointer = 'FULLSPACE'
  initial_samples 100
  truncation_method bing_li
  bootstrap_samples 150
```

### Theory

The idea behind active subspaces is to find directions in the input variable space in which the quantity of interest is nearly constant. After rotation of the input variables, this method can allow significant dimension reduction. Below is a brief summary of the process.

1. Compute the gradient of the quantity of interest, \( q = f(x) \), at several locations sampled from the full input space,
   \[
   \nabla_x f_i = \nabla f(x_i).
   \]

2. Compute the eigendecomposition of the matrix \( \hat{C} \),
   \[
   \hat{C} = \frac{1}{M} \sum_{i=1}^{M} \nabla_x f_i \nabla_x f_i^T = \hat{W} \hat{\Lambda} \hat{W}^T,
   \]
   where \( \hat{W} \) has eigenvectors as columns, \( \hat{\Lambda} = \text{diag}(\hat{\lambda}_1, \ldots, \hat{\lambda}_N) \) contains eigenvalues, and \( N \) is the total number of parameters.

3. Using a `truncation_method` or specifying a `dimension` to estimate the active subspace size, split the eigenvectors into active and inactive directions,

   \[
   \hat{W} = \begin{bmatrix} \hat{W}_1 & \hat{W}_2 \end{bmatrix}.
   \]

   These eigenvectors are used to rotate the input variables.

4. Next the input variables, \( x \), are expanded in terms of active and inactive variables,
   \[
   x = \hat{W}_1 y + \hat{W}_2 z.
   \]
5. A surrogate is then built as a function of the active variables,

\[ g(y) \approx f(x) \]

For additional information, see:

7.3.5.1 truth_model_pointer

- Keywords Area
- model
- active_subspace
- truth_model_pointer

Pointer to specify a full-space model, from which to construct a lower dimensional surrogate

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: actual_model_pointer

Argument(s): STRING

Description

This must point to a model block, identified by id_model. That model will be run to generate gradient data, from which an active subspace model will be identified and built.

See block_pointer for details about pointers.

7.3.5.2 initial_samples

- Keywords Area
- model
- active_subspace
- initial_samples

Initial number of samples for sampling-based methods
Specification

Alias: none
Argument(s): INTEGER
Default: model-dependent

Description

The `initial_samples` keyword is used to define the number of initial samples (i.e., randomly chosen sets of variable values) at which to execute a model. The initial samples may later be augmented in an iterative process.

Default Behavior

By default, Dakota will use the minimum number of samples required by the chosen method.

Usage Tips

To obtain linear sensitivities or to construct a linear response surface, at least $\dim+1$ samples should be used, where $\dim$ is the number of variables. For sensitivities to quadratic terms or quadratic response surfaces, at least $(\dim+1)(\dim+2)/2$ samples are needed. For uncertainty quantification, we recommend at least $10\times\dim$ samples. For `variance_based_decomp`, we recommend hundreds to thousands of samples. Note that for `variance_based_decomp`, the number of simulations performed will be $N\times(\dim+2)$.

Examples

```
method
  sampling
    sample_type random
    initial_samples = 20
    refinement_samples = 5
```

7.3.5.3 sample_type

- Keywords Area
- model
- active_subspace
- sample_type

Selection of sampling strategy

Specification

Alias: none
Argument(s): none
Default: random
Child Keywords:
### Description

The `sample_type` keyword allows the user to select between two types of sampling: Monte Carlo (pure random) and Latin hypercube (stratified) sampling.

The incremental keywords are deprecated; instead use `samples` together with `refinement_samples`.

### Default Behavior

If the `sample_type` keyword is present, it must be accompanied by `lhs` or `random`. In most contexts, `lhs` is the default (exception: multilevel_sampling uses Monte Carlo by default).

### Examples

```plaintext
method
  sampling
    sample_type lhs
    samples = 20
    seed = 83921
```

#### 7.3.5.3.1 lhs

- **Keywords Area**
- **model**
- **active_subspace**
- **sample_type**
- **lhs**

Uses Latin Hypercube Sampling (LHS) to sample variables

### Specification

**Alias:** none

**Argument(s):** none

### Description

The `lhs` keyword invokes Latin Hypercube Sampling as the means of drawing samples of uncertain variables according to their probability distributions. This is a stratified, space-filling approach that selects variable values from a set of equi-probable bins.

### Default Behavior
Latin Hypercube Sampling is the default sampling mode in most contexts (exception: multilevel_sampling). To explicitly specify LHS in the Dakota input file, the `lhs` keyword must appear in conjunction with the `sample_type` keyword.

**Usage Tips**

Latin Hypercube Sampling is very robust and can be applied to any problem. It is fairly effective at estimating the mean of model responses and linear correlations with a reasonably small number of samples relative to the number of variables.

**Examples**

```plaintext
method
  sampling
    sample_type lhs
    samples = 20
```

7.3.5.3.2 random

- **Keywords Area**
- model
- active_subspace
- sample_type
- random

Uses purely random Monte Carlo sampling to sample variables

**Specification**

*Alias*: none

*Argument(s)*: none

**Description**

The random keyword invokes Monte Carlo sampling as the means of drawing samples of uncertain variables according to their probability distributions.

**Default Behavior**

In most contexts, Monte Carlo sampling is not the default sampling mode (exception: multilevel_sampling). To change this behavior, the random keyword must be specified in conjunction with the sample_type keyword.

**Usage Tips**

Monte Carlo sampling is more computationally expensive than Latin Hypercube Sampling as it requires a larger number of samples to accurately estimate statistics.

**Examples**

```plaintext
method
  sampling
    sample_type random
    samples = 200
```
7.3.5.4 truncation_method

- Keywords Area
- model
- active_subspace
- truncation_method

Metric that estimates active subspace size

Specification

**Alias:** none

**Argument(s):** none

**Default:** constantine

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional Group</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>bing_li</td>

<td></td>
<td>Truncate the subspace based on eigenvalue energy</td>
</tr>
<tr>
<td>Optional</td>
<td>cross_validation</td>
<td></td>
<td>Truncate the subspace to minimize surrogate cross-validation error</td>
</tr>
</tbody>
</table>

**Description**

Metric that controls how many basis vectors are retained in the active subspace.

**Default Behavior**

The default is to use the constantine diagnostic.

**Usage Tips**

If the automated subspace identification methods do not yield desirable results, consider using the explicit dimension truncation option.

7.3.5.4.1 bing_li

- Keywords Area
- model
Use the Bing Li "ladle" diagnostic to truncate subspace

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

Uses a trade-off criterion to determine where to truncate the active subspace. The criterion is a function of the eigenvalues and eigenvectors of the active subspace gradient matrix. This function compares the decrease in eigenvalue amplitude with the increase in eigenvector variability under bootstrap sampling of the gradient matrix. The active subspace size is taken to be the index of the first minimum of this quantity.

**Usage Tips**

If this automated diagnostic does not yield desirable results, consider using the explicit dimension truncation option or one of the other truncation methods.

**Theory**

Below is a brief outline of the Bing Li method of active subspace identification. The first two steps are common to all active subspace truncation methods.

1. Compute the gradient of the quantity of interest, \( q = f(x) \), at several locations sampled from the input space,  
\[
\nabla_x f_i = \nabla f(x_i).
\]

2. Compute the eigendecomposition of the matrix \( \hat{C} \),  
\[
\hat{C} = \frac{1}{M} \sum_{i=1}^{M} \nabla_x f_i \nabla_x f_i^T = \hat{W} \hat{\lambda} \hat{W}^T,
\]

where \( \hat{W} \) has eigenvectors as columns, \( \hat{\lambda} = \text{diag}(\hat{\lambda}_1, \ldots, \hat{\lambda}_N) \) contains eigenvalues, and \( N \) is the total number of parameters.

3. Normalize the eigenvalues,  
\[
\hat{\lambda}_i = \frac{\hat{\lambda}_i}{\sum_j N \hat{\lambda}_j}.
\]

4. Use bootstrap sampling of the gradients found in step 1 to compute replicate eigendecompositions,  
\[
\hat{C}_j = \hat{W}_j \hat{\lambda}_j \hat{W}_j^T.
\]

5. Compute variability of eigenvectors,  
\[
f_i^0 = \frac{1}{M_{\text{boot}}} \sum_j M_{\text{boot}} \left\{ 1 - |\det(\hat{W}_j^T \hat{W}_j^*)| \right\},
\]

where \( \hat{W}_i \) and \( \hat{W}_j^* \) both contain only the first \( i \) eigenvectors and \( M_{\text{boot}} \) is the number of bootstrap samples. The value of the variability at the first index, \( f_1^0 \), is defined as zero.
6. Normalize the eigenvector variability,
\[ f_i = \frac{f_0^i}{\sum_j f_0^j}. \]

7. The criterion, \( g_i \), is defined as,
\[ g_i = \hat{\lambda}_i + f_i. \]

8. The index of first minimum of \( g_i \) is then the estimated active subspace rank.

For additional information, see Luo, Wei, and Bing Li. "Combining eigenvalues and variation of eigenvectors for order determination." SIAM, 2015.

7.3.5.4.2 constantine

- Keywords: Area
- model
- active_subspace
- truncation_method
- constantine

Use the Constantine diagnostic to truncate subspace

**Specification**

**Alias**: none

**Argument(s)**: none

**Description**

Uses a criterion based on the variability of the subspace estimate. Eigenvectors are computed for bootstrap samples of the gradient matrix. The subspace size associated with the minimum distance between bootstrap eigenvectors and the nominal eigenvectors is the estimated active subspace size.

**Usage Tips**

If this automated diagnostic does not yield desirable results, consider using the explicit dimension truncation option or one of the other truncation methods.

**Theory**

Below is a brief outline of the Constantine method of active subspace identification. The first two steps are common to all active subspace truncation methods.

1. Compute the gradient of the quantity of interest, \( q = f(x) \), at several locations sampled from the input space,
\[ \nabla_x f_i = \nabla f(x_i). \]

2. Compute the eigendecomposition of the matrix \( \mathbf{\hat{C}} \),
\[ \mathbf{\hat{C}} = \frac{1}{M} \sum_{i=1}^{M} \nabla_x f_i \nabla_x f_i^T = \mathbf{\hat{W}} \mathbf{\hat{\Lambda}} \mathbf{\hat{W}}^T, \]
where \( \mathbf{\hat{W}} \) has eigenvectors as columns, \( \mathbf{\hat{\Lambda}} = \text{diag}(\hat{\lambda}_1, \ldots, \hat{\lambda}_N) \) contains eigenvalues, and \( N \) is the total number of parameters.
3. Use bootstrap sampling of the gradients found in step 1 to compute replicate eigendecompositions,

\[ \hat{C}_j^* = \hat{W}_j^* (\hat{W}_j^*)^T. \]

4. Compute the average distance between nominal and bootstrap subspaces,

\[ e_n^* = \frac{1}{M_{\text{boot}}} \sum_j \text{dist}(\text{ran}(\hat{W}_n), \text{ran}(\hat{W}_j^*, n)) = \frac{1}{M_{\text{boot}}} \sum_j \| \hat{W}_n \hat{W}_n^T - \hat{W}_j^* (\hat{W}_j^*)^T \|, \]

where \( M_{\text{boot}} \) is the number of bootstrap samples, \( \hat{W}_n \) and \( \hat{W}_j^*, n \) both contain only the first \( n \) eigenvectors, and \( n < N \).

5. The estimated subspace rank, \( r \), is then,

\[ r = \arg\min_n e_n^*. \]

For additional information, see Constantine, Paul G. "Active Subspaces: Emerging Ideas for Dimension Reduction in Parameter Studies". Vol. 2. SIAM, 2015.

7.3.5.4.3 energy

- Keywords Area
- model
- active_subspace
- truncation_method
- energy

Truncate the subspace based on eigenvalue energy

**Specification**

**Alias**: none

**Argument(s)**: none

**Child Keywords**:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>truncation_-tolerance</td>
<td>Specify the maximum percentage (as a decimal) of the eigenvalue energy not captured by the active subspace representation.</td>
</tr>
</tbody>
</table>

**Description**

Uses a criterion based on the derivative matrix eigenvalue energy.

**Usage Tips**

This subspace truncation method may work best when working with non-normally distributed uncertain variables. If this automated diagnostic does not yield desirable results, consider using the explicit dimension truncation option or one of the other truncation methods.
7.3 model

Theory

Using the eigenvalue energy truncation metric, the subspace size is determined using the following equation:

\[ n = \inf \left\{ d \in \mathbb{Z} \mid 1 \leq d \leq N \land 1 - \frac{\sum_{i=1}^{d} \lambda_i}{\sum_{i=1}^{N} \lambda_i} < \varepsilon \right\} \]

where \( \varepsilon \) is the truncation_tolerance, \( n \) is the estimated subspace size, \( N \) is the size of the full space, and \( \lambda_i \) are the eigenvalues of the derivative matrix.

7.3.5.4.3.1 truncation_tolerance

- Keywords Area
- model
- active_subspace
- truncation_method
- energy
- truncation_tolerance

Specify the maximum percentage (as a decimal) of the eigenvalue energy not captured by the active subspace representation.

Specification

Alias: none

Argument(s): REAL

Description

The truncation_tolerance is used in the energy truncation method to identify an active subspace. The truncation tolerance is used in the following equation to determine the subspace size:

\[ n = \inf \left\{ d \in \mathbb{Z} \mid 1 \leq d \leq N \land 1 - \frac{\sum_{i=1}^{d} \lambda_i}{\sum_{i=1}^{N} \lambda_i} < \varepsilon \right\} \]

where \( \varepsilon \) is the truncation_tolerance, \( n \) is the estimated subspace size, \( N \) is the size of the full space, and \( \lambda_i \) are the eigenvalues of the derivative matrix.

The default value for truncation_tolerance is \( 1 \times 10^{-6} \).

7.3.5.4.4 cross_validation

- Keywords Area
- model
- active_subspace
- truncation_method
- cross_validation

Truncate the subspace to minimize surrogate cross-validation error.
**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** relative

Choose subspace with cross-validation error less than tolerance

**Specification**

*Alias*: none  
*Argument(s)*: none

**Description**

Select smallest subspace with cross-validation error less than specified tolerance.

7.3.5.4.4.3 decrease

* Keywords Area
* model
* active_subspace
* truncation_method
* cross_validation
* decrease

Choose subspace where cross-validation error stabilizes
Specification

Alias: none
Argument(s): none

Description

Select smallest subspace where change in cross-validation error to next larger subspace falls below specified tolerance.

7.3.5.4.4.4 relative_tolerance

- Keywords Area
- model
- active_subspace
- truncation_method
- cross_validation
- relative_tolerance

Tolerance for cross-validation error value

Specification

Alias: none
Argument(s): REAL
Default: 1.0e-6

Description

Select smallest subspace where change in cross-validation error falls below specified tolerance.

7.3.5.4.4.5 decrease_tolerance

- Keywords Area
- model
- active_subspace
- truncation_method
- cross_validation
- decrease_tolerance

Tolerance for cross-validation error stabilization

Specification

Alias: none
Argument(s): REAL
Default: 1.0e-6
Description

Select smallest subspace where change in cross-validation error falls below specified tolerance.

7.3.5.4.4.6 max_rank

- Keywords Area
- model
- active_subspace
- truncation_method
- cross_validation
- max_rank

Maximum subspace dimension to consider

Specification

Alias: none

Argument(s): INTEGER

Default: number fullspace vars

Description

In cross-validation, only consider subspace dimensions from 1 to max_rank.

7.3.5.4.4.7 exhaustive

- Keywords Area
- model
- active_subspace
- truncation_method
- cross_validation
- exhaustive

Assess all admissible subspace dimensions

Specification

Alias: none

Argument(s): none

Default: on

Description

Assess cross-validation error for all admissible subspace dimensions, even if a particular dimension meets specified cross-validation tolerance(s).
7.3.5.5 dimension

- Keywords Area
- model
- active_subspace
- dimension

Explicitly specify the desired subspace size

**Specification**

**Alias**: none

**Argument(s)**: INTEGER

**Description**

This control explicitly indicates the number of basis vectors to retain. The subspace model will include exactly dimension variables.

**Default Behavior**

Active for adapted basis. Not active for active subspace (the number of basis vectors will be chosen by one of the truncation methods).

**Usage Tips**

This control can be helpful when a priori studies give insight to the appropriate subspace size.

7.3.5.6 bootstrap_samples

- Keywords Area
- model
- active_subspace
- bootstrap_samples

Number of bootstrap replicates used in truncation metrics

**Specification**

**Alias**: none

**Argument(s)**: INTEGER

**Description**

The number of bootstrap replicates used to estimate the active subspace size.

**Default Behavior**

Use 100 replicates.
7.3.5.7  build_surrogate

- Keywords Area
- model
- active_subspace
- build_surrogate

Construct moving least squares surrogate over active subspace

**Specification**

**Alias:** none

**Argument(s):** none

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>refinement__samples</td>
<td>Number of supplementary surrogate build samples</td>
</tr>
</tbody>
</table>

**Description**

Once the active subspace variables have been identified, replace the fullspace truth model with a moving least squares surrogate model over the reduced variables. The surrogate is constructed using the fullspace function value samples collected during subspace identification, possibly supplemented with additional refinement_samples in the fullspace.

**Default Behavior**

No surrogate is constructed by default.

**Examples**

```model
active_subspace
   id_model = 'SUBSPACE'
   truth_model_pointer = 'FULLSPACE'
   initial_samples 100
build_surrogate
   refinement_\_samples 10
```

7.3.5.7.1  refinement_samples

- Keywords Area
- model
- active_subspace
- build_surrogate
- refinement_samples

Number of supplementary surrogate build samples
Specification

**Alias:** none

**Argument(s):** INTEGERLIST

**Default:** 0

Description

Augment the function value data collected during subspace identification with the specified number of refinement_samples to build the surrogate model.

7.3.5.8 normalization

- **Keywords Area**
- **model**
- **active_subspace**
- **normalization**

Normalize gradient samples

Specification

**Alias:** none

**Argument(s):** none

**Child Keywords:**

<td>mean_gradient</td>
<td>Normalize by sample mean of gradient norms</td>
</tr>
<tr>
<td></td>
<td></td>
<td>local_gradient</td>
<td>Normalize each gradient sample by its norm</td>
</tr>
</tbody>
</table>

Description

Normalize the matrix of sampled gradients before identifying subspace.

**Default Behavior**

The default is local_gradient

7.3.5.8.1 mean_value

- **Keywords Area**
Normalize by sample mean of function values

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

For each response function $f_i$, normalize its gradient data by the mean $m_i$ of the function values taken across samples $j = 1, \ldots, J$:

$$m_i = \frac{1}{J} \sum_{j=1}^{J} f_i^j$$

7.3.5.8.2 mean_gradient

- **Keywords Area**  
- **model**  
- **active_subspace**  
- **normalization**  
- **mean_gradient**

Normalize by sample mean of gradient norms

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

For each response function $f_i$, normalize its gradient data by the mean $m_i$ of the gradient two-norms taken across samples $j = 1, \ldots, J$:

$$m_i = \frac{1}{J} \sum_{j=1}^{J} \|\nabla f_i^j\|_2$$
7.3.5.8.3 **local_gradient**

- **Keywords Area**

<td></td>
<td>truncation_-tolerance</td>
<td>Convergence tolerance used to identify the (reduced) dimension of the rotation matrix</td>
</tr>
</tbody>
</table>
Description

A model that transforms the original model (given by `truth_model_pointer`) to one with a rotated set of variables. The current implementation does not support the reduction of the dimension for the new model and only transform the variable set in a rotated one in which the variables are arranged in a decreasing importance order.

An initial PCE representation is built with a sparse grid method and the PCE coefficients are then used to build a rotation matrix. This matrix is also reported as a result of the code execution. The new model can subsequently be used for an UQ workflow.

Expected Output  A basis adaptation model will perform an initial sparse grid design to identify the rotation matrix.

Examples

Perform an initial sparse grid design (level 1) to evaluate the PCE expansion and evaluate the rotation matrix. Afterwards, 100 samples are generated for the model in the rotated space to obtain its statistics.

```
method,
  sampling
    model_pointer = ’SUBSPACE’
    samples = 100 seed = 1234567

model
  id_model = ’SUBSPACE’
  adapted_basis
    truth_model_pointer = ’FULLSPACE’
    sparse_grid_level = 1
```

Theory

The idea behind the Basis Adaptation method is to generate a PCE representation and rotate it such that the new set of rotated variables are organized in a decreasing importance ordering. Subsequently this rotation matrix can be truncated according to some criterion to only include the significant directions.

The first step of the Basis Adaptation is to compute a PCE expansion (we assume here $\xi$ to have a standard multivariate Gaussian distribution)

$$Q(\xi) = \sum_{\alpha \in J_{d,p}} Q_{\alpha} \psi_{\alpha}(\xi),$$

where $\alpha = (\alpha_1, ..., \alpha_d) \in J_{d,p} := (\mathbb{N}_0)^d$ with $|\alpha| = \sum_{i=1}^d \alpha_i \leq d$ is multi-index of dimension $d$ and order up to $p$.

Afterwards, a multivariate Gaussian distribution $\eta$ is sought such that

$$\eta = A \xi,$$

where $A$ is an isometry such that $AA^T = I$.

The basis adaptation model is obtained by expressing the original model with respect to the rotated set of variables $\eta$ as

$$Q^A(\eta) = \sum_{\beta \in J_{d,p}} Q^A_{\beta} \psi_{\beta}(\eta).$$

Since the basis for both the original and the adapted basis model span the same space, we know that $Q^A(\eta(\xi)) = Q(\xi)$ and therefore a relationships between the PCE coefficients exists

$$Q_{\alpha} = \sum_{\beta \in J_{d,p}} Q^A_{\beta} \langle \psi^A_{\beta}, \psi_{\alpha} \rangle, \alpha \in J_{d,p}.$$

The linear adaptation strategy is used at this time in Dakota to obtain the rotation matrix $A$. The steps to obtain the matrix $A$ are the following:
1. The first variable $\eta_1$ is obtained by directly combining the first order terms, that is

$$\eta_1 = \sum_{\alpha \in J_{d,1}} Q_\alpha \psi_\alpha(\xi) = \sum_{i=1}^{d} Q_{\epsilon_i} \xi_i,$$

where $\epsilon_i$ is the $d$-dimensional multi-index with 1 at the $i$th location and zero elsewhere.

2. The remaining rows of the $A$ matrix ($A \in \mathbb{R}^{d \times d}$) are obtained by using the largest coefficient, row after row, placed in the column that it occupies in the first row. All other terms are set to zero.

3. As last step, in order to obtain an isometry, the Gram-Schmidt procedure is followed on $A$.

See the theory manual for more details.

#### Description

This must point to a model block, identified by `id_model`. That model will be run to generate training data, from which a surrogate model will be constructed.

See `block_pointer` for details about pointers.

### 7.3.6.1.1 sparse_grid_level

- **Keywords** Area
- model
- adapted_basis
- truth_model_pointer
- sparse_grid_level

Level to use in sparse grid integration or interpolation

#### Specification

**Alias:** none

**Argument(s):** INTEGER

#### Description

Multi-dimensional integration by the Smolyak sparse grid method (specified with `sparse_grid_level` and, optionally, `dimension_preference`). The underlying one-dimensional integration rules are the same as for the tensor-product quadrature case; however, the default rule selection is nested for sparse grids (Genz-Keister for normals/transformed normals and Gauss-Patterson for uniforms/transformed uniforms). This default can be overridden with an explicit `non_nested` specification (resulting in Gauss-Hermite for normals/transformed normals and Gauss-Legendre for uniforms/transformed uniforms). As for tensor quadrature, the `dimension_preference` specification enables the use of anisotropic sparse grids (refer to the PCE description in the User's Manual for the anisotropic index set constraint definition). Similar to anisotropic tensor grids, the dimension with greatest preference will have resolution at the full `sparse_grid_level` and all other dimension resolutions will be reduced in proportion to their reduced preference. For PCE with either isotropic or anisotropic sparse grids, a summation of tensor-product expansions is used, where each anisotropic tensor-product quadrature rule underlying the sparse grid construction results in its own anisotropic tensor-product expansion as described in case 1. These anisotropic tensor-product expansions are summed into a sparse PCE using the standard Smolyak summation (again, refer to the User's Manual for additional details). As for `quadrature_order`, the `sparse_grid_level` specification admits an array input for enabling specification of multiple grid resolutions used by certain advanced solution methodologies.

A corresponding sequence specification is documented at, e.g., `sparse_grid_level_sequence` and `sparse_grid_level_sequence`

<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>collocation_ratio</td>
<td>Set the number of points used to build a PCE via regression to be proportional to the number of terms in the expansion.</td>
</tr>
</tbody>
</table>

**Description**

When the `expansion_order` for a polynomial chaos expansion is specified, the coefficients may be computed by integration based on random samples or by regression using either random or sub-sampled tensor product quadrature points.

Multidimensional integration by Latin hypercube sampling (specified with `expansion_samples`). In this case, the expansion order $p$ cannot be inferred from the numerical integration specification and it is necessary to provide an `expansion_order` to specify $p$ for a total-order expansion.

Linear regression (specified with either `collocation_points` or `collocation_ratio`). A total-order expansion is used and must be specified using `expansion_order` as described in the previous option. To avoid requiring the user to calculate $N$ from $n$ and $p$, the `collocation_ratio` allows for specification of a constant factor applied to $N$ (e.g., `collocation_ratio = 2` produces samples = $2N$). In addition, the default linear relationship with $N$ can be overridden using a real-valued exponent specified using `ratio_order`. In this case, the number of samples becomes $cN^o$ where $c$ is the `collocation_ratio` and $o$ is the `ratio_order`. The `use_derivatives` flag informs the regression approach to include derivative matching equations (limited to gradients at present) in the least squares solutions, enabling the use of fewer collocation points for a given expansion order and dimension (number of points required becomes $\frac{cN^o}{p^o}$). When admissible, a constrained least squares approach is employed in which response values are first reproduced exactly and error in reproducing response derivatives is minimized. Two collocation grid options are supported: the default is Latin hypercube sampling,...
("point collocation"), and an alternate approach of "probabilistic collocation" is also available through inclusion of the `tensor_grid` keyword. In this alternate case, the collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

If `collocation_points` or `collocation_ratio` is specified, the PCE coefficients will be determined by regression. If no regression specification is provided, appropriate defaults are defined. Specifically SVD-based least-squares will be used for solving over-determined systems and under-determined systems will be solved using LASSO. For the situation when the number of function values is smaller than the number of terms in a PCE, but the total number of samples including gradient values is greater than the number of terms, the resulting over-determined system will be solved using equality constrained least squares. Technical information on the various methods listed below can be found in the Linear regression section of the Theory Manual. Some of the regression methods (OMP, LASSO, and LARS) are able to produce a set of possible PCE coefficient vectors (see the Linear regression section in the Theory Manual). If cross validation is inactive, then only one solution, consistent with the `noise_tolerance`, will be returned. If cross validation is active, Dakota will choose between possible coefficient vectors found internally by the regression method across the set of expansion orders (1,...,`expansion_order`) and the set of specified noise tolerances and return the one with the lowest cross validation error indicator.

7.3.6.1.2.1 collocation_ratio

- Keywords Area
- model
- adapted_basis
- truth_model_pointer
- expansion_order
- collocation_ratio

Set the number of points used to build a PCE via regression to be proportional to the number of terms in the expansion.

Specification

- **Alias**: none
- **Argument(s)**: REAL

Description

Set the number of points used to build a PCE via regression to be proportional to the number of terms in the expansion. To avoid requiring the user to calculate N from n and p, the collocation_ratio allows for specification of a constant factor applied to N (e.g., collocation_ratio = 2, produces samples = 2N). In addition, the default linear relationship with N can be overridden using a real-valued exponent specified using ratio_order. In this case, the number of samples becomes \(cN^\alpha\) where \(c\) is the collocation_ratio and \(\alpha\) is the ratio_order. The use_derivatives flag informs the regression approach to include derivative matching equations (limited to gradients at present) in the least squares solutions, enabling the use of fewer collocation points for a given expansion order and dimension (number of points required becomes \(cN^\alpha\)).
Prescribe the number of active dimensions

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Description**

If a prescribed dimension for the rotation matrix is desired, this can be specified with the keyword `dimension`. In this case, the algorithm does not use the `truncation_method` or the `truncation_tolerance` to determine the truncation of the rotation matrix, but it just selects the first $d$ dimensions, where $d$ is assigned by `dimension`.

**Examples**

The following block

``` lua
model
  id_model = 'SUBSPACE'
  adapted_basis
    truth_model_pointer = 'FULLSPACE'
    sparse_grid_level = 1
  dimension = 3
```

prescribes the selection of the first three most important directions to build the rotation matrix and the reduced model representation.

### 7.3.6.1.4 rotation_method

**Keywords Area**

**model**

**adapted_basis**

**truth_model_pointer**

**rotation_method**

Method used to build the rotation matrix

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** norm

**Child Keywords:**
### Description

The rotation matrix for the Adapted Basis method is built starting from a matrix which includes the linear PCE coefficients. The entries of the first row are the linear PCE coefficients. For all the other rows, each row has only one nonzero entry. Depending on the way used to construct all the rows, from the second to last one, there are two implemented methods, **unranked** and **ranked**. A followed Gram-schmidt process is applied on the resulting matrix to make it an isometry.

**Default Behavior**

The default is to use the **ranked**.

**Usage Tips**

**Examples**

The following method block

```dakota
model
  id_model = 'SUBSPACE'
  adapted_basis
    truth_model_pointer = 'FULLSPACE'
  sparse_grid_level = 1
  rotation_method = unranked
```

changes the default method to the **unranked** method.

#### 7.3.6.1.4.1 **unranked**

- **Keywords Area**
- **model**
- **adapted_basis**
- **truth_model_pointer**
- **rotation_method**
- **unranked**

Use the unranked method to obtain the rotation matrix

**Specification**

**Alias:** none

**Argument(s):** none
Description

In this case the construction of the second to last rows of the rotation matrix is performed by using the value 1 in the diagonal terms and zeros elsewhere.

7.3.6.1.4.2 ranked

- Keywords Area
- model
- adapted_basis
- truth_model_pointer
- rotation_method
- ranked

Use the ranked method to obtain the rotation matrix

Specification

Alias: none

Argument(s): none

Description

In this case the construction of the $i$th row, with $i \geq 2$, of the rotation matrix is performed by putting the $(i - 1)$th largest linear PCE coefficient in the column that it occupies in the first row.

Theory

The first row of the rotation captures the complete Gaussian components and is suggested as the leading direction. By the construction in this method, the other rotated variables are the variables in the original space that have the greatest sensitivity in descending order. The particular construction makes sure that the importance of the adapted variables is in descending order, which permits the possibility of reduced representation.

7.3.6.2 truncation_tolerance

- Keywords Area
- model
- adapted_basis
- truncation_tolerance

Convergence tolerance used to identify the (reduced) dimension of the rotation matrix

Specification

Alias: none

Argument(s): REAL

Default: 0.8
Description

This convergence tolerance controls the dimension of the rotation matrix after the truncation. The metric controlled by this convergence tolerance is a quantity varying between [0,1]. If a more aggressive dimension truncation is desired, the default value (0.8) can be reduced to a lower value.

Examples

The following block

```dakota
model
  id_model = 'SUBSPACE'
  adapted_basis
    truth_model_pointer = 'FULLSPACE'
    sparse_grid_level = 1
    truncation_tolerance = 0.9
```

increases the default value (0.8) for the `truncation_tolerance` to 0.9 to obtain a rotation matrix and, consequently, a reduced model that more closely approximates the full dimensional model.

7.3.7 random_field

- Keywords Area
- model
- random_field

Experimental capability to generate a random field representation. from data, from simulation runs, or from a covariance matrix. The representation may then be sampled for use as a random field input to another simulation. THIS IS AN EXPERIMENTAL CAPABILITY.

Specification

**Alias:** none

**Argument(s):** none

THIS IS AN EXPERIMENTAL CAPABILITY.</td>
</tr>
</tbody>
</table>
the random field may be a file with data (where the N rows of data correspond to N samples of the random field and the M columns correspond to field values), or it may be a simulation that generates field data, or it may be specified given a mesh and a covariance matrix governing how the field varies over the mesh. In the case of using a simulation to generate field data, the simulation is defined with `dace_method_pointer`. In the case of using a mesh and a covariance, the form of the covariance is defined with `analytic_covariance`.

The next section of the random field model specifies the form of the expansion, `expansion_form`. This can be either a Karhunen-Loeve expansion or a Principal components analysis. These are very similar: both involve the eigenvalues of the covariance matrix of the field data. The only difference is in the treatment of the estimation of the coefficients of the eigenvector basis functions. In the PCA case, we have developed an approach which makes the coefficients explicit functions of the uncertain variables used to generate the random field. The specification of the random field can also include the number of bases to retain or a truncation tolerance, which defines the percent variance that the expansion should capture.

The final section of the random field model allows the user to specify a pointer to a model over which the random field will be propagated, meaning the model which will be driven with the random field input. This part of the specification is optional: one can build a random field but not use it in a downstream model.

**Examples**

As stated above, this is an emerging capability. The syntax currently looks like the following:

