Abstract

The Dakota toolkit provides a flexible and extensible interface between simulation codes and iterative analysis methods. Dakota contains algorithms for optimization with gradient and nongradient-based methods; uncertainty quantification with sampling, reliability, and stochastic expansion methods; parameter estimation with nonlinear least squares methods; and sensitivity/variance analysis with design of experiments and parameter study methods. These capabilities may be used on their own or as components within advanced strategies such as surrogate-based optimization, mixed integer nonlinear programming, or optimization under uncertainty. By employing object-oriented design to implement abstractions of the key components required for iterative systems analyses, the Dakota toolkit provides a flexible and extensible problem-solving environment for design and performance analysis of computational models on high performance computers.

This report serves as a reference manual for the commands specification for the Dakota software, providing input overviews, option descriptions, and example specifications.

Chapter 1

Main Page

The Dakota software (http://dakota.sandia.gov/) delivers advanced parametric analysis techniques enabling quantification of margins and uncertainty, risk analysis, model calibration, and design exploration with computational models. Its methods include optimization, uncertainty quantification, parameter estimation, and sensitivity analysis, which may be used individually or as components within surrogate-based and other advanced strategies.

Author

The Reference Manual documents all the input keywords that can appear in a Dakota input file to configure a Dakota study. Its organization closely mirrors the structure of dakota.input.summary. For more information see Dakota Input Specification. For information on software structure, refer to the Developers Manual [3], and for a tour of Dakota features and capabilities, including a tutorial, refer to the User's Manual [5].

Dakota 6.14 and newer include a refreshed Examples Library, ranging from examples of Dakota input files and basic studies through complete case studies. These can be found in binary distributions in dakota/share/dakota/examples/official (dakota/dakota-examples in source distributions). Legacy examples, including many from the Dakota software manuals appear in other directories in dakota/share/dakota/examples (dakota/examples for source).

1.1 How to Use this Manual

- To learn how to run Dakota from the command line, see Running Dakota
- To learn how to restart Dakota studies, see Restarting Dakota Studies
- To learn about the Dakota restart utility, see The Dakota Restart Utility

To find more information about a specific keyword

1. Use the search box at the top right (currently only finds keyword names)
2. Browse the Keywords tree on the left navigation pane
3. Look at the Dakota Input Specification
4. Navigate through the keyword pages, starting from the Keywords Area

To find more information about a Dakota related topic
1. Browse the Topics Area on the left navigation pane
2. Navigate through the topics pages, starting from the Topics Area

A small number of examples are included (see Sample Input Files) along with a description of the test problems (see Test Problems).

A bibliography for the Reference Manual is provided in Bibliographic References
Chapter 2

Running Dakota

The Dakota executable file is named dakota (dakota.exe on Windows) and is most commonly run from a terminal or command prompt.

2.1 Usage

If the dakota command is entered at the command prompt without any arguments, a usage message similar to the following appears:

usage: dakota [options and <args>]
    -help (Print this summary)
    -version (Print DAKOTA version number)
    -input <$val> (REQUIRED DAKOTA input file $val)
    -preproc [$val] (Pre-process input file with pyprepro or tool $val)
    -output <$val> (Redirect DAKOTA standard output to file $val)
    -error <$val> (Redirect DAKOTA standard error to file $val)
    -parser <$val> (Parsing technology: nidr[strict]][:dumpfile])
    -no_input_echo (Do not echo DAKOTA input file)
    -check (Perform input checks)
    -pre_run [$val] (Perform pre-run (variables generation) phase)
    -run [$val] (Perform run (model evaluation) phase)
    -post_run [$val] (Perform post-run (final results) phase)
    -read_restart [$val] (Read an existing DAKOTA restart file $val)
    -stop_restart <$val> (Stop restart file processing at restart record $val)
    -write_restart [$val] (Write a new DAKOTA restart file $val)

Of these command line options, only input is required, and the -input switch can be omitted if the input file name is the final item appearing on the command line (see Examples); all other command-line inputs are optional.

- help prints the usage message above.

- version prints version information for the executable.

- check invokes a dry-run mode in which the input file is processed and checked for errors, but the study is not performed.

- input provides the name of the Dakota input file, which can optionally be pre-processed as a template using the preproc option.

- output and error options provide file names for redirection of the Dakota standard output (stdout) and standard error (stderr), respectively.

- The parser option is for debugging and will not be further described here.
• By default, Dakota will echo the input file to the output stream, but no_input_echo can override this behavior.

• read_restart and write_restart commands provide the names of restart databases to read from and write to, respectively.

• stop_restart command limits the number of restart records read from the restart database (the default is all the records) for those cases in which some evaluations were erroneous or corrupted. Restart records are recorded in order of completion. Restart management is an important technique for retaining data from expensive engineering applications.

• -pre_run, -run, and -post_run instruct Dakota to run one or more execution phases, excluding others. The commands must be followed by filenames as described in Execution Phases.

Command line switches can be abbreviated so long as the abbreviation is unique, so the following are valid, unambiguous specifications: -h, -v, -c, -i, -o, -e, -s, -w, -re, -ru, and -po and can be used in place of the longer forms of the command line options.

For information on restarting Dakota, see Restarting Dakota Studies and The Dakota Restart Utility.