```plaintext
random_field
   build_source
      rf_data_file | dace_method_pointer | analytic_covariance
   expansion_form
      karhunen_loeve | principal_components
   expansion_bases
   truncation_tolerance
   propagation_model_pointer
```

**7.3.7.1 build_source**

- **Keywords Area**
  - model
  - random_field
  - build_source

Specify how the random field will be built: from a data file, from simulation runs, or from a covariance matrix. THIS IS AN EXPERIMENTAL CAPABILITY.

**Specification**

- **Alias:** none
- **Argument(s):** none
- **Child Keywords:** none
### Description

As part of the capability to generate a random field representation, the user needs to specify the data used to generate the random field representation. This data may reside in a data file, it may be generated by running a set of simulations and generating field responses, or it may be generated by a covariance matrix defined over a mesh. THIS IS AN EXPERIMENTAL CAPABILITY UNDER ACTIVE DEVELOPMENT.

**Default Behavior** Currently, the `build_source` that is fully working is the `dace_method_pointer`. The others are not fully operational.

#### 7.3.7.1.1 rf_data_file

- **Keywords Area**
  - model
  - random_field
  - build_source
  - rf_data_file

Specify that the random field will be built from a file of data. THIS IS AN EXPERIMENTAL CAPABILITY.

### Specification

**Alias:** none
Argument(s): STRING
Default: none

Description
As part of the capability to generate a random field representation, the user needs to specify the data used to generate the random field representation. In the case of rf_data_file, the data should reside in that file. The rows of this file represent separate samples, and the columns represent the field data. For example, if you have 100 samples of a random field of length 500, the data file will be of dimension 100 x 500. Currently, this option is not operational. THIS IS AN EXPERIMENTAL CAPABILITY UNDER ACTIVE DEVELOPMENT.

Default Behavior  Currently, the build_source that is fully working is the dace_method_pointer. The others are not fully operational.

7.3.7.1.2 dace_method_pointer

• Keywords Area
• model
• random_field
• build_source
• dace_method_pointer

Pointer to a DACE method for purposes of generating an ensemble of field responses to be used in estimating a random field model. THIS IS AN EXPERIMENTAL CAPABILITY.

Specification

Alias: none
Argument(s): STRING
Default: no design of experiments data

Description
As part of the capability to generate a random field representation, the user needs to specify the data used to generate the random field representation. One way to do this is to run a set of simulations and generating field responses. Dakota will then take the full set of field responses (e.g. multiple samples, where each sample has a field response) and construct a random field model representing the uncertainty in the ensemble. The dace_method_pointer is a pointer to a Design and Analysis of Computer Experiments (DACE) method, typically which is a sampling method. In this case, the sampling method should be on a simulation which can generate field responses (e.g. field_responses, field_objectives, or field_calibration terms.) THIS IS AN EXPERIMENTAL CAPABILITY UNDER ACTIVE DEVELOPMENT.

Default Behavior  Currently, the build_source that is fully working is the dace_method_pointer. The others are not fully operational.

7.3.7.1.3 analytic_covariance

• Keywords Area
• model
• random_field
• build_source
Use an analytic covariance function for the purposes of generating a random field model. THIS IS AN EXPERIMENTAL CAPABILITY.

Specification

Description

As part of the capability to generate a random field representation, the user needs to specify the data used to generate the random field representation. If analytic_covariance is specified, an analytic covariance function will be used to generate instantiations of a random field over a mesh. The form of the covariance function must be specified (e.g. exponential or squared_exponential). THIS IS AN EXPERIMENTAL CAPABILITY UNDER ACTIVE DEVELOPMENT.

Default Behavior Currently, the build_source that is fully working is the dace_method_pointer. The others are not fully operational.

7.3.7.1.3.1 squared_exponential

- Keywords Area
- model
- random_field
- build_source
- analytic_covariance
Specify a squared exponential covariance in the case where the random field is built from an analytic covariance function. THIS IS AN EXPERIMENTAL CAPABILITY.

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

THIS IS AN EXPERIMENTAL CAPABILITY UNDER ACTIVE DEVELOPMENT.

**Default Behavior** Currently, the `build_source` that is fully working is the `dace_method_pointer`. The others are not fully operational.

**7.3.7.1.3.2 exponential**

Specify an exponential covariance in the case where the random field is built from an analytic covariance function. THIS IS AN EXPERIMENTAL CAPABILITY.

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

THIS IS AN EXPERIMENTAL CAPABILITY UNDER ACTIVE DEVELOPMENT.

**Default Behavior** Currently, the `build_source` that is fully working is the `dace_method_pointer`. The others are not fully operational.

**7.3.7.2 expansion_form**

Specify the form of the expansion to be used in the random field representation. THIS IS AN EXPERIMENTAL CAPABILITY.
Specification

**Alias:** none

**Argument(s):** none

**Child Keywords:**

<table>

<td>principal_components</td>
<td>Specify Principal Components as the form of the expansion to be used in the random field representation. THIS IS AN EXPERIMENTAL CAPABILITY.</td>
</tr>
</tbody>
</table>

**Description**

This control allows the user to specify the form of the random field representation (e.g. either a Karhunen-Loeve or Principal Components expansion). THIS IS AN EXPERIMENTAL CAPABILITY UNDER ACTIVE DEVELOPMENT.

**Default Behavior** The default expansion form is Karhunen-Loeve.

7.3.7.2.1 karhunen_loeve

- Keywords Area
- model
- random_field
- expansion_form
- karhunen_loeve

Specify Karhunen-Loeve as the expansion form to be used in the random field representation. THIS IS AN EXPERIMENTAL CAPABILITY.

**Specification**

**Alias:** none

**Argument(s):** none
Description

THIS IS AN EXPERIMENTAL CAPABILITY UNDER ACTIVE DEVELOPMENT.

Default Behavior The default expansion form is Karhunen-Loève.

7.3.7.2.2 principal_components

- Keywords Area
- model
- random_field
- expansion_form
- principal_components

Specify Principal Components as the form of the expansion to be used in the random field representation. THIS IS AN EXPERIMENTAL CAPABILITY.

Specification

Alias: none
Argument(s): none

Description

Principal Components and Karhunen-Loève are very similar functional forms of the expansion. They both use basis functions which are eigenvectors of the covariance matrix of the random field data. However, in principal components, we parameterize the coefficients of the expansion to be Gaussian process models which are functions of the uncertain parameters used to generate the initial ensemble of data representing the random field. THIS IS AN EXPERIMENTAL CAPABILITY UNDER ACTIVE DEVELOPMENT.

Default Behavior The default expansion form is Karhunen-Loève.

7.3.7.3 expansion_bases

- Keywords Area
- model
- random_field
- expansion_bases

Specify the number of basis functions to be used in the random field representation. THIS IS AN EXPERIMENTAL CAPABILITY.

Specification

Alias: none
Argument(s): INTEGER
Description

This control allows the user to specify the number of basis functions to be used in the random field representation (e.g. either a Karhunen-Loeve or Principal Components expansion). Typically, a small number of basis functions (3-5) will be sufficient to represent a significant amount of the variance in the response field. However, this depends on the particulars of the problem. THIS IS AN EXPERIMENTAL CAPABILITY UNDER ACTIVE DEVELOPMENT.

Default Behavior  If the user specifies neither truncation_tolerance nor expansion_bases, then the number of expansion bases that captures 95% of the variance will be used.

7.3.7.4 truncation_tolerance

• Keywords Area
• model
• random_field
• truncation_tolerance

Specify a percent of the response variance that should be captured with the random field representation. THIS IS AN EXPERIMENTAL CAPABILITY.

Specification

Alias: none
Argument(s): REAL

Description

This control allows the user to specify the percent variance to be capture in the random field representation (e.g. either a Karhunen-Loeve or Principal Components expansion). Typically, the user would specify something like 0.9 or 0.95, where 0.9 means that 90% of the variance of the response field will be captured by the random field. THIS IS AN EXPERIMENTAL CAPABILITY UNDER ACTIVE DEVELOPMENT.

Default Behavior  If the user specifies neither truncation_tolerance nor expansion_bases, then the truncation tolerance is set to 0.95 and the number of expansion bases that captures 95% of the variance will be used.

7.3.7.5 propagation_model_pointer

• Keywords Area
• model
• random_field
• propagation_model_pointer

Pointer to the model that will accept realizations of the random field and use them for subsequent analysis. Typically, this model will take the random field as inputs, e.g. a random field defining a pressure boundary or temperature boundary condition over a structure. THIS IS AN EXPERIMENTAL CAPABILITY.

Specification

Alias: none
Argument(s): STRING
Description

After a random field representation has been generated, Dakota will generate samples of that random field based on the representation. These sample realizations can then be used to drive another set of simulation analyses. The `propagation_model_pointer` is the model on which the random field realizations will be propagated. THIS IS AN EXPERIMENTAL CAPABILITY UNDER ACTIVE DEVELOPMENT.

Default Behavior

7.3.8 variables_pointer

- Keywords Area
- model
- variables_pointer

Specify which variables block will be included with this model block

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none

Argument(s): STRING

Default: model use of last variables parsed

Description

The `variables_pointer` is used to specify which variables block will be used by the model, by cross-referencing with `id_variables` keyword in the `variables` block. See `block_pointer` for details about pointers.

Default Behavior

When a variables pointer is not specified, the model will use the last variables block parsed from the input file.

7.3.9 responses_pointer

- Keywords Area
- model
- responses_pointer

Specify which responses block will be used by this model block

Topics

This keyword is related to the topics:

- block_pointer
Specification

**Alias:** none

**Argument(s):** STRING

**Default:** model use of last responses parsed

**Description**

The `responses_pointer` is used to specify which responses block will be used by the model, by cross-referencing with `id_responses` keyword in the `responses` block.

See `block_pointer` for details about pointers.

**Default Behavior**

When a responses pointer is not specified, the model will use the last responses block parsed from the input file.

7.3.10 hierarchical_tagging

- **Keywords Area**
- **model**
- **hierarchical_tagging**

Enables hierarchical evaluation tagging

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** no hierarchical tagging

**Description**

The hierarchical tagging option is useful for studies involving multiple models with a nested or hierarchical relationship. For example a nested model has a sub-method, which itself likely operates on a sub-model, or a hierarchical approximation involves coordination of low and high fidelity models. Specifying `hierarchical_tagging` will yield function evaluation identifiers ("tags") composed of the evaluation IDs of the models involved, e.g., `outermodel.-innermodel.interfaceid = 4.9.2`. This communicates the outer contexts to the analysis driver when performing a function evaluation.

**Examples**

test/dakota_uq_timeseries_ivp_optinterf.in test/dakota_uq_timeseries_sop_optinterf.in

**See Also**

These keywords may also be of interest:

- `file_tag` model-nested

Description

The variables specification in a Dakota input file specifies the parameter set to be iterated by a particular method. In the case of

- An optimization study: These variables are adjusted in order to locate an optimal design.
- Parameter studies/sensitivity analysis/design of experiments: These parameters are perturbed to explore the parameter space.
- Uncertainty analysis: The variables are associated with distribution/interval characterizations which are used to compute corresponding distribution/interval characterizations for response functions.

To accommodate these different studies, Dakota supports different:

- Variable types
  - design
  - aleatory uncertain
  - epistemic uncertain
  - state

- Variable domains
  - continuous
  - discrete
    - discrete range
    - discrete integer set
    - discrete string set
    - discrete real set

Use the variables page to browse the available variables by type and domain.

Variable Types

- Design Variables
  - Design variables are those variables which are modified for the purposes of seeking an optimal design.
  - The most common type of design variables encountered in engineering applications are of the continuous type. These variables may assume any real value within their bounds.
  - All but a handful of the optimization algorithms in Dakota support continuous design variables exclusively.
• Aleatory Uncertain Variables
  – Aleatory uncertainty is also known as inherent variability, irreducible uncertainty, or randomness.
  – Aleatory uncertainty is predominantly characterized using probability theory. This is the only option implemented in Dakota.

• Epistemic Uncertain Variables
  – Epistemic uncertainty is uncertainty due to lack of knowledge.
  – In Dakota, epistemic uncertainty is assessed by interval analysis or the Dempster-Shafer theory of evidence.
  – Continuous or discrete interval or set-valued variables are used to define set-valued probabilities or basic probability assignments (BPA) which define a belief structure.
  – Note that epistemic uncertainty can also be modeled with probability density functions (as done with aleatory uncertainty). Dakota does not support this capability.

• State Variables
  – State variables consist of “other” variables which are to be mapped through the simulation interface, in that they are not to be used for design and they are not modeled as being uncertain.
  – State variables provide a convenient mechanism for managing additional model parameterizations such as mesh density, simulation convergence tolerances, and time step controls.
  – Only parameter studies and design of experiments methods will iterate on state variables.
  – The initial_value is used as the only value for the state variable for all other methods, unless active state is invoked.
  – See more details on the state_variables page.

Variable Domains
Continuous variables are typically defined by bounds. Discrete variables can be defined in one of three ways, which are discussed on the page discrete_variables.

Ordering of Variables
The ordering of variables is important, and a consistent ordering is employed throughout the Dakota software. The ordering is shown in dakota.input.summary (and in the hierarchical order of this reference manual) and can be summarized as:

1. design
   (a) continuous
   (b) discrete integer
   (c) discrete string
   (d) discrete real

2. aleatory uncertain
   (a) continuous
   (b) discrete integer
   (c) discrete string
   (d) discrete real

3. epistemic uncertain
   (a) continuous
   (b) discrete integer
   (c) discrete string
   (d) discrete real
4. state
   (a) continuous
   (b) discrete integer
   (c) discrete string
   (d) discrete real

Ordering of variable types below this granularity (e.g., from normal to histogram bin within aleatory uncertain - continuous ) is defined somewhat arbitrarily, but is enforced consistently throughout the code.

Active Variables

The reason variable types exist is that methods have the capability to treat variable types differently. All methods have default behavior that determines which variable types are "active" and will be assigned values by the method. For example, optimization methods will only vary the design variables - by default.

The default behavior should be described on each method page, or on topics pages that relate to classes of methods. In addition, the default behavior can be modified using the active keyword.

At least one type of variables that are active for the method in use must have nonzero size (at least 1 active variable) or an input error message will result.

Inferred Default Values and Bounds

The concept of active variables allows any Dakota variable type to be used in any method context. Some methods, e.g., bound-constrained optimization or multi-dimensional or centered parameter studies, require bounds and/or an initial point on the variables, however uncertain variables may not be naturally defined in terms of these characteristics.

Distribution lower and upper bounds are explicit portions of the normal, lognormal, uniform, loguniform, triangular, and beta specifications, whereas they are implicitly defined for others. For example, bounds are naturally defined for histogram bin, histogram point, and interval variables (from the extreme values within the bin/point/interval specifications) as well as for binomial (0 to num_trials) and hypergeometric (0 to min(num_drawn, num_selected)) variables.

If not specified, distribution bounds are also inferred for normal and lognormal (if optional bounds are unspecified) as well as for exponential, gamma, gumbel, frechet, weibull, poisson, negative binomial, and geometric (which have no bounds specifications); these bounds are \([0, \mu + 3\sigma]\) for exponential, gamma, frechet, weibull, poisson, negative binomial, geometric, and unspecified lognormal, and \([\mu - 3\sigma, \mu + 3\sigma]\) for gumbel and unspecified normal.

When an initial point is needed and not explicitly specified in user input, it is assigned as described in the initial_point or initial_state specification, e.g., initial_point. For example, uncertain variables are initialized to their means, where mean values for bounded normal and bounded lognormal may be further adjusted to satisfy any user-specified distribution bounds, mean values for discrete integer range distributions are rounded down to the nearest integer, and mean values for discrete set distributions are rounded to the nearest set value.

Examples

Several examples follow. In the first example, two continuous design variables are specified:

```plaintext
variables,
  continuous_design = 2
  initial_point 0.9 1.1
  upper_bounds 5.8 2.9
  lower_bounds 0.5 -2.9
  descriptors 'radius' 'location'
```

In the next example, defaults are employed. In this case, initial_point will default to a vector of 0. values, upper_bounds will default to vector values of DBL_MAX (the maximum number representable in double precision for a particular platform), lower_bounds will default to a vector of -DBL_MAX values, and descriptors will default to a vector of 'cdv_i' strings, where i ranges from one to two:

```plaintext
```
In the following example, the syntax for a normal-lognormal distribution is shown. One normal and one lognormal uncertain variable are completely specified by their means and standard deviations. In addition, the dependence structure between the two variables is specified using the `uncertain_correlation_matrix`.

```
variables,
    normal_uncertain = 1
    means = 1.0
    std_deviations = 1.0
    descriptors = 'TF1n'
    lognormal_uncertain = 1
    means = 2.0
    std_deviations = 0.5
    descriptors = 'TF2ln'
    uncertain_correlation_matrix = 1.0 0.2
                                 0.2 1.0
```

An example of the syntax for a state variables specification follows:

```
variables,
    continuous_state = 1
    initial_state 4.0
    lower_bounds 0.0
    upper_bounds 8.0
    descriptors 'CS1'
    discrete_state_range = 1
    initial_state 104
    lower_bounds 100
    upper_bounds 110
    descriptors 'DS1'
```

And in a more advanced example, a variables specification containing a set identifier, continuous and discrete design variables, normal and uniform uncertain variables, and continuous and discrete state variables is shown:

```
variables,
    id_variables = 'V1'
    continuous_design = 2
    initial_point 0.9 1.1
    upper_bounds 5.8 2.9
    lower_bounds 0.5 -2.9
    descriptors 'radius' 'location'
    discrete_design_range = 1
    initial_point 2
    upper_bounds 1
    lower_bounds 3
    descriptors 'material'
    normal_uncertain = 2
    means = 248.89, 593.33
    std_deviations = 12.4, 29.7
    descriptors = 'TF1n' 'TF2n'
    uniform_uncertain = 2
    lower_bounds = 199.3, 474.63
    upper_bounds = 298.5, 712.
    descriptors = 'TF1u' 'TF2u'
    continuous_state = 2
    initial_state = 1.e-4 1.e-6
    descriptors = 'EPSIT1' 'EPSIT2'
    discrete_state_set
    integer = 1
    initial_state = 100
    set_values = 100 212 375
    descriptors = 'load_case'
```

7.4.1 `id_variables`

- Keywords Area
• variables
• id_variables

Name the variables block; helpful when there are multiple

Topics
This keyword is related to the topics:

• block_identifier

Specification

Alias: none
Argument(s): STRING
Default: use of last variables parsed

Description
The optional id_variables keyword accepts a string that uniquely identifies this variables block. A model can then use these variables by specifying the same string in its variables_pointer specification.

Default Behavior
If the id_variables specification is omitted, a particular variables specification will be used by a model only if that model does not include an variables_pointer and the variables block was the last (or only) one parsed.

Usage Tips

• It is a best practice to always use explicit variables IDs and pointers to avoid confusion.
• If only one variables block exists, then id_variables can be safely omitted from the variables block (and variables_pointer omitted from the model specification(s)), since there is no ambiguity.

Examples
For example, a model specification including

```
model
  variables_pointer = 'V1'
```

will link to a response set with

```
id_variables = 'V1'
```

**Description**

There are certain situations where the user may want to explicitly control the subset of variables that is considered active for a certain Dakota method. This is done by specifying the keyword *active* in the variables specification block, followed by one of the following: *all*, *design*, *uncertain*, *aleatory*, *epistemic*, or *state*.

Specifying one of these subsets of variables will allow the Dakota method to operate on the specified variable types and override the default active subset.

If the user does not specify any explicit override of the active view of the variables, Dakota first considers the response function specification.

- If the user specifies objective functions or calibration terms in the response specification block, then we can infer that the active variables should be the design variables (since design variables are used within optimization and least squares methods).
- If the user instead specifies the generic response type of *response_functions*, then Dakota cannot infer the active variable subset from the response specification and will instead infer it from the method selection.
  1. If the method is a parameter study, or any of the methods available under dace, psuade, or fsu methods, the active view is set to all variables.
  2. For uncertainty quantification methods, if the method is sampling, then the view is set to aleatory if only aleatory variables are present, epistemic if only epistemic variables are present, or uncertain (covering both aleatory and epistemic) if both are present.
  3. If the uncertainty method involves interval estimation or evidence calculations, the view is set to epistemic.
  4. For other uncertainty quantification methods not mentioned in the previous sentences (e.g., reliability methods or stochastic expansion methods), the default view is set to aleatory.
  5. Finally, for verification studies using the Richardson extrapolation method, the active view is set to state.
  6. Note that in surrogate-based optimization, where the surrogate is built on points defined by the method defined by the *dace_method_pointer*, the sampling used to generate the points is performed only over the design variables as a default unless otherwise specified (e.g. state variables will not be sampled for surrogate construction).
As alluded to in the previous section, the iterative method selected for use in Dakota determines what subset, or view, of the variables data is active in the iteration. The general case of having a mixture of various different types of variables is supported within all of the Dakota methods even though certain methods will only modify certain types of variables (e.g., optimizers and least squares methods only modify design variables, and uncertainty quantification methods typically only utilize uncertain variables). This implies that variables which are not under the direct control of a particular iterator will be mapped through the interface in an unmodified state. This allows for a variety of parameterizations within the model in addition to those which are being used by a particular iterator, which can provide the convenience of consolidating the control over various modeling parameters in a single file (the Dakota input file). An important related point is that the variable set that is active with a particular iterator is the same variable set for which derivatives are typically computed.

Examples

For example, the default behavior for a nondeterministic sampling method is to sample the uncertain variables. However, if the user specifies `active all` in the variables specification block, the sampling would be performed over all variables (e.g., design and state variables in addition to the uncertain variables). This may be desired in situations such as surrogate-based optimization under uncertainty, where a surrogate may be constructed to span both design and uncertain variables. This is an example where we expand the active subset beyond the default, but in other situations, we may wish to restrict from the default. An example of this would be performing design of experiments in the presence of multiple variable types (for which all types are active by default), but only wanting to sample over the design variables for purposes of constructing a surrogate model for optimization.

Theory

The optional status of the different variable type specifications allows the user to specify only those variables which are present (rather than explicitly specifying that the number of a particular type of variables is zero). However, at least one type of variables that are active for the iterator in use must have nonzero size or an input error message will result.

**Default:** relaxed (branch and bound), mixed (all other methods)

Description

The variables domain specifies how the discrete variables are treated. If the user specifies `mixed` in the variable specification block, the continuous and discrete variables are treated separately. If the user specifies `relaxed` in the variable specification block, the discrete variables are relaxed and treated as continuous variables. This may be useful in optimization problems involving both continuous and discrete variables when a user would like to use an optimization method that is designed for continuous variable optimization. All Dakota methods have a default value of `mixed` for the domain type except for the branch-and-bound method which has a default domain type of `relaxed`. Note that the branch-and-bound method is under development at this time. Finally, note that the domain selection applies to all variable types: design, aleatory uncertain, epistemic uncertain, and state.

With respect to domain type, if the user does not specify an explicit override of `mixed` or `relaxed`, Dakota infers the domain type from the method. As mentioned above, all methods currently use a `mixed` domain as a default, except the branch-and-bound method which is under development.

**Description**

Continuous variables are defined by a real interval and are changed during the search for the optimal design.

**7.4.5.1 initial_point**

- **Keywords** Area
- **variables**
- **continuous_design**
- **initial_point**

Initial values for variables

**Specification**

**Alias:** cdv_initial_point

**Argument(s):** REALLIST

**Default:** 0.0

**Description**

Specifies the initial or default value a variable should assume, for example when starting a method or fixing the value of an inactive variable.

**Default Behavior**

Range variables, including `continuous_design`, `continuous_state`, `discrete_design_range`, and `discrete_state_range` are initialized to:

- Mean/midpoint (or next smaller integer value) when doubly-bounded
- 0 when unbounded
- 0 when semi-bounded and zero is in the half interval, otherwise to the specified lower or upper bound

Set variables, including `discrete_design_set` and `discrete_state_set` default to the middle (or next smaller) value of the ordered set of admissible values.

Uncertain variables default initialize to their mean (or nearest admissible discrete) value, truncating to any specified lower or upper bounds as needed. Epistemic uncertain variable means are calculated making a probabilistic assumption on the specified intervals or set values.
7.4.5.2 lower_bounds

- Keywords Area
- variables
- continuous_design
- lower_bounds

Specify minimum values

Specification

Alias: cdv_lower_bounds
Argument(s): REALLIST
Default: -infinity

Description

Specify minimum values

7.4.5.3 upper_bounds

- Keywords Area
- variables
- continuous_design
- upper_bounds

Specify maximum values

Specification

Alias: cdv_upper_bounds
Argument(s): REALLIST
Default: infinity

Description

Specify maximum values

7.4.5.4 scale_types

- Keywords Area
- variables
- continuous_design
- scale_types

How to scale each continuous design variable
7.4 variables

Specification

**Alias:** cdv_scale_types

**Argument(s):** STRINGLIST

**Default:** vector values = 'none'

Description

Each string in `scale_types` indicates the scaling type for each continuous design variable. They only have effect when the associated method specifies `scaling`.

The options are:

- `'value'` - characteristic value by which variables will be divided. If this is chosen, then `scales` must also be specified; 'value' is assumed if scales are given without `scale_types`

- `'auto'` - automatic scaling based on bounds.

- `'log'` - logarithmic scaling (can be used together with `scales`).

If a single string is specified it will apply to all continuous design variables. Otherwise, a scale type must be specified for each continuous design variable.

**Usage Tips:**

See the scaling information under specific methods, e.g., `method-∗-scaling` for details on how to use this keyword.

**Examples**

Two continuous design variables, one scaled by 4.0, the other by 0.1, then further log scaled:

```plaintext
continuous_design = 2
initial_point  -1.2  1.0
lower_bounds   -2.0  0.001
upper_bounds   2.0   2.0
descriptors    'x1'   'x2'
scale_types     'value' 'log'
scales          4.0   0.1
```

7.4.5.5 scales

- **Keywords Area**
- **variables**
- **continuous_design**
- **scales**

Characteristic values to scale continuous design variables

**Specification**

**Alias:** cdv_scales

**Argument(s):** REALLIST

**Default:** vector values = 1. (no scaling)
Description

Each real value in scales is a nonzero characteristic value to be used in scaling each continuous design variable. They only have effect when the associated method specifies scaling.

This keyword is required for scale_types of ‘value’ and optional for ‘auto’ and ‘log’. When specified in conjunction with log, scale values are applied prior to the logarithm, to permit log scaling of strictly negative design variables.

If a single real value is specified it will apply to all continuous design variables. Otherwise, a scale value must be specified for each continuous design variable.

Usage Tips:

When scales are specified, but not scale_types, the scaling type is assumed to be ‘value’ for all continuous design variables.

Use scale values of 1.0 to selectively avoid scaling a subset of the variables.

Scaling for linear constraints is applied after any continuous variable scaling.

See the scaling information under specific methods, e.g., method-*-scaling for details on how to use this keyword.

Examples

Two continuous design variables, one scaled by the characteristic value 4.0, the other log-scaled without additional value scaling

```
continuous_design = 2
    initial_point -1.2 1.0
    lower_bounds -200 0.001
    upper_bounds 200 2.0
    descriptors ‘x1’ "x2"
    scale_types = ‘value’ ‘log’
    scales = 4.0 1.0
```
7.4.6 discrete_design_range

- Keywords Area

Description

These variables take on a range of integer values from the specified lower bound to the specified upper bound (integer interval). The details of how to specify this discrete variable are located on the discrete_variables page.

7.4.6.1 initial_point

- Keywords Area
- variables
- discrete_design_range
- initial_point

Initial values for variables
Specification

Alias: ddv_initial_point
Argument(s): INTEGERLIST
Default: 0

Description

Specifies the initial or default value a variable should assume, for example when starting a method or fixing the value of an inactive variable.

Default Behavior

Range variables, including continuous_design, continuous_state, discrete_design_range, and discrete_state_range are initialized to:

- Mean/midpoint (or next smaller integer value) when doubly-bounded
- 0 when unbounded
- 0 when semi-bounded and zero is in the half interval, otherwise to the specified lower or upper bound

Set variables, including discrete_design_set and discrete_state_set default to the middle (or next smaller) value of the ordered set of admissible values.

Uncertain variables default initialize to their mean (or nearest admissible discrete) value, truncating to any specified lower or upper bounds as needed. Epistemic uncertain variable means are calculated making a probabilistic assumption on the specified intervals or set values.

</tbody>
</table>

Description

A design variable whose values come from a specified set of admissible integers. The details of how to specify this discrete variable are located on the discrete_variables page.

Examples

Four integer variables whose values will be selected from the following sets during the search for an optimal design. y₁ ∈ {0, 1}, y₂ ∈ {0, 1}, y₃ ∈ {0, 5} and y₄ ∈ {10, 15, 20, 23}.

discrete_design_set
integer 4
descriptors 'y1' 'y2' 'y3' 'y4'
elements_per_variable 2 2 2 4
elements 0 1 0 5 10 15 20 23

7.4.7.1.1 elements_per_variable

- Keywords Area
- variables
- discrete_design_set
- integer
- elements_per_variable
Number of admissible elements for each set variable

Specification

Alias: num_set_values
Argument(s): INTEGERLIST
Default: equal distribution

Description

Discrete set variables (including design, uncertain, and state) take on only a fixed set of values. For each type (integer, string, or real), this keyword specifies how many admissible values are provided for each variable. If not specified, equal apportionment of elements among variables is assumed, and the number of elements must be evenly divisible by the number of variables.

7.4.7.1.2 elements

- Keywords Area
- variables
- discrete_design_set
- integer
- elements

The permissible values for each discrete variable

Specification

Alias: set_values
Argument(s): INTEGERLIST

Description

Specify the permissible values for discrete set variables (of type integer, string, or real). See the description on the discrete_variables page.

7.4.7.1.3 categorical

- Keywords Area
- variables
- discrete_design_set
- integer
- categorical

Whether the set-valued variables are categorical or relaxable
Specification

Alias: none

Argument(s): STRINGLIST

Child Keywords:
### Description

A list of strings of length equal to the number of set (integer, string, or real) variables indicating whether they are strictly categorical, meaning may only take on values from the provided set, or relaxable, meaning may take on any integer or real value between the lowest and highest specified element. Valid categorical strings include 'yes', 'no', 'true', and 'false', or any abbreviation in \[yYnNtTfF\]∗.

### Examples

Discrete\_design\_set variable, 'rotor\_blades', can take on only integer values, 2, 4, or 7 by default. Since categorical is specified to be false, the integrality can be relaxed and 'rotor\_blades' can take on any value between 2 and 7, e.g., 3, 6, or 5.5.

```
discrete\_design\_set
  integer 1
  elements 2 4 7
descriptor 'rotor\_blades'
categorical 'no'
```

### Specification

**Alias**: none  
**Argument(s)**: INTEGERLIST

### Default Behavior

The `adjacency_matrix` keyword is associated with `discrete\_design\_set` variables that are specified to be categorical. Each such variable is associated with one \(k \times k\) symmetric matrix, where \(k\) is the number of values (or levels) of the variable. Entry \(i, j\) of a matrix should be 1 if level \(i\) and level \(j\) are related by some subjective criteria or if \(i = j\); it should be 0 otherwise. The matrices for all variables of the same type (string, real, or integer) are entered sequentially as a list of integers as shown in the examples below.
The adjacency_matrix keyword is only relevant for discrete_design_set real and discrete_design_set integer variables if one or more of them have been specified to be categorical. It is always relevant for discrete_design_set string variables. If the user does not define an adjacency matrix, the default is method dependent. Currently, the only method that makes use of the adjacency matrix is mesh_adaptive_search, which uses a tri-diagonal adjacency matrix by default.

Expected Output
The expected output is method dependent.

Usage Tips
If an adjacency matrix is defined for one type of (categorical) discrete_design_set variable, it must be defined for all variables of that type, even for those not defined to be categorical. Those for the non-categorical set variables will be ignored.

Examples
The following example shows a variables specification where some real and some integer discrete_design_set variables are categorical.

```
variables
continuous_design = 3
  initial_point -1.0 1.5 2.0
  lower_bounds -10.0 -10.0 -10.0
  upper_bounds 10.0 10.0 10.0
descriptors 'x1' 'x2' 'x3'
discrete_design_range = 2
  initial_point 2 2
  lower_bounds 1 1
  upper_bounds 4 9
descriptors 'y1' 'y2'
discrete_design_set
  real = 2
elements_per_variable = 4 5
elements = 1.2 2.3 3.4 4.5 1.2 3.3 4.4 5.5 7.7
descriptors 'y3' 'y4'
categorical 'no' 'yes'
adjacency_matrix 1 1 0 0 # Begin entry of 4x4 matrix for y3
  1 1 1 0
  0 1 1 1
  0 0 1 1
  1 0 1 1 1 # Begin entry of 5x5 matrix for y4
  0 1 0 1 0
  1 0 1 0 1
  0 1 0 1 0
  1 0 1 0 1

discrete_design_set
  integer = 2
elements_per_variable = 2 3
elements = 4 7 8 9 12
descriptors 'z1' 'z2'
categorical 'yes' 'yes'
```

Note that for the real case, the user wants to define an adjacency matrix for the categorical variable, so adjacency matrices for both variables must be specified. The matrix for the first one will be ignored. Note that no adjacency matrix is specified for either integer categorical variable. The default will be used in both cases. Currently the only method taking advantage of adjacency matrices is mesh_adaptive_search, which uses a tri-diagonal adjacency matrix by default. Thus, the matrices used would be

```
z1: 1 1
   1 1
z2: 1 1 0
   1 1
   0 1
```

The following example shows a variables specification for string variables. Note that string variables are always
considered to be categorical. If an adjacency matrix is not specified, a method-dependent default matrix will be used.

```plaintext
variables,
  continuous_design = 2
  initial_point  0.5  0.5
  lower_bounds  0.  0.
  upper_bounds  1.  1.
  descriptors = 'x' 'y'
discrete_design_set string = 1
  elements = 'aniso1' 'aniso2' 'iso1' 'iso2' 'iso3'
descriptors = 'ancomp'
  adjacency_matrix
    1 1 0 0 0
    1 1 0 0 0
    0 0 1 1 1
    0 0 1 1 1
    0 0 1 1 1
```

7.4.7.2.3 adjacency_matrix

- Keywords Area
- variables
- discrete_design_set
- string
- adjacency_matrix

1-0 matrix defining which categorical variable levels are related.

Specification

Alias: none

Argument(s): INTEGERLIST
7.4 variables

Description

The adjacency_matrix keyword is associated with discrete_design_set variables that are specified to be categorical. Each such variable is associated with one \( k \times k \) symmetric matrix, where \( k \) is the number of values (or levels) of the variable. Entry \( i, j \) of a matrix should be 1 if level \( i \) and level \( j \) are related by some subjective criteria or if \( i = j \); it should be 0 otherwise. The matrices for all variables of the same type (string, real, or integer) are entered sequentially as a list of integers as shown in the examples below.

Default Behavior

The adjacency_matrix keyword is only relevant for discrete_design_set real and discrete_design_set integer variables if one or more of them have been specified to be categorical. It is always relevant for discrete_design_set string variables. If the user does not define an adjacency matrix, the default is method dependent. Currently, the only method that makes use of the adjacency matrix is mesh_adaptive_search, which uses a tri-diagonal adjacency matrix by default.

Expected Output

The expected output is method dependent.

Usage Tips

If an adjacency matrix is defined for one type of (categorical) discrete_design_set variable, it must be defined for all variables of that type, even for those not defined to be categorical. Those for the non-categorical set variables will be ignored.

Examples

The following example shows a variables specification where some real and some integer discrete_design_set variables are categorical.

```
variables
  continuous_design = 3
    initial_point -1.0 1.5 2.0
    lower_bounds -10.0 -10.0 -10.0
    upper_bounds 10.0 10.0 10.0
    descriptors 'x1' 'x2' 'x3'
  discrete_design_range = 2
    initial_point 2 2
    lower_bounds 1 1
    upper_bounds 4 9
    descriptors 'y1' 'y2'
  discrete_design_set
    real = 2
      elements_per_variable = 4 5
      elements = 1.2 2.3 3.4 4.5 1.2 3.3 4.4 5.5 7.7
      descriptors 'y3' 'y4'
      categorical 'no' 'yes'
      adjacency_matrix 1 1 0 0 # Begin entry of 4x4 matrix for y3
        1 1 0
        0 1 1
        0 0 1
        1 0 1 1 # Begin entry of 5x5 matrix for y4
        0 1 0 1 0
        1 0 1 0 1
        0 1 0 1 0
        1 0 1 0 1
    integer = 2
      elements_per_variable = 2 3
      elements = 4 7 8 9 12
      descriptors 'z1' 'z2'
      categorical 'yes' 'yes'
```
only method taking advantage of adjacency matrices is `mesh_adaptive_search`, which uses a tri-diagonal adjacency matrix by default. Thus, the matrices used would be

\[
\begin{bmatrix}
 1 & 1 \\
 1 & 1 \\
0 & 1 & 1 \\
\end{bmatrix}, \quad \begin{bmatrix}
1 & 1 & 0 \\
1 & 1 & 1 \\
0 & 1 & 1 \\
\end{bmatrix}
\]

The following example shows a variables specification for string variables. Note that string variables are always considered to be categorical. If an adjacency matrix is not specified, a method-dependent default matrix will be used.

```dakota
variables,
continuous_design = 2
  initial_point 0.5 0.5
  lower_bounds 0. 0.
  upper_bounds 1. 1.
  descriptors = 'x' 'y'
discrete_design_set string = 1
  elements = 'aniso1' 'aniso2' 'iso1' 'iso2' 'iso3'
  descriptors = 'ancomp'
  adjacency_matrix 1 1 0 0 0
                   1 1 0 0 0
                   0 0 1 1 1
                   0 0 1 1 1
```

Initial values for variables

Specification

Alias: none

Argument(s): STRINGLIST

Default: middle set value, or rounded down

Description

Specifies the initial or default value a variable should assume, for example when starting a method or fixing the value of an inactive variable.

Default Behavior
Range variables, including `continuous_design`, `continuous_state`, `discrete_design_range`, and `discrete_state_range` are initialized to:

- Mean/midpoint (or next smaller integer value) when doubly-bounded
- 0 when unbounded
- 0 when semi-bounded and zero is in the half interval, otherwise to the specified lower or upper bound

Set variables, including `discrete_design_set` and `discrete_state_set` default to the middle (or next smaller) value of the ordered set of admissible values.

Uncertain variables default initialize to their mean (or nearest admissible discrete) value, truncating to any specified lower or upper bounds as needed. Epistemic uncertain variable means are calculated making a probabilistic assumption on the specified intervals or set values.

7.4.7.2.5 descriptors

- Keywords Area
- variables
- discrete_design_set
- string
- descriptors

Labels for the variables

**Specification**

**Alias:** none

**Argument(s):** STRINGLIST

**Description**

The optional variable labels specification descriptors is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

7.4.7.3 real

- Keywords Area
- variables

Description

A design variable whose values come from a specified set of admissible reals. The details of how to specify this discrete variable are located on the discrete_variables page.

Examples

Two continuous, restricted variables whose values will be selected from the following sets during the search for an optimal design. \( y_1 \in \{0.25,1.25,2.25,3.25,4.25\}, y_2 \in \{0,5\} \)

```plaintext
discrete_design_set
   real 2
   descriptors 'y1' 'y2'
   elements_per_variable 5 2
elements 0.25 1.25 2.25 3.25 4.25 0 5
```
7.4 variables

7.4.7.3.1 elements_per_variable

- Keywords Area
- variables
- discrete_design_set
- real
- elements_per_variable

Number of admissible elements for each set variable

Specification

Alias: num_set_values
Argument(s): INTEGERLIST
Default: equal distribution

Description

Discrete set variables (including design, uncertain, and state) take on only a fixed set of values. For each type (integer, string, or real), this keyword specifies how many admissible values are provided for each variable. If not specified, equal apportionment of elements among variables is assumed, and the number of elements must be evenly divisible by the number of variables.

7.4.7.3.2 elements

- Keywords Area
- variables
- discrete_design_set
- real
- elements

The permissible values for each discrete variable

Specification

Alias: set_values
Argument(s): REALLIST

Description

Specify the permissible values for discrete set variables (of type integer, string, or real). See the description on the discrete_variables page.
Whether the set-valued variables are categorical or relaxable

**Specification**

**Alias:** none

**Argument(s):** STRINGLIST

<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>adjacency_matrix</td>
<td>1-0 matrix defining which categorical variable levels are related.</td>
</tr>
</tbody>
</table>

**Description**

A list of strings of length equal to the number of set (integer, string, or real) variables indicating whether they are strictly categorical, meaning may only take on values from the provided set, or relaxable, meaning may take on any integer or real value between the lowest and highest specified element. Valid categorical strings include ‘yes’, ‘no’, ‘true’, and ‘false’, or any abbreviation in [yYnNtTfF][.]

**Examples**

Discrete design set variable, ‘rotor_blades’, can take on only integer values, 2, 4, or 7 by default. Since categorical is specified to be false, the integrality can be relaxed and ‘rotor_blades’ can take on any value between 2 and 7, e.g., 3, 6, or 5.5.

```plaintext
discrete_design_set
  integer 1
  elements 2 4 7
  descriptor 'rotor_blades'
  categorical 'no'
```

**7.4.7.3.1 adjacency_matrix**

<table>

</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>adjacency_matrix</td>
<td>1-0 matrix defining which categorical variable levels are related.</td>
</tr>
</tbody>
</table>
7.4 variables

Speciation

Alias: none
Argument(s): INTEGERLIST

Description

The `adjacency_matrix` keyword is associated with `discrete_design_set` variables that are specified to be categorical. Each such variable is associated with one \( k \times k \) symmetric matrix, where \( k \) is the number of values (or levels) of the variable. Entry \( i, j \) of a matrix should be 1 if level \( i \) and level \( j \) are related by some subjective criteria or if \( i = j \); it should be 0 otherwise. The matrices for all variables of the same type (string, real, or integer) are entered sequentially as a list of integers as shown in the examples below.

Default Behavior

The `adjacency_matrix` keyword is only relevant for `discrete_design_set` real and `discrete_design_set` integer variables if one or more of them have been specified to be categorical. It is always relevant for `discrete_design_set` string variables. If the user does not define an adjacency matrix, the default is method dependent. Currently, the only method that makes use of the adjacency matrix is `mesh_adaptive_search`, which uses a tri-diagonal adjacency matrix by default.

Expected Output

The expected output is method dependent.

Usage Tips

If an adjacency matrix is defined for one type of (categorical) `discrete_design_set` variable, it must be defined for all variables of that type, even for those not defined to be categorical. Those for the non-categorical set variables will be ignored.

Examples

The following example shows a variables specification where some real and some integer `discrete_design_set` variables are categorical.

```plaintext
variables
    continuous_design = 3
    initial_point  -1.0  1.5  2.0
    lower_bounds   -10.0 -10.0 -10.0
    upper_bounds   10.0  10.0  10.0
    descriptors    'x1' 'x2' 'x3'
discrete_design_range = 2
    initial_point  2
    lower_bounds   1
    upper_bounds   4 9
    descriptors    'y1' 'y2'
discrete_design_set
    real = 2
        elements_per_variable = 4 5
        elements = 1.2 3.4 3.4 4.5 1.2 3.3 4.4 5.5 7.7
        descriptors 'y3' 'y4'
        categorical 'no' 'yes'
        adjacency_matrix 1 1 0 0 # Begin entry of 4x4 matrix for y3
          1 1 1 0
          0 1 1 0
          1 0 1 0 # Begin entry of 5x5 matrix for y4
          1 0 1 0
          1 0 1 0 1
        integer = 2
        elements_per_variable = 2
        elements = 4 7 8 9 12
```
Note that for the real case, the user wants to define an adjacency matrix for the categorical variable, so adjacency matrices for both variables must be specified. The matrix for the first one will be ignored. Note that no adjacency matrix is specified for either integer categorical variable. The default will be used in both cases. Currently the only method taking advantage of adjacency matrices is `mesh_adaptive_search`, which uses a tri-diagonal adjacency matrix by default. Thus, the matrices used would be

\[
\begin{array}{ccc}
1 & 1 \\
1 & 1 \\
\end{array}
\]

\[
\begin{array}{ccc}
1 & 1 & 0 \\
1 & 1 & 1 \\
0 & 1 & 1 \\
\end{array}
\]

The following example shows a variables specification for string variables. Note that string variables are always considered to be categorical. If an adjacency matrix is not specified, a method-dependent default matrix will be used.