### 2.2 Examples

To run Dakota with a particular input file, the following syntax can be used:

```bash
dakota -i dakota.in
```

or more simply

```bash
dakota dakota.in
```

This will echo the standard output (stdout) and standard error (stderr) messages to the terminal. To redirect stdout and stderr to separate files, the -o and -e command line options may be used:

```bash
dakota -i dakota.in -o dakota.out -e dakota.err
```

or

```bash
dakota -o dakota.out -e dakota.err dakota.in
```

Alternatively, any of a variety of Unix redirection variants can be used. Refer to [6] for more information on Unix redirection. The simplest of these redirects stdout to another file:

```bash
dakota dakota.in > dakota.out
```

The specified Dakota input file may instead be a dprepro/aprepro-style template file to be pre-processed prior to running Dakota. For example it might contain template expressions in curly braces:

```bash
# {MyLB = 2.0} {MyUB = 8.6}
variables
uniform_uncertain 3
  upper_bounds {MyUB} {MyUB} {MyUB}
  lower_bounds {MyLB} {MyLB} {MyLB}
```

(See the Interfaces chapter in the Dakota User’s Manual [?] for more information and use cases.) To pre-process the input file, specify the preproc flag which generates an intermediate temporary input file for use in Dakota. If Dakota’s pyprepro.py utility is not available on the execution PATH and/or additional pre-processing options are needed, the tool location and syntax can be specified, for example:
2.3 Execution Phases

Dakota has three execution phases: **pre-run**, **run**, and **post-run**.

- **pre-run** can be used to generate variable sets
- **run** (core run) invokes the simulation to evaluate variables, producing responses
- **post-run** accepts variable/response sets and analyzes the results (for example, calculate correlations from a set of samples). Currently only two modes are supported and only for sampling, parameter study, and DACE methods:

1. **pre-run** only with optional tabular output of variables:
   
   dakota -i dakota.in -pre_run [::myvariables.dat]

2. **post-run** only with required tabular input of variables/responses:

   dakota -i dakota.in -post_run myvarsresponses.dat::

2.4 Restarting Dakota Studies

Dakota is often used to solve problems that require repeatedly running computationally expensive simulation codes. In some cases you may want to repeat an optimization study, but with a tighter final convergence tolerance. This would be costly if the entire optimization analysis had to be repeated. Interruptions imposed by computer usage policies, power outages, and system failures could also result in costly delays. However, Dakota automatically records the variable and response data from all function evaluations so that new executions of Dakota can pick up where previous executions left off. The Dakota restart file (dakota.rst by default) archives the tabulated interface evaluations in a binary format. The primary restart commands at the command line are **-read_restart**, **-write_restart**, and **-stop_restart**.

2.4.1 Writing Restart Files

To write a restart file using a particular name, the **-write_restart** command line input (may be abbreviated as **-w**) is used:

   dakota -i dakota.in -write_restart my_restart_file

If no **-write_restart** specification is used, then Dakota will still write a restart file, but using the default name dakota.rst instead of a user-specified name.

To turn restart recording off, the user may use the **restart_file** keyword, in the interface block. This can increase execution speed and reduce disk storage requirements, but at the expense of a loss in the ability to recover and continue a run that terminates prematurely. This option is not recommended when function evaluations are costly or prone to failure. Please note that using the **deactivate restart_file** specification will result in a zero length restart file with the default name dakota.rst, which can overwrite an exiting file.
2.4.2 Using Restart Files

To restart Dakota from a restart file, the `-read_restart` command line input (may be abbreviated as `-r`) is used:

```
dakota -i dakota.in -read_restart my_restart_file
```

If no `-read_restart` specification is used, then Dakota will not read restart information from any file (i.e., the default is no restart processing).

To read in only a portion of a restart file, the `-stop_restart` control (may be abbreviated as `-s`) is used to specify the number of entries to be read from the database. Note that this integer value corresponds to the restart record processing counter (as can be seen when using the `print` utility (see The Dakota Restart Utility) which may differ from the evaluation numbers used in the previous run if, for example, any duplicates were detected (since these duplicates are not recorded in the restart file). In the case of a `-stop_restart` specification, it is usually desirable to specify a new restart file using `-write_restart` so as to remove the records of erroneous or corrupted function evaluations. For example, to read in the first 50 evaluations from `dakota.rst`:

```
dakota -i dakota.in -r dakota.rst -s 50 -w dakota_new.rst
```

The `dakota_new.rst` file will contain the 50 processed evaluations from `dakota.rst` as well as any new evaluations. All evaluations following the 50th in `dakota.rst` have been removed from the latest restart record.

2.4.3 Appending to a Restart File

If the `-write_restart` and `-read_restart` specifications identify the same file (including the case where `-write_restart` is not specified and `-read_restart` identifies `dakota.rst`), then new evaluations will be appended to the existing restart file.

2.4.4 Working with multiple Restart Files

If the `-write_restart` and `-read_restart` specifications identify different files, then the evaluations read from the file identified by `-read_restart` are first written to the `-write_restart` file. Any new evaluations are then appended to the `-write_restart` file. In this way, restart operations can be chained together indefinitely with the assurance that all of the relevant evaluations are present in the latest restart file.

2.4.5 How it Works

Dakota's restart algorithm relies on its duplicate detection capabilities. Processing a restart file populates the list of function evaluations that have been performed. Then, when the study is restarted, it is started from the beginning (not a warm start) and many of the function evaluations requested by the iterator are intercepted by the duplicate detection code. This approach has the primary advantage of restoring the complete state of the iteration (including the ability to correctly detect subsequent duplicates) for all methods/iterators without the need for iterator-specific restart code. However, the possibility exists for numerical round-off error to cause a divergence between the evaluations performed in the previous and restarted studies. This has been rare in practice.

2.5 The Dakota Restart Utility

The Dakota restart utility program provides a variety of facilities for managing restart files from Dakota executions. The executable program name is `dakota_restart_util` and it has the following options, as shown by the usage message returned when executing the utility without any options:

Usage:
```
dakota_restart_util command <arg1> [<arg2> <arg3> ...] --options
dakota_restart_util print <restart_file>
dakota_restart_util to_neutral <restart_file> <neutral_file>
dakota_restart_util from_neutral <neutral_file> <restart_file>
dakota_restart_util to_tabular <restart_file> <text_file>
```
Several of these functions involve format conversions. In particular, the binary format used for restart files can be converted to ASCII text and printed to the screen, converted to and from a neutral file format, or converted to a tabular format for importing into 3rd-party plotting programs. In addition, a restart file with corrupted data can be repaired by value or id, and multiple restart files can be combined to create a master database.

### 2.5.1 Print Command

The `print` option is useful to show contents of a restart file, since the binary format is not convenient for direct inspection. The restart data is printed in full precision, so that exact matching of points is possible for restarted runs or corrupted data removals. For example, the following command

```
dakota_restart_util print dakota.rst
```

results in output similar to the following:

```
------------------------------------------
Restart record 1 (evaluation id 1):
------------------------------------------
Parameters:
  1.8000000000000000e+00 intake_dia
  1.0000000000000000e+00 flatness

Active response data:
Active set vector = [ 3 3 3 ]
  -2.4355973813420619e+00 obj_fn
  -4.7428486677140930e-01 nln_ineq_con_1
  -4.5000000000000000e+00 nln_ineq_con_2
  1.3971143170299741e-01 nln_ineq_con_3

  [ -4.364429863447897e-01 1.4999999999999999e-01 ] obj_fn gradient
  [ 1.385513637818300e-01 0.0000000000000000e+00 ] nln_ineq_con_1 gradient
  [ 0.0000000000000000e+00 1.4999999999999999e-01 ] nln_ineq_con_2 gradient
  [ 0.0000000000000000e+00 -1.9485571585149869e-01 ] nln_ineq_con_3 gradient

Restart file processing completed: 11 evaluations retrieved.
```
2.5.2 Neutral File Format

A Dakota restart file can be converted to a neutral file format using a command like the following:

```
dakota_restart_util to_neutral dakota.rst dakota.neu
```

which results in a report similar to the following:

```
Writing neutral file dakota.neu
Restart file processing completed: 11 evaluations retrieved.
```

Similarly, a neutral file can be returned to binary format using a command like the following:

```
dakota_restart_util from_neutral dakota.neu dakota.rst
```

which results in a report similar to the following:

```
Reading neutral file dakota.neu
Writing new restart file dakota.rst
Neutral file processing completed: 11 evaluations retrieved.
```

The contents of the generated neutral file are similar to the following (from the first two records for the Cylinder example in [5]).

```
6 7 2 1.8000000000000000e+00 intake_dia 1.0000000000000000e+00 flatness 0 0 0 0
NULL 4 2 1 0 3 3 3 1 2 obj_fn nln_ineq_con_1 nln_ineq_con_2 nln_ineq_con_3
-4.35557313426019e+00 -4.724848667714093e-01 -4.5000000000000000e-01
1.39714317029974e-01 -4.364298963447897e-01 1.4999999999999999e-01
1.3855136437818300e-01 0.0000000000000000e+00 0.0000000000000000e+00
1.4999999999999999e-01 0.0000000000000000e+00 -1.9485571585149869e-01 1
6 7 2 2.1640000000000001e+00 intake_dia 1.7169994018008317e+00 flatness 0 0 0 0
NULL 4 2 1 0 3 3 3 1 2 obj_fn nln_ineq_con_1 nln_ineq_con_2 nln_ineq_con_3
-4.869127192988887e+00 6.92569879989843e-01 -3.4245008972987528e-01
8.714220793715791e-03 -4.364298963447897e-01 1.4999999999999999e-01
2.9814239699999757e+01 0.0000000000000000e+00 0.0000000000000000e+00
1.4999999999999999e-01 0.0000000000000000e+00 -1.6998301742872701e-01 2
```

This format is not intended for direct viewing (print should be used for this purpose). Rather, the neutral file capability has been used in the past for managing portability of restart data across platforms (recent use of more portable binary formats has largely eliminated this need) or for advanced repair of restart records (in cases where the remove command was insufficient).

2.5.3 Tabular Format

Conversion of a binary restart file to a tabular format enables convenient import of this data into 3rd-party post-processing tools such as Matlab, TECplot, Excel, etc. This facility is nearly identical to the output activated by the `tabular_data` keyword in the Dakota input file specification, but with two important differences:

1. No function evaluations are suppressed as they are with `tabular_data` (i.e., any internal finite difference evaluations are included).
2. The conversion can be performed later, i.e., for Dakota runs executed previously.

An example command for converting a restart file to tabular format is:

```
dakota_restart_util to_tabular dakota.rst dakota.m
```

which results in a report similar to the following:

```
Writing tabular text file dakota.m
Restart file processing completed: 10 evaluations tabulated.
```
The contents of the generated tabular file are similar to the following (from the example in the Restart section of [5]). Note that while evaluations resulting from numerical derivative offsets would be reported (as described above), derivatives returned as part of the evaluations are not reported (since they do not readily fit within a compact tabular format):

%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 NO_ID 0.9 1.1 0.0002 0.26 0.76
2 NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 NO_ID 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
4 NO_ID 0.9 1.10011 0.0002004407265 0.259945 0.7602420121
5 NO_ID 0.9 1.09989 0.0001995607255 0.260055 0.7597580121
6 NO_ID 0.58256179 0.4772224441 0.1050555937 0.1007670171 -0.06353963386
7 NO_ID 0.5826200462 0.4772224441 0.1050386469 0.1008348962 -0.06356876195
8 NO_ID 0.5825035339 0.4772224441 0.1050725476 0.1006991449 -0.06355967195
9 NO_ID 0.58256179 0.4772701663 0.1050283245 0.100743156 -0.06349408333
10 NO_ID 0.58256179 0.4771747219 0.1050828704 0.1007908783 -0.0635817983
...