```plaintext
variables,
  continuous_design = 2
  initial_point 0.5 0.5
  lower_bounds 0. 0.
  upper_bounds 1. 1.
  descriptors = 'x' 'y'
  discrete_design_set string = 1
  elements = 'aniso1' 'aniso2' 'iso1' 'iso2' 'iso3'
  descriptors = 'ancomp'
  adjacency_matrix 1 1 0 0 0
                   1 1 0 0 0
                   0 0 1 1 1
                   0 0 1 1 1
                   0 0 1 1 1
```

<td></td>
<td>descriptors</td>
<td>Labels for the variables</td>
</tr>
</tbody>
</table>

Description

The number of normal uncertain variables, their means, and standard deviations are required specifications, while the distribution lower and upper bounds and variable descriptors are optional specifications. The normal distribution is widely used to model uncertain variables such as population characteristics. It is also used to model the mean of a sample: as the sample size becomes very large, the Central Limit Theorem states that the distribution of the mean becomes approximately normal, regardless of the distribution of the original variables.

The density function for the normal distribution is:

\[
f(x) = \frac{1}{\sqrt{2\pi}\sigma} \exp \left( -\frac{1}{2} \left( \frac{x - \mu}{\sigma} \right)^2 \right)\]

where \(\mu\) and \(\sigma\) are the mean and standard deviation of the normal distribution, respectively.

Note that if you specify bounds for a normal distribution, the sampling occurs from the underlying distribution with the given mean and standard deviation, but samples are not taken outside the bounds (see "bounded normal" distribution type in [93]). This can result in the mean and the standard deviation of the sample data being different from the mean and standard deviation of the underlying distribution. For example, if you are sampling from a normal distribution with a mean of 5 and a standard deviation of 3, but you specify bounds of 1 and 7, the resulting mean of the samples will be around 4.3 and the resulting standard deviation will be around 1.6. This is because you have bounded the original distribution significantly, and asymmetrically, since 7 is closer to the original mean than 1.
Theory

When used with some methods such as design of experiments and multidimensional parameter studies, distribution bounds are inferred to be $[\mu - 3\sigma, \mu + 3\sigma]$.

For some methods, including vector and centered parameter studies, an initial point is needed for the uncertain variables. When not given explicitly, these variables are initialized to their means, correcting to bounds if needed.

</tbody>
</table>

Description

If the logarithm of an uncertain variable $X$ has a normal distribution, that is $\log X \sim N(\mu, \sigma)$, then $X$ is distributed with a lognormal distribution. The lognormal is often used to model:

1. time to perform some task
2. variables which are the product of a large number of other quantities, by the Central Limit Theorem
3. quantities which cannot have negative values.
The number of lognormal uncertain variables, their means, and either standard deviations or error factors must be specified, while the distribution lower and upper bounds and variable descriptors are optional specifications. These distribution bounds can be used to truncate the tails of lognormal distributions, which as for bounded normal, can result in the mean and the standard deviation of the sample data being different from the mean and standard deviation of the underlying distribution (see "bounded lognormal" and "bounded lognormal-n" distribution types in [93]).

For the lognormal variables, one may specify either the mean \( \mu \) and standard deviation \( \sigma \) of the actual lognormal distribution (option 1), the mean \( \mu \) and error factor \( \varepsilon \) of the actual lognormal distribution (option 2), or the mean \( \lambda \) ("lambda") and standard deviation \( \zeta \) ("zeta") of the underlying normal distribution (option 3).

The conversion equations from lognormal mean \( \mu \) and either lognormal error factor \( \varepsilon \) or lognormal standard deviation \( \sigma \) to the mean \( \lambda \) and standard deviation \( \zeta \) of the underlying normal distribution are as follows:

\[
\zeta = \frac{\ln(\varepsilon)}{1.645} \\
\zeta^2 = \ln\left(\frac{\sigma^2}{\mu^2} + 1\right) \\
\lambda = \ln(\mu) - \frac{\zeta^2}{2}
\]

Conversions from \( \lambda \) and \( \zeta \) back to \( \mu \) and \( \varepsilon \) or \( \sigma \) are as follows:

\[
\mu = \exp\left(\lambda + \frac{\zeta^2}{2}\right) \\
\sigma^2 = \exp(2\lambda + \zeta^2) (\exp(\zeta^2) - 1) \\
\varepsilon = \exp(1.645\zeta)
\]

The density function for the lognormal distribution is:

\[
f(x) = \frac{1}{\sqrt{2\pi}\zeta x} \exp\left(-\frac{1}{2} \left(\frac{\ln(x) - \lambda}{\zeta}\right)^2\right)
\]

**Theory**

When used with some methods such as design of experiments and multidimensional parameter studies, distribution bounds are inferred to be \([0, \mu + 3\sigma]\).

For some methods, including vector and centered parameter studies, an initial point is needed for the uncertain variables. When not given explicitly, these variables are initialized to their means, correcting to bounds if needed.

<td>Optional</td>
<td></td>
<td>descriptors</td>
<td>Labels for the variables</td>
</tr>
</tbody>
</table>
Description

The number of uniform uncertain variables and their distribution lower and upper bounds are required specifications, while variable descriptors is an optional specification. The uniform distribution has the density function:

$$f(x) = \frac{1}{U-L}$$

where $U$ and $L$ are the upper and lower bounds of the uniform distribution, respectively. The mean of the uniform distribution is $\frac{U+L}{2}$ and the variance is $\frac{(U-L)^2}{12}$.

Theory

This distribution is a special case of the more general beta distribution.

For some methods, including vector and centered parameter studies, an initial point is needed for the uncertain variables. When not given explicitly, these variables are initialized to their means.

7.4 variables

Description

If the logarithm of an uncertain variable $X$ has a uniform distribution, that is $\log X \sim U(L_{LU}, U_{LU})$, then $X$ is distributed with a loguniform distribution. The distribution lower bound is $L_{LU}$ and upper bound is $U_{LU}$. The loguniform distribution has the density function:

$$f(x) = \frac{1}{x (\ln(U_{LU}) - \ln(L_{LU}))}$$

Theory

For some methods, including vector and centered parameter studies, an initial point is needed for the uncertain variables. When not given explicitly, these variables are initialized to their means.

7.4.11.1 lower_bounds

- Keywords Area
- variables
- loguniform_uncertain
- lower_bounds

Specify minimum values

Specification

Alias: luuv_lower_bounds

Argument(s): REALLIST

Description

Specify minimum values

7.4.11.2 upper_bounds

- Keywords Area
- variables
- loguniform_uncertain
- upper_bounds

Specify maximum values

Specification

Alias: luuv_upper_bounds

Argument(s): REALLIST

Description

Specify maximum values
7.4.11.3 initial_point

- Keywords Area
- variables
- loguniform_uncertain
- initial_point

Initial values for variables

Specification

Alias: none
Argument(s): REALLIST

Description

Specifies the initial or default value a variable should assume, for example when starting a method or fixing the value of an inactive variable.

Default Behavior

Range variables, including continuous_design, continuous_state, discrete_design_range, and discrete_state_range are initialized to:

- Mean/midpoint (or next smaller integer value) when doubly-bounded
- 0 when unbounded
- 0 when semi-bounded and zero is in the half interval, otherwise to the specified lower or upper bound

Set variables, including discrete_design_set and discrete_state_set default to the middle (or next smaller) value of the ordered set of admissible values.

Uncertain variables default initialize to their mean (or nearest admissible discrete) value, truncating to any specified lower or upper bounds as needed. Epistemic uncertain variable means are calculated making a probabilistic assumption on the specified intervals or set values.

7.4.11.4 descriptors

- Keywords Area
- variables
- loguniform_uncertain
- descriptors

Labels for the variables

Specification

Alias: luuv_descriptors
Argument(s): STRINGLIST
Default: luuv_{i}
7.4 variables

Description

The optional variable labels specification descriptors is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

7.4.12 triangular_uncertain

- Keywords Area
- variables
- triangular_uncertain

Aleatory uncertain variable - triangular

Topics

This keyword is related to the topics:
- continuous_variables
- aleatory_uncertain_variables

Specification

Alias: none

Argument(s): INTEGER

Default: no triangular uncertain variables

Child Keywords:

Description

The triangular distribution is often used when one does not have much data or information, but does have an estimate of the most likely value and the lower and upper bounds. The number of triangular uncertain variables, the modes, and the distribution lower and upper bounds are required specifications, while variable descriptors is an optional specification.
The density function for the triangular distribution is:

\[ f(x) = \frac{2(x - L)}{(U - L)(M - L)} \]

if \( L \leq x \leq M \), and

\[ f(x) = \frac{2(U - x)}{(U - L)(U - M)} \]

if \( M \leq x \leq U \), and 0 elsewhere. In these equations, \( L \) is the lower bound, \( U \) is the upper bound, and \( M \) is the mode of the triangular distribution.

7.4.12.1 modes

- Keywords Area
- variables
- triangular_uncertain
- modes

Distribution parameter

Specification

Alias: tuv_modes

Argument(s): REALLIST

Description

Specify the modes

7.4.12.2 lower_bounds

- Keywords Area
- variables
- triangular_uncertain
- lower_bounds

Specify minimum values

Specification

Alias: tuv_lower_bounds

Argument(s): REALLIST

Description

Specify minimum values
7.4 variables

7.4.12.3  upper_bounds

- Keywords Area
- variables
- triangular_uncertain
- upper_bounds

Specify maximum values

Specification

**Alias:** tuv_upper_bounds

**Argument(s):** REALLIST

Description

Specify maximum values

7.4.12.4  initial_point

- Keywords Area
- variables
- triangular_uncertain
- initial_point

Initial values for variables

Specification

**Alias:** none

**Argument(s):** REALLIST

Description

Specifies the initial or default value a variable should assume, for example when starting a method or fixing the value of an inactive variable.

**Default Behavior**

Range variables, including continuous_design, continuous_state, discrete_design_range, and discrete_state_range are initialized to:

- Mean/midpoint (or next smaller integer value) when doubly-bounded
- 0 when unbounded
- 0 when semi-bounded and zero is in the half interval, otherwise to the specified lower or upper bound
Set variables, including `discrete_design_set` and `discrete_state_set` default to the middle (or next smaller) value of the ordered set of admissible values.

Uncertain variables default initialize to their mean (or nearest admissible discrete) value, truncating to any specified lower or upper bounds as needed. Epistemic uncertain variable means are calculated making a probabilistic assumption on the specified intervals or set values.

7.4.12.5 descriptors

- Keywords Area
- variables
- triangular_uncertain
- descriptors

Labels for the variables

Specification

**Alias:** `tuv_descriptors`

**Argument(s):** STRINGLIST

**Default:** `tuv_[i]`

**Description**

The optional variable labels specification `descriptors` is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

7.4.13 exponential_uncertain

- Keywords Area
- variables
- exponential_uncertain

Aleatory uncertain variable - exponential

**Topics**

This keyword is related to the topics:

- continuous_variables
- aleatory_uncertain_variables
Specification

**Alias**: none

**Argument(s)**: INTEGER

**Default**: no exponential uncertain variables

**Child Keywords**: 
The exponential distribution is often used for modeling failure rates. The density function for the exponential distribution is given by:

\[ f(x) = \frac{1}{\beta} \exp\left(-\frac{x}{\beta}\right) \]

where \( \mu_E = \beta \) and \( \sigma^2_E = \beta^2 \).

Note that this distribution is a special case of the more general gamma distribution.

Theory

When used with some methods such as design of experiments and multidimensional parameter studies, distribution bounds are inferred to be [0, \( \mu + 3\sigma \)].

For some methods, including vector and centered parameter studies, an initial point is needed for the uncertain variables. When not given explicitly, these variables are initialized to their means.

7.4.13.1 betas

- Keywords Area
- variables
- exponential_uncertain
- betas

Parameter of the exponential distribution

Specification

**Alias:** euv_betas

**Argument(s):** REALLIST

**Description:**

Specifies the list of \( \beta \) parameters to define the distributions of the exponential random variables. Length must match the other parameters and the number of exponential random variables.
7.4 variables

7.4.13.2 initial_point

- Keywords Area
- variables
- exponential_uncertain
- initial_point

Initial values for variables

Specification

Alias: none
Argument(s): REALLIST

Description

Specifies the initial or default value a variable should assume, for example when starting a method or fixing the value of an inactive variable.

Default Behavior

Range variables, including continuous_design, continuous_state, discrete_design_range, and discrete_state_range are initialized to:

- Mean/midpoint (or next smaller integer value) when doubly-bounded
- 0 when unbounded
- 0 when semi-bounded and zero is in the half interval, otherwise to the specified lower or upper bound

Set variables, including discrete_design_set and discrete_state_set default to the middle (or next smaller) value of the ordered set of admissible values.

Uncertain variables default initialize to their mean (or nearest admissible discrete) value, truncating to any specified lower or upper bounds as needed. Epistemic uncertain variable means are calculated making a probabilistic assumption on the specified intervals or set values.

7.4.13.3 descriptors

- Keywords Area
- variables
- exponential_uncertain
- descriptors

Labels for the variables

Specification

Alias: euv_descriptors
Argument(s): STRINGLIST
Default: euv_[i]
Description

The optional variable labels specification descriptors is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

7.4.14 beta_uncertain

- Keywords Area
- variables
- beta_uncertain

Aleatory uncertain variable - beta

Topics

This keyword is related to the topics:

- continuous_variables
- aleatory_uncertain_variables

Specification

Alias: none

Argument(s): INTEGER

Default: no beta uncertain variables

</tbody>
</table>

Description

The number of beta uncertain variables, the alpha and beta parameters, and the distribution upper and lower bounds are required specifications, while the variable descriptors is an optional specification. The beta distribution can be
helpful when the actual distribution of an uncertain variable is unknown, but the user has a good idea of the bounds, the mean, and the standard deviation of the uncertain variable. The density function for the beta distribution is

\[ f(x) = \frac{\Gamma(\alpha + \beta)}{\Gamma(\alpha)\Gamma(\beta)} \frac{(x - L)^{\alpha-1}(U - x)^{\beta-1}}{(U - L)^{\alpha+\beta-1}} \]

where \( \Gamma(\alpha) \) is the gamma function and \( B(\alpha, \beta) = \frac{\Gamma(\alpha)\Gamma(\beta)}{\Gamma(\alpha+\beta)} \) is the beta function. To calculate the mean and standard deviation from the alpha, beta, upper bound, and lower bound parameters of the beta distribution, the following expressions may be used.

\[ \mu = L + \frac{\alpha}{\alpha + \beta}(U - L) \]

\[ \sigma^2 = \frac{\alpha\beta}{(\alpha + \beta)^2(\alpha + \beta + 1)}(U - L)^2 \]

Solving these for \( \alpha \) and \( \beta \) gives:

\[ \alpha = (\mu - L)(\mu - L)(U - \mu) - \sigma^2 \]

\[ \beta = (U - \mu)(\mu - L)(U - \mu) - \sigma^2 \]

Note that the uniform distribution is a special case of this distribution for parameters \( \alpha = \beta = 1 \).

### Theory

For some methods, including vector and centered parameter studies, an initial point is needed for the uncertain variables. When not given explicitly, these variables are initialized to their means.

7.4.14.1 alphas

- **Keywords** Area
- **variables**
- **beta_uncertain**
- **alphas**

First parameter of the beta distribution

**Specification**

**Alias:** buv_alphas

**Argument(s):** REALLIST

**Description**

Specifies the list of \( \alpha \) parameters to define the distributions of the beta random variables. Length must match the other parameters and the number of beta random variables.
7.4.14.2 betas

- Keywords Area
- variables
- beta_uncertain

7.4.14.5 initial_point

• Keywords Area
  • variables
  • beta_uncertain
  • initial_point

Initial values for variables

Specification

Alias: none

Argument(s): REALLIST

Description

Specifies the initial or default value a variable should assume, for example when starting a method or fixing the value of an inactive variable.

Default Behavior

Range variables, including continuous_design, continuous_state, discrete_design_range, and discrete_state_range are initialized to:

• Mean/midpoint (or next smaller integer value) when doubly-bounded

• 0 when unbounded

• 0 when semi-bounded and zero is in the half interval, otherwise to the specified lower or upper bound

Set variables, including discrete_design_set and discrete_state_set default to the middle (or next smaller) value of the ordered set of admissible values.

Uncertain variables default initialize to their mean (or nearest admissible discrete) value, truncating to any specified lower or upper bounds as needed. Epistemic uncertain variable means are calculated making a probabilistic assumption on the specified intervals or set values.

7.4.14.6 descriptors

• Keywords Area
  • variables
• beta_uncertain
• descriptors

Labels for the variables

Specification

Alias: buv_descriptors
Argument(s): STRINGLIST
Default: buv_{i}

Description

The optional variable labels specification descriptors is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

7.4.15 gamma_uncertain

• Keywords Area
• variables
• gamma_uncertain

Aleatory uncertain variable - gamma

Topics

This keyword is related to the topics:

**Description**

The gamma distribution is sometimes used to model time to complete a task, such as a repair or service task. It is a very flexible distribution with its shape governed by alpha and beta.

The density function for the gamma distribution is given by:

\[
f(x) = \frac{x^{\alpha-1} \exp \left( \frac{-x}{\beta} \right)}{\beta^\alpha \Gamma(\alpha)},
\]

\[
\mu = \alpha \beta, \quad \sigma^2 = \alpha \beta^2.
\]

Note that the exponential distribution is a special case of this distribution for parameter \( \alpha = 1 \).

**Theory**

When used with some methods such as design of experiments and multidimensional parameter studies, distribution bounds are inferred to be \([0, \mu + 3\sigma]\).

For some methods, including vector and centered parameter studies, an initial point is needed for the uncertain variables. When not given explicitly, these variables are initialized to their means.

**Description**

The Gumbel distribution is also referred to as the Type I Largest Extreme Value distribution. The distribution of maxima in sample sets from a population with a normal distribution will asymptotically converge to this distribution. It is commonly used to model demand variables such as wind loads and flood levels.

The density function for the Gumbel distribution is given by:

\[
f(x) = \alpha \exp\left(-\alpha(x - \beta)\right) \exp\left(-e^{-\alpha(x - \beta)}\right),
\]

\[\mu = \beta + \frac{0.5772}{\alpha}, \quad \text{and} \quad \sigma = \frac{\pi}{\sqrt{6} \alpha}.\]

**Theory**

When used with some methods such as design of experiments and multidimensional parameter studies, distribution bounds are inferred to be \([\mu - 3\sigma, \mu + 3\sigma]\).

For some methods, including vector and centered parameter studies, an initial point is needed for the uncertain variables. When not given explicitly, these variables are initialized to their means.

### Description

The Frechet distribution is also referred to as the Type II Largest Extreme Value distribution. The distribution of maxima in sample sets from a population with a lognormal distribution will asymptotically converge to this distribution. It is commonly used to model non-negative demand variables.

The density function for the frechet distribution is:

\[
f(x) = \frac{\alpha}{\beta} \left( \frac{\beta}{x} \right)^{\alpha + 1} \exp \left( -\left( \frac{\beta}{x} \right)^\alpha \right),
\]

\[
\mu = \beta \Gamma(1 - \frac{1}{\alpha}), \text{ and } \sigma^2 = \beta^2 \left[ \Gamma(1 - \frac{2}{\alpha}) - \Gamma^2(1 - \frac{1}{\alpha}) \right]
\]

### Theory

When used with some methods such as design of experiments and multidimensional parameter studies, distribution bounds are inferred to be \([0, \mu + 3\sigma]\).

For some methods, including vector and centered parameter studies, an initial point is needed for the uncertain variables. When not given explicitly, these variables are initialized to their means.

#### 7.4.17.1 alphas

Specifies the list of $\beta$ parameters to define the distributions of the Weibull random variables. Length must match the other parameters and the number of Weibull random variables.

7.4.18.3 initial_point

- **Keywords Area**
- **variables**
- **weibull_uncertain**
- **initial_point**

Initial values for variables

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Description**

Specifies the initial or default value a variable should assume, for example when starting a method or fixing the value of an inactive variable.

**Default Behavior**

Range variables, including `continuous_design`, `continuous_state`, `discrete_design_range`, and `discrete_state_range` are initialized to:

- Mean/midpoint (or next smaller integer value) when doubly-bounded
- 0 when unbounded
- 0 when semi-bounded and zero is in the half interval, otherwise to the specified lower or upper bound

Set variables, including `discrete_design_set` and `discrete_state_set` default to the middle (or next smaller) value of the ordered set of admissible values.

Uncertain variables default initialize to their mean (or nearest admissible discrete) value, truncating to any specified lower or upper bounds as needed. Epistemic uncertain variable means are calculated making a probabilistic assumption on the specified intervals or set values.
7.4.18 descriptors

- Keywords Area
- variables
- weibull_uncertain
- descriptors

Labels for the variables

Specification

Alias: wuv_descriptors

Argument(s): STRINGLIST

Default: wuv_{i}

Description

The optional variable labels specification descriptors is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

7.4.19 histogram_bin_uncertain

- Keywords Area
- variables
- histogram_bin_uncertain

Aleatory uncertain variable - continuous histogram

Topics

This keyword is related to the topics:

- continuous_variables
- aleatory_uncertain_variables

Specification

Alias: none

Argument(s): INTEGER

Default: no histogram bin uncertain variables

Child Keywords:
Description

Histogram uncertain variables are typically used to model a set of empirical data. The bin histogram (contrast: histogram_point_uncertain) is a continuous aleatory distribution characterized by bins of non-zero width where the uncertain variable may lie, together with the relative frequencies of each bin. Hence it can be used to specify a marginal probability density function arising from data.

The histogram_bin_uncertain keyword specifies the number of variables to be characterized as continuous histograms. The required sub-keywords are: abscissas (ranges of values the variable can take on) and either ordinates or counts (characterizing each variable’s frequency information). When using histogram bin variables, each variable must be defined by at least one bin (with two bounding value pairs). When more than one histogram bin variable is active, pairs_per_variable can be used to specify unequal apportionment of provided bin pairs among the variables.

The abscissas specification defines abscissa values (”x” coordinates) for the probability density function of each histogram variable. When paired with counts, the specifications provide sets of (x,c) pairs for each histogram variable where c defines a count (i.e., a frequency or relative probability) associated with a bin. If using bins of unequal width and specification of probability densities is more natural, then the counts specification can be replaced with an ordinates specification (”y” coordinates) in order to support interpretation of the input as (x,y) pairs defining the profile of a ”skyline” probability density function.

Conversion between the two specifications is straightforward: a count/frequency is a cumulative probability quantity defined from the product of the ordinate density value and the x bin width. Thus, in the cases of bins of equal width, ordinate and count specifications are equivalent. In addition, ordinates and counts may be relative values; it is not necessary to scale them as all user inputs will be normalized.

To fully specify a bin-based histogram with n bins (potentially of unequal width), n+1 (x,c) or (x,y) pairs must be specified with the following features:

• x is the parameter value for the left boundary of a histogram bin and c is the corresponding count for that bin. Alternatively, y defines the ordinate density value for this bin within a skyline probability density function. The right boundary of the bin is defined by the left boundary of the next pair.

• the final pair specifies the right end of the last bin and must have a c or y value of zero.
• the $x$ values must be strictly increasing.

• all $c$ or $y$ values must be positive, except for the last which must be zero.

• a minimum of two pairs must be specified for each bin-based histogram variable.

Examples

The `pairs_per_variable` specification provides for the proper association of multiple sets of $(x,c)$ or $(x,y)$ pairs with individual histogram variables. For example, in this input snippet

```plaintext
histogram_bin_uncertain = 2
pairs_per_variable = 3 4
abscissas = 5 8 10 .1 .2 .3 .4
counts = 17 21 0 12 24 12 0
descriptors = 'hbu_1' 'hbu_2'
```

`pairs_per_variable` associates the first 3 $(x,c)$ pairs from `abscissas` and `counts` as follows: the first bin is defined between 5 and 8 with a count of 17 and another bin is defined between 8 and 10 with a count of 21. The following set of 4 $(x,c)$ pairs defines a second bin-based histogram variable containing three equal-width bins with counts 12, 24, and 12 (middle bin is twice as probable as the other two).

See Also

These keywords may also be of interest:

• `histogram_point_uncertain`

FAQ

**Difference between bin and point histograms:** A (continuous) bin histogram specifies bins of non-zero width, whereas a (discrete) point histogram specifies individual point values, which can be thought of as bins with zero width. In the terminology of LHS [93], the bin pairs specification defines a "continuous linear" distribution and the point pairs specification defines a "discrete histogram" distribution (although the points are real-valued, the number of possible values is finite).
Description

By default, the list of abscissas and counts or ordinates will be evenly divided among the histogram_bin_uncertain variables. pairs_per_variable is a list of integers that specify the number of pairs to apportion to each variable.

7.4.19.2 abscissas

- Keywords Area
- variables
- histogram_bin_uncertain
- abscissas

Real abscissas for a bin histogram

Specification

Alias: huv_bin_abscissas

Argument(s): REALLIST

Description

A list of real abscissa ("x" coordinate) values characterizing the probability density function for each of the histogram_bin_uncertain variables. These are paired with either counts or ordinates. See histogram_bin_uncertain for details and examples.

7.4.19.3 ordinates

- Keywords Area
- variables
- histogram_bin_uncertain
- ordinates

Ordinates specifying a "skyline" probability density function

Specification

Alias: huv_bin_ordinates

Argument(s): REALLIST

Description

The ordinates list of real values defines the profile of a "skyline" probability density function by pairing with the specified abscissas. See histogram_bin_uncertain for details.
7.4.19.4 counts

- Keywords Area
- variables
- histogram_bin_uncertain
- counts

Frequency or relative probability of each bin

Specification

**Alias:** huv_bin_counts

**Argument(s):** REALLIST

Description

The counts list of real values gives the frequency or relative probability for each bin in a histogram_bin_uncertain specification. These are paired with the specified abscissas. See histogram_bin_uncertain for details.

7.4.19.5 initial_point

- Keywords Area
- variables
- histogram_bin_uncertain
- initial_point

Initial values for variables

Specification

**Alias:** none

**Argument(s):** REALLIST

Description

Specifies the initial or default value a variable should assume, for example when starting a method or fixing the value of an inactive variable.

**Default Behavior**

Range variables, including continuous_design, continuous_state, discrete_design_range, and discrete_state_range are initialized to:

- Mean/midpoint (or next smaller integer value) when doubly-bounded
- 0 when unbounded
- 0 when semi-bounded and zero is in the half interval, otherwise to the specified lower or upper bound
Set variables, including `discrete_design_set` and `discrete_state_set` default to the middle (or next smaller) value of the ordered set of admissible values.

Uncertain variables default initialize to their mean (or nearest admissible discrete) value, truncating to any specified lower or upper bounds as needed. Epistemic uncertain variable means are calculated making a probabilistic assumption on the specified intervals or set values.

### 7.4.19.6 descriptors

- **Keywords Area**
- **variables**
- **histogram_bin_uncertain**
- **descriptors**

Labels for the variables

**Specification**

**Alias:** `huv_bin_descriptors`

**Argument(s):** STRINGLIST

**Default:** `hbuv_{i}`

**Description**

The optional variable labels specification `descriptors` is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

### 7.4.20 poisson_uncertain

- **Keywords Area**
- **variables**
- **poisson_uncertain**

Aleatory uncertain discrete variable - Poisson

**Topics**

This keyword is related to the topics:

- `discrete_variables`
- `aleatory_uncertain_variables`
Specification

**Alias**: none

**Argument(s)**: INTEGER

**Default**: no poisson uncertain variables

**Child Keywords**: 
The Poisson distribution is used to predict the number of discrete events that happen in a single time interval. The random events occur uniformly and independently. The expected number of occurrences in a single time interval is \( \lambda \), which must be a positive real number. For example, if events occur on average 4 times per year and we are interested in the distribution of events over six months, \( \lambda \) would be 2. However, if we were interested in the distribution of events occurring over 5 years, \( \lambda \) would be 20.

The probability mass function for the poisson distribution is given by:

\[
f(x) = \frac{\lambda^x e^{-\lambda}}{x!}
\]

where

- \( \lambda \) is the expected number of events occurring in a single time interval
- \( x \) is the number of events that occur in this time period
- \( f(x) \) is the probability that \( x \) events occur in this time period

### Theory

When used with some methods such as design of experiments and multidimensional parameter studies, distribution bounds are inferred to be \([0, \mu + 3\sigma]\).

For some methods, including vector and centered parameter studies, an initial point is needed for the uncertain variables. When not given explicitly, these variables are initialized to their means.

#### 7.4.20.1 lambdas

- **Keywords Area**
- **variables**
- **poisson_uncertain**
- **lambdas**

The parameter for the Poisson distribution, the expected number of events in the time interval of interest

### Specification

**Alias**: none

**Argument(s)**: REALLIST
Description

The density function for the Poisson distribution is given by:

\[ f(x) = \frac{\lambda e^{-\lambda}}{x!} \]

where \( \lambda \) is the frequency of events happening, and \( x \) is the number of events that occur.

7.4.20.2 initial_point

- Keywords Area
- variables
- poisson_uncertain
- initial_point

Initial values for variables

Specification

Alias: none

Argument(s): INTEGERLIST

Description

Specifies the initial or default value a variable should assume, for example when starting a method or fixing the value of an inactive variable.

Default Behavior

Range variables, including continuous_design, continuous_state, discrete_design_range, and discrete_state_range are initialized to:

- Mean/midpoint (or next smaller integer value) when doubly-bounded
- 0 when unbounded
- 0 when semi-bounded and zero is in the half interval, otherwise to the specified lower or upper bound

Set variables, including discrete_design_set and discrete_state_set default to the middle (or next smaller) value of the ordered set of admissible values.

Uncertain variables default initialize to their mean (or nearest admissible discrete) value, truncating to any specified lower or upper bounds as needed. Epistemic uncertain variable means are calculated making a probabilistic assumption on the specified intervals or set values.

7.4.20.3 descriptors

- Keywords Area
- variables
- poisson_uncertain
- descriptors

Labels for the variables
Specification

Alias: none
Argument(s): STRINGLIST
Default: $puv_{[i]}$

Description

The optional variable labels specification descriptors is a list of strings which identify the variables. These are used in console and tabular output.
The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

**Description**

The binomial distribution describes probabilities associated with a series of independent Bernoulli trials. A Bernoulli trial is an event with two mutually exclusive outcomes, such as 0 or 1, yes or no, success or fail. The probability of success remains the same (the trials are independent).

The density function for the binomial distribution is given by:

\[ f(x) = \binom{n}{x} p^x (1-p)^{n-x} \]

where \( p \) is the probability of failure per trial, \( n \) is the number of trials and \( x \) is the number of successes.

**Theory**

The binomial distribution is typically used to predict the number of failures or defective items in a total of \( n \) independent tests or trials, where each trial has the probability \( p \) of failing or being defective.

7.4.21.1 probability_per_trial

- **Keywords Area**
- **variables**
- **binomial_uncertain**
- **probability_per_trial**

A distribution parameter for the binomial distribution

**Specification**

**Alias:** prob_per_trial

**Argument(s):** REALLIST

**Description**

The binomial distribution is typically used to predict the number of failures (or defective items or some type of event) in a total of \( n \) independent tests or trials, where each trial has the probability \( p \) of failing or being defective. Each particular test can be considered as a Bernoulli trial.

7.4.21.2 num_trials

7.4.24 hypergeometric_uncertain

- Keywords Area
- variables
- hypergeometric_uncertain

Aleatory uncertain discrete variable - hypergeometric

Topics

This keyword is related to the topics:

- discrete_variables
- aleatory_uncertain_variables

Specification

Alias: none

Argument(s): INTEGER

Default: no hypergeometric uncertain variables

Child Keywords:
The hypergeometric probability density is used when sampling without replacement from a total population of elements where

- The resulting element of each sample can be separated into one of two non-overlapping sets
- The probability of success changes with each sample.

The density function for the hypergeometric distribution is given by:

\[
f(x) = \binom{m}{x} \binom{N-m}{n-x} \binom{N}{n}
\]

where the three distribution parameters are:

- N is the total population
- m is the number of items in the selected population (e.g. the number of white balls in the full urn of N items)
- n is the size of the sample drawn (e.g. number of balls drawn)

In addition,

- x, the abscissa of the density function, indicates the number of successes (e.g. drawing a white ball)
- \( \binom{a}{b} \) indicates a binomial coefficient ("a choose b")
The hypergeometric is often described using an urn model. For example, say we have a total population containing \( N \) balls, and we know that \( m \) of the balls are white and the remaining balls are green. If we draw \( n \) balls from the urn without replacement, the hypergeometric distribution describes the probability of drawing \( x \) white balls.

7.4.24.1  total_population

- Keywords Area
- variables
- hypergeometric_uncertain
- total_population

Parameter for the hypergeometric probability distribution describing the size of the total population

**Specification**

**Alias:** none

**Argument(s):** INTEGERLIST

**Description**

The density function for the hypergeometric distribution is given by:

\[
f(x) = \binom{m}{x} \binom{N-m}{n-x} \binom{N}{n}
\]

where the three distribution parameters are:

- \( N \) is the total population
- \( m \) is the number of items in the selected population (e.g. the number of white balls in the full urn of \( N \) items)
- \( n \) is the size of the sample drawn (e.g. number of balls drawn)

In addition,

- \( x \), the abscissa of the density function, indicates the number of successes (e.g. drawing a white ball)

**Child Keywords:**
Histogram uncertain variables are typically used to model a set of empirical data. When the variables take on only discrete values or categories, a discrete, or point histogram is used to describe their probability mass function (one could think of this as a histogram_bin_uncertain variable with "bins" of zero width). Dakota supports integer-, string-, and real-valued point histograms.

Point histograms are similar to discrete_design_set and discrete_state_set, but as they are uncertain variables, include the relative probabilities of observing the different values within the set.

The histogram_point_uncertain keyword is followed by one or more of integer, string, or real, each of which specify the number of variables to be characterized as discrete histograms of that sub-type.

Each discrete histogram variable is specified by one or more abscissa/count pairs. The abscissas, are the possible values the variable can take on ("x" coordinates of type integer, string, or real), and must be specified in increasing order. These are paired with counts c which provide the frequency of the given value or string, relative to other possible values/strings.

Thus, to fully specify a point-based histogram with n points, n (x,c) pairs must be specified with the following features:

- x is the point value (integer, string, or real) and c is the corresponding count for that value.
- the x values must be strictly increasing (lexicographically for strings).
- all c values must be positive.
- a minimum of one pair must be specified for each point-based histogram.

Examples

The pairs_per_variable specification provides for the proper association of multiple sets of (x,c) or (x,y) pairs with individual histogram variables. For example, in the following specification,

```
histogram_point_uncertain
  integer = 2
  pairs_per_variable = 2 3
  abscissas = 3 4 100 200 300
  counts = 1 1 1 2 1
```

pairs_per_variable associates the (x,c) pairs ((3,1),(4,1)) with one point-based histogram variable (where the values 3 and 4 are equally probable) and associates the (x,c) pairs ((100,1),(200,2),(300,1)) with a second point-based histogram variable (where the value 200 is twice as probable as either 100 or 300).

These keywords may also be of interest:

- histogram_bin_uncertain

FAQ

**Difference between bin and point histograms:** A (continuous) bin histogram specifies bins of non-zero width, whereas a (discrete) point histogram specifies individual point values, which can be thought of as bins with zero width. In the terminology of LHS [93], the bin pairs specification defines a "continuous linear" distribution and the point pairs specification defines a "discrete histogram" distribution (although the points are real-valued, the number of possible values is finite).

**Description**

This probability mass function is integer-valued; the abscissa values must all be integers. The \( n \) abscissa values are paired with \( n \) counts which indicate the relative frequency (mass) of each integer relative to the other specified integers.

**Examples**

```plaintext
histogram_point_uncertain
  integer = 2
  pairs_per_variable = 2 3
  abscissas = 3 4 100 200 300
  counts = 1 1 1 2 1
```

There are two variables, the first one has two possible integer values which are equally probable. The second one has three options, and 200 is twice as probable as either 100 or 300.

7.4.25.1.1 pairs_per_variable

- **Keywords** Area
- **variables**
- **histogram_point_uncertain**
- **integer**
- **pairs_per_variable**

Number of pairs defining each histogram point integer variable

**Specification**

**Alias:** num_pairs

**Argument(s):** INTEGERLIST

**Default:** equal distribution

**Description**

By default, the list of abscissas and counts will be evenly divided among the histogram point integer variables. The number of pairs_per_variable specifies the apportionment of abscissa/count pairs among the histogram point integer variables. It must specify one integer \( \geq 1 \) per variable that indicates how many of the \((\text{abscissa, count}) = (x,c)\) pairs to associate with that variable.

7.4.25.1.2 abscissas

- **Keywords** Area
- **variables**
- **histogram_point_uncertain**
- **integer**
• abscissas

Integer abscissas for a point histogram

Specification

Alias: none

Argument(s): INTEGERLIST

Description

A list of integer abscissa ("x" coordinate) values characterizing the probability density function for each of the integer histogram_point_uncertain variables. These must be listed in increasing order for each variable, and are paired with counts. See histogram_point_uncertain for details and examples.

7.4.25.1.3 counts

• Keywords Area
  • variables
    • histogram_point_uncertain
    • integer
    • counts

Counts for integer-valued point histogram

Specification

Alias: none

Argument(s): REALLIST

Description

Count or frequency for each of abscissas. See histogram_point_uncertain for details and examples.

7.4.25.1.4 initial_point

• Keywords Area
  • variables
    • histogram_point_uncertain
    • integer
    • initial_point

Initial values for variables

Specification

Alias: none

Argument(s): INTEGERLIST
Description

Specifies the initial or default value a variable should assume, for example when starting a method or fixing the value of an inactive variable.

Default Behavior

Range variables, including continuous_design, continuous_state, discrete_design_range, and discrete_state_range are initialized to:

- Mean/midpoint (or next smaller integer value) when doubly-bounded
- 0 when unbounded
- 0 when semi-bounded and zero is in the half interval, otherwise to the specified lower or upper bound

Set variables, including discrete_design_set and discrete_state_set default to the middle (or next smaller) value of the ordered set of admissible values.

Uncertain variables default initialize to their mean (or nearest admissible discrete) value, truncating to any specified lower or upper bounds as needed. Epistemic uncertain variable means are calculated making a probabilistic assumption on the specified intervals or set values.

7.4.25.1.5 descriptors

- Keywords Area
- variables
- histogram_point_uncertain
- integer
- descriptors

Labels for the variables

Specification

Alias: none

Argument(s): STRINGLIST

Default: hpiv_{i}

Description

The optional variable labels specification descriptors is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

7.4.25.2 string

- Keywords Area
- variables
- histogram_point_uncertain
- string

String (categorical) valued point histogram variable
Specification

**Alias:** none

**Argument(s):** INTEGER

**Child Keywords:**

<table>

</tr>
</tbody>
</table>

**Description**

This probability mass function is string-valued; the abscissa values must all be strings. The \( n \) abscissa values are paired with \( n \) counts which indicate the relative frequency (mass) of each string relative to the other specified strings.

**Examples**

```plaintext
histogram_point_uncertain
string = 2
pairs_per_variable = 2 3
abscissas = 'no' 'yes' 'function1' 'function2' 'function3'
counts = 1 1 1 2 1
descriptors = 'vote' 'which_function'
```

Here there are two variables, the first one ('vote') has two possible string values 'yes' and 'no' which are equally probable. The second one has three options for 'which_function', and 'function2' is twice as probable as 'function1' or 'function3'.

- initial_point

Initial values for variables

Specification

Alias: none

Argument(s): REALLIST

Description

Specifies the initial or default value a variable should assume, for example when starting a method or fixing the value of an inactive variable.

Default Behavior

Range variables, including continuous_design, continuous_state, discrete_design_range, and discrete_state_range are initialized to:
• Mean/midpoint (or next smaller integer value) when doubly-bounded

• 0 when unbounded

• 0 when semi-bounded and zero is in the half interval, otherwise to the specified lower or upper bound

Set variables, including `discrete_design_set` and `discrete_state_set` default to the middle (or next smaller) value of the ordered set of admissible values.

Uncertain variables default initialize to their mean (or nearest admissible discrete) value, truncating to any specified lower or upper bounds as needed. Epistemic uncertain variable means are calculated making a probabilistic assumption on the specified intervals or set values.

7.4.25.3.5 descriptors

• Keywords Area
• variables
• histogram_point_uncertain
• real
• descriptors

Labels for the variables

Specification

Alias: none

Argument(s): STRINGLIST

Default: hpruv_{i}

Description

The optional variable labels specification descriptors is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

7.4.26 uncertain_correlation_matrix

• Keywords Area
• variables
• uncertain_correlation_matrix

Correlation among aleatory uncertain variables

Specification

Alias: none

Argument(s): REALLIST

Default: identity matrix (uncorrelated)
Description

Aleatory uncertain variables may have correlations specified through use of an uncertain_correlation_matrix specification. This specification is generalized in the sense that its specific meaning depends on the nondeterministic method in use.

When the method is a nondeterministic sampling method (i.e., sampling), then the correlation matrix specifies rank correlations [53].

When the method is a reliability (i.e., local_reliability or global_reliability) or stochastic expansion (i.e., polynomial_chaos or stoch_collocation) method, then the correlation matrix specifies correlation coefficients (normalized covariance) [43].

In either of these cases, specifying the identity matrix results in uncorrelated uncertain variables (the default). The matrix input should be symmetric and have all \( n^2 \) entries where \( n \) is the total number of aleatory uncertain variables.

Ordering of the aleatory uncertain variables is:

1. normal
2. lognormal
3. uniform
4. loguniform
5. triangular
6. exponential
7. beta
8. gamma
9. gumbel
10. frechet
11. weibull
12. histogram bin
13. poisson
14. binomial
15. negative binomial
16. geometric
17. hypergeometric
18. histogram point

When additional variable types are activated, they assume uniform distributions, and the ordering is as listed on variables.

Examples

Consider the following random variables, distributions and correlations:

- \( X_1 \), normal, uncorrelated with others
- \( X_2 \), normal, correlated with \( X_3, X_4 \) and \( X_5 \)
- \( X_3 \), weibull, correlated with \( X_5 \)
• $X_4$, exponential, correlated with $X_3$, $X_4$ and $X_5$
• $X_5$, normal, correlated with $X_3$ These correlations are captured by the following commands (order of the variables is respected).