**Controlling tabular format:** The command-line options `--freeform` and `--custom_annotated` give control of headers in the resulting tabular file. Freeform will generate a tabular file with no leading row nor columns (variable and response values only). Custom annotated format accepts any or all of the options:

- **header:** include %-commented header row with labels
- **eval_id:** include leading column with evaluation ID
- **interface_id:** include leading column with interface ID

For example, to recover Dakota 6.0 tabular format, which contained a header row, leading column with evaluation ID, but no interface ID:

```
dakota_restart_util to_tabular dakota.rst dakota.m --custom_annotated header eval_id
```

Resulting in

```
%eval_id x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 0.9 1.1 0.0002 0.26 0.76
2 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...
```

Finally, `--output_precision integer` will generate tabular output with the specified integer digits of precision.

### 2.5.4 Concatenation of Multiple Restart Files

In some instances, it is useful to combine restart files into a single master function evaluation database. For example, when constructing a data fit surrogate model, data from previous studies can be pulled in and reused to create a combined data set for the surrogate fit. An example command for concatenating multiple restart files is:

```
dakota_restart_util cat dakota.rst.1 dakota.rst.2 dakota.rst.3 dakota.rst.all
```

which results in a report similar to the following:

```
Writing new restart file dakota.rst.all
dakota.rst.1 processing completed: 10 evaluations retrieved.
dakota.rst.2 processing completed: 110 evaluations retrieved.
dakota.rst.3 processing completed: 65 evaluations retrieved.
```

The `dakota.rst.all` database now contains 185 evaluations and can be read in for use in a subsequent Dakota study using the `-read_restart` option to the `dakota` executable.
2.5.5 Removal of Corrupted Data

On occasion, a simulation or computer system failure may cause a corruption of the Dakota restart file. For example, a simulation crash may result in failure of a post-processor to retrieve meaningful data. If 0’s (or other erroneous data) are returned from the user’s analysis_driver, then this bad data will get recorded in the restart file. If there is a clear demarcation of where corruption initiated (typical in a process with feedback, such as gradient-based optimization), then use of the -stop_restart option for the dakota executable can be effective in continuing the study from the point immediately prior to the introduction of bad data. If, however, there are interspersed corruptions throughout the restart database (typical in a process without feedback, such as sampling), then the remove and remove_ids options of dakota_restart_util can be useful.

An example of the command syntax for the remove option is:

```
dakota_restart_util remove 2.e-04 dakota.rst dakota.rst.repaired
```

which results in a report similar to the following:

```
Writing new restart file dakota.rst.repaired
Restart repair completed: 65 evaluations retrieved, 2 removed, 63 saved.
```

where any evaluations in dakota.rst having an active response function value that matches 2.e-04 within machine precision are discarded when creating dakota.rst.repaired.

An example of the command syntax for the remove_ids option is:

```
dakota_restart_util remove_ids 12 15 23 44 57 dakota.rst dakota.rst.repaired
```

which results in a report similar to the following:

```
Writing new restart file dakota.rst.repaired
Restart repair completed: 65 evaluations retrieved, 5 removed, 60 saved.
```

where evaluation ids 12, 15, 23, 44, and 57 have been discarded when creating dakota.rst.repaired.

An important detail is that, unlike the -stop_restart option which operates on restart record numbers, the remove_ids option operates on evaluation ids. Thus, removal is not necessarily based on the order of appearance in the restart file. This distinction is important when removing restart records for a run that contained either asynchronous or duplicate evaluations, since the restart insertion order and evaluation ids may not correspond in these cases (asynchronous evaluations have ids assigned in the order of job creation but are inserted in the restart file in the order of job completion, and duplicate evaluations are not recorded which introduces offsets between evaluation id and record number). This can also be important if removing records from a concatenated restart file, since the same evaluation id could appear more than once. In this case, all evaluation records with ids matching the remove_ids list will be removed.

If neither of these removal options is sufficient to handle a particular restart repair need, then the fallback position is to resort to direct editing of a neutral file to perform the necessary modifications.
Chapter 3

Dakota HDF5 Output

Beginning with release 6.9, Dakota gained the ability to write many method results such as the correlation matrices computed by sampling studies and the best parameters discovered by optimization methods to disk in HDF5. In Dakota 6.10 and above, evaluation data (variables and responses for each model or interface evaluation) may also be written. Many users may find this newly supported format more convenient than scraping or copying and pasting from Dakota’s console output.

To enable HDF5 output, the results_output keyword with the hdf5 option must be added to the Dakota input file. In addition, Dakota must have been built with HDF5 support. Beginning with Dakota 6.10, HDF5 is enabled in our publicly available downloads. HDF5 support is considered a somewhat experimental feature. The results of some Dakota methods are not yet written to HDF5, and in a few, limited situations, enabling HDF5 will cause Dakota to crash.

3.1 HDF5 Concepts

HDF5 is a format that is widely used in scientific software for efficiently storing and organizing data. The HDF5 standard and libraries are maintained by the HDF Group.

In HDF5, data are stored in multidimensional arrays called datasets. Datasets are organized hierarchically in groups, which also can contain other groups. Datasets and groups are conceptually similar to files and directories in a filesystem. In fact, every HDF5 file contains at least one group, the root group, denoted “/”, and groups and datasets are referred to using slash-delimited absolute or relative paths, which are more accurately called link names.

HDF5 has as one goal that data be “self-documenting” through the use of metadata. Dakota output files include two kinds of metadata.

- **Dimension Scales.** Each dimension of a dataset may have zero or more scales, which are themselves datasets. Scales are often used to provide, for example, labels analogous to column headings in a table (see the dimension scales that Dakota applies to moments) or numerical values of an independent variable (user-specified probability levels in level mappings).

- **Attributes.** key:value pairs that annotate a group or dataset. A key is always a character string, such as dakota_version, and (in Dakota output) the value can be a string-, integer-, or real-valued scalar. Dakota stores the number of samples that were requested in a sampling study in the attribute ‘samples’.