```
uncertain_correlation_matrix
# ordering normal, exponential, weibull
# $X_1$ $X_2$ $X_5$ $X_4$ $X_3$
1.00 0.00 0.00 0.00 0.00
0.00 1.00 0.50 0.24 0.78
0.00 0.50 1.00 0.00 0.20
0.00 0.24 0.00 1.00 0.49
0.00 0.78 0.20 0.49 1.0
```

### 7.4.27 continuous_interval_uncertain

</tbody>
</table>
Continuous interval uncertain variables are epistemic types. They can specify a single interval per variable which may be used in interval analysis, where the goal is to determine the interval bounds on the output corresponding to the interval bounds on the input. All values between the bounds are permissible. More detailed continuous interval representations can specify a set of belief structures based on intervals that may be contiguous, overlapping, or disjoint. This is used in specifying the inputs necessary for an epistemic uncertainty analysis using Dempster-Shafer theory of evidence.

Other epistemic types include:

- `discrete_interval_uncertain`
- `discrete_uncertain_set integer`
- `discrete_uncertain_set string`
- `discrete_uncertain_set real`

**Examples**

The following specification is for an interval analysis:

```plaintext
continuous_interval_uncertain = 2
lower_bounds = 2.0 4.0
upper_bounds = 2.5 5.0
```

The following specification is for a Dempster-Shafer analysis:

```plaintext
continuous_interval_uncertain = 2
num_intervals = 3 2
interval_probs = 0.25 0.5 0.25 0.4 0.6
lower_bounds = 2.0 4.0 4.5 1.0 3.0
upper_bounds = 2.5 5.0 6.0 5.0 5.0
```

Here there are 2 interval uncertain variables. The first one is defined by three intervals, and the second by two intervals. The three intervals for the first variable have basic probability assignments of 0.2, 0.5, and 0.3, respectively, while the basic probability assignments for the two intervals for the second variable are 0.4 and 0.6. The basic probability assignments for each interval variable must sum to one. The interval bounds for the first variable are [2, 2.5], [4, 5], and [4.5, 6], and the interval bounds for the second variable are [1.0, 5.0] and [3.0, 5.0]. Note that the intervals can be overlapping or disjoint. The BPA for the first variable indicates that it is twice as likely that the value occurs on the interval [4,5] than either [2,2.5] or [4.5,6].

**Theory**

The continuous interval uncertain variable is NOT a probability distribution. Although it may seem similar to a histogram, the interpretation of this uncertain variable is different. It is used in epistemic uncertainty analysis, where one is trying to model uncertainty due to lack of knowledge. The continuous interval uncertain variable is used in both interval analysis and in Dempster-Shafer theory of evidence.

- interval analysis -only one interval is allowed for each `continuous_interval_uncertain variable`
- the interval is defined by lower and upper bounds -the value of the random variable lies somewhere in this interval -output is the minimum and maximum function value conditional on the specified interval
• Dempster-Shafer theory of evidence - multiple intervals can be assigned to each continuous_interval_uncertain variable. A Basic Probability Assignment (BPA) is associated with each interval. The BPA represents a probability that the value of the uncertain variable is located within that interval. Each interval is defined by lower and upper bounds. Outputs are called "belief" and "plausibility." Belief represents the smallest possible probability that is consistent with the evidence, while plausibility represents the largest possible probability that is consistent with the evidence. Evidence is the intervals together with their BPA.

7.4.27.1 num_intervals

• Keywords Area

• variables

• continuous_interval_uncertain

• num_intervals

Specify the number of intervals for each variable

Specification

Alias: iuv_num_intervals

Argument(s): INTEGERLIST

Default: Equal apportionment of intervals among variables

Description

In Dakota, epistemic uncertainty analysis is performed using either interval estimation or Dempster-Shafer theory of evidence. In these approaches, one does not assign a probability distribution to each uncertain input variable. Rather, one divides each uncertain input variable into one or more intervals. The input parameters are only known to occur within intervals; nothing more is assumed. num_intervals specifies the number of such intervals associated with each interval uncertain parameter.

7.4.27.2 interval_probabilities

• Keywords Area

• variables

• continuous_interval_uncertain

• interval_probabilities

Assign probability mass to each interval

Specification

Alias: interval_probs iuv_interval_probs

Argument(s): REALLIST

Default: Equal probability assignments for each interval (1/num_intervals[i])
Description

The basic probability assignments for each interval variable must sum to one. For example, if an interval variable is defined with three intervals, the probabilities for these intervals could be 0.2, 0.5, and 0.3 which sum to one, but could not be 0.5, 0.5, and 0.5 which do not sum to one.

Description

Specify maximum values
7.4.27.5  initial_point

- Keywords Area
- variables
  - continuous_interval_uncertain
  - initial_point

Initial values for variables

Specification

Alias: none
Argument(s): REALLIST

Description

Specifies the initial or default value a variable should assume, for example when starting a method or fixing the value of an inactive variable.

Default Behavior

Range variables, including continuous_design, continuous_state, discrete_design_range, and discrete_state_range are initialized to:

- Mean/midpoint (or next smaller integer value) when doubly-bounded
- 0 when unbounded
- 0 when semi-bounded and zero is in the half interval, otherwise to the specified lower or upper bound

Set variables, including discrete_design_set and discrete_state_set default to the middle (or next smaller) value of the ordered set of admissible values.

Uncertain variables default initialize to their mean (or nearest admissible discrete) value, truncating to any specified lower or upper bounds as needed. Epistemic uncertain variable means are calculated making a probabilistic assumption on the specified intervals or set values.

7.4.27.6  descriptors

- Keywords Area
- variables
  - continuous_interval_uncertain
  - descriptors

Labels for the variables

Specification

Alias: iuv_descriptors
Argument(s): STRINGLIST
Default: ciuv_[i]
Description

The optional variable labels specification `descriptors` is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

7.4.28 discrete_interval_uncertain

- **Keywords Area**
- **variables**
- **discrete_interval_uncertain**

Epistemic uncertain variable - values from one or more discrete intervals

Topics

This keyword is related to the topics:

Description

Discrete interval uncertain variables are epistemic types. They can specify a single interval per variable which may be used in interval analysis, where the goal is to determine the interval bounds on the output corresponding to the
interval bounds on the input. Permissible values are any integer within the bound. More detailed continuous interval representations can specify a set of belief structures based on intervals that may be contiguous, overlapping, or disjoint. This is used in specifying the inputs necessary for an epistemic uncertainty analysis using Dempster–Shafer theory of evidence.

Other epistemic types include:

- `continuous_interval_uncertain`
- `discrete_uncertain_set integer`
- `discrete_uncertain_set string`
- `discrete_uncertain_set real`

**Examples**

Let $d1$ be 2, 3 or 4 with probability 0.2, 4 or 5 with probability 0.5 and 6 with probability 0.3. Let $d2$ be 4, 5 or 6 with probability 0.4 and 6, 7 or 8 with probability 0.6. The following specification is for a Dempster-Shafer analysis:

```
discrete_interval_uncertain = 2
num_intervals = 3 2
interval_probs = 0.2 0.5 0.3 0.4 0.6
lower_bounds = 2 4 6 4 6
upper_bounds = 4 5 6 6 8
```

**Theory**

- Dempster-Shafer theory of evidence - multiple intervals can be assigned to each `discrete_interval_uncertain` variable - a Basic Probability Assignment (BPA) is associated with each interval. The BPA represents a probability that the value of the uncertain variable is located within that interval. - each interval is defined by lower and upper bounds - outputs are called “belief” and “plausibility.” Belief represents the smallest possible probability that is consistent with the evidence, while plausibility represents the largest possible probability that is consistent with the evidence. Evidence is the intervals together with their BPA.

7.4.28.1 num_intervals

- **Keywords Area**
- **variables**
- `discrete_interval_uncertain`
- **num_intervals**

Specify the number of intervals for each variable

**Specification**

**Alias:** none

**Argument(s):** INTEGERLIST

**Default:** Equal apportionment of intervals among variables
Description

In Dakota, epistemic uncertainty analysis is performed using either interval estimation or Dempster-Shafer theory of evidence. In these approaches, one does not assign a probability distribution to each uncertain input variable. Rather, one divides each uncertain input variable into one or more intervals. The input parameters are only known to occur within intervals; nothing more is assumed. `num_intervals` specifies the number of such intervals associated with each interval uncertain parameter.

### 7.4.28.2 interval_probabilities

- Keywords Area
- variables
- `discrete_interval_uncertain`
- `interval_probabilities`

Assign probability mass to each interval

**Specification**

**Alias:** `interval_probs` range_probabilities range_probs

**Argument(s):** REALIST

**Default:** Equal probability assignments for each interval (1/num_intervals[i])

**Description**

The basic probability assignments for each interval variable must sum to one. For example, if an interval variable is defined with three intervals, the probabilities for these intervals could be 0.2, 0.5, and 0.3 which sum to one, but could not be 0.5,0.5, and 0.5 which do not sum to one.

### 7.4.28.3 lower_bounds

- Keywords Area
- variables
- `discrete_interval_uncertain`
- `lower_bounds`

Specify minimum values

**Specification**

**Alias:** none

**Argument(s):** INTEGERLIST

**Description**

Specify minimum values
7.4.28.4 upper_bounds

- Keywords Area
- variables
- discrete_interval_uncertain
- upper_bounds

Specify maximum values

Specification

Alias: none

Argument(s): INTEGERLIST

Description

Specify maximum values

7.4.28.5 initial_point

- Keywords Area
- variables
- discrete_interval_uncertain
- initial_point

Initial values for variables

Specification

Alias: none

Argument(s): INTEGERLIST

Description

Specifies the initial or default value a variable should assume, for example when starting a method or fixing the value of an inactive variable.

Default Behavior

Range variables, including continuous_design, continuous_state, discrete_design_range, and discrete_state_range are initialized to:

- Mean/midpoint (or next smaller integer value) when doubly-bounded
- 0 when unbounded
- 0 when semi-bounded and zero is in the half interval, otherwise to the specified lower or upper bound
Set variables, including `discrete_design_set` and `discrete_state_set` default to the middle (or next smaller) value of the ordered set of admissible values.

Uncertain variables default initialize to their mean (or nearest admissible discrete) value, truncating to any specified lower or upper bounds as needed. Epistemic uncertain variable means are calculated making a probabilistic assumption on the specified intervals or set values.

### 7.4.28.6 descriptors

- Keywords Area
- variables
- `discrete_interval_uncertain`
- descriptors

Labels for the variables

**Specification**

**Alias**: none

**Argument(s)**: STRINGLIST

**Default**: `diuv_{i}`

**Description**

The optional variable labels specification `descriptors` is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

### 7.4.29 discrete_uncertain_set

- Keywords Area
- variables
- `discrete_uncertain_set`

Epistemic uncertain variable - discrete set-valued

**Topics**

This keyword is related to the topics:

- `discrete_variables`
- `epistemic_uncertain_variables`

**Specification**

**Alias**: none

**Argument(s)**: none

**Description**

Discrete set variables may be used to specify categorical choices which are epistemic. For example, if we have three possible forms for a physics model (model 1, 2, or 3) and there is epistemic uncertainty about which one is correct, a discrete uncertain set may be used to represent this type of uncertainty.

This variable is defined by a set of integers, in which the discrete value may take any value within the integer set (for example, the set may be defined as 1, 2, and 4)

Other epistemic types include:

- `continuous_interval_uncertain`
- `discrete_interval_uncertain`
- `discrete_uncertain_set string`
- `discrete_uncertain_set real`

**Examples**

Let d1 be 2 or 13 and d2 be 4, 5 or 26. The following specification is for an interval analysis:

```plaintext
discrete_uncertain_set
   integer
   num_set_values 2 3
   set_values 2 13 4 5 26
   descriptors 'di1' 'di2'
```

---

Dakota Version 6.16 Reference Manual generated on May 12, 2022
Theory

The `discrete_uncertain_set-integer` variable is NOT a discrete random variable. It can be contrasted to the histogram-defined random variables: `histogram_bin_uncertain` and `histogram_point_uncertain`. It is used in epistemic uncertainty analysis, where one is trying to model uncertainty due to lack of knowledge.

The discrete uncertain set integer variable is used in both interval analysis and in Dempster-Shafer theory of evidence.

- **interval analysis** - the values are integers, equally weighted - the true value of the random variable is one of the integers in this set - output is the minimum and maximum function value conditional on the specified inputs

- **Dempster-Shafer theory of evidence** - the values are integers, but they can be assigned different weights - outputs are called "belief" and "plausibility." Belief represents the smallest possible probability that is consistent with the evidence, while plausibility represents the largest possible probability that is consistent with the evidence. Evidence is the values together with their weights.

7.4.29.1.1 elements_per_variable

- **Keywords Area**
- **variables**
- **discrete_uncertain_set**
- **integer**
- **elements_per_variable**

Number of admissible elements for each set variable

**Specification**

**Alias:** num_set_values

**Argument(s):** INTEGERLIST

**Default:** equal distribution

**Description**

Discrete set variables (including design, uncertain, and state) take on only a fixed set of values. For each type (integer, string, or real), this keyword specifies how many admissible values are provided for each variable. If not specified, equal apportionment of elements among variables is assumed, and the number of elements must be evenly divisible by the number of variables.

7.4.29.1.2 elements

- **Keywords Area**
- **variables**
- **discrete_uncertain_set**
- **integer**
- **elements**

The permissible values for each discrete variable
7.4 variables

Specification

Alias: set_values
Argument(s): INTEGERLIST

Description

Specify the permissible values for discrete set variables (of type integer, string, or real). See the description on the discrete_variables page.

7.4.29.1.3 set_probabilities

- Keywords Area
- variables
- discrete_uncertain_set
- integer
- set_probabilities

This keyword defines the probabilities for the various elements of discrete sets.

Specification

Alias: set_probs
Argument(s): REALLIST
Default: Equal probability assignments for each set member (1/num_set_values[i])

Description

There are three types of discrete_uncertain_set variables: integer, string, or real sets. With each of these types, one defines the number of elements of the set per that variable, the values of those elements, and the associated probabilities. For example, if one has an integer discrete uncertain set variable with 3 elements {3,4,8}, then one could define the probabilities associated with those set elements as (for example) 0.2, 0.5, and 0.3. The set_probabilities for a particular variable should sum to one over all the elements in that set.

7.4.29.1.4 categorical

- Keywords Area
- variables
- discrete_uncertain_set
- integer
- categorical

Whether the set-valued variables are categorical or relaxable

Specification

Alias: none
Argument(s): STRINGLIST
Description

A list of strings of length equal to the number of set (integer, string, or real) variables indicating whether they are strictly categorical, meaning may only take on values from the provided set, or relaxable, meaning may take on any integer or real value between the lowest and highest specified element. Valid categorical strings include ‘yes’, ‘no’, ‘true’, and ‘false’, or any abbreviation in [yYnNtTfF].

Examples

Discrete_design_set variable, ‘rotor_blades’, can take on only integer values, 2, 4, or 7 by default. Since categorical is specified to be false, the integrality can be relaxed and ‘rotor_blades’ can take on any value between 2 and 7, e.g., 3, 6, or 5.5.

discrete_design_set
  integer 1
  elements 2 4 7
  descriptor ‘rotor_blades’
  categorical ‘no’

7.4.29.1.5 initial_point

• Keywords Area
• variables
• discrete_uncertain_set
  • integer
  • initial_point

Initial values for variables

Specification

Alias: none

Argument(s): INTEGERLIST

Description

Specifies the initial or default value a variable should assume, for example when starting a method or fixing the value of an inactive variable.

Default Behavior

Range variables, including continuous_design, continuous_state, discrete_design_range, and discrete_state_range are initialized to:

• Mean/midpoint (or next smaller integer value) when doubly-bounded

• 0 when unbounded

• 0 when semi-bounded and zero is in the half interval, otherwise to the specified lower or upper bound

Set variables, including discrete_design_set and discrete_state_set default to the middle (or next smaller) value of the ordered set of admissible values.

Uncertain variables default initialize to their mean (or nearest admissible discrete) value, truncating to any specified lower or upper bounds as needed. Epistemic uncertain variable means are calculated making a probabilistic assumption on the specified intervals or set values.
7.4 variables

7.4.29.1.6 descriptors

- Keywords Area
- variables
- discrete_uncertain_set
- integer
- descriptors

Labels for the variables

Specification

Alias: none
Argument(s): STRINGLIST
Default: dusiv_{i}

Description

The optional variable labels specification descriptors is a list of strings which identify the variables. These are used in console and tabular output.
The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

7.4.29.2 string

- Keywords Area
- variables
- discrete_uncertain_set
- string

Discrete, epistemic uncertain variable - strings within a set

Topics

This keyword is related to the topics:

- discrete_variables
- epistemic_uncertain_variables

Specification

Alias: none
Argument(s): INTEGER
Default: no discrete uncertain set string variables
Child Keywords:
Discrete set variables may be used to specify categorical choices which are epistemic. Description

Discrete set variables may be used to specify categorical choices which are epistemic. For example, if we have three possible forms for a physics model (model 1, 2, or 3) and there is epistemic uncertainty about which one is correct, a discrete uncertain set may be used to represent this type of uncertainty.

This variable is defined by a set of reals, in which the discrete variable may take any value defined within the real set (for example, a parameter may have two allowable real values, 3.285 or 4.79).

Other epistemic types include:

- continuous_interval_uncertain
- discrete_interval_uncertain
- discrete_uncertain_set integer
- discrete_uncertain_set string

Examples

Let $d1$ be 2.1 or 1.3 and $d2$ be 0.4, 5 or 2.6. The following specification is for an interval analysis:

```
 discrete_uncertain_set
  integer
  num_set_values 2 3
  set_values 2.1 1.3 0.4 5 2.6
  descriptors 'd1' 'd2'
```

Theory

The `discrete_uncertain_set_integer` variable is NOT a discrete random variable. It can be contrasted to the histogram-defined random variables: `histogram_bin_uncertain` and `histogram_point_uncertain`. It is used in epistemic uncertainty analysis, where one is trying to model uncertainty due to lack of knowledge.

The `discrete_uncertain_set integer` variable is used in both interval analysis and in Dempster-Shafer theory of evidence.
• interval analysis - the values are integers, equally weighted - the true value of the random variable is one of the integers in this set - output is the minimum and maximum function value conditional on the specified inputs.

• Dempster-Shafer theory of evidence - the values are integers, but they can be assigned different weights - outputs are called "belief" and "plausibility." Belief represents the smallest possible probability that is consistent with the evidence, while plausibility represents the largest possible probability that is consistent with the evidence. Evidence is the values together with their weights.

### 7.4.29.3.1 elements_per_variable

**Description**

Discrete state variables defined by bounds (an integer interval).

The details of how to specify this discrete variable are located on the [discrete.variables](#) page.

See the [state.variables](#) page for details on the behavior of state variables.

### 7.4.31.1 initial_state

- **Keywords Area**
  - variables
    - discrete_state_range
    - initial_state

**Initial values for variables**

**Specification**

*Alias*: dsv_initial_state

*Argument(s):* INTEGERLIST

*Default*: 0

**Description**

Specifies the initial or default value a variable should assume, for example when starting a method or fixing the value of an inactive variable.

**Default Behavior**

Range variables, including continuous_design, continuous_state, discrete_design_range, and discrete_state_range are initialized to:

- Mean/midpoint (or next smaller integer value) when doubly-bounded
- 0 when unbounded
- 0 when semi-bounded and zero is in the half interval, otherwise to the specified lower or upper bound
Set variables, including `discrete_design_set` and `discrete_state_set` default to the middle (or next smaller) value of the ordered set of admissible values.

Uncertain variables default initialize to their mean (or nearest admissible discrete) value, truncating to any specified lower or upper bounds as needed. Epistemic uncertain variable means are calculated making a probabilistic assumption on the specified intervals or set values.

### 7.4.31.2 lower_bounds

- **Keywords Area**
- **variables**
- **discrete_state_range**
- **lower_bounds**

Specify minimum values

#### Specification

**Alias:** `dsv_lower_bounds`

**Argument(s):** INTEGERLIST

**Default:** INT_MIN

**Description**

Specify minimum values

### 7.4.31.3 upper_bounds

- **Keywords Area**
- **variables**
- **discrete_state_range**
- **upper_bounds**

Specify maximum values

#### Specification

**Alias:** `dsv_upper_bounds`

**Argument(s):** INTEGERLIST

**Default:** INT_MAX

**Description**

Specify maximum values
7.4.31.4  descriptors

- Keywords Area
- variables
- discrete_state_range
- descriptors

Labels for the variables

Specification

**Alias:** dsv_descriptors

**Argument(s):** STRINGLIST

**Default:** dsriv_{i}

**Description**

The optional variable labels specification descriptors is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

7.4.32  discrete_state_set

- Keywords Area
- variables
- discrete_state_set

State variable - discrete set-valued

Topics

This keyword is related to the topics:

- discrete_variables
- state_variables

Specification

**Alias:** none

**Argument(s):** none

**Child Keywords:**

Dakota Version 6.16 Reference Manual generated on May 12, 2022
Description

Discrete state variables whose values come from a set of admissible elements. Each variable specified must be of type integer, string, or real.

7.4.32.1 integer

- Keywords Area
- variables
- discrete_state_set
- integer

Discrete state variables, each defined by a set of permissible integers

Topics

This keyword is related to the topics:

- discrete_variables
- state_variables

Specification

Alias: none

Argument(s): INTEGER

Default: no discrete state set integer variables

Child Keywords:
### Description

Discrete state variables defined by a set of permissible integers.

The details of how to specify this discrete variable are located on the `discrete_variables` page.

See the `state_variables` page for details on the behavior of state variables.

### 7.4.32.1.1 elements_per_variable

- **Keywords Area**
- **variables**
- **discrete_state_set**
- **integer**
- **elements_per_variable**

Number of admissible elements for each set variable

### Specification

**Alias:** num_set_values

**Argument(s):** INTEGERLIST

**Default:** equal distribution

### Description

Discrete set variables (including design, uncertain, and state) take on only a fixed set of values. For each type (integer, string, or real), this keyword specifies how many admissible values are provided for each variable. If not specified, equal apportionment of elements among variables is assumed, and the number of elements must be evenly divisible by the number of variables.
7.4 variables

7.4.32.1.2 elements

- Keywords Area
- variables
- discrete_state_set
- integer
- elements

The permissible values for each discrete variable

Specification

Alias: set_values

Argument(s): INTEGERLIST

Description

Specify the permissible values for discrete set variables (of type integer, string, or real). See the description on the discrete_variables page.

7.4.32.1.3 categorical

- Keywords Area
- variables
- discrete_state_set
- integer
- categorical

Whether the set-valued variables are categorical or relaxable

Specification

Alias: none

Argument(s): STRINGLIST

Description

A list of strings of length equal to the number of set (integer, string, or real) variables indicating whether they are strictly categorical, meaning may only take on values from the provided set, or relaxable, meaning may take on any integer or real value between the lowest and highest specified element. Valid categorical strings include 'yes', 'no', 'true', and 'false', or any abbreviation in [yYnNtTfF][.]*

Examples

Discrete_design_set variable, 'rotor_blades', can take on only integer values, 2, 4, or 7 by default. Since categorical is specified to be false, the integrality can be relaxed and 'rotor_blades' can take on any value between 2 and 7, e.g., 3, 6, or 5.5.
discrete_design_set
  integer 1
     elements 2 4 7
descriptor 'rotor_blades'
  categorical 'no'

7.4.32.1.4 initial_state

  • Keywords Area
  • variables
  • discrete_state_set
    • integer
      • initial_state

Initial values for variables

Specification

Alias: none

Argument(s): INTEGERLIST

Default: middle set value, or rounded down

Description

Specifies the initial or default value a variable should assume, for example when starting a method or fixing the value of an inactive variable.

Default Behavior

Range variables, including continuous_design, continuous_state, discrete_design_range, and discrete_state_range are initialized to:

  • Mean/midpoint (or next smaller integer value) when doubly-bounded
  • 0 when unbounded
  • 0 when semi-bounded and zero is in the half interval, otherwise to the specified lower or upper bound

Set variables, including discrete_design_set and discrete_state_set default to the middle (or next smaller) value of the ordered set of admissible values.

Uncertain variables default initialize to their mean (or nearest admissible discrete) value, truncating to any specified lower or upper bounds as needed. Epistemic uncertain variable means are calculated making a probabilistic assumption on the specified intervals or set values.

7.4.32.1.5 descriptors

  • Keywords Area
  • variables
  • discrete_state_set
    • integer
      • descriptors

Labels for the variables
7.4 variables

Specification

Alias: none
Argument(s): STRINGLIST
Default: dssiv_{i}

Description

The optional variable labels specification descriptors is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

7.4.32.2 string

• Keywords Area
  • variables
    • discrete_state_set
  • string

String-valued discrete state set variables

Topics

This keyword is related to the topics:

• discrete_variables
  • state_variables

Specification

Alias: none
Argument(s): INTEGER
Default: no discrete state set string variables

Child Keywords:

### Description

Discrete state variables whose values come from a specified set of admissible strings. The details of how to specify this discrete variable are located on the `discrete_variables` page. See the `state_variables` page for details on the behavior of state variables. Each string element value must be quoted and may contain alphanumeric, dash, underscore, and colon. White space, quote characters, and backslash/metacharacters are not permitted.

#### 7.4.32.2.1 elements_per_variable

- **Keywords Area**
- **variables**
- **discrete_state_set**
- **string**
- **elements_per_variable**

Number of admissible elements for each set variable

#### Specification

**Alias:** `num_set_values`

**Argument(s):** `INTEGERLIST`

**Default:** equal distribution

#### Description

Discrete set variables (including design, uncertain, and state) take on only a fixed set of values. For each type (integer, string, or real), this keyword specifies how many admissible values are provided for each variable. If not specified, equal apportionment of elements among variables is assumed, and the number of elements must be evenly divisible by the number of variables.

#### 7.4.32.2.2 elements

- **Keywords Area**
- **variables**
- **discrete_state_set**
- **string**
- **elements**

The permissible values for each discrete variable
7.4 variables

Specification

Alias: set_values
Argument(s): STRINGLIST

Description

Specify the permissible values for discrete set variables (of type integer, string, or real). See the description on the discrete_variables page.

7.4.32.2.3 initial_state

- Keywords Area
- variables
- discrete_state_set
- string
- initial_state

Initial values for variables

Specification

Alias: none
Argument(s): STRINGLIST
Default: middle set value, or rounded down

Description

Specifies the initial or default value a variable should assume, for example when starting a method or fixing the value of an inactive variable.

Default Behavior

Range variables, including continuous_design, continuous_state, discrete_design_range, and discrete_state_range are initialized to:

- Mean/midpoint (or next smaller integer value) when doubly-bounded
- 0 when unbounded
- 0 when semi-bounded and zero is in the half interval, otherwise to the specified lower or upper bound

Set variables, including discrete_design_set and discrete_state_set default to the middle (or next smaller) value of the ordered set of admissible values.

Uncertain variables default initialize to their mean (or nearest admissible discrete) value, truncating to any specified lower or upper bounds as needed. Epistemic uncertain variable means are calculated making a probabilistic assumption on the specified intervals or set values.
7.4.32.4 descriptors

- Keywords Area
- variables
- discrete_state_set
- string
- descriptors

Labels for the variables

Specification

**Alias:** none

**Argument(s):** STRINGLIST

**Default:** dsssv_{i}

Description

The optional variable labels specification descriptors is a list of strings which identify the variables. These are used in console and tabular output.

The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

7.4.32.3 real

- Keywords Area
- variables
- discrete_state_set
- real

Discrete state variables, each defined by a set of permissible real numbers

Topics

This keyword is related to the topics:

- discrete_variables
- state_variables

Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** no discrete state set real variables

**Child Keywords:**
### 7.4 variables

#### Description

Discrete state variables defined by a set of permissible real numbers. The details of how to specify this discrete variable are located on the discrete_variables page. See the state_variables page for details on the behavior of state variables.

#### 7.4.32.3.1 elements_per_variable

- **Keywords Area**
  - variables
  - discrete_state_set
  - real
  - elements_per_variable

Number of admissible elements for each set variable

#### Specification

**Alias:** num_set_values

**Argument(s):** INTEGERLIST

**Default:** equal distribution

#### Description

Discrete set variables (including design, uncertain, and state) take on only a fixed set of values. For each type (integer, string, or real), this keyword specifies how many admissible values are provided for each variable. If not specified, equal apportionment of elements among variables is assumed, and the number of elements must be evenly divisible by the number of variables.
The permissible values for each discrete variable

**Specification**

**Alias:** set_values

**Argument(s):** REALLIST

**Description**

Specify the permissible values for discrete set variables (of type integer, string, or real). See the description on the discrete_variables page.

**Examples**

Discrete_design_set variable, 'rotor_blades', can take on only integer values, 2, 4, or 7 by default. Since categorical is specified to be false, the integrality can be relaxed and 'rotor_blades' can take on any value between 2 and 7, e.g., 3, 6, or 5.5.
7.4 variables

discrete_design_set
    integer 1
        elements 2 4 7
descriptor ‘rotor_blades’
categorical ‘no’

7.4.32.3.4 initial_state

- Keywords Area
- variables
- discrete_state_set
- real
- initial_state

Initial values for variables

Specification

Alias: none

Argument(s): REALLIST

Default: middle set value, or rounded down

Description

Specifies the initial or default value a variable should assume, for example when starting a method or fixing the value of an inactive variable.

Default Behavior

Range variables, including continuous_design, continuous_state, discrete_design_range, and discrete_state_range are initialized to:

- Mean/midpoint (or next smaller integer value) when doubly-bounded
- 0 when unbounded
- 0 when semi-bounded and zero is in the half interval, otherwise to the specified lower or upper bound

Set variables, including discrete_design_set and discrete_state_set default to the middle (or next smaller) value of the ordered set of admissible values.

Uncertain variables default initialize to their mean (or nearest admissible discrete) value, truncating to any specified lower or upper bounds as needed. Epistemic uncertain variable means are calculated making a probabilistic assumption on the specified intervals or set values.

7.4.32.3.5 descriptors

- Keywords Area
- variables
- discrete_state_set
- real
- descriptors

Labels for the variables
Specification

Alias: none
Argument(s): STRINGLIST
Default: dssrv_{i}

Description

The optional variable labels specification descriptors is a list of strings which identify the variables. These are used in console and tabular output.
The default descriptor strings use a variable type-dependent root string plus a numeric identifier.

7.4.33 linear_inequality_constraint_matrix

- Keywords Area
- variables
- linear_inequality_constraint_matrix

Define coefficients of the linear inequality constraints

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none
Argument(s): REALLIST
Default: no linear inequality constraints

Description

In the inequality case, the constraint matrix $A$ provides coefficients for the variables in the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where the bounds are optionally specified by linear_inequality_lower_bounds, and linear_inequality_upper_bounds. The bounds, if not specified, will default to -infinity, and 0, respectively, resulting in one-sided inequalities of the form

$$Ax \leq 0.0$$

The linear_constraints topics page (linked above) outlines a few additional things to consider when using linear constraints.
Examples

In the first example, an optimization involving two variables, \(x_1\) and \(x_2\), is to be performed. These variables must satisfy two constraints:

\[
1.5 \cdot x_1 + 1.0 \cdot x_2 \leq 5.0 \\
x_1 \leq x_2 \implies x_1 - x_2 \leq 0.0
\]

The pair of constraints can be written in matrix form as:

\[
\begin{bmatrix}
1.5 & 1.0 \\
1.0 & -1.0
\end{bmatrix}
\begin{bmatrix}
x_1 \\
x_2
\end{bmatrix}
\leq
\begin{bmatrix}
5.0 \\
0.0
\end{bmatrix}
\]

The coefficient matrix and right hand side of this matrix inequality are expressed to Dakota in the variables section of the input file:

```
variables
continuous_design 2
  descriptors 'x1' 'x2'
linear_inequality_constraint_matrix = 1.5 1.0 \\
                                1.0 -1.0
linear_inequality_upper_bounds = 5.0 0.0
```

The second example is more complex in two respects. First, some, but not all, of the constraints are "two sided", with both lower and upper bounds. Second, not all variables participate in all constraints.

There are four variables, \(x_1, x_2, x_3,\) and \(x_4\), and four constraints.

\[
-2.0 \leq 5.0 \cdot x_1 + 2.0 \cdot x_2 \leq 9.0 \\
0.0 \leq x_1 + x_3 \\
-8.0 \leq x_2 + 6.0 \cdot x_4 \leq 8.0 \\
x_1 + x_2 + x_3 \leq 9.0
\]

Or, in matrix form,

\[
\begin{bmatrix}
-2.0 \\
0.0 \\
-8.0 \\
-\infty
\end{bmatrix}
\leq
\begin{bmatrix}
5.0 & 2.0 & 0.0 & 0.0 \\
1.0 & 0.0 & 1.0 & 0.0 \\
0.0 & 1.0 & 0.0 & 6.0 \\
1.0 & 1.0 & 1.0 & 0.0
\end{bmatrix}
\begin{bmatrix}
x_1 \\
x_2 \\
x_3 \\
x_4
\end{bmatrix}
\leq
\begin{bmatrix}
9.0 \\
\infty \\
8.0 \\
9.0
\end{bmatrix}
\]

The Dakota specification for this matrix inequality is:

```
variables
continuous_design 4
  descriptors 'x1' 'x2' 'x3' 'x4'
linear_inequality_constraint_matrix = 5.0 2.0 0.0 0.0 \\
                                1.0 0.0 1.0 0.0 \\
                                0.0 1.0 0.0 6.0 \\
                                1.0 1.0 1.0 0.0
linear_inequality_lower_bounds = -2.0 \\
                                0.0 \\
                                -8.0 \\
                                -\infty
linear_inequality_upper_bounds = 9.0 \\
                                \infty \\
                                8.0 \\
                                9.0
```
7.4.34 linear_inequality_lower_bounds

Define lower bounds for the linear inequality constraint

**Topics**

This keyword is related to the topics:

- linear_constraints

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Default:** vector values = -infinity

**Description**

In the inequality case, the lower \( a_l \) and upper \( a_u \) bounds provide constraint limits for the two-sided formulation:

\[
a_l \leq Ax \leq a_u
\]

Where \( A \) is the constrain matrix of variable coefficients.

As with nonlinear inequality constraints (see objective_functions), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

\[
Ax \leq 0.0
\]

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than +bigRealBoundSize (1.e+30, as defined in Minimizer) are treated as +infinity and any lower bound values less than -bigRealBoundSize are treated as -infinity.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since -DBL_MAX < -bigRealBoundSize).

**Examples**

Examples of specifying linear inequality constraints to Dakota are provided on the linear_inequality_constraint_matrix page.

7.4.35 linear_inequality_upper_bounds

Define upper bounds for the linear inequality constraint
Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): REALIST

Default: vector values = 0.

Description

In the inequality case, the lower $a_l$ and upper $a_u$ bounds provide constraint limits for the two-sided formulation:

$$a_l \leq Ax \leq a_u$$

Where $A$ is the constraining matrix of variable coefficients.

As with nonlinear inequality constraints (see objective_functions), the default linear inequality constraint bounds are selected so that one-sided inequalities of the form

$$Ax \leq 0$$

result when there are no user bounds specifications (this provides backwards compatibility with previous Dakota versions).

In a user bounds specification, any upper bound values greater than $+\text{bigRealBoundSize}$ (1.e+30, as defined in Minimizer) are treated as $+\infty$ and any lower bound values less than $-\text{bigRealBoundSize}$ are treated as $-\infty$.

This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since $-\text{DBL_MAX} <-\text{bigRealBoundSize}$).

Examples

Examples of specifying linear inequality constraints to Dakota are provided on the linear_inequality_constraint_matrix page.

7.4.36 linear_inequality_scale_types

- Keywords Area
- variables
- linear_inequality_scale_types

How to scale each linear inequality constraint

Topics

This keyword is related to the topics:

- linear_constraints
Specification

**Alias:** none

**Argument(s):** STRINGLIST

**Default:** vector values = "none"

**Description**

Each string in `linear_inequality_scale_types` indicates the scaling type for each linear inequality constraint. They only have effect when the associated method specifies scaling.

The options are:

- `'value'` - characteristic value. If this is chosen, then `linear_inequality_scales` must be specified; `'value'` is assumed if scales are given without `scale_types`

- `'auto'` - automatic scaling.

If a single string is specified it will apply to all linear inequality constraints. Otherwise the number of strings specified should be equal to the number of linear inequalities.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables $x$:

$$\tilde{x}_j = \frac{x_j - x_O}{x_M - x_O}$$

we have the following system for linear inequality constraints

$$a_L \leq A_i x \leq a_U$$

$$a_L \leq A_i (\text{diag}(x_M) \tilde{x} + x_O) \leq a_U$$

$$a_L - A_i x_O \leq A_i \text{diag}(x_M) \tilde{x} \leq a_U - A_i x_O$$

$$\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U$$

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to [0,1].

See the scaling information under specific methods, e.g., `method-<method>-scaling` for details on how to use this keyword.

7.4.37 linear_inequality_scales

- Keywords Area
- variables
- linear_inequality_scales

Characteristic values to scale linear inequalities

**Topics**

This keyword is related to the topics:

- linear_constraints
7.4 variables

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = 1 . (no scaling)

Description

Each real value in linear_inequality_scales is a nonzero characteristic value to be used in scaling each constraint. They only have effect when the associated method specifies scaling.

This keyword is required for linear_inequality_scale_types of 'value' and optional for 'auto'.

If a single real value is specified it will apply to all linear inequality constraints. Otherwise the number of values should be equal to the number of linear inequalities.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables x:

\[ \tilde{x}^j = \frac{x^j - x^j_O}{x^j_M} \]

we have the following system for linear inequality constraints

\[ a_L \leq A_i \tilde{x} \leq a_U \]
\[ a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U \]
\[ a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O \]
\[ \tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U \]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinity to [0,1].

See the scaling information under specific methods, e.g., method-*-scaling for details on how to use this keyword.

7.4.38 linear_equality_constraint_matrix

- Keywords Area
- variables
  - linear_equality_constraint_matrix

Define coefficients of the linear equalities

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): REALLIST

Default: no linear equality constraints
Description

In the equality case, the constraint matrix $A$ provides coefficients for the variables on the left hand side of:

$$Ax = a_t$$

The linear_constraints topics page (linked above) outlines a few additional things to consider when using linear constraints.

Examples

An optimization involving three variables, $x_1$, $x_2$, and $x_3$, is to be performed. These variables must satisfy a pair of linear equality constraints:

\[
\begin{align*}
1.5 \cdot x_1 + 1.0 \cdot x_2 &= 5.0 \\
3.0 \cdot x_1 - 4.0 \cdot x_3 &= 0.0
\end{align*}
\]

The pair of constraints can be written in matrix form as:

$$ \begin{bmatrix} 1.5 & 1.0 & 0.0 \\ 3.0 & 0.0 & -4.0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 5.0 \\ 0.0 \end{bmatrix} $$

The coefficient matrix and right hand side are expressed to Dakota in the variables section of the input file:

```
variables
  continuous_design 2
  descriptors 'x1' 'x2'
  linear_equality_constraint_matrix = 1.5 1.0 0.0
                                     3.0 0.0 -4.0
  linear_equality_targets = 5.0
                          0.0
```

For related examples, see the linear_inequality_constraint_matrix keyword page.

7.4.39  linear_equality_targets

- Keywords Area
- variables
- linear_equality_targets

Define target values for the linear equality constraints

Topics

This keyword is related to the topics:

- linear_constraints
7.4 variables

Specification

Alias: none

Argument(s): REALLIST

Default: vector values = 0.

Description

In the equality case, the targets $a_t$ provide the equality constraint right hand sides:

$$Ax = a_t$$

If this is not specified, the defaults for the equality constraint targets enforce a value of 0. for each constraint: $Ax = 0.0$

Examples

Examples of specifying linear equality constraints to Dakota are provided on the linear_equality_constraint_matrix page.

7.4.40 linear_equality_scale_types

- Keywords Area
- variables
- linear_equality_scale_types

How to scale each linear equality constraint

Topics

This keyword is related to the topics:

- linear_constraints

Specification

Alias: none

Argument(s): STRINGLIST

Default: vector values = "none"

Description

Each string in linear_equality_scale_types indicates the scaling type for each linear equality constraint. They only have effect when the associated method specifies scaling.

The options are:

- ‘value’ - characteristic value. If this is chosen, then linear_equality_scales must be specified; ‘value’ is assumed if scales are given without a scale_types
• ‘auto’ - automatic scaling.

If a single string is specified it will apply to all linear equality constraints. Otherwise the number of strings specified should be equal to the number of linear equalities.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables \(x\):

\[
\tilde{x}^j = \frac{x^j - x_O^j}{x_M^j}
\]

we have the following system for linear equality constraints

\[
\begin{align*}
    a_L & \leq A_i x \leq a_U \\
    a_L & \leq A_i (\text{diag}(x_M) \tilde{x} + x_O) \leq a_U \\
    a_L - A_i x_O & \leq A_i \text{diag}(x_M) \tilde{x} \leq a_U - A_i x_O \\
    \tilde{a}_L & \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
\end{align*}
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to \([0,1]\).

See the scaling information under specific methods, e.g., method-\*^scaling for details on how to use this keyword.

### 7.4.41 linear_equality_scales

- **Keywords Area**
- **variables**
- **linear_equality_scales**

Characteristic values to scale linear equalities

**Topics**

This keyword is related to the topics:

- **linear_constraints**

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Default:** vector values = 1. (no scaling)

**Description**

Each real value in \textit{linear_equality_scales} is a nonzero characteristic value to be used in scaling each constraint. They only have effect when the associated method specifies \textit{scaling}.

This keyword is required for \textit{linear_equality_scale_types} of ‘value’ and optional for ‘auto’.
If a single real value is specified it will apply to all linear equality constraints. Otherwise the number of values should be equal to the number of linear equalities.

Scaling for linear constraints is applied after any continuous variable scaling.

For example, for variable scaling on continuous design variables \( x \):

\[
\tilde{x}^j = \frac{x^j - x^j_O}{x_M^j}
\]

we have the following system for linear inequality constraints

\[
a_L \leq A_i x \leq a_U
\]

\[
a_L \leq A_i (\text{diag}(x_M)\tilde{x} + x_O) \leq a_U
\]

\[
a_L - A_i x_O \leq A_i \text{diag}(x_M)\tilde{x} \leq a_U - A_i x_O
\]

\[
\tilde{a}_L \leq \tilde{A}_i \tilde{x} \leq \tilde{a}_U
\]

and user-specified or automatically computed scaling multipliers are applied to this final transformed system, which accounts for continuous design variable scaling. When automatic scaling is in use for linear constraints they are linearly scaled by a computed characteristic value, but not affinely to \([0,1]\).

See the scaling information under specific methods, e.g., method-**scaling** for details on how to use this keyword.

### 7.5 interface

- **Keywords Area**
- **interface**

Specifies how function evaluations will be performed in order to map the variables into the responses.

**Topics**

This keyword is related to the topics:

- **block**

**Specification**

**Alias:** none  
**Argument(s):** none

7.5 interface

| Optional | analysis_-scheduling | Specify the scheduling of concurrent analyses when Dakota is run in parallel |

**Description**

The interface section in a Dakota input file specifies how function evaluations will be performed in order to map the variables into the responses. The term "interface" refers to the bridge between Dakota and the underlying simulation code.

In this context, a “function evaluation” is the series of operations that takes the variables and computes the responses. This can be comprised of one or many codes, scripts, and glue, which are generically referred to as “analysis drivers” (and optional input/output filters). The mapping actions of analysis_drivers may be combined with explicit algebraic_mappings.

**Parallelism Options**

- The asynchronous keyword enables concurrent local function evaluations or analyses via operating system process management. Its child keywords allow tailoring the evaluation and analysis concurrency.

- The evaluation servers, scheduling mode (master, peer static or dynamic), and processor keywords allow a user to override Dakota's default evaluation configuration when running in parallel (MPI) mode.

- The analysis servers and scheduling mode (master, peer static or dynamic) keywords allow a user to override Dakota's default analysis configuration when running in parallel (MPI) mode.

Note: see direct for the specific processors_per_analysis specification supported for direct interfaces.

**Theory**

Function evaluations are performed using either interfaces to simulation codes, algebraic mappings, or a combination of the two.

When employing mappings with simulation codes, the interface invokes the simulation using either forks, direct function invocations, or computational grid invocations.

- In the fork case, Dakota will treat the simulation as a black-box and communication between Dakota and the simulation occurs through parameter and result files. This is the most common case.

- In the direct function case, the simulation is internal to Dakota and communication occurs through the function parameter list. The direct case can involve linked simulation codes or test functions which are compiled into the Dakota executable. The test functions allow for rapid testing of algorithms without process creation overhead or engineering simulation expense.

- The grid case is deprecated, but was an experiment in interfacing Dakota to distributed computing engines.

When employing algebraic mappings, the AMPL solver library [29] is used to evaluate a directed acyclic graph (DAG) specification from a separate stub.nl file. Separate stub.col and stub.row files are also required to declare the string identifiers of the subset of inputs and outputs, respectively, that will be used in the algebraic mappings.
7.5.1  id_interface

• Keywords Area
• interface
• id_interface

Name the interface block; helpful when there are multiple

Topics

This keyword is related to the topics:

• block_identifier

Specification

Alias: none

Argument(s): STRING

Default: use of last interface parsed

Description

The optional id_interface keyword accepts a string that uniquely identifies this interface block. A model can then use this interface by specifying the same string in its interface_pointer specification.

Default Behavior

If the id_interface specification is omitted, a particular interface specification will be used by a model only if that model does not include an interface_pointer and the interface block was the last (or only) one parsed.

Usage Tips

• It is a best practice to always use explicit interface IDs and pointers to avoid confusion.
• If only one interface block exists, then id_interface can be safely omitted from the interface block (and interface_pointer omitted from the model specification(s)), since there is no ambiguity.

Examples

For example, a model specification including

```
model
  interface_pointer = ’I1’
```

will link to an interface with

```
id_interface = ’I1’
```

7.5.2  analysis_drivers

• Keywords Area
• interface
• analysis_drivers

Define how Dakota should run a function evaluation

### Description

The `analysis_drivers` keyword provides the names of one or more executable analysis programs or scripts, a.k.a. "drivers" which comprise a function evaluation. The optional and required sub-keywords specify how Dakota will manage directories and files, and run the driver(s).

### Types of Interfaces

Dakota has two recommended ways of running analysis drivers:

- as an external processes (`fork`), or
- using internal code to couple to the analysis driver (`direct`)

Other options are available for advanced users, and are not as well documented, supported, or tested:

- external processes (`system`)
- internal coupling (`python`, `matlab`, `scilab`, `grid`)

### Use Cases

The internally coupled codes have few options because many of the details are already handled with the coupling. Their behavior is described in the `direct` keyword.

For external processes using the `fork` keyword,

A function evaluation may comprise:

1. A single analysis driver: Function evaluation, including all pre- and post-processing is contained entirely within a single script/executable.

2. A single analysis driver with filters: Function evaluation is explicitly split into pre-processing (performed by the input filter), analysis, and post-processing (by the output filter).

3. A single analysis driver with environment variables: Function evaluation is contained within one analysis driver, but it requires environment variables to be set before running.

4. Multiple analysis drivers: Drivers are run sequentially or concurrently (See the `asynchronous` keyword) and can have any of the above options as well.
For fork and system interfaces, the analysis_driver list contains the names of one or more executable programs or scripts taking parameters files as input and producing results files as output. The first field in each analysis driver string must be an executable program or script for Dakota to spawn to perform the function evaluation. Drivers support:

- One set of nested quotes, for arguments with spaces
- Dakota will define special environment variables `DAKOTA_PARAMETERS_FILE` and `DAKOTA_RESULTS_FILE` which can be used in the driver script.
- Dakota will replace the tokens `{PARAMETERS}` and `{RESULTS}` in an analysis driver string with the names of the parameters and results files for that analysis/evaluation. Along with the `verbatim` keyword, which prevents Dakota from appending the names of the parameters and results files as command line arguments, this feature provides users with greater control over how their analysis drivers are invoked by Dakota.
- Variable definitions preceding the executable program or script, such as `MY_VAR=2 run_analysis.sh` are no longer supported.

For details and examples see the Simulation Interface Components section of the Interfaces chapter of the User’s Manual; for details on the filters and environment variables, see the subsection on Syntax for Filter and Driver Strings.

**Examples**

Examples:

1. `analysis_drivers = 'run_simulation_part1.sh' 'run_simulation_part2.sh'`
2. `analysis_driver = 'run_simulation.sh -option "option 1"'
3. `analysis_driver = 'simulation.exe -option value -dakota_params $DAKOTA_PARAMETERS_FILE -input sim.in -dakota_results_file $DAKOTA_RESULTS_FILE'`

**FAQ**

Where will Dakota look for the analysis_driver? Dakota will locate analysis_driver programs first in (or relative to) the present working directory (".", the interface-analysis_drivers-fork-work_directory if used, otherwise the directory in which Dakota is started), then the directory from which Dakota is started, then using the system $PATH environment variable (Path% on Windows).

Where should the driver be located? When the driver is a script it is most commonly placed in the same directory as the Dakota input file. When using a work_directory, Dakota will also look for drivers in the specified working directory, so link_files or copy_files may specify the driver to get copied or linked into the work directory. When executable programs are used as drivers, they are often elsewhere on the filesystem. These can be specified using absolute paths, or by prepending the PATH environment variable so Dakota finds them.

What if Dakota fails to run my analysis_driver? Prepend the absolute location of the driver to the PATH environment variable before running Dakota, or specify an absolute path to the driver in the Dakota input file.

7.5.2.1 input_filter

- Keywords Area
- interface
- analysis_drivers
- input_filter

Run a pre-processing script before the analysis drivers
Specification

**Alias:** none  

**Argument(s):** STRING  

**Default:** no input filter

**Description**

The optional *input_filter* and *output_filter* specifications provide the names of separate pre- and post-processing programs or scripts which assist in mapping Dakota parameters files into analysis input files and mapping analysis output files into Dakota results files, respectively.

If there is only a single analysis driver, then it is usually most convenient to combine pre- and post-processing requirements into a single analysis driver script and omit the separate input and output filters. However, in the case of multiple analysis drivers, the input and output filters provide a convenient location for non-repeated pre- and post-processing requirements. That is, input and output filters are only executed once per function evaluation, regardless of the number of analysis drivers, which makes them convenient locations for data processing operations that are shared among the analysis drivers.

The *verbatim* keyword applies to input and output filters as well as analysis drivers, and Dakota also will substitute the names of the parameters and results files for the tokens `{PARAMETERS}` and `{RESULTS}` in input and output filter strings, as explained in the documentation for *analysis_drivers*.

### 7.5.2.2 output_filter

- **Keywords Area**
- **interface**
- **analysis_drivers**
- **output_filter**

Run a post-processing script after the analysis drivers

**Specification**

**Alias:** none  

**Argument(s):** STRING  

**Default:** no output filter

**Description**

The optional *input_filter* and *output_filter* specifications provide the names of separate pre- and post-processing programs or scripts which assist in mapping Dakota parameters files into analysis input files and mapping analysis output files into Dakota results files, respectively.

If there is only a single analysis driver, then it is usually most convenient to combine pre- and post-processing requirements into a single analysis driver script and omit the separate input and output filters. However, in the case of multiple analysis drivers, the input and output filters provide a convenient location for non-repeated pre- and post-processing requirements. That is, input and output filters are only executed once per function evaluation, regardless of the number of analysis drivers, which makes them convenient locations for data processing operations that are shared among the analysis drivers.

The *verbatim* keyword applies to input and output filters as well as analysis drivers, and Dakota also will substitute the names of the parameters and results files for the tokens `{PARAMETERS}` and `{RESULTS}` in input and output filter strings, as explained in the documentation for *analysis_drivers*.
### 7.5.2.3 system

- **Keywords Area**
  - interface
  - analysis_drivers
  - system

(Not recommended) Launch analysis drivers with a system call

**Specification**

**Alias:** none  
**Argument(s):** none

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>

<td></td>
<td>Perform each function evaluation in a separate working directory</td>
</tr>
<tr>
<td>Optional</td>
<td>allow_existing_results</td>
<td></td>
<td>Change how Dakota deals with existing results files</td>
</tr>
</tbody>
</table>
Description

The system call interface is included in Dakota for portability and backward compatibility. Users are strongly encouraged to use the *fork* interface if possible, reverting to system only when necessary. To enable the system call interface, replace the *fork* keyword with *system*. All other keywords have identical meanings to those for the *fork* interface.

See Also

These keywords may also be of interest:

- *fork*

### 7.5.2.3.1 parameters_file

- Keywords Area
- interface
- analysis_drivers
- system
- parameters_file

Specify the name of the parameters file.

**Specification**

**Alias:** none

**Argument(s):** STRING

**Default:** Unix temp files

**Description**

The parameters file is used by Dakota to pass the parameter values to the analysis driver. The name of the file can be optionally specified using the *parameters_file* keyword.

If this is not specified, the default data transfer files are temporary files with system-generated names (e.g., /tmp/dakota_params_aaaa0886).

### 7.5.2.3.2 results_file

- Keywords Area
- interface
- analysis_drivers
- system
7.5 interface

- results_file

Specify the name of the results file

Specification

Alias: none
Argument(s): STRING
Default: Unix temp files

Description

The results file must be written by the analysis driver. It is read by Dakota to determine the response values for each function evaluation. The name of the file can be optionally specified using the results_file keyword. If this is not specified, the default data transfer files are temporary files with system-generated names (e.g., /tmp/dakota_results_aaaa0886).

7.5.2.3.3 file_tag

- Keywords Area
- interface
- analysis_drivers
- system
- file_tag

Tag each parameters & results file name with the function evaluation number

Specification

Alias: none
Argument(s): none
Default: no tagging

Description

If this keyword is used, Dakota will append a period and the function evaluation number to the names of the parameter and results files. If this keyword is omitted, the default is no file tagging.

Usage Tips

- File tagging is most useful when multiple function evaluations are running simultaneously using files in a shared disk space. The analysis driver will be able to infer the function evaluation number from the file names.
- Note that when the file_save keyword is used, Dakota automatically renames parameters and results files, giving them tags after execution of the analysis driver if they otherwise would be overwritten by the next evaluation.
Examples

If the following is included in the interface section of the Dakota input:

```csharp
parameters_file = params.in
results_file = results.out
file_tag
```

Then for the 3rd evaluation, Dakota will write `params.in.3`, and will expect `results.out.3` to be written by the analysis driver.

7.5.2.3.4 file_save

- Keywords Area
- interface
- analysis_drivers
- system
- file_save

Keep the parameters & results files after the analysis driver completes

Specification

Alias: none
Argument(s): none
Default: file cleanup

Description

If `file_save` is used, Dakota will not delete the parameters and results files after the function evaluation is completed.

The default behavior is NOT to save these files.

If `file_tag` is not specified and the saved files would be overwritten by a future evaluation, Dakota renames them after the analysis driver has run by tagging them with the evaluation number.

File saving is most useful when debugging the data communication between Dakota and the simulation.

7.5.2.3.5 labeled

- Keywords Area
- interface
- analysis_drivers
- system
- labeled

Requires correct function value labels in results file
Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Default: Function value labels optional

Description

The labeled keyword directs Dakota to enforce a stricter results file format and enables more detailed error reporting.

When the labeled keyword is used, function values in results files must be accompanied by their corresponding descriptors. If the user did not supply response descriptors in her Dakota input file, then Dakota auto-generated descriptors are expected.

Distinct error messages are emitted for function values that are out-of-order, repeated, or missing. Labels that appear without a function value and unexpected data are also reported as errors. Dakota attempts to report all errors in a results file, not just the first it encounters. After reporting results file errors, Dakota aborts.

Labels for analytic gradients and Hessians currently are not supported.

Although the labeled keyword is optional, its use is recommended to help catch and identify problems with results files. The User's Manual contains further information about the results file format.

Default Behavior

By default, Dakota does not require labels for function values, and ignores them if they are present.

7.5.2.3.6 aprepro

- Keywords Area
- interface
- analysis_drivers
- system
- aprepro

Write parameters files in APREPRO syntax

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: dprepro

Argument(s): none

Default: standard parameters file format
Description

The format of data in the parameters files can be modified for direct usage with the APREPRO pre-processing tool [78] using the `aprepro` specification.

Without this keyword, the parameters file are written in DPrePro format. DPrePro is a utility included with Dakota, described in the Users Manual [5].

7.5.2.3.7 work_directory

- Keywords Area
- interface
- analysis_drivers
- system
- work_directory

Perform each function evaluation in a separate working directory.

Specification

**Alias:** none

**Argument(s):** none

**Default:** no work directory

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>named</td>

<td></td>
<td>Files and directories to be copied into each working directory</td>
</tr>
</tbody>
</table>
## 7.5 interface

<table>
<thead>
<tr>
<th>Optional</th>
<th>replace</th>
<th>Overwrite existing files within a work directory</th>
</tr>
</thead>
</table>

### Description

When performing concurrent evaluations, it is typically necessary to cloister simulation input and output files in separate directories to avoid conflicts. When the `work_directory` feature is enabled, Dakota will create a directory for each evaluation, with optional tagging (`directory_tag`) and saving (`directory_save`), as with files, and execute the analysis driver from that working directory.

The directory may be `named` with a string, or left anonymous to use an automatically-generated directory in the system's temporary file space, e.g., `/tmp/dakota_work_c93vb71z/`. The optional `link_files` and `copy_files` keywords specify files or directories which should appear in each working directory.

When using `work_directory`, the `analysis_drivers` may be given by an absolute path, located in (or relative to) the startup directory alongside the Dakota input file, in the list of template files linked or copied, or on the `$PATH` (Path% on Windows).

### 7.5.2.3.7.1 named

- Keywords Area
- `interface`
- `analysis_drivers`
- `system`
- `work_directory`
- `named`

The base name of the work directory created by Dakota

### Specification

**Alias:** none

**Argument(s):** STRING

**Default:** dakota_work_xxxxxxxx

### Description

The `named` keyword is followed by a string, indicating the name of the work directory created by Dakota. If relative, the work directory will be created relative to the directory from which Dakota is invoked.

If `named` is not used, the default work directory is a temporary directory with a system-generated name (e.g., `/tmp/dakota_work_c93vb71z/`).

### See Also

These keywords may also be of interest:

- `directory_tag`
- `directory_save`
7.5.2.3.7.2 directory_tag

- Keywords Area
- interface
- analysis_drivers
- system
- work_directory
- directory_tag

Tag each work directory with the function evaluation number

Specification

**Alias:** dir_tag

**Argument(s):** none

**Default:** no work directory tagging

Description

If this keyword is used, Dakota will append a period and the function evaluation number to the work directory names. If this keyword is omitted, the default is no tagging, and the same work directory will be used for ALL function evaluations. Tagging is most useful when multiple function evaluations are running simultaneously.

7.5.2.3.7.3 directory_save

- Keywords Area
- interface
- analysis_drivers
- system
- work_directory
- directory_save

Preserve the work directory after function evaluation completion

Specification

**Alias:** dir_save

**Argument(s):** none

**Default:** remove work directory

Description

By default, when a working directory is created by Dakota using the **work_directory** keyword, it is deleted after the evaluation is completed. The **directory_save** keyword will cause Dakota to leave (not delete) the directory.
7.5.2.3.7.4  link_files

- Keywords Area
- interface
- analysis_drivers
- system
- work_directory
- link_files

Paths to be linked into each working directory

**Specification**

**Alias:** none

**Argument(s):** STRINGLIST

**Default:** no linked files

**Description**

Specifies the paths (files or directories) that will be symbolically linked from each working directory. Wildcards using * and ? are permitted. Linking is space-saving and useful for files not modified during the function evaluation. However, not all filesystems support linking, for example, support on Windows varies.

**Examples**

Specifying

```
link_files = 'siminput*.in' '/path/to/simdir1' 'simdir2/*'
```

will create copies

```
workdir/siminput*.in  # links to each of rundir / siminput*.in
workdir/simdir1/      # whole directory simdir1 linked
workdir/*             # each entry in directory simdir2 linked
```

7.5.2.3.7.5  copy_files

- Keywords Area
- interface
- analysis_drivers
- system
- work_directory
- copy_files

Files and directories to be copied into each working directory
Specification

Alias: none

Argument(s): STRINGLIST

Default: no copied files

Description

Specifies the files or directories that will be recursively copied into each working directory. Wildcards using * and ? are permitted.

Examples

Specifying

\[ \text{copy\_files} = '\text{siminput*}.in' '/path/to/simdir1' 'simdir2/*' \]

will create copies

\[
\begin{align*}
\text{workdir/siminput*.in} & \quad \text{# files rundir/siminput*.in copied} \\
\text{workdir/simdir1/} & \quad \text{# whole directory simdir1 recursively copied} \\
\text{workdir/*} & \quad \text{# contents of directory simdir2 recursively copied}
\end{align*}
\]

where rundir is the directory in which Dakota was started.

7.5.2.3.7.6 replace

• Keywords Area
  • interface
  • analysis\_drivers
  • system
  • work\_directory
  • replace

Overwrite existing files within a work directory

Specification

Alias: none

Argument(s): none

Default: do not overwrite files

Description

By default, Dakota will not overwrite any existing files in a work directory. The replace keyword changes this behavior to force overwriting.
7.5.2.3.8 allow_existing_results

- Keywords Area
- interface
- analysis_drivers
- system
- allow_existing_results

Change how Dakota deals with existing results files

Specification

Alias: none

Argument(s): none

Default: results files removed before each evaluation

Description

By default Dakota will remove existing results files before invoking the analysis_driver to avoid problems created by stale files in the current directory. To override this behavior and not delete existing files, specify allow_existing_results.

7.5.2.3.9 verbatim

- Keywords Area
- interface
- analysis_drivers
- system
- verbatim

Specify the command Dakota uses to launch analysis driver(s) and filters

Specification

Alias: none

Argument(s): none

Default: driver/filter invocation syntax augmented with file names

Description

The typical commands that Dakota uses to launch analysis drivers are:

> analysis_driver parameters_file_name results_file_name

Dakota will automatically arrange the executables and file names.

If the analysis driver requires a different syntax, the entire command can be specified as the analysis driver and the verbatim keyword will tell Dakota to use this as the command.
Note, this will not allow the use of file_tag, because the exact command must be specified.
For additional information on invocation syntax, see the Interfaces chapter of the Users Manual [5].

Examples

In the following example, the analysis_driver command is run without any edits from Dakota.

```
interface
  analysis_driver = "matlab -nodesktop -nojvm -r 'MatlabDriver_hardcoded_filenames; exit' "
  fork
    parameters_file 'params.in'
    results_file 'results.out'
    verbatim # this tells Dakota to fork the command exactly as written, instead of appending I/O filenames
```

The -r flag identifies the commands that will be run by matlab. The Matlab script has the parameters_file and results_file names hardcoded, so no additional arguments are required.

7.5.2.4 fork

- Keywords Area
- interface
- analysis_drivers
- fork

Launch analysis drivers using fork command

Specification

Alias: none
Argument(s): none

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>

<td>For additional information on invocation syntax, see the Interfaces chapter of the Users Manual [5].</td>
</tr>
</tbody>
</table>

#### Description

The **fork** interface is the most common means by which Dakota launches a separate application analysis process. The **fork** interface is recommended over **system** for most analysis drivers that are external to Dakota, i.e., any driver not linked in via the **direct** interface.

As explained in the Users Manual, the parameters and results file names are passed on the command line to the analysis driver(s). If input/output filters are specified, they will be run before/after the analysis drivers. The **verbatim** keyword is used to modify the default driver/filter commands.

For additional information on invocation syntax, see the Interfaces chapter of the Users Manual [5].

#### Examples

Spawn (fork) an external executable/script called 'rosenbrock' which reads variables from `params.in` and writes responses to `results.out`. Preserve the analysis files for each function evaluation with tag and save.

```
interface
  analysis_drivers = 'rosenbrock'
  fork
    parameters_file = 'params.in'
    results_file = 'results.out'
    file_tag
    file_save
```
Specify the name of the parameters file

**Specification**

**Alias:** none  
**Argument(s):** STRING  
**Default:** Unix temp files

**Description**

The parameters file is used by Dakota to pass the parameter values to the analysis driver. The name of the file can be optionally specified using the `parameters_file` keyword. If this is not specified, the default data transfer files are temporary files with system-generated names (e.g., `/tmp/dakota_params_aaaa0886`).

7.5.2.4.2 results_file

- Keywords Area
- interface
- analysis_drivers
- fork
- results_file

Specify the name of the results file

**Specification**

**Alias:** none  
**Argument(s):** STRING  
**Default:** Unix temp files

**Description**

The results file must be written by the analysis driver. It is read by Dakota to determine the response values for each function evaluation. The name of the file can be optionally specified using the `results_file` keyword.

If this is not specified, the default data transfer files are temporary files with system-generated names (e.g., `/tmp/dakota_results_aaaa0886`).

7.5.2.4.3 file_tag

- Keywords Area
- interface
- analysis_drivers
7.5 interface

- fork
- file_tag

Tag each parameters & results file name with the function evaluation number

Specification

Alias: none
Argument(s): none
Default: no tagging

Description

If this keyword is used, Dakota will append a period and the function evaluation number to the names of the parameter and results files.

Default Behavior: If this keyword is omitted, the default is no file tagging.

Usage Tips

- File tagging is most useful when multiple function evaluations are running simultaneously using files in a shared disk space. The analysis driver will be able to infer the function evaluation number from the file names.
- Note that when the file_save keyword is used, Dakota automatically renames parameters and results files, giving them tags after execution of the analysis driver if they otherwise would be overwritten by the next evaluation.

Examples

If the following is included in the interface section of the Dakota input:

```
parameters_file = params.in
results_file = results.out
file_tag
```

Then for the 3rd evaluation, Dakota will write `params.in.3`, and will expect `results.out.3` to be written by the analysis driver.

7.5.2.4.4 file_save

- Keywords Area
- interface
- analysis_drivers
- fork
- file_save

Keep the parameters & results files after the analysis driver completes
Specification

**Alias:** none  
**Argument(s):** none  
**Default:** file cleanup

**Description**

If `file_save` is used, Dakota will not delete the parameters and results files after the function evaluation is completed. The default behavior is NOT to save these files.

If `file_tag` is not specified and the saved files would be overwritten by a future evaluation, Dakota renames them after the analysis driver has run by tagging them with the evaluation number.

File saving is most useful when debugging the data communication between Dakota and the simulation.

7.5.2.4.5 labeled

- **Keywords Area**
- **interface**
- **analysis_drivers**
- **fork**
- **labeled**

Requires correct function value labels in results file

**Topics**

This keyword is related to the topics:

- **file_formats**

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** Function value labels optional

**Description**

The `labeled` keyword directs Dakota to enforce a stricter results file format and enables more detailed error reporting.

When the `labeled` keyword is used, function values in results files must be accompanied by their corresponding descriptors. If the user did not supply response descriptors in her Dakota input file, then Dakota auto-generated descriptors are expected.

Distinct error messages are emitted for function values that are out-of-order, repeated, or missing. Labels that appear without a function value and unexpected data are also reported as errors. Dakota attempts to report all errors in a results file, not just the first it encounters. After reporting results file errors, Dakota aborts.
Labels for analytic gradients and Hessians currently are not supported. Although the labeled keyword is optional, its use is recommended to help catch and identify problems with results files. The User’s Manual contains further information about the results file format.

**Default Behavior**
By default, Dakota does not require labels for function values, and ignores them if they are present.

7.5.2.4.6 aprepro

- **Keywords Area**
- interface
- analysis_drivers
- fork
- aprepro

Write parameters files in APREPRO syntax

**Topics**
This keyword is related to the topics:

- file_formats

**Specification**

**Alias:** dprepro

**Argument(s):** none

**Default:** standard parameters file format

**Description**
The format of data in the parameters files can be modified for direct usage with the APREPRO pre-processing tool [78] using the aprepro specification

Without this keyword, the parameters file are written in DPrePro format. DPrePro is a utility included with Dakota, described in the Users Manual [5].

7.5.2.4.7 work_directory

- **Keywords Area**
- interface
- analysis_drivers
- fork
- work_directory

Perform each function evaluation in a separate working directory
Specification

**Alias:** none

**Argument(s):** none

**Default:** no work directory

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>named</td>
<td>The base name of the work directory created by Dakota</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>directory_tag</td>
<td>Tag each work directory with the function evaluation number</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>directory_save</td>
<td>Preserve the work directory after function evaluation completion</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>link_files</td>
<td>Paths to be linked into each working directory</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>copy_files</td>
<td>Files and directories to be copied into each working directory</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>replace</td>
<td>Overwrite existing files within a work directory</td>
</tr>
</tbody>
</table>

**Description**

When performing concurrent evaluations, it is typically necessary to cloister simulation input and output files in separate directories to avoid conflicts. When the `work_directory` feature is enabled, Dakota will create a directory for each evaluation, with optional tagging (`directory_tag`) and saving (`directory_save`), as with files, and execute the analysis driver from that working directory.

The directory may be named with a string, or left anonymous to use an automatically-generated directory in the system’s temporary file space, e.g., `/tmp/dakota_work_c93vb71z/`. The optional `link_files` and `copy_files` keywords specify files or directories which should appear in each working directory.

When using `work_directory`, the `analysis_drivers` may be given by an absolute path, located in (or relative to) the startup directory alongside the Dakota input file, in the list of template files linked or copied, or on the $PATH (Path% on Windows).

7.5.2.4.7.1 named

- **Keywords Area**
- **interface**
- **analysis_drivers**
The base name of the work directory created by Dakota

**Specification**

*Alias*: none  
*Argument(s):* STRING  
*Default*: dakota_work_xxxxxxxx

**Description**

The `named` keyword is followed by a string, indicating the name of the work directory created by Dakota. If relative, the work directory will be created relative to the directory from which Dakota is invoked. If `named` is not used, the default work directory is a temporary directory with a system-generated name (e.g., `/tmp/dakota_work_c93vb71z/`).

**See Also**

These keywords may also be of interest:

- `directory_tag`
- `directory_save`

7.5.2.4.7.2 directory_tag

Tag each work directory with the function evaluation number

**Specification**

*Alias*: dir_tag  
*Argument(s):* none  
*Default*: no work directory tagging
Description

If this keyword is used, Dakota will append a period and the function evaluation number to the work directory names. If this keyword is omitted, the default is no tagging, and the same work directory will be used for ALL function evaluations. Tagging is most useful when multiple function evaluations are running simultaneously.

7.5.2.4.7.3 directory_save

- Keywords Area
- interface
- analysis_drivers
- fork
- work_directory
- directory_save

Preserve the work directory after function evaluation completion

Specification

Alias: dir_save
Argument(s): none
Default: remove work directory

Description

By default, when a working directory is created by Dakota using the work_directory keyword, it is deleted after the evaluation is completed. The directory_save keyword will cause Dakota to leave (not delete) the directory.

7.5.2.4.7.4 link_files

- Keywords Area
- interface
- analysis_drivers
- fork
- work_directory
- link_files

Paths to be linked into each working directory

Specification

Alias: none
Argument(s): STRINGLIST
Default: no linked files
7.5 interface

Description

Specifies the paths (files or directories) that will be symbolically linked from each working directory. Wildcards using * and ? are permitted. Linking is space-saving and useful for files not modified during the function evaluation. However, not all filesystems support linking, for example, support on Windows varies.

Examples

Specifying

\texttt{link\_files = \textquotesingle siminput\*.in\textquotesingle '/path/to/simdir1' 'simdir2/*'}

will create copies

\begin{itemize}
  \item \texttt{workdir/siminput*.in} # links to each of rundir / siminput*.in
  \item \texttt{workdir/simdir1/} # whole directory simdir1 linked
  \item \texttt{workdir/*/} # each entry in directory simdir2 linked
\end{itemize}

7.5.2.4.7.5 copy_files

- **Keywords Area**
- **interface**
- **analysis\_drivers**
- **fork**
- **work\_directory**
- **copy\_files**

Files and directories to be copied into each working directory

Specification

**Alias:** none

**Argument(s):** STRINGLIST

**Default:** no copied files

Description

Specifies the files or directories that will be recursively copied into each working directory. Wildcards using * and ? are permitted.

Examples

Specifying

\texttt{copy\_files = \textquotesingle siminput\*.in\textquotesingle '/path/to/simdir1' 'simdir2/*'}

will create copies

\begin{itemize}
  \item \texttt{workdir/siminput*.in} # files rundir/siminput*.in copied
  \item \texttt{workdir/simdir1/} # whole directory simdir1 recursively copied
  \item \texttt{workdir/*/} # contents of directory simdir2 recursively copied
\end{itemize}

where rundir is the directory in which Dakota was started.
7.5.2.4.7.6 replace

- Keywords Area
- interface
- analysis_drivers
- fork
- work_directory
- replace

Overwrite existing files within a work directory

Specification

Alias: none
Argument(s): none
Default: do not overwrite files

Description

By default, Dakota will not overwrite any existing files in a work directory. The replace keyword changes this behavior to force overwriting.

7.5.2.4.8 allow_existing_results

- Keywords Area
- interface
- analysis_drivers
- fork
- allow_existing_results

Change how Dakota deals with existing results files

Specification

Alias: none
Argument(s): none
Default: results files removed before each evaluation

Description

By default Dakota will remove existing results files before invoking the analysis_driver to avoid problems created by stale files in the current directory. To override this behavior and not delete existing files, specify allow-existing_results.
7.5.2.4.9 verbatim

- Keywords Area
- interface
- analysis_drivers
- fork
- verbatim

Specify the command Dakota uses to launch analysis driver(s) and filters

**Specification**

Alias: none

Argument(s): none

Default: driver/filter invocation syntax augmented with file names

**Description**

The typical commands that Dakota uses to launch analysis drivers are:

```
> analysis_driver parameters_file_name results_file_name
```

Dakota will automatically arrange the executables and file names.

If the analysis driver requires a different syntax, the entire command can be specified as the analysis driver and the verbatim keyword will tell Dakota to use this as the command.

Note, this will not allow the use of file_tag, because the exact command must be specified.

For additional information on invocation syntax, see the Interfaces chapter of the Users Manual [5].

**Examples**

In the following example, the analysis_driver command is run without any edits from Dakota.