3.2 Accessing Results

Many popular programming languages have support, either natively or from a third-party library, for reading and writing HDF5 files. The HDF Group itself supports C/C++ and Java libraries. The Dakota Project suggests the h5py module for Python. Examples that demonstrate using h5py to access and use Dakota HDF5 output may be found in the Dakota installation at dakota/share/dakota/examples/official/hdf5.
3.3 Organization of Results

Currently, complete or nearly complete coverage of results from sampling, optimization and calibration methods, parameter studies, and stochastic expansions exists. Coverage will continue to expand in future releases to include not only the results of all methods, but other potentially useful information such as interface evaluations and model transformations.

Methods in Dakota have a character string Id and are executed by Dakota one or more times. (Methods are executed more than once in studies that include a nested model, for example.) The Id may be provided by the user in the input file using the id_method keyword, or it may be automatically generated by Dakota. Dakota uses the label NO_METHOD_ID for methods that are specified in the input file without an id_method, and NOSPEC_METHOD_ID_<N> for methods that it generates for its own internal use. The <N> in the latter case is an incrementing integer that begins at 1.

The results for the <N>th execution of a method that has the label <method Id> are stored in the group

/methods/<method Id>/results/execution:<N>/

The /methods group is always present in Dakota HDF5 files, provided at least one method added results to the output. (In a future Dakota release, the top level groups /interfaces and /models will be added.) The group execution:1 also is always present, even if there is only a single execution.

The groups and datasets for each type of result that Dakota is currently capable of storing are described in the following sections. Every dataset is documented in its own table. These tables include:

- A brief description of the dataset.
- The location of the dataset relative to /methods/<method Id>/execution:<N>. This path may include both literal text that is always present and replacement text. Replacement text is <enclosed in angle brackets and italicized>, Two examples of replacement text are <response descriptor> and <variable descriptor>, which indicate that the name of a Dakota response or variable makes up a portion of the path.
- Clarifying notes, where appropriate.
- The type (String, Integer, or Real) of the information in the dataset.
- The shape of the dataset; that is, the number of dimensions and the size of each dimension.
- A description of the dataset’s scales, which includes
  - The dimension of the dataset that the scale belongs to.
  - The type (String, Integer, or Real) of the information in the scale.
  - The label or name of the scale.
  - The contents of the scale. Contents that appear in plaintext are literal and will always be present in a scale. Italicized text describes content that varies.
  - notes that provide further clarification about the scale.

- A description of the dataset’s attributes, which are key:value pairs that provide helpful context for the dataset.

The Expected Output section of each method’s keyword documentation indicates the kinds of output, if any, that method currently can write to HDF5. These are typically in the form of bulleted lists with clarifying notes that refer back to the sections that follow.

3.3.1 Study Metadata

Several pieces of information about the Dakota study are stored as attributes of the top-level HDF5 root group (/). These include:
3.3 Organization of Results

3.3.2 A Note about Variables Storage

Variables in most Dakota output (e.g. tabular data files) and input (e.g. imported data to construct surrogates) are listed in "input spec" order. (The variables keyword section is arranged by input spec order.) In this ordering, they are sorted first by function:

1. Design
2. Aleatory
3. Epistemic
4. State

And within each of these categories, they are sorted by domain:

1. Continuous
2. Discrete integer (sets and ranges)
3. Discrete string
4. Discrete real

A shortcoming of HDF5 is that datasets are homogeneous; for example, string- and real-valued data cannot readily be stored in the same dataset. As a result, Dakota has chosen to flip "input spec" order for HDF5 and sort first by domain, then by function when storing variable information. When applicable, there may be as many as four datasets to store variable information: one to store continuous variables, another to store discrete integer variables, and so on. Within each of these, variables will be ordered by function.

3.3.3 Sampling Moments

sampling produces moments (e.g. mean, standard deviation or variance) of all responses, as well as 95% lower and upper confidence intervals for the 1st and 2nd moments. These are stored as described below. When sampling is used in incremental mode by specifying refinement_samples, all results, including the moments group, are placed within groups named increment:<N>, where <N> indicates the increment number beginning with 1.

3.3.4 Correlations

A few different methods produce information about the correlations between pairs of variables and responses (collectively: factors). The four tables in this section describe how correlation information is stored. One important note is that HDF5 has no special, native type for symmetric matrices, and so the simple correlations and simple rank correlations are stored in dense 2D datasets.

3.3.5 Probability Density

Some aleatory UQ methods estimate the probability density of responses.

3.3.6 Level Mappings

Aleatory UQ methods can calculate level mappings (from user-specified probability, reliability, or generalized reliability to response, or vice versa).
3.3.7 Variance-Based Decomposition (Sobol' Indices)

Dakota’s sampling method can produce main and total effects; stochastic expansions (polynomial_chaos, stoch_-collocation) additionally can produce interaction effects.

Each order (pair, 3-way, 4-way, etc) of interaction is stored in a separate dataset. The scales are unusual in that they are two-dimensional to contain the labels of the variables that participate in each interaction.

3.3.8 Integration and Expansion Moments

Stochastic expansion methods can obtain moments two ways.

3.3.9 Extreme Responses

sampling with epistemic variables produces extreme values (minimum and maximum) for each response.

3.3.10 Parameter Sets

All parameter studies (vector_parameter_study, list_parameter_study, multidim_parameter_study, centered_-parameter_study) record tables of evaluations (parameter-response pairs), similar to Dakota’s tabular output file. Centered parameter studies additionally store evaluations in an order that is more natural to interpret, which is described below.

In the tabular-like listing, variables are stored according to the scheme described in a previous section.

3.3.11 Variable Slices

Centered parameter studies store “slices” of the tabular data that make evaluating the effects of each variable on each response more convenient. The steps for each individual variable, including the initial or center point, and corresponding responses are stored in separate groups.

3.3.12 Best Parameters

Dakota’s optimization and calibration methods report the parameters at the best point (or points, for multiple final solutions) discovered. These are stored using the scheme described in the variables section. When more than one solution is reported, the best parameters are nested in groups named set:<N>, where <N> is a integer numbering the set and beginning with 1.