```
interface
  analysis_driver = "matlab -nodesktop -nojvm -r 'MatlabDriver_hardcoded_filenames; exit' "
  fork
  parameters_file 'params.in'
  results_file 'results.out'
  verbatim # this tells Dakota to fork the command exactly as written, instead of appending I/O filenames
```

The -r flag identifies the commands that will be run by matlab. The Matlab script has the parameters_file and results_file names hardcoded, so no additional arguments are required.

---

7.5.2.5 direct

- Keywords Area
- interface
- analysis_drivers
- direct

Run analysis drivers that are linked-to or compiled-with Dakota
**Specification**

**Alias:** none  
**Argument(s):** none  
**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>processors_per_analysis</td>
<td>Specify the number of processors per analysis when Dakota is run in parallel</td>
</tr>
</tbody>
</table>

**Description**

Direct interfaces are used to compile/link simulation programs into Dakota and to invoke Dakota’s built-in algebraic test problems.

Direct simulation interfaces communicate variable and response data in-core instead of through the filesystem. This typically requires modification to simulator programs so that they can be linked into Dakota; however it can be more efficient due to elimination of external processes and auxiliary simulator output, more accurate due to higher numerics, and more flexible in terms of MPI parallelism.

Direct interfaces are also used to invoke internal test functions that perform parameter to response mappings for simple functions as inexpensively as possible. These problems are compiled directly into the Dakota executable as part of the direct function interface class and are used for algorithm testing.

Dakota supports direct interfaces to a few select simulation codes such as Matlab, Python, and Scilab. Another example is ModelCenter, a commercial simulation management framework from Phoenix Integration. To utilize this interface, a user must first define the simulation specifics within a ModelCenter session and then save these definitions to a ModelCenter configuration file. The `analysis_components` specification provides the means to communicate this configuration file to Dakota’s ModelCenter interface.

**Examples**

The rosenbrock function is available as an executable, which can be launched with `fork`, and is also compiled with Dakota. The internal version can be used with:

```c
interface
analysis_drivers = 'rosenbrock'
direct
```

7.5.2.5.1 processors_per_analysis

- **Keywords Area**
- **interface**
- **analysis_drivers**
- **direct**
- **processors_per_analysis**

Specify the number of processors per analysis when Dakota is run in parallel.
7.5 interface

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none

Argument(s): INTEGER

Default: automatic (see discussion)

Description

For direct function interfaces, `processors_per_analysis` can be used to specify multiprocessor analysis partitions. As with the `evaluation_servers`, `analysis_servers`, `evaluation_self_scheduling`, `evaluation_static_scheduling`, `analysis_self_scheduling`, and `analysis_static_scheduling` specifications, `processors_per_analysis` provides a means for the user to override the automatic parallel configuration (refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [5]) for the number of processors used for each analysis partition.

Usage Tips

- If both `analysis_servers` and `processors_per_analysis` are specified and they are not in agreement, then `analysis_servers` takes precedence.

7.5.2.6 plugin

- Keywords Area
- interface
- analysis_drivers
- plugin

Dynamically load a plugin analysis driver

Specification

Alias: none

Argument(s): none

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required</td>
<td>library_path</td>
<td></td>
<td>Path to the plugin shared object file</td>
</tr>
</tbody>
</table>

Description

Dakota 6.16 allows for run-time loading of a C++ or Python plugin analysis driver as a shared object file. Python plugins support batch evaluations (batch) through a list of dictionaries.
Examples

See dakota/src/plugins and dakota/share/dakota/test/dakota_plugin.in for C++ and Python demos. These have only been tested on Linux.

7.5.2.6.1 library_path

Path to the plugin shared object file

Specification

Alias: none

Argument(s): STRING

Default: none

Description

Dakota 6.16 requires the path to the plugin. We plan to make this specification more flexible in a future release.

7.5.2.7 matlab

Run Matlab through a direct interface - requires special Dakota build

Specification

Alias: none

Argument(s): none

Description

Dakota supports a library-linked interface to Matlab, but it must be explicitly enabled when compiling Dakota from source. Consult the Users Manual [5] for discussion and examples. Contact the Dakota users mailing list for assistance building and using Dakota with these interfaces.

The analysis_drivers specifies a Matlab file which implements the parameter to response mapping.
Examples

See dakota/share/dakota/examples/users/MATLAB/linked

7.5.2.8 python

- Keywords Area
- interface
- analysis_drivers
- python

Run Python through a Pybind11-based direct interface - requires a special Dakota build

Specification

Alias: none

Argument(s): none

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>numpy</td>
<td>Enable the use of numpy in Dakota’s Python interface</td>
</tr>
</tbody>
</table>

Description

Dakota supports a library-linked interface to Python, but it must be explicitly enabled when compiling Dakota from source. Consult the Users Manual [5] for discussion, examples, and documentation of the dictionary-based API. Contact the Dakota users mailing list for assistance building and using Dakota with these interfaces.

The analysis_drivers keyword specifies a Python module:function which implements the parameter to response mapping. List data structures are the default, but NumPy is also supported, if enabled in the build.

Batch evaluations (batch) are supported through a list of dictionaries.

Examples

See dakota/share/dakota/examples/official/drivers/Python/linked and dakota/share/dakota/examples/official/drivers/Python/linked_di for an example of its integration with dakota.interfacing.

7.5.2.8.1 numpy

- Keywords Area
- interface
- analysis_drivers
- python
- numpy

Enable the use of numpy in Dakota’s Python interface
Specification

Alias: none
Argument(s): none
Default: Python list dataflow

Description

When the `numpy` keyword is used, Dakota expects responses in the form of a Python dictionary of numpy arrays. See the example in `dakota/share/dakota/examples/official/drivers/Python/linked`.

7.5.2.9 legacy_python

- Keywords Area
- interface
- analysis_drivers
- legacy_python

Run Python through a deprecated C-based direct interface - requires a special Dakota build

Specification

Alias: none
Argument(s): none

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>numpy</td>
<td>Enable the use of numpy in Dakota’s Python interface</td>
</tr>
</tbody>
</table>

Description

This interface has been superseded by a Pybind11 implementation `python`.

Dakota supports a library-linked interface to Python, but it must be explicitly enabled when compiling Dakota from source. The `analysis_drivers` keyword specifies a Python module:function which implements the parameter to response mapping. List data structures are the default, but NumPy is also supported, if enabled in the build.

7.5.2.9.1 numpy

- Keywords Area
- interface
- analysis_drivers
- legacy_python
- numpy

Enable the use of numpy in Dakota’s Python interface
7.5 interface

Specification

Alias: none
Argument(s): none
Default: Python list dataflow

Description

When the numpy keyword is used, Dakota expects responses in the form of a Python dictionary of numpy arrays.

7.5.2.10 scilab

- Keywords Area
- interface
- analysis_drivers
- scilab

Run Scilab through a direct interface - requires special Dakota build

Specification

Alias: none
Argument(s): none

Description

Dakota supports a library-linked interface to Scilab, but it must be explicitly enabled when compiling Dakota from source. Consult the Users Manual [5] for discussion and examples. Contact the Dakota users mailing list for assistance building and using Dakota with these interfaces.

The analysis_drivers specifies a Scilab file which implements the parameter to response mapping.

Examples

See dakota/share/dakota/examples/users/Scilab/linked

7.5.2.11 grid

- Keywords Area
- interface
- analysis_drivers
- grid

Deprecated grid computing interface
 specification

**Alias:** none

**Argument(s):** none

**Description**

Interface Dakota directly to a grid (distributed) computing engine. This deprecated capability was historically used for interfaces with IDEA and JAVASpaces in the past and was intended as a placeholder for future work with Condor and/or Globus services. It is not currently operational.

7.5.2.12 analysis_components

- **Keywords Area**
- **interface**
- **analysis_drivers**
- **analysis_components**

Provide additional identifiers to analysis drivers.

**Specification**

**Alias:** none

**Argument(s):** STRINGLIST

**Default:** no additional identifiers

**Description**

The optional `analysis_components` specification allows the user to provide additional identifiers (e.g., mesh file names) for use by the analysis drivers. This is particularly useful when the same analysis driver is to be reused multiple times for slightly different analyses. The specific content within the strings is open-ended and can involve whatever syntax is convenient for a particular analysis driver. The number of analysis components $n_c$ should be an integer multiple of the number of drivers $n_d$, and the first $n_c/n_d$ component strings will be passed to the first driver, etc.

7.5.3 algebraic_mappings

- **Keywords Area**
- **interface**
- **algebraic_mappings**

Use AMPL to define algebraic input-output mappings

**Specification**

**Alias:** none

**Argument(s):** STRING

**Default:** no algebraic mappings
Description

Dakota can evaluate algebraic input-output mappings using AMPL [26]. The mappings are expressed in 3 files: stub.nl, stub.col, and stub.row, where stub is a particular root name describing a particular problem. The file names are communicated to Dakota using the algebraic_mappings keyword. It may either specify the full stub.nl filename, or alternatively, just the stub basename.

Dakota then extracts the input and output identifier strings from stub.col and stub.row and employs the AMPL solver library [29] to process the directed acyclic graph (DAG) specification in stub.nl. The variable and objective function names declared within AMPL should be a subset of the variable and response descriptors specified in the variables and responses blocks. Ordering is not important, as Dakota will reorder data as needed.

Examples

An interface employing both algebraic and simulation-based mappings. The results from the individual algebraic and simulation mappings are overlaid based on the variable and response descriptors used by the individual mappings.

```plaintext
interface,
    algebraic_mappings = 'ampl/fma.nl'
fork
    analysis_driver = 'text_book'
    parameters_file = 'tb.in'
    results_file = 'tb.out'
```

7.5.4 failure_capture

- Keywords Area
  - interface
  - failure_capture

Determine how Dakota responds to analysis driver failure

Specification

**Alias:** none

**Argument(s):** none

**Default:** abort

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required (Choose One)</td>
<td>Failure Mitigation (Group 1)</td>
<td>abort</td>
<td>(Default) Abort the Dakota job</td>
</tr>
<tr>
<td></td>
<td></td>
<td>retry</td>
<td>Rerun failed analyses</td>
</tr>
<tr>
<td></td>
<td></td>
<td>recover</td>
<td>Substitute dummy values for the responses</td>
</tr>
</tbody>
</table>
Dakota can deal with analysis failure in a few ways. The first step is that Dakota must detect analysis failure. Importantly, Dakota always expects a results file to be written by the analysis driver, even when a failure has occurred. If the file does not exist when the analysis driver exits, a Dakota error results, causing Dakota itself to terminate. The analysis driver communicates an analysis failure to Dakota by writing a results file beginning with the (case-insensitive) word "fail". Any file contents after "fail" are ignored.

Once Dakota detects analysis failure, the failure can be mitigated in four ways:

- **abort** (the default)
- **retry**
- **recover**
- **continuation**

### 7.5.4.1 abort

- **Keywords Area**
- **interface**
- **failure_capture**
- **abort**

(Default) Abort the Dakota job

**Specification**

- **Alias**: none
- **Argument(s)**: none

**Description**

Stop the Dakota job, as well as any other running analysis drivers when a failure is communicated.

### 7.5.4.2 retry

- **Keywords Area**
- **interface**
- **failure_capture**
7.5 interface

- retry

Rerun failed analyses

Specification

Alias: none
Argument(s): INTEGER

Description

Number of times to retry a failing analysis

7.5.4.3 recover

- Keywords Area
- interface
- failure_capture
- recover

Substitute dummy values for the responses

Specification

Alias: none
Argument(s): REALLIST

Description

When a simulation failure is detected, substitute the provided dummy function values in the response. Gradient and Hessian are not supported.

7.5.4.4 continuation

- Keywords Area
- interface
- failure_capture
- continuation

Cause Dakota to step toward the failed "target" simulation from a nearby successful "source"

Specification

Alias: none
Argument(s): none
Description

When failure_capture continuation is enabled and an evaluation fails, then Dakota will attempt to march incrementally from a previous good evaluation (the "source") toward the failing one (the "target"). Further details about the algorithm employed by Dakota are supplied in the User's Manual [5].

7.5.5 deactivate

- Keywords Area
- interface
- deactivate

Deactivate Dakota interface features for simplicity or efficiency

Specification

Alias: none
Argument(s): none
Default: Active set vector control, function evaluation cache, and restart file features are active

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>active_set_vector</td>
<td></td>
<td>Deactivate the Active Set Vector</td>
</tr>
<tr>
<td>Optional</td>
<td>evaluation_cache</td>
<td></td>
<td>Do not retain function evaluation history in memory</td>
</tr>
<tr>
<td>Optional</td>
<td>strict_cache_equal</td>
<td></td>
<td>Do not require strict cache equality when finding duplicates</td>
</tr>
<tr>
<td>Optional</td>
<td>restart_file</td>
<td></td>
<td>Deactivate writing to the restart file</td>
</tr>
</tbody>
</table>

Description

The optional deactivate specification block allows a user to deactivate interface features in order to simplify interface development, increase execution speed, and/or reduce memory and disk requirements. Any or all of these features may be specified concurrently.

- Active set vector (ASV) control: deactivate so that Dakota expects the same response data (all functions, gradients, Hessian) back from the simulation on every evaluation, instead of only those components required by the method for this particular function evaluation.

- Function evaluation cache: save memory by not caching the function evaluation history. May result in additional (duplicate) function evaluations.
7.5 interface

- Strict cache equality: allow a relaxed tolerance when detecting duplicate function evaluations. Can be useful when importing data or restarting across machines.

- Restart file: improve efficiency and eliminate restart file storage at the risk of not being able to recover a failed or partial Dakota study.

7.5.5.1 active_set_vector

- Keywords Area
- interface
- deactivate
- active_set_vector

Deactivate the Active Set Vector

Specification

Alias: none
Argument(s): none

Description

Allows the user to turn off any variability in ASV values so that active set logic can be omitted in the user's simulation interface. This option trades some efficiency for simplicity in interface development.

The default behavior is to request the minimum amount of data required by an algorithm at any given time, which implies that the ASV values may vary from one function evaluation to the next. Since the user's interface must return the data set requested by the ASV values, this interface must contain additional logic to account for any variations in ASV content.

Deactivating this ASV control causes Dakota to always request a "full" data set (the full function, gradient, and Hessian data that is available from the interface as specified in the responses specification) on each function evaluation. For example, if ASV control has been deactivated and the responses section specifies four response functions, analytic gradients, and no Hessians, then the ASV on every function evaluation will be \{ 3 3 3 3 \}, regardless of what subset of this data is currently needed. While wasteful of computations in many instances, this simplifies the interface and allows the user to return the same data set on every evaluation. Conversely, if ASV control is active (the default behavior), then the ASV requests in this example might vary from \{ 1 1 1 1 \} to \{ 2 0 0 2 \}, etc., according to the specific data needed on a particular function evaluation. This will require the user's interface to read the ASV requests and perform the appropriate logic in conditionally returning only the data requested.

Usage Tips

- In general, the default ASV behavior is recommended for the sake of computational efficiency, unless interface development time is a critical concern.

- Whether active or inactive, the data returned to Dakota from the user's interface must match the ASV passed in, or else a response recovery error will result. However, when the ASV control is deactivated, the ASV values are invariant and need not be checked on every evaluation.

- Deactivating the ASV control can have a positive effect on load balancing for parallel Dakota executions. Thus, there is significant overlap in this ASV control option with speculative gradients. There is also overlap with the mode override approach used with certain optimizers to combine individual value, gradient, and Hessian requests.
7.5.5.2 evaluation_cache

- Keywords Area
- interface
- deactivate
- evaluation_cache

Do not retain function evaluation history in memory

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

Do not retain the complete function evaluation history in memory.

This can be important for reducing memory requirements in large-scale applications (i.e., applications with a large number of variables or response functions) and for eliminating the overhead of searching for duplicates within the function evaluation cache prior to each new function evaluation (e.g., for improving speed in problems with 1000’s of inexpensive function evaluations or for eliminating overhead when performing timing studies).

However, the downside is that unnecessary computations may be performed since duplication in function evaluation requests may not be detected. For this reason, this option is not recommended when function evaluations are costly.

Note: duplication detection within Dakota can be deactivated, but duplication detection features within specific optimizers may still be active.

7.5.5.3 strict_cache_equality

- Keywords Area
- interface
- deactivate
- strict_cache_equality

Do not require strict cache equality when finding duplicates

**Specification**

**Alias:** none

**Argument(s):** none

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>cache_tolerance</td>
<td>Specify tolerance when identifying duplicate function evaluations</td>
</tr>
</tbody>
</table>
Description

By default, Dakota's evaluation cache and restart capabilities are based on strict binary equality. This provides a performance advantage, as it permits a hash-based data structure to be used to search the evaluation cache. However, deactivating strict equality may prevent cache misses, which can occur when attempting to use a restart file on a machine different from the one on which it was generated.

7.5.5.3.1 cache_tolerance

Specify tolerance when identifying duplicate function evaluations

Specification

Alias: none
Argument(s): REAL

Description

Described on parent page

7.5.5.4 restart_file

Deactivate writing to the restart file

Specification

Alias: none
Argument(s): none

Description

Eliminate the output of each new function evaluation to the binary restart file. This can increase speed and reduce disk storage requirements, but at the expense of a loss in the ability to recover and continue a run that terminates prematurely (e.g., due to a system crash or network problem).

Usage Tips

- This option is not recommended when function evaluations are costly or prone to failure.
• Using the `deactivate restart_file` specification will result in a zero length restart file with the default name `dakota.rst`.

7.5.6 batch

• Keywords Area

• interface

• batch

Perform evaluations in batches

Topics

This keyword is related to the topics:

• concurrency_and_parallelism

Specification

Alias: none

Argument(s): none

Default: sequential interface usage

Child Keywords:

<table>
<thead>
<tr>
<th></th>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Optional</td>
<td>size</td>
<td></td>
<td>Limit the number of evaluations in a batch</td>
</tr>
</tbody>
</table>

Description

When the optional batch keyword is used, Dakota performs evaluations in batches. In batch mode, Dakota writes the parameters for multiple (a batch of) evaluations to a single file, invokes the analysis driver once for the whole batch, and expects to find results for the entire batch in a single file after the analysis driver has exited. Batch mode may be useful when a user desires to take greater control over job management. For example, the analysis driver can perform the evaluations in the batch in any sequence or in concurrent sub-batches.

The names of the parameters file and results file are provided as command line arguments to the analysis driver, just as in a conventional, non-batch evaluation. By default, all currently available evaluations will be performed in a single batch, but the batch size can be limited using the size keyword.

Batch mode has a few important limitations.

• Only one batch at a time may be executed. Asynchronous execution of multiple concurrent batches is not supported.

• No `input_filter` or `output_filter` is permitted.

• Only one `analysis_driver` is allowed.

• `failure_capture` modes are restricted to `abort` and `recover`.

Dakota Version 6.16 Reference Manual generated on May 12, 2022
Some of these restrictions may be lifted in future Dakota releases.

File Formats

A batch parameters file written by Dakota is simply a concatenated set of parameters files for the set of evaluations, either in aprepro or default Dakota format.

The batch results file is also a concatenated set of results files for the individual evaluations. However, because Dakota’s results file format is not as rich as its parameters file format, evaluations in the batch results file must be separated by a line that begins with the ‘#’ character.

The order of evaluations in the batch results file must match the order in the batch parameters file.

Tagging and Work Directories

When Dakota’s work_directory feature is enabled, one directory is created per batch. If file_tag or directory_tag is used, parameters/results files and work directories are tagged with a batch Id, which is an integer that begins with 1 and increments for each new batch.

7.5.6.1 size

- Keywords Area
  - interface
  - batch
  - size

Limit the number of evaluations in a batch

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none

Argument(s): INTEGER

Default: local: unlimited batch size, hybrid: zero batch size

Description

When batch execution is enabled, the default behavior is to add all available evaluations to the current batch. The size keyword limits the number of evaluations in a batch.

7.5.7 asynchronous

- Keywords Area
  - interface
  - asynchronous

Specify local evaluation or analysis concurrency
Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none
Argument(s): none
Default: synchronous interface usage

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional Group</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>evaluation_concurrency</td>
<td>Determine how many concurrent evaluations Dakota will schedule</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>local_evaluation_scheduling</td>
<td>Control how local asynchronous jobs are scheduled</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>analysis_concurrency</td>
<td>Limit the number of analysis drivers within an evaluation that Dakota will schedule</td>
</tr>
</tbody>
</table>

Description

The optional asynchronous keyword specifies use of asynchronous protocols (i.e., background system calls, nonblocking forks, POSIX threads) when evaluations or analyses are invoked. Evaluation and analysis concurrency can be independently controlled, as can the scheduling mode (static vs. dynamic) of the local evaluations.

Default Behavior

- when running Dakota on a single processor in asynchronous mode, the default concurrency of evaluations and analyses is all concurrency that is available. The evaluation_concurrency and analysis_concurrency specifications can be used to limit this concurrency in order to avoid machine overload or usage policy violation.

- when running Dakota on multiple processors in message passing mode, the default concurrency of evaluations and analyses on each of the servers is one (i.e., the parallelism is exclusively that of the message passing). With the evaluation_concurrency and analysis_concurrency specifications, a hybrid parallelism can be selected through combination of message passing parallelism with asynchronous parallelism on each server.

7.5.7.1 evaluation_concurrency

- Keywords Area
- interface
- asynchronous
7.5 interface

- **evaluation_concurrency**

Determine how many concurrent evaluations Dakota will schedule

**Topics**

This keyword is related to the topics:

- concurrency_and_parallelism

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** local: unlimited concurrency, hybrid: no concurrency

**Description**

When asynchronous execution is enabled, the default behavior is to launch all available evaluations simultaneously. The `evaluation_concurrency` keyword can be used to limit the number of concurrent evaluations.

7.5.7.2 local_evaluation_scheduling

- **Keywords Area**
- **interface**
- **asynchronous**
- **local_evaluation_scheduling**

Control how local asynchronous jobs are scheduled

**Topics**

This keyword is related to the topics:

- concurrency_and_parallelism

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** dynamic

**Child Keywords:**

<table>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Dakota Version 6.16 Reference Manual generated on May 12, 2022
### Description

When performing asynchronous local evaluations, the `local_evaluation_scheduling` keyword controls how new evaluation jobs are dispatched when one completes.

The two options are:

- **dynamic**
- **static**

If the `local_evaluation_scheduling` is specified as dynamic (the default), each completed evaluation will be replaced by the next in the local evaluation queue.

If `local_evaluation_scheduling` is specified as static, each completed evaluation will be replaced by an evaluation number that is congruent modulo the `evaluation_concurrency`. This is helpful for relative node scheduling as described in `dakota/share/dakota/examples/parallelism`. For example, assuming only asynchronous local concurrency (no MPI), if the local concurrency is 6 and job 2 completes, it will be replaced with job 8.

For the case of hybrid parallelism, static local scheduling results in evaluation replacements that are modulo the total capacity, defined as the product of the evaluation concurrency and the number of evaluation servers. Both of these cases can result in idle processors if runtimes are non-uniform, so the default dynamic scheduling is preferred when relative node scheduling is not required.

#### 7.5.7.2.1 dynamic

- **Keywords Area**
- **interface**
- **asynchronous**
- **local_evaluation_scheduling**
- **dynamic**

Dynamic local scheduling (sequential)

#### Specification

**Alias**: none

**Argument(s)**: none

#### Description

If the `local_evaluation_scheduling` is specified as dynamic (the default), each completed evaluation will be replaced by the next in the local evaluation queue.
• asynchronous
• local_evaluation_scheduling
• static

Static local scheduling (tiled)

Specification

Alias: none
Argument(s): none

Description

If local_evaluation_scheduling is specified as static, each completed evaluation will be replaced by an evaluation number that is congruent modulo the evaluation_concurrency. This is helpful for relative node scheduling as described in dakota/share/dakota/examples/parallelism. For example, assuming only asynchronous local concurrency (no MPI), if the local concurrency is 6 and job 2 completes, it will be replaced with job 8.

For the case of hybrid parallelism, static local scheduling results in evaluation replacements that are modulo the total capacity, defined as the product of the evaluation concurrency and the number of evaluation servers. Both of these cases can result in idle processors if runtimes are non-uniform, so the default dynamic scheduling is preferred when relative node scheduling is not required.

7.5.7.3 analysis_concurrency

• Keywords Area
• interface
• asynchronous
• analysis_concurrency

Limit the number of analysis drivers within an evaluation that Dakota will schedule

Topics

This keyword is related to the topics:

• concurrency_and_parallelism

Specification

Alias: none
Argument(s): INTEGER
Default: local: unlimited concurrency, hybrid: no concurrency

Description

When asynchronous execution is enabled and each evaluation involves multiple analysis drivers, then the default behavior is to launch all drivers simultaneously. The analysis_concurrency keyword can be used to limit the number of concurrently run drivers.
7.5.8 evaluation_servers

Specify the number of evaluation servers when Dakota is run in parallel

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** automatic (see discussion)

Description

The optional `evaluation_servers` specification supports user override of the automatic parallel configuration for the number of evaluation servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the evaluation parallelism level. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [5] for additional information.

7.5.9 evaluation_scheduling

Specify the scheduling of concurrent evaluations when Dakota is run in parallel

Specification

**Alias:** none  
**Argument(s):** none  
**Default:** automatic (see discussion)  
**Child Keywords:**
7.5 interface

<table>
<thead>
<tr>
<th>Required/Optional</th>

<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required (Choose One)</td>
<td></td>
<td>master</td>
<td>Specify a dedicated master partition for parallel evaluation scheduling</td>
</tr>
<tr>
<td>peer</td>
<td></td>
<td></td>
<td>Specify a peer partition for parallel evaluation scheduling</td>
</tr>
</tbody>
</table>

**Description**

When Dakota is run in parallel, the partition type and scheduling for the evaluation servers are determined automatically. If these settings are undesirable, they may be overridden by the user using the `evaluation_scheduling` keyword.

**7.5.9.1 master**

- **Keywords Area**
- interface
- evaluation_scheduling
- master

Specify a dedicated master partition for parallel evaluation scheduling

**Topics**

This keyword is related to the topics:

- concurrency_and_parallelism

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

This option overrides the Dakota parallel automatic configuration, forcing the use of a dedicated master partition. In a dedicated master partition, one processor (the "master") dynamically schedules work on the evaluation servers. This reduces the number of processors available to create servers by 1.

**7.5.9.2 peer**

- **Keywords Area**
- interface
- evaluation_scheduling
- peer
Specify a peer partition for parallel evaluation scheduling

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

**Alias:** none

**Argument(s):** none

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional Required (Choose One)</th>
<th>Description of Group Scheduling Mode (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>dynamic</td>
<td>Specify dynamic scheduling in a peer partition when Dakota is run in parallel.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>static</td>
<td>Specify static scheduling in a peer partition when Dakota is run in parallel.</td>
</tr>
</tbody>
</table>

**Description**

This option overrides the Dakota parallel automatic configuration, forcing the use of a peer partition. In a peer partition, all processors are available to be assigned to evaluation servers. The scheduling, static or dynamic, must also be specified.

7.5.9.2.1 dynamic

- Keywords Area
- interface
- evaluation_scheduling
- peer
- dynamic

Specify dynamic scheduling in a peer partition when Dakota is run in parallel.

Topics

This keyword is related to the topics:

- concurrency_and_parallelism
7.5 interface

Specification

Alias: none
Argument(s): none
Default: dynamic (see discussion)

Description

In dynamic scheduling, evaluations are assigned to servers as earlier evaluations complete. Dynamic scheduling is advantageous when evaluations are of uneven duration.

7.5.9.2.2 static

- Keywords Area
- interface
- evaluation_scheduling
- peer
- static

Specify static scheduling in a peer partition when Dakota is run in parallel.

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none
Argument(s): none

Description

In static scheduling, all available evaluations are assigned to servers in a predetermined fashion. Each completed evaluation is replaced with one congruent modulo the evaluation concurrency. For example, with 6 servers, eval number 2 will be replaced by eval number 8.

7.5.10 processors_per_evaluation

- Keywords Area
- interface
- processors_per_evaluation

Specify the number of processors per evaluation server when Dakota is run in parallel
Keywords Area

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none

Argument(s): INTEGER

Default: automatic (see discussion)

Description

The optional \texttt{processors\_per\_evaluation} specification supports user override of the automatic parallel configuration for the number of processors in each evaluation server. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired server size at the evaluation parallelism level. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [5] for additional information.

7.5.11 analysis_servers

Specify the number of analysis servers when Dakota is run in parallel

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none

Argument(s): INTEGER

Default: automatic (see discussion)

Description

The optional \texttt{analysis\_servers} specification supports user override of the automatic parallel configuration for the number of analysis servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the analysis parallelism level. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [5] for additional information.
7.5.12 analysis_scheduling

- Keywords Area
- interface
- analysis_scheduling

Specify the scheduling of concurrent analyses when Dakota is run in parallel

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none

Argument(s): none

Default: automatic (see discussion)

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional Required (Choose One)</th>
<th>Description of Group Scheduling Mode (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>master</td>
<td>Specify a dedicated master partition for parallel analysis scheduling</td>
</tr>
</tbody>
</table>

Description

When Dakota is run in parallel, the partition type for the analysis servers is determined automatically. If this setting is undesirable, it may be overridden by the user using the analysis_scheduling keyword.

7.5.12.1 master

- Keywords Area
- interface
- analysis_scheduling
- master

Specify a dedicated master partition for parallel analysis scheduling

Topics

This keyword is related to the topics:

- concurrency_and_parallelism
Specification

**Alias:** none

**Argument(s):** none

**Description**

This option overrides the Dakota parallel automatic configuration, forcing the use of a dedicated master partition. In a dedicated master partition, one processor (the "master") dynamically schedules work on the analysis servers. This reduces the number of processors available to create servers by 1.

### 7.5.12.2 peer

- **Keywords Area**
- **interface**
- **analysis_scheduling**
- **peer**

Specify a peer partition for parallel analysis scheduling

**Topics**

This keyword is related to the topics:

- **concurrency_and_parallelism**

Specification

**Alias:** none

**Argument(s):** none

**Description**

This option overrides the Dakota parallel automatic configuration, forcing the use of a peer partition. In a peer partition, all processors are available to be assigned to analysis servers. Note that unlike the case of `evaluation_scheduling`, it is not possible to specify `static` or `dynamic`.

### 7.6 responses

- **Keywords Area**
- **responses**

Description of the model output data returned to Dakota upon evaluation of an interface.

**Topics**

This keyword is related to the topics:

- **block**
### Specification

**Alias:** none  
**Argument(s):** none

</tbody>
</table>
### Description

The `responses` specification in a Dakota input file indicates the types of data that can be returned by an interface when invoked during Dakota’s execution. The specification includes three groups and two optional keywords.

The **response type group** indicates the type and number of responses expected by Dakota. It must be one of three types:

1. **Optimization**: objective and constraint functions
2. **Calibration**: calibration (least squares) terms and constraint functions
3. **Uncertainty Quantification**: generic response functions

The response type specified should be consistent with the iterative technique called for in the method specification. Certain general-purpose iterative techniques, such as parameter studies and design of experiments methods, can be used with any of these response types.

The **gradient type group** indicates the availability of first derivatives (gradient vectors) for the response functions. The gradient specification also links back to the iterative method used. Gradients commonly are needed when the iterative study involves gradient-based optimization, local reliability analysis for uncertainty quantification, or local sensitivity analysis. They can optionally be used to build some types of surrogate models.

The **Hessian type group** specifies the availability of second derivatives (Hessian matrices) for the response functions. Hessian availability for the response functions is similar to the gradient availability specifications, with the addition of support for "quasi-Hessians". The Hessian specification also links back to the iterative method in use; Hessians commonly would be used in gradient-based optimization by full Newton methods or in reliability analysis with second-order limit state approximations or second-order probability integrations.
Examples

Several examples follow. The first example shows an optimization data set containing an objective function and two nonlinear inequality constraints. These three functions have analytic gradient availability and no Hessian availability.

```
responses
  objective_functions = 1
  nonlinear_inequality_constraints = 2
  analytic_gradients
  no_hessians
```

The next example shows a typical specification for a calibration data set. The six residual functions will have numerical gradients computed using the dakota finite differencing routine with central differences of 0.1% (plus/minus delta relative to current variables value = .001*value).

```
responses
  calibration_terms = 6
  numerical_gradients
  method_source dakota
  interval_type central
  fd_gradient_step_size = .001
  no_hessians
```

The last example shows a generic specification that could be used with a nondeterministic sampling iterator. The three response functions have no gradient or Hessian availability; therefore, only function values will be used by the iterator.

```
responses
  response_functions = 3
  no_gradients
  no_hessians
```

Parameter study and design of experiments iterators are not restricted in terms of the response data sets which may be catalogued; they may be used with any of the function specification examples shown above.

Theory

Responses specify the total data set that is available for use by the method over the course of iteration. This is distinguished from the data subset described by an active set vector (see Dakota File Data Formats in the Users Manual [Adams et al., 2010]) indicating the particular subset of the response data needed for a particular function evaluation. Thus, the responses specification is a broad description of the data to be used during a study whereas the active set vector indicates the subset currently needed.

7.6.1 id_responses

- Keywords Area
- responses
- id_responses

Name the responses block; helpful when there are multiple

Topics

This keyword is related to the topics:

- block_identifier
Specification

Alias: none

Argument(s): STRING

Default: use of last responses parsed

Description

The optional id_responses keyword accepts a string that uniquely identifies this responses block. A model can then use these responses by specifying the same string in its responses_pointer specification.

Default Behavior

If the id_responses specification is omitted, a particular responses specification will be used by a model only if that model does not include an responses_pointer and the responses block was the last (or only) one parsed.

Usage Tips

• It is a best practice to always use explicit responses IDs and pointers to avoid confusion.

• If only one responses block exists, then id_responses can be safely omitted from the responses block (and responses_pointer omitted from the model specification(s)), since there is no ambiguity.

Examples

For example, a model specification including

```dakota
model
  responses_pointer = 'R1'
```

will link to a response set with

```dakota
id_responses = 'R1'
```

7.6.2 descriptors

• Keywords Area

• responses

• descriptors

Labels for the responses

Specification

Alias: response_descriptors

Argument(s): STRINGLIST

Default: root strings plus numeric identifiers

Description

A list of strings which identify the responses. These are used in console and tabular output. Response descriptors are ordered by primary response functions (objective, calibration, or response functions), followed by inequality, then equality constraints, if present.
Default Behavior

The default descriptor strings use a response type-dependent root string plus a one-based numeric identifier:

- Objective functions: `obj_fn_i`
- Calibration terms: `least_sq_term_i`
- Nonlinear inequality constraints: `nln_ineq_con_i`
- Nonlinear equality constraints: `nln_eq_con_i`
- Response functions: `response_fn_`

Expected Output Dakota will label the various response functions in console and tabular output.

Usage Tips When specifying descriptors for scalar and/or field responses, include as many descriptors as top-level scalar + field responses, e.g.,

```plaintext
responses
descriptors 'scalar1' 'scalar2' 'scalar3' 'field1' 'field2'
response_functions 5
  scalar_responses 3
  field_responses 2
  field_lengths 42 24
```

Dakota will append a numeric identifier for each field entry, for a total of 42 field1_j and 24 field2_k in this example.

Examples

```plaintext
responses
descriptors 'cost' 'impact' 'safety'
objective_functions 2
  nonlinear_inequality_constraints 1
```

7.6.3 objective_functions

- Keywords Area

- responses

- objective_functions

Response type suitable for optimization

Specification

**Alias:** num_objective_functions

**Argument(s):** INTEGER

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>sense</td>
<td>Whether to minimize or maximize each objective function</td>
</tr>
</tbody>
</table>
Description

Specifies the number (1 or more) of objective functions \( f_j \) returned to Dakota for use in the general optimization problem formulation:

\[
\begin{align*}
\text{minimize:} & \quad f(x) = \sum_j w_j f_j \\
\text{subject to:} & \quad \begin{align*}
& g_L \leq g(x) \leq g_U \\
& h(x) = h_t \\
& a_L \leq A_x \leq a_U \\
& A_e x = a_t \\
& x_L \leq x \leq x_U
\end{align*}
\end{align*}
\]

Unless \texttt{sense} is specified, Dakota will minimize the objective functions.

The keywords \texttt{nonlinear	extunderscore inequality	extunderscore constraints} and \texttt{nonlinear	extunderscore equality	extunderscore constraints} specify the number of nonlinear inequality constraints \( g \), and nonlinear equality constraints \( h \), respectively. When interfacing to external applications, the responses must be returned to Dakota in this order in the \texttt{results	extunderscore file}:

1. objective functions
2. nonlinear	extunderscore inequality	extunderscore constraints
3. nonlinear	extunderscore equality	extunderscore constraints

An optimization problem’s linear constraints are provided to the solver at startup only and do not need to be included in the data returned on every function evaluation. Linear constraints are therefore specified in the \texttt{variables} block through the \texttt{linear	extunderscore inequality	extunderscore constraint	extunderscore matrix} \( A_i \) and \texttt{linear	extunderscore equality	extunderscore constraint	extunderscore matrix} \( A_e \).

Lower and upper bounds on the design variables \( x \) are also specified in the \texttt{variables} block.
The optional keywords relate to scaling the objective functions (for better numerical results), formulating the problem as minimization or maximization, and dealing with multiple objective functions through weights $w$. If scaling is used, it is applied before multi-objective weighted sums are formed, so, e.g., when both weighting and characteristic value scaling are present the ultimate objective function would be:

$$ f = \sum_{j=1}^{n} w_j \frac{f_j}{s_j} $$

7.6.3.1 sense

Whether to minimize or maximize each objective function

Specification

Alias: none

Argument(s): STRINGLIST

Default: vector values = ‘minimize’

Description

The sense keyword is used to declare whether each objective function should be minimized or maximized. The argument options are:

- "minimization" (can be abbreviated to "min")
- "maximization" (can be abbreviated to "max")

If a single string is specified it will apply to each objective function. Otherwise, the number of strings should either be equal to the number of objective functions (objective_functions). Thus, when scalar and/or field responses are specified, the number of sense strings must equal the number of scalars plus the number of fields, not the total elements in the fields.
7.6.3.2 primary_scale_types

- Keywords Area
- responses
- objective_functions
- primary_scale_types

How to scale each objective function

Specification

Alias: objective_function_scale_types
Argument(s): STRINGLIST
Default: no scaling

Description

Each string in primary_scale_types indicates the scaling type for each objective function. They only have effect when the associated method specifies scaling.

The options are:

- ‘value’ - characteristic value by which response functions will be divided. If this is chosen, then primary_scales must also be specified; ‘value’ is assumed if scales are given without scale_types

- ‘log’ - logarithmic scaling (can be used together with primary_scales, which can be helpfully used to negate values prior to log transformation)

(Automatic scaling is disallowed due to lack of bounds or targets for primary responses.)

If a single string is specified it will apply to all objective_functions. Otherwise the length of primary_scale_types must have length equal to objective_functions. Thus, when scalar and/or field responses are specified, the number of primary_scale_types must equal the number of scalars plus the number of fields, not the total elements in the fields.

Usage Tips:

When scaling is active, it is applied to objective functions prior to any weights and multi-objective sum formation.

See the scaling information under specific methods, e.g., method-**-scaling for details on how to use this keyword.

7.6.3.3 primary_scales

- Keywords Area
- responses
- objective_functions
- primary_scales

Characteristic values to scale each objective function

Dakota Version 6.16 Reference Manual generated on May 12, 2022
Specification

Alias: objective_function_scales
Argument(s): REALLIST
Default: 1.0 (no scaling)

Description

Each real value in primary_scales is a nonzero characteristic value to be used in scaling each objective function. They only have effect when the associated method specifies scaling.

This keyword is required for primary_scale_types of 'value' and optional for 'log'. When specified in conjunction with log, scale values are applied prior to the logarithm, to permit log scaling of strictly negative response functions.

Length: When specified, primary_scales must have length one of:

- One (the single value will be applied to each objective function); or
- Number of response groups (objective_functions), so the number of scalars plus the number of fields when fields are present; or
- Total number of response elements, so the number of scalar responses plus the sum of the lengths of the fields.

Usage Tips:

When primary_scales are specified, but not primary_scale_types, the scaling type is assumed to be 'value' for all primary response functions.

Use scale values of 1.0 to selectively avoid scaling a subset of response functions.

When scaling is active, it is applied to objective functions prior to any weights and multi-objective sum formation. See the equations in objective_functions.

See the scaling information under specific methods, e.g., method-**-scaling for details on how to use this keyword.

7.6.3.4 weights

- Keywords Area
- responses
- objective_functions
- weights

Specify weights for each objective function

Specification

Alias: multi_objective_weights
Argument(s): REALLIST
Default: equal weights
Description

For multi-objective optimization problems (where the number of objective functions is greater than 1), then a weights specification provides a simple weighted-sum approach to combining multiple objectives into a single objective:

\[ f = \sum_{i=1}^{n} w_i f_i \]

Length: The weights must have length equal to objective_functions. Thus, when scalar and/or field responses are specified, the number of weights must equal the number of scalars plus the number of fields, not the total elements in the fields.

Default Behavior If weights are not specified, then each response is given equal weighting:

\[ f = \frac{\sum_{i=1}^{n} f_i}{n} \]

where, in both of these cases, a "minimization" sense will retain a positive weighting for a minimizer and a "maximization" sense will apply a negative weighting.

Usage Tips:

Weights are applied as multipliers, scales as characteristic values / divisors.

When scaling is active, it is applied to objective functions prior to any weights and multi-objective sum formation. See the equations in objective_functions.

Dakota Version 6.16 Reference Manual generated on May 12, 2022
### Description

Specifies the number of nonlinear inequality constraint functions returned by the interface.

The `lower_bounds` and `upper_bounds` specifications provide the lower and upper bounds for 2-sided nonlinear inequalities of the form

\[ g_l \leq g(x) \leq g_u \]

When constraint bounds are not specified, the problem is assumed to have one-sided inequalities bounded above by zero:

\[ g(x) \leq 0.0. \]

This provides backwards compatibility with previous Dakota versions.

In a user bounds specification, any upper bound values greater than `+bigRealBoundSize` (1.e+30, as defined in Minimizer) are treated as `+infinity` and any lower bound values less than `-bigRealBoundSize` are treated as `-infinity`. This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since `-DBL_MAX < -bigRealBoundSize`). The same approach is used for nonexistent linear inequality bounds and for nonexistent design variable bounds.

The `scale_types` and `scales` keywords are related to scaling of \( g(x) \). See the scaling information under specific methods, e.g., method-∗-scaling for details on how to use this keyword.

- nonlinear_equality_constraints
- scales

Characteristic values to scale each nonlinear constraint

**Specification**

**Alias:** nonlinear_equality_scales  
**Argument(s):** REALLIST  
**Default:** 1.0 (no scaling)

**Description**

Each real value in `scales` is a nonzero characteristic value to be used in scaling each nonlinear inequality (equality) constraint. They only have effect when the associated method specifies `scaling`.  
This keyword is required for `scale_types` of `value` and optional for `log`. When specified in conjunction with log, scale values are applied prior to the logarithm, to permit log scaling of strictly negative response functions. If a single scale value is specified it will apply to all of the nonlinear inequality (equality) constraints. Otherwise a value must be specified for each nonlinear inequality (equality) constraint.

**Usage Tips:**
When `scales` are specified, but not `scale_types`, the scaling type is assumed to be `value` for this set of nonlinear inequality (equality) constraints.
Use scale values of 1.0 to selectively avoid scaling a subset of response functions.
See the scaling information under specific methods, e.g., method-∗-scaling for details on how to use this keyword.

7.6.3.7 scalar_objectives

- Keywords Area
- responses
- objective_functions
- scalar_objectives

Number of scalar objective functions

**Specification**

**Alias:** num_scalar_objectives  
**Argument(s):** INTEGER
Description

This keyword describes the number of scalar objective functions. It is meant to be used in conjunction with field_objectives, which describes the number of field objectives functions. The total number of objective functions, both scalar and field, is given by objective_functions. If only scalar objective functions are specified, it is not necessary to specify the number of scalar terms explicitly: one can simply say objective_functions = 5 and get 5 scalar objectives. However, if there are three scalar objectives and 2 field objectives, then objective_functions = 5 but scalar_objectives = 3 and field_objectives = 2.

Objective functions are responses that are used with optimization methods in Dakota. Currently, each term in a field objective is added to the total objective function presented to the optimizer. For example, if you have one field objective with 100 terms (e.g. a time-temperature trace with 100 time points and 100 corresponding temperature points), the 100 temperature values will be added to create the overall objective.

See Also

These keywords may also be of interest:

- field_objectives

7.6.3.8 field_objectives

- Keywords Area
- responses
- objective_functions
- field_objectives

Number of field objective functions

Specification

Alias: num_field_objectives

Argument(s): INTEGER

Child Keywords:

<table>
<thead>

<tr>
<td>Optional</td>
<td>read_field_coordinates</td>
<td>read_field_coordinates</td>
<td>Add context to data: flag to indicate that field coordinates should be read</td>
</tr>
</tbody>
</table>
This keyword describes the number of field objective functions. A field function is a set of related response values collected over a range of independent coordinate values which may or may not be specified by the user. For example, voltage over time would be a field function, where voltage is the field_objective and time is the independent coordinate. Similarly, temperature over time and space would be a field response, where the independent coordinates would be both time and spatial coordinates such as (x,y) or (x,y,z), depending on the application. The main difference between scalar objectives and field objectives is that for field data, we plan to implement methods that take advantage of the correlation or relationship between the field values.

Note that if there is one field_objective, and it has length 100 (meaning 100 values), then the user’s simulation code must return 100 values. Also, if there are both scalar and field objectives, the user should specify the number of scalar objectives as scalar_objectives. If there are only field objectives, it still is necessary to specify both objective_functions = NN and field_objectives = NN, where NN is the number of field objectives.

Objective functions are responses that are used with optimization methods in Dakota. Currently, each term in a field objective is added to the total objective function presented to the optimizer. For example, if you have one field objective with 100 terms (e.g. a time-temperature trace with 100 time points and 100 corresponding temperature points), the 100 temperature values will be added to create the overall objective.

7.6.3.8.3 read_field_coordinates

- Keywords Area
- responses
- objective_functions
- field_objectives
- read_field_coordinates

Add context to data: flag to indicate that field coordinates should be read
Specification

Alias: none
Argument(s): none

Description

Field coordinates specify independent variables (e.g. spatial or temporal coordinates) upon which the field depends. For example, the voltage level above might be a function of time, so time is the field coordinate. If the user has field coordinates to read, they need to specify read_field_coordinates. The field coordinates will then be read from a file named response_descriptor.coords, where response_descriptor is the user-provided descriptor for the field response. The number of columns in the coords file should be equal to the number of field coordinates.

Optional (Choose One) Calibration Data (Group 1)

calibration_data | Supply field or mixed field/scalar calibration data
### Description

Responses for a calibration study are specified using `calibration_terms` and optional keywords for weighting/scaling, data, and constraints. In general when calibrating, Dakota automatically tunes parameters $\theta$ to minimize discrepancies or residuals between the model and the data:

$$ R_i = \text{Model}_i(\theta) - \text{Data}_i. $$

Note that the problem specification affects what must be returned to Dakota in the `results_file`:

- If calibration data is not specified, then each of the calibration terms returned to Dakota through the interface is a residual $R_i$ to be driven toward zero.

- If calibration data is specified, then each of the calibration terms returned to Dakota must be a response $\text{Model}_i(\theta)$, which Dakota will difference with the data in the specified data file.

### Constraints

(See general problem formulation at `objective_functions`.) The keywords `nonlinear_inequality_constraints` and `nonlinear_equality_constraints` specify the number of nonlinear inequality constraints $g$, and nonlinear equality constraints $h$, respectively. When interfacing to external applications, the responses must be returned to Dakota in this order in the `results_file`:

1. calibration terms
2. nonlinear inequality constraints
3. nonlinear equality constraints

An optimization problem’s linear constraints are provided to the solver at startup only and do not need to be included in the data returned on every function evaluation. Linear constraints are therefore specified in the `variables` block through the `linear_inequality_constraint_matrix` $A_i$ and `linear_equality_constraint_matrix` $A_e$.

Lower and upper bounds on the design variables $x$ are also specified in the `variables` block.

### Problem Transformations

Weighting or scaling calibration terms is often appropriate to account for measurement error or to condition the problem for easier solution. Weighting or scaling transformations are applied in the following order:

1. When present, observation error variance $\sigma_i$, or full covariance $\Sigma$, optionally specified through `experiment_variance_type`, is applied to residuals first:
\[ R_i^{(1)} = \frac{R_i}{\sigma_i} = \frac{y_i^{\text{Model}}(\theta) - y_i^{\text{Data}}}{\sigma_i}, \]

or

\[ R^{(1)} = \Sigma^{-1/2}R = \Sigma^{-1/2} \left( y^{\text{Model}}(\theta) - y^{\text{Data}} \right), \]

resulting in the typical variance-weighted least squares formulation

\[ \min_{\theta} R(\theta)^T \Sigma^{-1} R(\theta) \]

2. Any active scaling transformations are applied next, e.g., for characteristic value scaling:

\[ R_i^{(2)} = \frac{R_i^{(1)}}{s_i} \]

3. Finally the optional weights are applied in a way that preserves backward compatibility:

\[ R_i^{(3)} = \sqrt{w_i} R_i^{(2)} \]

so the ultimate least squares formulation, e.g., in a scaled and weighted case would be

\[ f = \sum_{i=1}^{n} w_i \left( \frac{y_i^{\text{Model}}(\theta) - y_i^{\text{Data}}}{s_i} \right)^2 \]

Note that specifying observation error variance and weights are mutually exclusive in a calibration problem.

Theory

Dakota calibration terms are typically used to solve problems of parameter estimation, system identification, and model calibration/inversion. Local least squares calibration problems are most efficiently solved using special-purpose least squares solvers such as Gauss-Newton or Levenberg-Marquardt; however, they may also be solved using any general-purpose optimization algorithm in Dakota. While Dakota can solve these problems with either least squares or optimization algorithms, the response data sets to be returned from the simulator are different when using objective_functions versus calibration_terms.

Least squares calibration involves a set of residual functions, whereas optimization involves a single objective function (sum of the squares of the residuals), i.e.,

\[ f = \sum_{i=1}^{n} R_i^2 = \sum_{i=1}^{n} \left( y_i^{\text{Model}}(\theta) - y_i^{\text{Data}} \right)^2 \]

where \( f \) is the objective function and the set of \( R_i \) are the residual functions, most commonly defined as the difference between a model response and data. Therefore, function values and derivative data in the least squares case involve the values and derivatives of the residual functions, whereas the optimization case involves values and derivatives of the sum of squares objective function. This means that in the least squares calibration case, the user must return each of \( n \) residuals separately as a separate calibration term. Switching between the two approaches sometimes requires different simulation interfaces capable of returning the different granularity of response data required, although Dakota supports automatic recasting of residuals into a sum of squares for presentation to an optimization method. Typically, the user must compute the difference between the model results and the observations when computing the residuals. However, the user has the option of specifying the observational data (e.g. from physical experiments or other sources) in a file.

7.6.4.1 scalar_calibration_terms

- Keywords Area
- responses
- calibration_terms
- scalar_calibration_terms

Number of scalar calibration terms

Specification

Alias: none

Argument(s): INTEGER

Description

This keyword describes the number of scalar calibration terms. It is meant to be used in conjunction with field_-calibration_terms, which describes the number of field calibration terms. The total number of calibration terms, both scalar and field, is given by calibration_terms. If only scalar calibration terms are specified, it is not necessary to specify the number of scalar terms explicitly: one can simply say calibration_terms = 5 and get 5 scalar terms. However, if there are three scalar terms and 2 field terms, then calibration_terms = 5 but scalar_calibration_terms = 3 and field_calibration_terms = 2.

Calibration terms are responses that are used with calibration methods in Dakota, such as least squares optimizers. Currently, each scalar term is added to the total sum-of-squares error function presented to the optimizer. However, each individual field value is added as well. For example, if you have one field calibration term with length 100 (e.g. a time - temperature trace with 100 time points and 100 temperature points), the 100 temperature values will be added to create the overall sum-of-squares error function used in calibration.

These keywords may also be of interest:

- field_calibration_terms

7.6.4.2 field_calibration_terms

- Keywords Area
- responses
- calibration_terms
- field_calibration_terms

Number of field calibration terms

Specification

Alias: none

Argument(s): INTEGER

Child Keywords:
### Description

This keyword describes the number of field calibration terms. A set of field calibration terms is a set of related response values collected over a range of independent coordinate values which may or may not be specified by the user. For example, voltage over time would be a field function, where voltage is the field objective and time is the independent coordinate. Similarly, temperature over time and space would be a field response, where the independent coordinates would be both time and spatial coordinates such as (x,y) or (x,y,z), depending on the application. The main difference between scalar calibration terms and field calibration terms is that for field data, we plan to implement methods that take advantage of the correlation or relationship between the field values. For example, with calibration, if we want to calibrate parameters that result in a good model fit to a time-temperature curve, we may have to do some interpolation between the experimental data and the simulation data. That capability requires knowledge of the independent coordinates.

Note that if there is one field_calibration_terms, and it has length 100 (meaning 100 values), then the user’s simulation code must return 100 values. Also, if there are both scalar and field calibration, the user should specify the number of scalar terms as scalar_calibration_terms. If there are only field calibration terms, it still is necessary to specify both field_calibration_terms = NN and calibration_terms = NN, where NN is the number of field calibration terms.

Calibration terms are responses that are used with calibration methods in Dakota, such as least squares optimizers. Currently, each scalar term is added to the total sum-of-squares error function presented to the optimizer. However, each individual field value is added as well. For example, if you have one field calibration term with length 100 (e.g. a time-temperature trace with 100 time points and 100 temperature points), the 100 temperature values will be added to create the overall sum-of-squares error function used in calibration. We have an initial capability to interpolate the field data from the user’s simulation to the experimental data. For example, if the user has thermocouple readings at 20 time points, it will be an experimental field response with 20 time points and 20 temperature values. Dakota takes the 100 simulation time-temperature values (from the example above) and interpolates these to the 20 experimental points, to create 20 residual terms (simulation minus experimental data points) that will be used in calibration.

Argument(s): INTEGERLIST

Description

This keyword describes the number of independent coordinates for each field response. It is an integer vector of length field_responses. For example, if the field_responses = 2, an example would be num_coordinates_per_field = 2 1 means that the first field response has two sets of independent coordinates (perhaps x, y locations), but the second response only has one (for example, time where the field response is only dependent upon time). The actual coordinate values (e.g. the independent variables) corresponding to these field responses are defined in a file call response_descriptor.coords, where response_descriptor is the name of the individual field.
See Also

These keywords may also be of interest:

- `field_responses`

7.6.4.2.3 `read_field_coordinates`

- `Keywords Area`
- `responses`
- `calibration_terms`
- `field_calibration_terms`
- `read_field_coordinates`

Add context to data: flag to indicate that field coordinates should be read

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

Field coordinates specify independent variables (e.g. spatial or temporal coordinates) upon which the field depends. For example, the voltage level above might be a function of time, so time is the field coordinate. If the user has field coordinates to read, they need to specify `read_field_coordinates`. The field coordinates will then be read from a file named `response_descriptor.coords`, where `response_descriptor` is the user-provided descriptor for the field response. The number of columns in the coords file should be equal to the number of field coordinates.

7.6.4.3 `primary_scales`

- `Keywords Area`
- `responses`
- `calibration_terms`
- `primary_scales`

Characteristic values to scale each calibration term

**Specification**

**Alias:** `calibration_term_scales least_squares_term_scales`

**Argument(s):** REALLIST

**Default:** 1.0 (no scaling)
Description

Each real value in primary_scales is a nonzero characteristic value to be used in scaling each calibration term. They only have effect when the associated method specifies scaling.

Length: When specified, primary_scales must have length one of:

- One (the single value will be applied to each primary response); or
- Number of response groups (calibration_terms), so the number of scalars plus the number of fields when fields are present; or
- Total number of response elements, so the number of scalar responses plus the sum of the lengths of the fields.

Usage Tips:
Calibration only supports value-based scaling. Use scale values of 1.0 to selectively avoid scaling a subset of response functions.

Weights are applied as multipliers, scales as characteristic values / divisors.

When scaling is active, it is applied to calibration terms after any residual formation (accounting for experimental data and optionally measurement error covariance), and before any weights. See the equations in calibration_terms.

See the scaling information under specific methods, e.g., method-**-scaling for details on how to use this keyword.

7.6.4.4 weights

- Keywords Area
  - responses
  - calibration_terms
  - weights

Specify weights for each objective function

Specification

Alias: calibration_weights least_squares_weights

Argument(s): REALLIST

Default: equal weights

Description

Specifies relative emphasis through weights (multipliers) w on residual elements:

\[ f = \sum_{i=1}^{n} w_i R_i^2 = \sum_{i=1}^{n} w_i (y_i^{Model} - y_i^{Data})^2 \]

Length: The weights must have length equal to calibration_terms. Thus, when scalar and/or field responses are specified, the number of weights must equal the number of scalars plus the number of fields, not the total elements in the fields.

Default Behavior: If weights are not specified, then each residual is given equal weighting.
Usage Tips:
Weights are applied as multipliers, scales as charcteristic values / divisors.
When scaling is active, it is applied to calibration terms after any residual formation (accounting for experimental data and optionally measurement error covariance), and before any weights. See the equations in calibration_terms.

7.6.4.5 calibration_data

- Keywords Area
- responses
- calibration_terms
- calibration_data

Supply field or mixed field/scalar calibration data

**Specification**

**Alias:** none

**Argument(s):** none

**Child Keywords:**

### Description

**calibration_data** specifies a keyword block that indicates that Dakota should read in experimental data for calibration. This block is primarily to support the reading of field calibration data. For simpler, scalar-only response cases, see **calibration_data_file**. The user will typically specify the number of experiments, **num_experiments**. If this is not specified, it is assumed there is only one experiment.

Up to four types of data may be read. They are read from a collection of files, one per response descriptor, per experiment. In this discussion, **DESC** refers to the response descriptor and **NUM** to the experiment number.

1. **Values**: The scalar or field-valued response function values, e.g., temperature values, voltage levels. These are read from files named **DESC.NUM.dat** (one per response descriptor, per experiment), e.g., **volts.1.dat**, **volts.2.dat**. Scalar files will contain a single value, while field files will each contain a column of field response values. Without **interpolate** enabled, the lengths of these files must match those specified using the responses-calibration_terms-field_calibration_terms-lengths keyword.

2. **Coordinates**: Field coordinates specify independent variables (e.g., spatial or temporal coordinates) upon which the field depends. For example, the voltage might be a function of time, so time is the field coordinate. These are read from files named **DESC.NUM.coords**, each containing **num_coordinates_per_field** columns. The number of rows must be the same as in the values files described in the previous bullet.

3. **Variances**: If **experiment_variance_type** is specified, variance values are read from files **DESC.NUM.sigma**. Note that a single **experiment_variance_type** may be specified, or a unique **experiment_variance_type** per response descriptor (per scalar or field). If the **experiment_variance_type** is:
   - 'scalar': a single variance value will be read from the file.
   - 'diagonal' (field responses only): a column vector of variance values (length equal to the number of experimental data points) will be read from the file. The values are the variances of each field value for this descriptor.
   - 'matrix' (field responses only): a matrix of covariance values (square with size the number of experimental values) will be read from the file. The matrix is a full covariance matrix for the components of this field response. While covariance among entries in a field response may be specified, covariance among experiments is not permitted.

4. **Configuration variables**: specify the conditions corresponding to different experiments. When responses-calibration_terms-calibration_data-num_config_variables is specified, the configuration variable values for each experiment should be placed in a file named **experiment.NUM.config**, where the number of items in that config file are the **num_config_variables**. These variables are used as auxilliary state variables for the simulation (for example) and are not calibrated.

   **Attention**: In versions of Dakota prior to 6.14, string-valued configuration variables were specified in data files with 0-based indices into the admissible values. As of Dakota 6.14, strings must be specified by value. For example a string-valued configuration variable for an experimental condition might appear in the file as **low_pressure vs. high_pressure**.

**Aggregating scalar data**: The above description is primarily relevant for field data (with files for field values, field coordinates, field variances). If the user also has scalar experimental data, it may be entered as described above, i.e., one file named **DESC.NUM.dat** per scalar response. However, an alternative is to provide the data for all scalar responses in aggregate in the simpler **scalar_data_file** format, with the number of rows of that file equal to the number of experiments. The scalar data file may be used in combination with the the separate field files described above.

**Interpolation**: One important feature of field data is the capability to interpolate between points in the field. For example, we may have simulation data at a set of responses **y** at time points **t**: ( **t_1, y_1**), ( **t_2, y_2**), etc. In this
example, \( t \) is the independent coordinate for the simulation, and the simulation time and response points are denoted with subscripts \( s_1, s_2, s_3, \ldots \). If the user has experimental data that is taken at different time points: \((t_1, y_{e1}), (t_2, y_{e2}), \ldots \), it is necessary to interpolate the simulation data to provide estimates of the simulation response at the experimental time points to construct the residual terms (model - experiment) at the experimental time points. Dakota can perform 1-D interpolation. The user must specify the keyword \texttt{interpolate}, and also provide the field coordinates as well as field values for the experiment data.

If the \texttt{interpolate} keyword is not specified, Dakota will assume that the simulation field data and the experiment field data is taken at the same set of independent coordinate values and simply construct the difference between these field terms to create the set of residuals for the sum-of-squares calculation. When \texttt{interpolate} is specified, the simulation coordinates are assumed fixed and the same for each simulation. These simulation coordinates are provided in DESC.coords. However, the experiment coordinates for each experiment can be different, and are provided in the files numbered by experiment with the file names given by DESC.NUM.coords, as indicated above.

**Examples**

Consider this field example with three field-valued responses (volts as a function of 7 time points, amps as a function of 3 time points, and power as a function of 5 time points). The experiments each have one coordinate (time) per field. The experiments were conducted given values of two configuration variables. There are four experiments (note that there often is only one experiment).

```plaintext
responses
descriptors = 'volts' 'amps' 'power'
calibration_terms = 3

# define field terms
field_calibration_terms = 3
lengths = 7 3 5
num_coordinates_per_field = 1 1 1
read_field_coordinates

# specify the data
calibration_data
num_experiments = 4
num_config_variables = 2
experiment_variance_type 'diagonal' 'scalar' 'matrix'
```

The field data will be read from separate files:

1. **Values**: 7 values for voltage as a function of time will be read from each of volts.1.dat ... volts.4.dat, while the 3 values of amperage come from amps.1.dat, ... , amps.4.dat and the 5 values of power will come from power.1.dat, ..., power.4.dat.

2. **Coordinates**: The corresponding time values will be read from a single column vector in each of the files volts.*.coords, amps.*.coords, and power.*.coords.

3. **Variances**: Will be read per-experiment (no covariance among experiments is permitted). The variance information is depicted graphically in \texttt{experiment_variance_type}
   - Volts specifies 'diagonal' covariance, so a column vector of length 7 with the diagonal variances will be read from each of volts.1.sigma, ..., volts.4.sigma.
   - Amps specifies 'scalar' covariance, so a single variance value will read from each of amps.1.sigma, ..., amps.4.sigma.
   - Power specifies 'matrix' covariance, so a square 5 x 5 covariance matrix will be read from each of power.1.sigma, ..., power.4.sigma.

4. **Configuration variables**: Will be read from a set of files named experiment.1.config, ..., experiment.4.config.
7.6.4.5.1 data_directory

- Keywords Area
- responses
- calibration_terms
- calibration_data
- data_directory

Specify a directory containing the calibration field data files used with the mixed case specification.

**Specification**

**Alias:** none  
**Argument(s):** STRING

**Description**

**Default Behavior**

The default directory is the path from which the Dakota study is launched, i.e. the directory containing the Dakota input file.

See **dakota/share/dakota/dakota_experiment_read.in**

7.6.4.5.2 num_experiments

- Keywords Area
- responses
- calibration_terms
- calibration_data
- num_experiments

Add context to data: number of different experiments

**Specification**

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** 1

**Description**

The number of different experiments. Dakota will expand the total number of residual terms based on the number of calibration terms and the number of experiments. For example, if the number of calibration terms are five scalars, and there are three experiments, the total number of residuals in the least squares formulation will be 15. See **calibration_data** or **calibration_data_file**.
7.6.4.5.3 num_config_variables

- Keywords Area
- responses
- calibration_terms
- calibration_data
- num_config_variables

Add context to data: number of configuration variables.

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 0

**Description**

If there are multiple experiments, there can be different configuration variables (e.g. experimental settings, boundary conditions, etc.) per experiment. See calibration_data or calibration_data_file.

During calibration, configuration variables are state variables which will be passed to the simulation, and are not treated as calibration parameters.

7.6.4.5.4 experiment_variance_type

- Keywords Area
- responses
- calibration_terms
- calibration_data
- experiment_variance_type

Add context to data: specify the type of experimental error

**Specification**

**Alias:** variance_type

**Argument(s):** STRINGLIST

**Default:** none

**Description**

There are four options for specifying the experimental error (e.g. the measurement error in the data you provide for calibration purposes): ’none’ (default), ’scalar’, ’diagonal’, or ’matrix.’

If the user specifies scalar, they can provide a scalar variance per calibration term. Note that for scalar calibration terms, only ’none’ or ’scalar’ are options for the measurement variance. However, for field calibration terms, there are two additional options. ’diagonal’ allows the user to provide a vector of measurement variances (one for each...
term in the calibration field). This vector corresponds to the diagonal of the full covariance matrix of measurement errors. If the user specifies ‘matrix’, they can provide a full covariance matrix (not just the diagonal terms), where each element (i,j) of the covariance matrix represents the covariance of the measurement error between the i-th and j-th field values.

Usage Tips

Variance information is specified on a per-response group (descriptor), per-experiment basis. Off-diagonal covariance between response groups or between experiments is not supported.

Examples

The figure below shows an observation vector with 5 responses; 2 scalar + 3 field (each field of length > 1). The corresponding covariance matrix has scalar variances \( \sigma_1^2, \sigma_2^2 \) for each of the scalars \( s_1, s_2 \), diagonal covariance \( D_3 \) for field \( f_3 \), scalar covariance \( \sigma_4^2 \) for field \( f_4 \), and full matrix covariance \( C_5 \) for field \( f_5 \). In total, Dakota supports block diagonal covariance \( \Sigma \) across the responses, with blocks \( \Sigma_i \), which could be fully dense within a given field response group. Covariance across the highest-level responses (off-diagonal blocks) is not supported, nor is covariance between experiments.

7.6.4.5.5 scalar_data_file

- Keywords Area
- responses
- calibration_terms
- calibration_data
- scalar_data_file

Specify a scalar data file to complement field data files (mixed case)

Specification

Alias: none

Argument(s): STRING

Child Keywords:

<table>
<thead>

<td>annotated</td>
<td>Selects annotated tabular file format for experiment data</td>
</tr>
<tr>
<td></td>
<td></td>
<td>freeform</td>
<td>Selects free-form tabular file format for experiment data</td>
</tr>
</tbody>
</table>

Description

When calibrating both scalar and field calibration terms, to associated experimental data, the scalar data may be provided in the file named by scalar_data_file. This file follows the same format as: calibration_data_file.
Default Behavior

If `scalar_data_file` is omitted, all calibration data, including for scalar responses, will be read from the generic field `calibration_data` format.

7.6.4.5.5.1 custom_annotated

- Keywords Area
- responses
- calibration_terms
- calibration_data
- scalar_data_file
- custom_annotated

Selects custom-annotated tabular file format for experiment data

Topics

This keyword is related to the topics:

- `file_formats`

Specification

Alias: none

Argument(s): none

Default: annotated format

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>header</td>
<td>Enable header row in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>exp_id</td>
<td>Enable experiment ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

Description

A custom-annotated tabular file is a whitespace-separated text file containing experiment data, including configuration variables, observations, and/or observation errors, depending on context. For experiment import, custom-annotated allows user options for whether header row and exp_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

By default, Dakota imports tabular experiment data files in annotated format. The `custom_annotated` keyword, followed by options can be used to select other formats.

Usage Tips
Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

Examples

Import an experimental data file containing a header row, no leading exp_id column, and experiment data in a calibration study

```
responses ...
  scalar_data_file 'shock_experiment.dat'
  custom_annotated header
```

Example data file with two measured quantities, three experiments:

```
% velocity stress
18.23 83.21
34.14 93.24
22.41 88.92
```

Enable header row in custom-annotated tabular file

Specification

Alias: none
Argument(s): none
Default: no header

Description

See description of parent custom_annotated

References
• calibration_data
• scalar_data_file
• custom_annotated
• exp_id

Enable experiment ID column in custom-annotated tabular file

Specification

Alias: none
Argument(s): none
Default: no exp_id column

Description

See description of parent custom_annotated

7.6.4.5.5.4 annotated

• Keywords Area
• responses
• calibration_terms
• calibration_data
• scalar_data_file
• annotated

Selects annotated tabular file format for experiment data

Topics

This keyword is related to the topics:

• file_formats

Specification

Alias: none
Argument(s): none
Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. For experiment data files, each subsequent row contains an experiment ID, followed by data for configuration variables, observations, and/or observation errors, depending on context.

Default Behavior
By default, Dakota imports tabular experiment data files in annotated format. The *annotated* keyword can be used to explicitly specify this.

**Usage Tips**

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

**Examples**

Import an annotated experimental data file containing a header row, leading exp_id column, and experiment data in a calibration study

```
responses
...
scalar_data_file 'shock_experiment.dat'
  annotated
```

Example data file with two measured quantities, three experiments:

```
%exp_id velocity stress
1   18.23   83.21
2   34.14   93.24
3   22.41   88.92
```

**7.6.4.5.5.5 freeform**

- **Keywords Area**

- **responses**

- **calibration_terms**

- **calibration_data**

- **scalar_data_file**

- **freeform**

Selects free-form tabular file format for experiment data

**Topics**

This keyword is related to the topics:

- **file_formats**

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** annotated format
Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. For experiment data files, each row contains data for configuration variables, observations, and/or observation errors, depending on context.

Default Behavior

By default, Dakota imports tabular experiment data files in annotated format. Specify freeform to instead select this format.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

Examples

Import a free-form experimental data file containing raw experiment data in a calibration study

```plaintext
responses
... scalar_data_file 'shock_experiment.dat'
  freeform
```

Example data file with two measured quantities, three experiments:

```
18.23  83.21
34.14  93.24
22.41  88.92
```

7.6.4.5.6 interpolate

- Keywords Area
- responses
- calibration_terms
- calibration_data
- interpolate

Flag to indicate interpolation of simulation values.

Specification

Alias: none
Argument(s): none

Description

If interpolate is specified, Dakota will interpolate between the simulation data and the experiment data to calculate the residuals for calibration methods. Specifically, the simulation data is interpolated onto the experimental data points. So, if the simulation data is a field of length 100 with one independent coordinate, and the experiment data is of length 5 with one independent coordinate, the interpolation is done between the 100 (t,f) simulation points (where t is the independent coordinate and f is the simulation field value) onto the five (t_e, f_e) points to obtain the residual differences between the simulation and experiment. See calibration_data.
7.6.4.6 calibration_data_file

- Keywords Area
- responses
- calibration_terms
- calibration_data_file

Supply scalar calibration data only

Specification

Alias: least_squares_data_file

Argument(s): STRING

Default: none

Child Keywords:

<table>
<thead>

<td>Add context to data: number of configuration variables</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>experiment_variance_type</td>
<td>Add context to data: specify the type of experimental error</td>
</tr>
</tbody>
</table>

Description

Enables text file import of experimental observations for use in calibration, for scalar responses only, with optional scalar variance information. For more complex data import cases see calibration_data Dakota will calibrate model variables to best match these data.

Key options include:
Keywords Area

- **format**: whether the data file is in annotated, custom_annotated, or freeform format
- **content**: where num_experiments, num_config_variables, and experiment_variance_type indicate which columns appear in the data.

In the most general case, the content of the data file is described by the arguments of three optional parameters.

- **num_experiments** \( (N_{\text{exp}}) \)
  
  Default: \( N_{\text{exp}} = 1 \)
  
  This indicates that the data represent multiple experiments, where each experiment might be conducted with different values of configuration variables. An experiment can also be thought of as a replicate, where the experiments are run at the same values of the configuration variables.

- **num_config_variables** \( (N_{\text{cfg}}) \)
  
  Configuration variables specify the values of experimental conditions at which data were collected. The variables in these columns must correspond to state variables in the calibration study. The simulation model will be run at each configuration and compared to the appropriate experiment data.

- **experiment_variance_type** ('none' or 'scalar')
  
  This indicates if the data file contains variances for measurement error of the experimental data. The default is 'none'.

While some components may be omitted, the most complete version of a an annotated calibration data file could include columns corresponding to experiment ID, configuration variables, function value observations, and variances (observation errors), shown here in annotated format:

<table>
<thead>
<tr>
<th>exp_id</th>
<th>configuration xvars</th>
<th>y data observations</th>
<th>y data variances</th>
</tr>
</thead>
<tbody>
<tr>
<td>7.8 7</td>
<td>21.9372 1.8687</td>
<td>0.25 0.04</td>
<td></td>
</tr>
<tr>
<td>8.6 2</td>
<td>19.0779 4.8976</td>
<td>0.25 0.04</td>
<td></td>
</tr>
<tr>
<td>8.4 8</td>
<td>38.2758 4.4559</td>
<td>0.25 0.04</td>
<td></td>
</tr>
<tr>
<td>4.2 1</td>
<td>39.7600 6.4631</td>
<td>0.25 0.04</td>
<td></td>
</tr>
</tbody>
</table>

Each row in the file corresponds to an experiment or replicate observation of an experiment to be compared to the model output. This example shows 4 experiments, governed by two configuration variables (one real-valued and one integer-valued), two responses (QOIs), and corresponding observation errors with standard deviation 0.5 and 0.2.

**Usage Tips**

- The **calibration_data_file** keyword is used when only scalar calibration terms are present. If there are field calibration terms, instead use **calibration_data**. For mixed scalar and field calibration terms, one may use the **scalar_data_file** specification, which uses the format described on this page.

- **Attention**: In versions of Dakota prior to 6.14, string-valued configuration variables were specified in data files with 0-based indices into the admissible values. As of Dakota 6.14, strings must be specified by value. For example a string-valued configuration variable for an experimental condition might appear in the file as `low_pressure vs. high_pressure`.

**Examples**

**Simple Case**: In the simplest case, no data content descriptors are specified:

```plaintext
responses
calibration_terms = 2
  descriptors = 'volts' 'amps'
calibration_data_file = 'circuit.dat'
annotated
```

And the data file `circuit.dat` must contain only the \( y \) observations which represent a single experimental observation. In this case, the data file should have \( N_{\text{terms}} = 2 \) columns (for volts, amps) and 1 row, where \( N_{\text{terms}} \) is the value of **calibration_terms**. The data file is shown here in annotated format:
For each function evaluation, Dakota will run the analysis driver, which must return $N_{\text{terms}} = 2$ model responses. Then the residuals are computed as:

$$R_i = y_i^{\text{Model}} - y_i^{\text{Data}}.$$ 

These residuals can be weighted using weights.

**Multiple experiments:** One might specify `num_experiments $N_E$` indicating that there are multiple experiments. When multiple experiments are present, Dakota will expand the number of residuals for the repeat measurement data and difference with the data accordingly. For example, if the user has $N_E = 4$ experiments in the example above with 2 calibration terms, the input file would contain

```plaintext
responses
calibration_terms = 2
descriptors = 'volts' 'amps'
calibration_data_file = 'circuit.dat'
annotated
num_experiments = 4
```

And the `calibration_data_file` would need to contain 2 rows (one for each experiment), and each row should contain 2 experimental data values that will be differenced with respect to the appropriate model response:

```plaintext
%exp_id | y data observations | y data variances
1 21.9372  1.8687  0.25  0.04
2 19.0779  4.8976      
3 38.2758  4.4559      
4 39.7600  6.4631      
```

To summarize, Dakota will calculate the sum of the squared residuals as:

$$f = \sum_{i=1}^{N_E} R_i^2$$

where the residuals now are calculated as:

$$R_i = y_i^{\text{Model}}(\theta) - y_i^{\text{Data}}.$$ 

**With experimental variances:** If information is known about the measurement error and the uncertainty in the measurement, that can be specified by sending the measurement error variance to Dakota. In this case, the keyword `experiment_variance_type` is added, followed by a string of variance types of length one or of length $N_{\text{terms}}$, where $N_{\text{terms}}$ is the value of `calibration_terms`. The `experiment_variance_type` for each response can be ‘none’ or ‘scalar’. NOTE: you must specify the same `experiment_variance_type` for all scalar terms. That is, they will all be ‘none’ or all be ‘scalar.’

```plaintext
responses
calibration_terms = 2
descriptors = 'volts' 'amps'
calibration_data_file = 'circuit.dat'
annotated
eperiment_variance_type 'scalar'
```

For each response that has a ‘scalar’ variance type, each row of the datafile will now have $N_{\text{terms}} = 2$ of $y$ data values (volts, amps) followed by $N_{\text{terms}} = 2$ columns that specify the measurement error (in units of variance, not standard deviation) for volts, amps. An example with two experiments in annotated format:

```plaintext
%exp_id | y data observations | y data variances
1 21.9372  1.8687  0.25  0.04
```
Dakota will run the analysis driver, which must return $N_{\text{terms}}$ responses. Then the residuals are computed as:

$$R_i = \frac{y_{\text{Model}} - y_{\text{Data}}}{\sqrt{\text{var}_i}}$$

for $i = 1 \ldots N_{\text{terms}}$.

**Putting all the options together:** Specifying all these options together might look like

```plaintext
responses
calibration_terms = 2
descriptors = 'volts' 'amps'
calibration_data_file = 'circuit.dat'
annotated
num_experiments = 4
experiment_variance_type 'scalar'
```

Dakota will expect a data file

```plaintext
%exp_id | configuration xvars | y data observations | y data variances
1       | 7.8 7               | 21.9372 1.8687     | 0.25 0.04
2       | 8.6 2               | 19.0779 4.8976     | 0.25 0.04
3       | 8.4 8               | 38.2758 4.4559     | 0.25 0.04
4       | 4.2 1               | 39.7600 6.4631     | 0.25 0.04
```

To compute residuals for each experiment, e.g., exp_id = 4, Dakota will

1. Evaluate the computational model at the specified configuration (state variables = [4.2, 1]).
2. Difference the resulting 2 function values with the data [39.7600 volts, 6.4631 amps]
3. Weight by the standard deviation = sqrt([0.25 0.04])

<td>header</td>
<td>Enable header row in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>exp_id</td>
<td>Enable experiment ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

**Description**

A custom-annotated tabular file is a whitespace-separated text file containing experiment data, including configuration variables, observations, and/or observation errors, depending on context. For experiment import, custom-annotated allows user options for whether header row and exp_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

**Default Behavior**

By default, Dakota imports tabular experiment data files in annotated format. The `custom_annotated` keyword, followed by options can be used to select other formats.

**Usage Tips**

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

**Examples**

Import an experimental data file containing a header row, no leading exp_id column, and experiment data in a calibration study

```plaintext
responses
... scalar_data_file 'shock_experiment.dat' custom_annotated header
```

Example data file with two measured quantities, three experiments:

```plaintext
% velocity stress
18.23 83.21
34.14 93.24
22.41 88.92
```
7.6.4.6.1.1 header

- annotated

Selects annotated tabular file format for experiment data

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none
Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. For experiment data files, each subsequent row contains an experiment ID, followed by data for configuration variables, observations, and/or observation errors, depending on context.

Default Behavior

By default, Dakota imports tabular experiment data files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

Examples

Import an annotated experimental data file containing a header row, leading exp_id column, and experiment data in a calibration study

```plaintext
responses
...
scalar_data_file 'shock_experiment.dat'
annotated
```

Example data file with two measured quantities, three experiments:
Selects free-form tabular file format for experiment data

**Topics**

This keyword is related to the topics:

- file_formats

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** annotated format

**Description**

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. For experiment data files, each row contains data for configuration variables, observations, and/or observation errors, depending on context.

**Default Behavior**

By default, Dakota imports tabular experiment data files in annotated format. Specify freeform to instead select this format.

**Usage Tips**

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

**Examples**

Import a free-form experimental data file containing raw experiment data in a calibration study

```
responses ...
  scalar_data_file 'shock_experiment.dat'
  freeform
```
Example data file with two measured quantities, three experiments:

```
  18.23  83.21
  34.14  93.24
  22.41  88.92
```

7.6.4.6.4 num_experiments

- Keywords Area
- responses
- calibration_terms
- calibration_data_file
- num_experiments

Add context to data: number of different experiments

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 1

**Description**

The number of different experiments. Dakota will expand the total number of residual terms based on the number of calibration terms and the number of experiments. For example, if the number of calibration terms are five scalars, and there are three experiments, the total number of residuals in the least squares formulation will be 15. See calibration_data or calibration_data_file.

7.6.4.6.5 num_config_variables

- Keywords Area
- responses
- calibration_terms
- calibration_data_file
- num_config_variables

Add context to data: number of configuration variables.

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 0
Description

If there are multiple experiments, there can be different configuration variables (e.g. experimental settings, boundary conditions, etc.) per experiment. See `calibration_data` or `calibration_data_file`.

During calibration, configuration variables are state variables which will be passed to the simulation, and are not treated as calibration parameters.

7.6.4.6.6 experiment_variance_type

- **Keywords Area**
  - responses
  - calibration_terms
  - calibration_data_file
  - experiment_variance_type

Add context to data: specify the type of experimental error

Specification

**Alias:** variance_type

**Argument(s):** STRINGLIST

**Default:** none

Description

There are four options for specifying the experimental error (e.g. the measurement error in the data you provide for calibration purposes): 'none' (default), 'scalar', 'diagonal', or 'matrix.'

If the user specifies scalar, they can provide a scalar variance per calibration term. Note that for scalar calibration terms, only 'none' or 'scalar' are options for the measurement variance. However, for field calibration terms, there are two additional options. 'diagonal' allows the user to provide a vector of measurement variances (one for each term in the calibration field). This vector corresponds to the diagonal of the full covariance matrix of measurement errors. If the user specifies 'matrix', they can provide a full covariance matrix (not just the diagonal terms), where each element (i,j) of the covariance matrix represents the covariance of the measurement error between the i-th and j-th field values.

**Usage Tips**

Variance information is specified on a per-response group (descriptor), per-experiment basis. Off-diagonal covariance between response groups or between experiments is not supported.

**Examples**

The figure below shows an observation vector with 5 responses; 2 scalar + 3 field (each field of length > 1). The corresponding covariance matrix has scalar variances $\sigma^2_1, \sigma^2_2$ for each of the scalars $s1,s2$, diagonal covariance $D_1$ for field $f3$, scalar covariance $\sigma^2_3$ for field $f4$, and full matrix covariance $C_5$ for field $f5$. In total, Dakota supports block diagonal covariance $\Sigma$ across the responses, with blocks $\Sigma_i$, which could be fully dense within a given field response group. Covariance across the highest-level responses (off-diagonal blocks) is not supported, nor is covariance between experiments.
7.6 responses

7.6.4.7 simulation_variance

- Keywords Area
- responses
- calibration_terms
- simulation_variance

Variance applied to simulation responses

Specification

Alias: none
Argument(s): REALLIST
Default: no variance

Description

The variance that is applied to simulations run by Dakota, i.e. using the analysis_drivers command. The user may supply a single variance or a vector of variances of length equal to the number of responses. In both cases, the values provided are treated as scalar variance types. If a single variance is provided, it is applied to all responses produced by the simulation code. If a vector is provided, each variance is applied to the corresponding response output produced by the simulation code.

It is important to note that the variance defined by this keyword differs from that defined using experiment_variance_type. These two commands apply to user-provided calibration data, specified, for example, by calibration_data or calibration_data_file. However, simulation_variance applies to those responses produced by simulation code that is run by Dakota, as described above.

Usage Tips

Currently, this keyword is only in use as part of the algorithm implemented by experimental_design. In this algorithm, two models (usually, one high-fidelity and one low-fidelity) are provided to Dakota, each with their own responses section of the input script, and each of which is allowed its own simulation_variance. The variance specified in the responses block belonging to the high-fidelity model is applied to any new high-fidelity data that is produced by Dakota running the high-fidelity model. In the experimental_design algorithm, low-fidelity model responses are used during the calibration of the model parameters, the calculation of the mutual information, and the calculation of any posterior statistics after the algorithm is complete. The simulation_variance is applied to the low-fidelity model responses that are used in the calculation of the mutual information. See the User’s and Theory Manuals for more information.

Examples

The example below shows two responses blocks, one for the low-fidelity model and one for the high-fidelity model. Both contain simulation_variance commands that will apply to the low- and high-fidelity model responses, respectively.