State (and other inactive variables) are reported when using objective functions and for some calibration studies. However, when using configuration variables in a calibration, state variables are suppressed.

3.3.13 Best Objective Functions

Dakota’s optimization methods report the objective functions at the best point (or points, for multiple final solutions) discovered. When more than one solution is reported, the best objective functions are nested in groups named set:<N>, where <N> is a integer numbering the set and beginning with 1.

3.3.14 Best Nonlinear Constraints

Dakota’s optimization and calibration methods report the nonlinear constraints at the best point (or points, for multiple final solutions) discovered. When more than one solution is reported, the best constraints are nested in groups named set:<N>, where N is a integer numbering the set and beginning with 1.
3.4 Organization of Evaluations

3.3.15 Calibration

When using calibration terms with an optimization method, or when using a nonlinear least squares method such as nl2sol, Dakota reports residuals and residual norms for the best point (or points, for multiple final solutions) discovered.

3.3.16 Parameter Confidence Intervals

Least squares methods (nl2sol, nlssol_sqp, optpp_g_newton) compute confidence intervals on the calibration parameters.

3.3.17 Best Model Responses (without configuration variables)

When performing calibration with experimental data (but no configuration variables), Dakota records, in addition to the best residuals, the best original model responses.

3.3.18 Best Model Responses (with configuration variables)

When performing calibration with experimental data that includes configuration variables, Dakota reports the best model responses for each experiment. These results include the configuration variables, stored in the scheme described in the variables section, and the model responses.

3.3.19 Multistart and Pareto Set

The multi_start and pareto_set methods are meta-iterators that control multiple optimization sub-iterators. For both methods, Dakota stores the results of the sub-iterators (best parameters and best results). For multi_start, Dakota additionally stores the initial points, and for pareto_set, it stores the objective function weights.

3.4 Organization of Evaluations

An evaluation is a mapping from variables to responses performed by a Dakota model or interface. Beginning with release 6.10, Dakota has the ability to report evaluation history in HDF5 format. The HDF5 format offers many advantages over existing console output and tabular output. Requiring no "scraping", it is more convenient for most users than the former, and being unrestricted to a two-dimensional, tabular arrangement of information, it is far richer than the latter.

This section begins by describing the Dakota components that can generate evaluation data. It then documents the high-level organization of the data from those components. Detailed documentation of the individual datasets (the "low-level" organization) where data are stored follows. Finally, information is provided concerning input keywords that control which components report evaluations.

3.4.1 Sources of Evaluation Data

Evaluation data are produced by only two kinds of components in Dakota: models and interfaces. The purpose of this subsection is to provide a basic description of models and interfaces for the purpose of equipping users to manage and understand HDF5-format evaluation data.

Because interfaces and models must be specified in even simple Dakota studies, most novice users of Dakota will have some familiarity with these concepts. However, the exact nature of the relationship between methods, models, and interfaces may be unclear. Moreover, the models and interfaces present in a Dakota study are not always limited to those specified by the user. Some input keywords or combinations of components cause Dakota to create new models or interfaces "behind the scenes" and without the user's direct knowledge. Not only can user-specified models and interfaces write evaluation data to HDF5, but also these auto-generated components. Accordingly, it
may be helpful for consumers of Dakota’s evaluation data to have a basic understanding of how Dakota creates and employs models and interfaces.

Consider first the input file shown here.

```
environment
tabular_data
results_output
  hdf5

method
  id_method 'sampling'
sampling
    samples 20
    model_pointer 'sim'

model
  id_model 'sim'
  single
  interface_pointer 'tb'

variables
  uniform_uncertain 2
    descriptors 'x1' 'x2'
    lower_bounds 0.0 0.0
    upper_bounds 1.0 1.0

responses
  response_functions 1
    descriptors 'f'
    no_gradients
    no_hessians

interface
  id_interface 'tb'
  fork
    analysis_drivers 'text_book'
```

This simple input file specifies a single method of type sampling, which also has the Id ‘sampling’. The ‘sampling’ method possesses a model of type single (alias simulation) named ‘sim’, which it uses to perform evaluations. (Dakota would have automatically generated a single model had one not been specified.) That is to say, for each variables-to-response mapping required by the method, it provides variables to the model and receives back responses from it.

Single/simulation models like ‘sim’ perform evaluations by means of an interface, typically an interface to an external simulation. In this case, the interface is ‘tb’. The model passes the variables to ‘tb’, which executes the text_book driver, and receives back responses.

It is clear that two components produce evaluation data in this study. The first is the single model ‘sim’, which receives and fulfills evaluation requests from the method ‘sampling’, and the second is the interface ‘tb’, which similarly receives requests from ‘sim’ and fulfills them by running the text_book driver.

Because tabular data was requested in the environment block, a record of the model's evaluations will be reported to a tabular file. The interface's evaluations could be dumped from the restart file using dakota_restart_util.

If we compared these evaluation histories from ‘sim’ and ‘tb’, we would see that they are identical to one another. The model ‘sim’ is a mere "middle man" whose only responsibility is passing variables from the method down to the interface, executing the interface, and passing responses back up to the method. However, this is not always the case.

For example, if this study were converted to a gradient-based optimization using optpp_q_newton, and the user specified numerical_gradients:

```
# model and interface same as above. Replace the method, variables, and responses with:

method
  id_method 'opt'
optpp_q_newton

variables
```

Dakota Version 6.16 Reference Manual generated on May 12, 2022
3.4 Organization of Evaluations

```
continuous_design 2
  descriptors 'x1' 'x2'
  lower_bounds 0.0 0.0
  upper_bounds 1.0 1.0
responses
  objective_functions 1
  descriptors 'f'
  numerical_gradients
  no_hessians
```

Then the model would have the responsibility of performing finite differencing to estimate gradients of the response 'f' requested by the method. Multiple function evaluations of 'tb' would map to a single gradient evaluation at the model level, and the evaluation histories of 'sim' and 'tb' would contain different information.