```dakota
responses,
  id_responses = 'low-fidelity'
  calibration_terms = 1
  simulation_variance = 0.5

responses,
  id_responses = 'high-fidelity'
  calibration_terms = 1
  calibration_data_file = 'dakota_bayes_expdesign.dat'
  freeform
```

Dakota Version 6.16 Reference Manual generated on May 12, 2022
num_config_variables = 1
num_experiments = 1
experiment_variance_type = 'none'
simulation_variance = 1.2

7.6.4.8 nonlinear_inequality_constraints

- Keywords Area
- responses
- calibration_terms
- nonlinear_inequality_constraints

Group to specify nonlinear inequality constraints

Topics

This keyword is related to the topics:

- nonlinear_constraints

Specification

Alias: num_nonlinear_inequality_constraints

Argument(s): INTEGER

Default: 0

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>lower_bounds</td>

<tr>
<td>Optional</td>
<td></td>
<td>scale_types</td>
<td>Specify maximum values</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>scales</td>
<td>How to scale each nonlinear constraint</td>
</tr>
</tbody>
</table>

Description

Specifies the number of nonlinear inequality constraint functions returned by the interface.

The lower_bounds and upper_bounds specifications provide the lower and upper bounds for 2-sided nonlinear inequalities of the form

\[ g_l \leq g(x) \leq g_u \]

When constraint bounds are not specified, the problem is assumed to have one-sided inequalities bounded above by zero:

\[ g(x) \leq 0.0. \]
This provides backwards compatibility with previous Dakota versions.

In a user bounds specification, any upper bound values greater than +bigRealBoundSize (1.e+30, as defined in Minimizer) are treated as +infinity and any lower bound values less than -bigRealBoundSize are treated as -infinity. This feature is commonly used to drop one of the bounds in order to specify a 1-sided constraint (just as the default lower bounds drop out since -DBL_MAX < -bigRealBoundSize). The same approach is used for nonexistent linear inequality bounds and for nonexistent design variable bounds.

The scale_types and scales keywords are related to scaling of \( g(x) \). See the scaling information under specific methods, e.g., method-**-scaling for details on how to use this keyword.

### 7.6.4.8.1 lower_bounds

- **Keywords Area**
- **responses**
- **calibration_terms**
- **nonlinear_inequality_constraints**
- **lower_bounds**

Specify minimum values

**Specification**

**Alias:** nonlinear_inequality_lower_bounds

**Argument(s):** REALLIST

**Default:** vector values = -infinity

**Description**

Specify minimum values

### 7.6.4.8.2 upper_bounds

- **Keywords Area**
- **responses**
- **calibration_terms**
- **nonlinear_inequality_constraints**
- **upper_bounds**

Specify maximum values

**Specification**

**Alias:** nonlinear_inequality_upper_bounds

**Argument(s):** REALLIST

**Default:** vector values = 0.

**Description**

Specify maximum values
7.6.4.8.3  scale_types

- Keywords Area
- responses
- calibration_terms
- nonlinear_inequality_constraints
- scale_types

How to scale each nonlinear constraint

Specification

**Alias:** nonlinear_inequality_scale_types  
**Argument(s):** STRINGLIST  
**Default:** no scaling  

Description

Each string in scale_types indicates the scaling type for each nonlinear inequality (equality) constraint. They only have effect when the associated method specifies scaling.

The options are:

- `'value'` - characteristic value by which nonlinear constraint values will be divided. If this is chosen, then scales must also be specified; `value` is assumed if scales are given without scale_types

- `'auto'` - automatic scaling based on bounds (inequalities) or targets (equalities)

- `'log'` - logarithmic scaling (can be used together with scales, which can be helpfully used to negate values prior to log transformation)

If a single string is specified it will apply to all of the nonlinear inequality (equality) constraints. Otherwise a string must be specified for each nonlinear inequality (equality) constraint.

Usage Tips:
See the scaling information under specific methods, e.g., method-=scaling for details on how to use this keyword.

7.6.4.8.4  scales

- Keywords Area
- responses
- calibration_terms
- nonlinear_inequality_constraints
- scales

Characteristic values to scale each nonlinear constraint
Specification

**Alias:** nonlinear_inequality_scales  
**Argument(s):** REALLIST  
**Default:** 1.0 (no scaling)

**Description**

Each real value in `scales` is a nonzero characteristic value to be used in scaling each nonlinear inequality (equality) constraint. They only have effect when the associated method specifies scaling.

This keyword is required for `scale_types` of ’value’ and optional for ’log’. When specified in conjunction with log, scale values are applied prior to the logarithm, to permit log scaling of strictly negative response functions.

If a single scale value is specified it will apply to all of the nonlinear inequality (equality) constraints. Otherwise a value must be specified for each nonlinear inequality (equality) constraint.

**Usage Tips:**

When `scales` are specified, but not `scale_types`, the scaling type is assumed to be ’value’ for this set of nonlinear inequality (equality) constraints.

Use scale values of 1.0 to selectively avoid scaling a subset of response functions.

See the scaling information under specific methods, e.g., method-*scaling for details on how to use this keyword.

7.6.4.9 nonlinear_equality_constraints

- Keywords Area
- responses
- calibration_terms
- nonlinear_equality_constraints

Group to specify nonlinear equality constraints

**Topics**

This keyword is related to the topics:

- nonlinear_constraints

**Specification**

**Alias:** num_nonlinear_equality_constraints  
**Argument(s):** INTEGER  
**Default:** 0  
**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
</table>

Optional | targets | Target values for the nonlinear equality constraint
Optional | scale_types | How to scale each nonlinear constraint
Optional | scales | Characteristic values to scale each nonlinear constraint

**Description**

Specifies the number of nonlinear equality constraint functions returned by the interface. The `targets` specification provides the targets for nonlinear equalities of the form

\[ h(x) = h_t \]

and the defaults for the equality targets enforce a value of 0.0 for each constraint:

\[ h(x) = 0.0 \]

The `scale_types` and `scales` keywords are related to scaling of \( h(x) \). See the scaling information under specific methods, e.g., method-\#-scaling for details on how to use this keyword.

### 7.6.4.9.1 targets

- **Keywords Area**
- **responses**
- **calibration_terms**
- **nonlinear_equality_constraints**
- **targets**

Target values for the nonlinear equality constraint

**Specification**

**Alias:** nonlinear_equality_targets

**Argument(s):** REALLIST

**Default:** vector values = 0.

**Description**

The `targets` specification provides the targets for nonlinear equalities of the form

\[ g(x) = g_t \]

and the defaults for the equality targets enforce a value of 0.0 for each constraint:

\[ g(x) = 0.0 \]
7.6.4.9.2 scale_types

- Keywords Area
- responses
- calibration_terms
- nonlinear_equality_constraints
- scale_types

How to scale each nonlinear constraint

**Specification**

**Alias:** nonlinear_equality_scale_types

**Argument(s):** STRINGLIST

**Default:** no scaling

**Description**

Each string in `scale_types` indicates the scaling type for each nonlinear inequality (equality) constraint. They only have effect when the associated method specifies `scaling`.

The options are:

- `'value'` - characteristic value by which nonlinear constraint values will be divided. If this is chosen, then `scales` must also be specified; ‘value’ is assumed if scales are given without `scale_types`

- `'auto'` - automatic scaling based on bounds (inequalities) or targets (equalities)

- `'log'` - logarithmic scaling (can be used together with `scales`, which can be helpfully used to negate values prior to log transformation)

If a single string is specified it will apply to all of the nonlinear inequality (equality) constraints. Otherwise a string must be specified for each nonlinear inequality (equality) constraint.

**Usage Tips:**

See the scaling information under specific methods, e.g., `method-+-scaling` for details on how to use this keyword.

7.6.4.9.3 scales

- Keywords Area
- responses
- calibration_terms
- nonlinear_equality_constraints
- scales

Characteristic values to scale each nonlinear constraint
Specification

**Alias:** nonlinear_equality_scales

**Argument(s):** REALLIST

**Default:** 1.0 (no scaling)

**Description**

Each real value in `scales` is a nonzero characteristic value to be used in scaling each nonlinear inequality (equality) constraint. They only have effect when the associated method specifies `scaling`.

This keyword is required for `scale_types` of ‘value’ and optional for ‘log’. When specified in conjunction with log, scale values are applied prior to the logarithm, to permit log scaling of strictly negative response functions.

If a single scale value is specified it will apply to all of the nonlinear inequality (equality) constraints. Otherwise a value must be specified for each nonlinear inequality (equality) constraint.

**Usage Tips:**

When `scales` are specified, but not `scale_types`, the scaling type is assumed to be ‘value’ for this set of nonlinear inequality (equality) constraints.

Use scale values of 1.0 to selectively avoid scaling a subset of response functions.

See the scaling information under specific methods, e.g., method-∗-scaling for details on how to use this keyword.

---

7.6.5 `response_functions`

- **Keywords Area**
- **responses**
- **response_functions**

Generic response type

**Specification**

**Alias:** num_response_functions

**Argument(s):** INTEGER

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>scalar_responses</td>
<td>Number of scalar response functions</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>field_responses</td>
<td>Number of field responses functions</td>
</tr>
</tbody>
</table>

**Description**

A generic response data set is specified using `response_functions`. Each of these functions is simply a response quantity of interest with no special interpretation taken by the method in use.

Whereas objective, constraint, and residual functions have special meanings for optimization and least squares algorithms, the generic response function data set need not have a specific interpretation and the user is free to define whatever functional form is convenient.
Theory

This type of data set is used by uncertainty quantification methods, in which the effect of parameter uncertainty on response functions is quantified, and can also be used in parameter study and design of experiments methods (although these methods are not restricted to this data set), in which the effect of parameter variations on response functions is evaluated.

See Also

These keywords may also be of interest:

- objective_functions
- calibration_terms

7.6.5.1 scalar_responses

- Keywords Area
- responses
- response_functions
- scalar_responses

Number of scalar response functions

Specification

Alias: num_scalar_responses

Argument(s): INTEGER

Description

This keyword describes the number of scalar response functions. It is meant to be used in conjunction with field_responses, which describes the number of field response functions. The total number of response functions, both scalar and field, is given by response_functions. If only scalar responses functions are specified, it is not necessary to specify the number of scalar terms explicitly: one can simply say response_functions = 5 and get 5 scalar responses. However, if there are three scalar responses and 2 field responses, then response_functions = 5 but scalar_responses = 3 and field_responses = 2.

This type of data set is used by uncertainty quantification methods, in which the effect of parameter uncertainty on response functions is quantified, and can also be used in parameter study and design of experiments methods (although these methods are not restricted to this data set), in which the effect of parameter variations on response functions is evaluated.

See Also

These keywords may also be of interest:

- field_responses
7.6.5.2 field_responses

- Keywords Area
- responses
- response_functions
- field_responses

Number of field responses functions

**Specification**

**Alias:** num_field_responses

**Argument(s):** INTEGER

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Required</strong></td>
<td><strong>lengths</strong></td>
<td></td>
<td>Lengths of field responses</td>

<td>Number of independent coordinates for field responses</td>
</tr>
<tr>
<td><strong>Optional</strong></td>
<td>read_field_coordinates</td>
<td></td>
<td>Add context to data: flag to indicate that field coordinates should be read</td>
</tr>
</tbody>
</table>

**Description**

This keyword describes the number of field response functions. A field function is a set of related response values collected over a range of independent coordinate values which may or may not be specified by the user. For example, voltage over time would be a field function, where voltage is the field_objective and time is the independent coordinate. Similarly, temperature over time and space would be a field response, where the independent coordinates would be both time and spatial coordinates such as (x,y) or (x,y,z), depending on the application. The main difference between scalar responses and field responses is that for field data, we plan to implement methods that take advantage of the correlation or relationship between the field values.

Note that if there is one field_response, and it has length 100 (meaning 100 values), then the user’s simulation code must return 100 values. Also, if there are both scalar and field responses, the user should specify the number of scalar responses as scalar_responses. If there are only field responses, it still is necessary to specify both response_functions = NN and field_responses = NN, where NN is the number of field responses.

This type of data set is used by uncertainty quantification methods, in which the effect of parameter uncertainty on response functions is quantified, and can also be used in parameter study and design of experiments methods (although these methods are not restricted to this data set), in which the effect of parameter variations on response functions is evaluated. Currently, field response functions will be translated back to scalar responses. So, a field of length 100 will be treated as 100 separate scalar responses. However, in future versions of Dakota, we plan to implement methods which can exploit the nature of field data.

7.6.5.2.1 lengths

- Keywords Area
- responses
- response_functions
- field_responses
- lengths

Lengths of field responses

Specification

Alias: none

Argument(s): INTEGERLIST

Description

This keyword describes the lengths of each field response. It is an integer vector of length field_responses. For example, if the field_responses = 2, an example would be lengths = 50 200, indicating that the first field response has 50 field elements but the second one has 200. The coordinate values (e.g. the independent variables) corresponding to these field responses are read in files labeled response_descriptor.coords.

See Also

These keywords may also be of interest:

- field_responses

7.6.5.2.2 num_coordinates_per_field

- Keywords Area
- responses
- response_functions
- field_responses
- num_coordinates_per_field

Number of independent coordinates for field responses

Specification

Alias: none

Argument(s): INTEGERLIST
Description

This keyword describes the number of independent coordinates for each field response. It is an integer vector of length field_responses. For example, if the field_responses = 2, an example would be num_coordinates_per_field = 2 1 means that the first field response has two sets of independent coordinates (perhaps x, y locations), but the second response only has one (for example, time where the field response is only dependent upon time). The actual coordinate values (e.g. the independent variables) corresponding to these field responses are defined in a file call response_descriptor.coords, where response_descriptor is the name of the individual field.

See Also

These keywords may also be of interest:

- field_responses

7.6.5.2.3 read_field_coordinates

- Keywords Area
- responses
- response_functions
- field_responses
- read_field_coordinates

Add context to data: flag to indicate that field coordinates should be read

Specification

**Alias:** none

**Argument(s):** none

Description

Field coordinates specify independent variables (e.g. spatial or temporal coordinates) upon which the field depends. For example, the voltage level above might be a function of time, so time is the field coordinate. If the user has field coordinates to read, they need to specify read_field_coordinates. The field coordinates will then be read from a file named response_descriptor.coords, where response_descriptor is the user-provided descriptor for the field response. The number of columns in the coords file should be equal to the number of field coordinates.

7.6.6 no_gradients

- Keywords Area
- responses
- no_gradients

Gradients will not be used
7.6 responses

Specification

**Alias:** none

**Argument(s):** none

Description

The `no_gradients` specification means that gradient information is not needed in the study. Therefore, it will neither be retrieved from the simulation nor computed with finite differences. The `no_gradients` keyword is a complete specification for this case.

See Also

These keywords may also be of interest:

- `numerical_gradients`
- `analytic_gradients`
- `mixed_gradients`

7.6.7 analytic_gradients

- **Keywords Area**
- **responses**
- **analytic_gradients**

Analysis driver will return gradients

Specification

**Alias:** none

**Argument(s):** none

Description

The `analytic_gradients` specification means that gradient information is available directly from the simulation (finite differencing is not required). The simulation must return the gradient data in the Dakota format (enclosed in single brackets; see Dakota File Data Formats in the Users Manual [5]) for the case of file transfer of data. The `analytic_gradients` keyword is a complete specification for this case.

Description

The `mixed_gradients` specification means that some gradient information is available directly from the simulation (analytic) whereas the rest will have to be finite differenced (numerical). This specification allows the user to make use of as much analytic gradient information as is available and then finite difference for the rest.
The method_source, interval_type, and fd_gradient_step_size specifications pertain to those functions listed by the id_numerical_gradients list.

Examples

For example, the objective function may be a simple analytic function of the design variables (e.g., weight) whereas the constraints are nonlinear implicit functions of complex analyses (e.g., maximum stress).

7.6.8.3 method_source

- Keywords Area
- responses
- mixed_gradients
- method_source

Specify which finite difference routine is used

Specification

Alias: none
Argument(s): none
Default: dakota
Description

The method_source setting specifies the source of the finite differencing routine that will be used to compute the numerical gradients:

- dakota (default)
- vendor

_dakota_ denotes Dakota’s internal finite differencing algorithm and _vendor_ denotes the finite differencing algorithm supplied by the iterator package in use (DOT, CONMIN, NPSOL, NL2SOL, NLSSOL, ROL, and OPT++ each have their own internal finite differencing routines). The _dakota_ routine is the default since it can execute in parallel and exploit the concurrency in finite difference evaluations (see Exploiting Parallelism in the Users Manual [5]).

However, the _vendor_ setting can be desirable in some cases since certain libraries will modify their algorithm when the finite differencing is performed internally. Since the selection of the _dakota_ routine hides the use of finite differencing from the optimizers (the optimizers are configured to accept user-supplied gradients, which some algorithms assume to be of analytic accuracy), the potential exists for the _vendor_ setting to trigger the use of an algorithm more optimized for the higher expense and/or lower accuracy of finite-differencing. For example, NPSOL uses gradients in its line search when in user-supplied gradient mode (since it assumes they are inexpensive), but uses a value-based line search procedure when internally finite differencing. The use of a value-based line search will often reduce total expense in serial operations. However, in parallel operations, the use of gradients in the NPSOL line search (user-supplied gradient mode) provides excellent load balancing without need to resort to speculative optimization approaches.

In summary, then, the _dakota_ routine is preferred for parallel optimization, and the _vendor_ routine may be preferred for serial optimization in special cases.

### 7.6.8.4 dakota

- Keywords Area
- responses
- mixed_gradients
- dakota

_(Default) Use internal Dakota finite differences algorithm_

**Specification**

Alias: none  
Argument(s): none  
Default: relative

</tr>
</thead>
<tbody>
<tr>
<td>absolute</td>
<td>Do not scale step-size</td>
</tr>
<tr>
<td>bounds</td>
<td>Scale step-size by the domain of the parameter</td>
</tr>
</tbody>
</table>

**Description**

The **dakota** routine is the default since it can execute in parallel and exploit the concurrency in finite difference evaluations (see Exploiting Parallelism in the Users Manual [5]).

When the **method_source** is **dakota**, the user may also specify the type of scaling desired when determining the finite difference step size. The choices are **absolute**, **bounds**, and **relative**. For **absolute**, the step size will be applied as is. For **bounds**, it will be scaled by the range of each parameter. For **relative**, it will be scaled by the parameter value.

### 7.6.8.4.1 ignore_bounds

- **Keywords Area**
- **responses**
- **mixed_gradients**
- **dakota**
- **ignore_bounds**

Do not respect bounds when computing gradients or Hessians

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** bounds respected

**Description**

When Dakota computes gradients or Hessians by finite differences and the variables in question have bounds, it by default chooses finite-differencing steps that keep the variables within their specified bounds. Older versions of Dakota generally ignored bounds when computing finite differences. To restore the older behavior, one can add keyword **ignore_bounds** to the response specification when **method_source dakota** (or just **dakota**) is also specified.

In forward difference or backward difference computations, honoring bounds is straightforward.

To honor bounds when approximating \( \frac{\partial f}{\partial x_i} \), i.e., component \( i \) of the gradient of \( f \), by central differences, Dakota chooses two steps \( h_1 \) and \( h_2 \) with \( h_1 \neq h_2 \), such that \( x + h_1 e_i \) and \( x + h_2 e_i \) both satisfy the bounds, and then computes

\[
\frac{\partial f}{\partial x_i} \approx \frac{h_2^2(f_1 - f_0) - h_1^2(f_2 - f_0)}{h_1 h_2 (h_2 - h_1)},
\]

with \( f_0 = f(x) \), \( f_1 = f(x + h_1 e_i) \), and \( f_2 = f(x + h_2 e_i) \).

7.6.8.6 interval_type

- Keywords Area
- responses
- mixed_gradients
- interval_type

Specify how to compute gradients and hessians

Specification

Alias: none
Argument(s): none
Default: forward
Description

The interval_type setting is used to select between forward and central differences in the numerical gradient calculations. The dakota, DOT vendor, and OPT++ vendor routines have both forward and central differences available, the CONMIN, NL2SOL and ROL vendor routines support forward differences only, and the NPSOL and NLSSOL vendor routines start with forward differences and automatically switch to central differences as the iteration progresses (the user has no control over this). The following forward difference expression

\[ \nabla f(x) \approx \frac{f(x + h e_i) - f(x)}{h} \]

and the following central difference expression

\[ \nabla f(x) \approx \frac{f(x + h e_i) - f(x - h e_i)}{2h} \]

are used to estimate the \( i^{th} \) component of the gradient vector.

7.6.8.9  fd_step_size

- Keywords Area
- responses
- mixed_gradients
- fd_step_size

Step size used when computing gradients and Hessians

Specification

*Alias*: fd_gradient_step_size

*Argument(s):* REALLIST

*Default*: 0.001

Description

*fd_step_size* specifies the relative finite difference step size to be used in the computations. Either a single value may be entered for use with all parameters, or a list of step sizes may be entered, one for each parameter.

The latter option of a list of step sizes is only valid for use with the Dakota finite differencing routine. For Dakota with an interval scaling type of *absolute*, the differencing interval will be *fd_step_size*.

For Dakota with and interval scaling type of *bounds*, the differencing intervals are computed by multiplying *fd_step_size* with the range of the parameter. For Dakota (with an interval scaling type of *relative*), DOT, CONMIN, and OPT++, the differencing intervals are computed by multiplying the *fd_step_size* with the current parameter value. In this case, a minimum absolute differencing interval is needed when the current parameter value is close to zero. This prevents finite difference intervals for the parameter which are too small to distinguish differences in the response quantities being computed. Dakota, DOT, CONMIN, and OPT++ all use \(0.01 \times \text{fd}_\text{step} \_\text{size}\) as their minimum absolute differencing interval. With a *fd_step_size* = 0.001, for example, Dakota, DOT, CONMIN, and OPT++ will use intervals of 0.001 current value with a minimum interval of 1.e-5. NPSOL and NLSSOL use a different formula for their finite difference intervals: \(\text{fd}_\text{step} \_\text{size} \times (1 + |\text{current parameter value}|)\). This definition has the advantage of eliminating the need for a minimum absolute differencing interval since the interval no longer goes to zero as the current parameter value goes to zero.

ROL's finite difference step size can not be controlled via Dakota. Therefore, *fd_step_size* will be ignored when ROL's finite differencing routines are used (vendor FD gradients are specified). ROL's differencing intervals are computed by multiplying the current parameter value with the square root of machine precision.

- responses
- numerical_gradients
- fd_step_size

Step size used when computing gradients and Hessians

Specification

Alias: fd_gradient_step_size
Argument(s): REALLIST
Default: 0.001

Description

fd_step_size specifies the relative finite difference step size to be used in the computations. Either a single value may be entered for use with all parameters, or a list of step sizes may be entered, one for each parameter.

The latter option of a list of step sizes is only valid for use with the Dakota finite differencing routine. For Dakota with an interval scaling type of absolute, the differencing interval will be fd_step_size.

For Dakota with and interval scaling type of bounds, the differencing intervals are computed by multiplying fd_step_size with the range of the parameter. For Dakota (with an interval scaling type of relative), DOT, CONMIN, and OPT++, the differencing intervals are computed by multiplying the fd_step_size with the current parameter value. In this case, a minimum absolute differencing interval is needed when the current parameter value is close to zero. This prevents finite difference intervals for the parameter which are too small to distinguish differences in the response quantities being computed. Dakota, DOT, CONMIN, and OPT++ all use \(0.01 \times \text{fd_step_size}\) as their minimum absolute differencing interval. With a \(\text{fd_step_size} = 0.001\), for example, Dakota, DOT, CONMIN, and OPT++ will use intervals of \(0.001 \times \text{current value}\) with a minimum interval of \(1.e-5\). NPSOL and NLSSOL use a different formula for their finite difference intervals: \(\text{fd_step_size} \times (1+|\text{current parameter value}|)\). This definition has the advantage of eliminating the need for a minimum absolute differencing interval since the interval no longer goes to zero as the current parameter value goes to zero.

ROL's finite difference step size can not be controlled via Dakota. Therefore, fd_step_size will be ignored when ROL's finite differencing routines are used (vendor FD gradients are specified). ROL's differencing intervals are computed by multiplying the current parameter value with the square root of machine precision.

7.6.10 no_hessians

- Keywords Area
• responses
  • no_hessians

Hessians will not be used

Specification

Alias: none
Argument(s): none

Description

The no_hessians specification means that the method does not require Dakota to manage the computation of any Hessian information. Therefore, it will neither be retrieved from the simulation nor computed by Dakota. The no_hessians keyword is a complete specification for this case. Note that, in some cases, Hessian information may still be being approximated internal to an algorithm (e.g., within a quasi-Newton optimizer such as optpp_q_newton); however, Dakota has no direct involvement in this process and the responses specification need not include it.

<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The `numerical_hessians` specification means that Hessian information is needed and will be computed with finite differences using either first-order gradient differencing (for the cases of `analytic_gradients` or for the functions identified by `id_analytic_gradients` in the case of `mixed_gradients`) or first- or second-order function value differencing (all other gradient specifications). In the former case, the following expression

\[ \nabla^2 f(x)_i \approx \frac{\nabla f(x + h e_i) - \nabla f(x)}{h} \]

estimates the \( i \)th Hessian column, and in the latter case, the following expressions

\[ \nabla^2 f(x)_{i,j} \approx \frac{f(x + h_i e_i + h_j e_j) - f(x + h_i e_i) - f(x - h_i e_i) + f(x)}{h_i h_j} \]

and

\[ \nabla^2 f(x)_{i,j} \approx \frac{f(x + h e_i + h e_j) - f(x + h e_i - h e_j) - f(x - h e_i + h e_j) + f(x - h e_i - h e_j)}{4h^2} \]

provide first- and second-order estimates of the \( i j \)th Hessian term. Prior to Dakota 5.0, Dakota always used second-order estimates. In Dakota 5.0 and newer, the default is to use first-order estimates (which honor bounds on the variables and require only about a quarter as many function evaluations as do the second-order estimates), but specifying `central` after `numerical_hessians` causes Dakota to use the old second-order estimates, which do not honor bounds. In optimization algorithms that use Hessians, there is little reason to use second-order differences in computing Hessian approximations.

**Description**

These keywords may also be of interest:

- fd_step_size

Step size used when computing gradients and Hessians

Specification

Alias: fd_hessian_step_size

Argument(s): REALLIST

Default: 0.001 (forward), 0.002 (central)

Description

fd_step_size specifies the relative finite difference step size to be used in the computations. Either a single value may be entered for use with all parameters, or a list of step sizes may be entered, one for each parameter.

The latter option of a list of step sizes is only valid for use with the Dakota finite differencing routine. For Dakota with an interval scaling type of absolute, the differencing interval will be fd_step_size.

For Dakota with and interval scaling type of bounds, the differencing intervals are computed by multiplying fd_step_size with the range of the parameter. For Dakota (with an interval scaling type of relative), DOT, CONMIN, and OPT++ use fd_step_size with the current parameter value. In this case, a minimum absolute differencing interval is needed when the current parameter value is close to zero. This prevents finite difference intervals for the parameter which are too small to distinguish differences in the response quantities being computed. Dakota, DOT, CONMIN, and OPT++ all use \(0.01 \times \text{fd_step_size}\) as their minimum absolute differencing interval. With a \(\text{fd_step_size} = 0.001\), for example, Dakota, DOT, CONMIN, and OPT++ will use intervals of \(0.001 \times \text{current value}\) with a minimum interval of 1.e-5. NPSOL and NLSSOL use a different formula for their finite difference intervals: \(\text{fd_step_size} \times (1 + |\text{current parameter value}|)\). This definition has the advantage of eliminating the need for a minimum absolute differencing interval since the interval no longer goes to zero as the current parameter value goes to zero.

ROL's finite difference step size can not be controlled via Dakota. Therefore, fd_step_size will be ignored when ROL's finite differencing routines are used (vendor FD gradients are specified). ROL's differencing intervals are computed by multiplying the current parameter value with the square root of machine precision.

7.6.11.2 relative

<tbody>
<tr>
<td><strong>Required (Choose One)</strong></td>
<td>bfgs</td>
<td><strong>Use BFGS method to compute quasi-hessians</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>sr1</td>
<td><strong>Use the Symmetric Rank 1 update method to compute quasi-Hessians</strong></td>
<td></td>
</tr>
</tbody>
</table>

**Description**

The `quasi_hessians` specification means that Hessian information is needed and will be approximated using secant updates (sometimes called "quasi-Newton updates", though any algorithm that approximates Newton's method is a quasi-Newton method).

Compared to finite difference numerical Hessians, secant approximations do not expend additional function evaluations in estimating all of the second-order information for every point of interest. Rather, they accumulate approximate curvature information over time using the existing gradient evaluations.

The supported secant approximations include the Broyden-Fletcher-Goldfarb-Shanno (BFGS) update (specified with the keyword `bfgs`) and the Symmetric Rank 1 (SR1) update (specified with the keyword `sr1`).

#### 7.6.12.1 bfgs

- **Keywords Area**
- `responses`
- `quasi_hessians`
- `bfgs`

Use BFGS method to compute quasi-hessians

**Specification**

**Alias:** none  
**Argument(s):** none  
**Child Keywords:**
Broyden-Fletcher-Goldfarb-Shanno (BFGS) update will be used to compute quasi-Hessians.

\[ B_{k+1} = B_k - \frac{B_k s_k s_k^T B_k}{s_k^T B_k s_k} + \frac{y_k y_k^T}{y_k^T s_k} \]

where \( B_k \) is the \( k^{th} \) approximation to the Hessian, \( s_k = x_{k+1} - x_k \) is the step and \( y_k = \nabla f_{k+1} - \nabla f_k \) is the corresponding yield in the gradients.

Notes

- Initial scaling of \( y_k^T s_k I \) is used for \( B_0 \) prior to the first update.
- Numerical safeguarding is used to protect against numerically small denominators within the updates.
- This safeguarding skips the update if \( |y_k^T s_k| < 10^{-6} s_k^T B_k s_k \)
- Additional safeguarding can be added using the `damped` option, which utilizes an alternative damped BFGS update when the curvature condition \( y_k^T s_k > 0 \) is nearly violated.

### Specification

**Alias**: none

**Argument(s)**: none

**Default**: undamped BFGS

### Description

See parent page.
Use the Symmetric Rank 1 update method to compute quasi-Hessians.

**Specification**

**Alias:** none

**Arguments:** none

**Description**

The Symmetric Rank 1 (SR1) update (specified with the keyword `sr1`) will be used to compute quasi-Hessians.

\[ B_{k+1} = B_k + \frac{(y_k - B_k s_k)(y_k - B_k s_k)^T}{(y_k - B_k s_k)^T s_k} \]

where \( B_k \) is the \( k^{th} \) approximation to the Hessian, \( s_k = x_{k+1} - x_k \) is the step and \( y_k = \nabla f_{k+1} - \nabla f_k \) is the corresponding yield in the gradients.

**Notes**

- Initial scaling of \( Y_k^T Y_k I \) is used for \( B_0 \) prior to the first update.
- Numerical safeguarding is used to protect against numerically small denominators within the updates.
- This safeguarding skips the update if \( |(y_k - B_k s_k)^T s_k| < 10^{-6}||s_k||_2||y_k - B_k s_k||_2 \)

7.6.13 analytic_hessians

- Keywords Area
- responses
- analytic_hessians

Hessians are needed and are available directly from the analysis driver.

**Specification**

**Alias:** none

**Arguments:** none

**Description**

The `analytic_hessians` specification means that Hessian information is available directly from the simulation. The simulation must return the Hessian data in the Dakota format (enclosed in double brackets; see Dakota File Data Formats in Users Manual [5]) for the case of file transfer of data. The `analytic_hessians` keyword is a complete specification for this case.

### Description

The `mixed_hessians` specification means that some Hessian information is available directly from the simulation (analytic) whereas the rest will have to be estimated by finite differences (numerical) or approximated by secant updating. As for mixed gradients, this specification allows the user to make use of as much analytic information as is available and then estimate/approximate the rest.

The `id_analytic_hessians` list specifies by number the functions which have analytic Hessians, and the `id_numerical_hessians` and `id_quasi_hessians` lists specify by number the functions which must use numerical Hessians and secant Hessian updates, respectively. Each function identifier, from 1 through the total number of functions, must appear once and only once within the union of the `id_analytic_hessians`, `id_numerical_hessians`, and `id_quasi_hessians` lists.

The `fd_hessian_step_size` and `bfgs`, damped `bfgs`, or `sr1` secant update selections are as described previously in `responses` and pertain to those functions listed by the `id_numerical_hessians` and `id_quasi_hessians` lists.

### Specification

**Alias:** none

**Argument(s):** INTEGERLIST

**Child Keywords:**
fd_step_size

Step size used when computing gradients and Hessians

Specification

Alias: fd_hessian_step_size
Argument(s): REALLIST
Default: 0.001 (forward), 0.002 (central)

Description

fd_step_size specifies the relative finite difference step size to be used in the computations. Either a single value may be entered for use with all parameters, or a list of step sizes may be entered, one for each parameter.

The latter option of a list of step sizes is only valid for use with the Dakota finite differencing routine. For Dakota with an interval scaling type of absolute, the differencing interval will be fd_step_size.

For Dakota with and interval scaling type of bounds, the differencing intervals are computed by multiplying fd_step_size with the range of the parameter. For Dakota (with an interval scaling type of relative), DOT, CONMIN, and OPT++, the differencing intervals are computed by multiplying the fd_step_size with the current parameter value. In this case, a minimum absolute differencing interval is needed when the current parameter value

See Also

These keywords may also be of interest:

• id_analytic_hessians
• id_quasi_hessians

7.6.14.1.1 fd_step_size

• Keywords Area
• responses
• mixed_hessians
• id_numerical_hessians
• fd_step_size

Description

The id_analytic_hessians list specifies by number the functions which have analytic Hessians, and the id_numerical_hessians and id_quasi_hessians lists specify by number the functions which must use numerical Hessians and secant Hessian updates, respectively. Each function identifier, from 1 through the total number of functions, must appear once and only once within the union of the id_analytic_hessians, id_numerical_hessians, and id_quasi_hessians lists.
value is close to zero. This prevents finite difference intervals for the parameter which are too small to distinguish
differences in the response quantities being computed. Dakota, DOT, CONMIN, and OPT++ all use .01*fd_step_size as their minimum absolute differencing interval. With a fd_step_size = .001, for example, Dakota, DOT, CONMIN, and OPT++ will use intervals of .001*current value with a minimum interval of 1.e-5. N-
PSOL and NLSSOL use a different formula for their finite difference intervals: fd_step_size*(1+|current parameter value|). This definition has the advantage of eliminating the need for a minimum absolute differ-
cencing interval since the interval no longer goes to zero as the current parameter value goes to zero.
ROL's finite difference step size can not be controlled via Dakota. Therefore, fd_step_size will be ignored
when ROL's finite differencing routines are used (vendor FD gradients are specified). ROL's differencing intervals
are computed by multiplying the current parameter value with the square root of machine precision.

7.6.14.7.2 sr1

• Keywords Area
• responses
• mixed_hessians
• id_quasi_hessians
• sr1

Use the Symmetric Rank 1 update method to compute quasi-Hessians

Specification

Alias: none
Argument(s): none

Description

The Symmetric Rank 1 (SR1) update (specified with the keyword sr1) will be used to compute quasi-Hessians.

\[ B_{k+1} = B_k + \frac{(y_k - B_k s_k)(y_k - B_k s_k)^T}{(y_k - B_k s_k)^T s_k} \]

where \( B_k \) is the \( k^{th} \) approximation to the Hessian, \( s_k = x_{k+1} - x_k \) is the step and \( y_k = \nabla f_{k+1} - \nabla f_k \) is the corresponding yield in the gradients.

Notes
• Initial scaling of $\frac{1}{\sqrt{\sum}}$ is used for $B_0$ prior to the first update.

• Numerical safeguarding is used to protect against numerically small denominators within the updates.

• This safeguarding skips the update if $|(y_k - B_k s_k)^T s_k| < 10^{-6}||s_k||_2||y_k - B_k s_k||_2$.

7.6.14.8  id_analytic_hessians

• Keywords Area
• responses
• mixed_hessians
• id_analytic_hessians

Identify which analytical Hessian corresponds to which response

Topics

This keyword is related to the topics:

• objective_function_pointer

Specification

Alias: none

Argument(s): INTEGERLIST

Description

The id_analytic_hessians list specifies by number the functions which have analytic Hessians, and the id_numerical_hessians and id_quasi_hessians lists specify by number the functions which must use numerical Hessians and secant Hessian updates, respectively. Each function identifier, from 1 through the total number of functions, must appear once and only once within the union of the id_analytic_hessians, id_numerical_hessians, and id_quasi_hessians lists.

• id_quasi_hessians

7.6.15  metadata

• Keywords Area
• responses
• metadata

(Experimental) Labels for floating point response metadata
Specification

**Alias:** none

**Argument(s):** STRINGLIST

**Default:** no metadata

Description

Specify the labels (field names) for floating point-valued metadata responses to be returned from the interface.

Dakota's emerging metadata responses are distinct from the response quantities of interest explored by a Dakota method. Some, such as simulation cost might be used by a method (such as method-multifidelity_sampling and related methods) to make algorithmic decisions. Other metadata might just be tabulated for user convenience.

Usage Tips

In a `results_file`, values and labels for metadata should follow any function values, gradients, or Hessians returned by the simulation.

Examples

A responses specification where the Dakota method will be applied to quantities of interest stress and displacement, while metadata simulation cost in minutes and number of dead elements will be tabulated for each evaluation:

```plaintext
responses
  descriptors 'stress' 'displacement'
  response_functions 2
  no_gradients
  no_hessians
  metadata 'simulation_cost_minutes' 'number_dead_elements'
```