Note that because it is unwieldy to report gradients (or Hessians) in a tabular format, they are not written to the tabular file, and historically were available only in the console output. The HDF5 format provides convenient access to both the "raw" evaluations performed by the interface and higher level model evaluations that include estimated gradients.

This pair of examples hopefully provides a basic understanding of the flow of evaluation data between a method, model, and interface, and explains why models and interfaces are producers of evaluation data.

Next consider a somewhat more complex study that includes a Dakota model of type surrogate. A surrogate model performs evaluations requested by a method by executing a special kind of interface called an approximation interface, which Dakota implicitly creates without the direct knowledge of the user. Approximation interfaces are a generic container for the various kinds of surrogates Dakota can use, such as gaussian processes.

A Dakota model of type global surrogate may use a user-specified dace method to construct the actual underlying model(s) that it evaluates via its approximation interface. The dace method will have its own model (typically of type single/simulation), which will have a user-specified interface.

In this more complicated case there are at least four components that produce evaluation data: (1) the surrogate model and (2) its approximation interface, and (3) the dace method's model and (4) its interface. Although only components (1), (3), and (4) are user-specified, evaluation data produced by (2) may be written to HDF5, as well. (As explained below, only evaluations performed by the surrogate model and the dace interface will be recorded by default. This can be overridden using hdf5 sub-keywords.) This is an example where "extra" and potentially confusing data appears in Dakota's output due to an auto-generated component.

An important family of implicitly-created models is the recast models, which have the responsibility of transforming variables and responses. One type of recast called a data transform model is responsible for computing residuals when a user provides experimental data in a calibration study. Scaling recast models are employed when scaling is requested by the user for variables and/or responses.

Recast models work on the principle of function composition, and "wrap" a submodel, which may itself also be a recast model. The innermost model in the recursion often will be the simulation or surrogate model specified by the user in the input file. Dakota is capable of recording evaluation data at each level of recast.

### 3.4.2 High-level Organization of Evaluation Data

This subsection describes how evaluation data produced by models and interfaces are organized at high level. A detailed description of the datasets and subgroups that contain evaluation data for a specific model or interface is given in the next subsection.

Two top level groups contain evaluation data, `/interfaces` and `/models`.

#### 3.4.2.1 Interfaces

Because interfaces can be executed by more than one model, interface evaluations are more precisely thought of as evaluations of an interface/model combination. Consequently, interface evaluations are grouped not only by interface Id ('tb' in the example above), but also the Id of the model that requested them ('sim').
If the user does not provide an Id for an interface that he specifies, Dakota assigns it the Id NO_ID. Approximation interfaces receive the Id APPROX_INTERFACE_<N>, where N is an incrementing integer beginning at 1. Other kinds of automatically generated interfaces are named NOSPEC_INTERFACE_ID_<N>.

3.4.2.2 Models

The top-level group for model evaluations is /models. Within this group, model evaluations are grouped by type: simulation, surrogate, nested, or recast, and then by model Id. That is:

/models/<type>/<model Id>/

Similar to interfaces, user-specified models that lack an Id are given one by Dakota. A single model is named NO_MODEL_ID. Some automatically generated models receive the name NOSPEC_MODEL_ID.

Recast models are a special case and receive the name RECAST_<WRAPPED-MODEL>_TYPE_<N>. In this string:

- WRAPPED-MODEL is the Id of the innermost wrapped model, typically a user-specified model
- TYPE is the specific kind of recast. The three most common recasts are:
  - RECAST: several generic responsibilities, including summing objective functions to present to a single-objective optimizer
  - DATA_TRANSFORM: Compute residuals in a calibration
  - SCALING: scale variables and responses
- N is an incrementing integer that begins with 1. It is employed to distinguish recasts of the same type that wrap the same underlying model.

The model’s evaluations may be the result of combining information from multiple sources. A simulation/single model will receive all the information it requires from its interface, but more complicated model types may use information not only from interfaces, but also other models and the results of method executions. Nested models, for instance, receive information from a submethod (the mean of a response from a sampling study, for instance) and potentially also an optional interface.

The sources of a model’s evaluations may be roughly identified by examining the contents of that models’ sources group. The sources group contains softlinks (note: softlinks are an HDF5 feature analogous to soft or symbolic links on many file systems) to groups for the interfaces, models, or methods that the model used to produce its evaluation data. (At this time, Dakota does not report the specific interface or model evaluations or method executions that were used to produce a specific model evaluation, but this is a planned feature.)

Method results likewise have a sources group that identifies the models or methods employed by that method. By following the softlinks contained in a method’s or model’s sources group, it is possible to “drill down” from a method to its ultimate sources of information. In the sampling example above, interface evaluations performed via the ‘sim’ model at the request of the ‘sampling’ method could be obtained at the HDF5 path: /methods/sampling/sources/sim/sources/tb/

3.4.3 Low-Level Organization of Evaluation Data

Within each model and interface’s “high-level” group, evaluation data are stored according to a “low-level” schema. This section describes the “low-level” schema.

Data are divided first of all into variables, responses, and properties groups. In addition, if a a user specifies metadata responses in his Dakota input, a metadata dataset will be present.

3.4.3.1 Variables

The variables group contains datasets that store the variables information for each evaluation. Four datasets may be present, one for each “domain”: continuous, discrete_integer, discrete_string, and...
discrete_real. These datasets are two-dimensional, with a row (0th dimension) for each evaluation and a column (1st dimension) for each variable. The 0th dimension has one dimension scale for the integer-valued evaluation Id. The 1st dimension has two scales. The 0th scale contains descriptors of the variables, and the 1st contains their variable Ids. In this context, the Ids are a 1-to-N ranking of the variables in Dakota "input spec" order.

3.4.3.2 Responses

The responses group contains datasets for functions and, when available, gradients and Hessians.

**Functions:** The functions dataset is two-dimensional and contains function values for all responses. Like the variables datasets, evaluations are stored along the 0th dimension, and responses are stored along the 1st. The evaluation Ids and response descriptors are attached as scales to these axes, respectively.

**Gradients:** The gradients dataset is three-dimensional. It has the shape evaluations \(\times\) responses \(\times\) variables. Dakota supports a specification of mixed_gradients, and the gradients dataset is sized and organized such that only those responses for which gradients are available are stored. When mixed_gradients are employed, a response will not necessarily have the same index in the functions and gradients datasets.

Because it is possible that the gradient could be computed with respect to any of the continuous variables, active or inactive, that belong to the associated model, the gradients dataset is sized to accommodate gradients taken with respect to all continuous variables. Components that were not included in a particular evaluation will be set to NaN (not a number), and the derivative_variables_vector (in the metadata group) for that evaluation can be examined as well.

**Hessians:** Hessians are stored in a four-dimensional dataset, evaluations \(\times\) responses \(\times\) variables \(\times\) variables. The hessians dataset shares many of the characteristics with the gradients: in the mixed_hessians case, it will be smaller in the response dimension than the functions dataset, and unrequested components are set to NaN.

3.4.3.3 Properties

The properties group contains up to four members.

**Active Set Vector:** The first is the active_set_vector dataset. It is two dimensional, with rows corresponding to evaluations and columns corresponding to responses. Each element contains an integer in the range 0-7, which indicates the request (function, gradient, Hessian) for the corresponding response for that evaluation. The 0th dimension has the evaluations Ids scale, and the 1st dimension has two scales: the response descriptors and the "default" or "maximal" ASV, an integer 0-7 for each response that indicates the information (function, gradient, Hessian) that possibly could have been requested during the study.

**Derivative Variables Vector:** The second item in the properties group is the derivative_variables_vector dataset. It is included only when gradients or Hessians are available. Like the ASV, it is two-dimensional. Each column of the DVV dataset corresponds to a continuous variable and contains a 0 or 1, indicating whether gradients and Hessians were computed with respect to that variable for the evaluation. The 0th dimension has the evaluation Ids as a scale, and the 1st dimension has two scales. The 0th is the descriptors of the continuous variables. The 1st contains the variable Ids of the continuous variables.

**Analysis Components:** The third member of the properties group is the analysis_components dataset. It is a 1D dataset that is present only when the user specified analysis components, and it contains those components as strings.

The final possible member of the properties group is the variable_parameters group. It is included only for models, which possess variables, and is described in a separate section below.

3.4.3.4 Metadata

Beginning with release 6.16, Dakota supports response metadata. If configured, metadata values are stored in the metadata dataset.
3.4.4 Selecting Models and Interfaces to Store

When HDF5 output is enabled (by including the hdf5 keyword), then by default evaluation data for the following components will be stored:

- The model that belongs to the top-level method. (Currently, if the top-level method is a metaiterator such as method-hybrid, no model evaluation data will be stored.)
- All simulation interfaces. (Interfaces of type fork, system, direct, etc).

The user can override these defaults using the keywords model_selection and interface_selection.

The choices for model_selection are:

- top_method: (default) Store evaluation data for the top method's model only.
- all_methods: Store evaluation data for all models that belong directly to a method. Note that these models may be recasts of user-specified models, not the user-specified models themselves.
- all: Store evaluation data for all models.
- none: Store evaluation data for no models.

The choices for interface_selection are:

- simulation: (default) Store evaluation data for simulation interfaces.
- all: Store evaluation data for all interfaces.
- none: Store evaluation data for no interfaces.

If a model or interface is excluded from storage by these selections, then they cannot appear in the sources group for methods or models.

3.5 Distribution Parameters

Variables are characterized by parameters such as the mean and standard deviation or lower and upper bounds. Typically, users provide these parameters as part of their input to Dakota, but Dakota itself may also compute them as it scales and transforms variables, normalizes empirical distributions (e.g. for histogram_bin_uncertain variables), or calculates alternative parameterizations (lambda and zeta vs mean and standard deviation for a lognormal_uncertain).

Beginning with release 6.11, models write their variable’s parameters to HDF5. The information is located in each model's properties/variable_parameters subgroup. Within this group, parameters are stored by Dakota variable type (e.g. normal_uncertain), with one 1D dataset per type. The datasets have the same names as their variable types and have one element per variable. Parameters are stored by name.

Consider the following variable specification, which includes two normal and two uniform variables:

```
variables
  normal_uncertain 2
  descriptors 'nuv_1' 'nuv_2'
  means 0.0 1.0
  std_devations 1.0 0.5
  uniform_uncertain 2
  descriptors 'uuv_1' 'uuv_2'
  lower_bounds -1.0 0.0
  upper_bounds 1.0 1.0
```

Given this specification, and assuming a model ID of “tb_model”, Dakota will write two 1D datasets, both of length 2, to the group /models/simulation/tb_model/metadata/variable_parameters, the first named normal_uncertain, and the second named uniform_uncertain. Using a JSON-like representation for illustration, the normal_uncertain dataset will appear as:
The `normal_uncertain` dataset will contain:

```json
[
  {
    "mean": 0.0,
    "std_deviation": 1.0,
    "lower_bound": -inf,
    "upper_bound": inf
  },
  {
    "mean": 1.0,
    "std_deviation": 0.5,
    "lower_bound": -inf,
    "upper_bound": inf
  }
]
```

The `uniform_uncertain` dataset will contain:

```json
[
  {
    "lower_bound": -1.0,
    "upper_bound": 1.0
  },
  {
    "lower_bound": 0.0,
    "upper_bound": 1.0
  }
]
```

In these representations of the `normal_uncertain` and `uniform_uncertain` datasets, the outer square brackets `[]` enclose the dataset, and each element within the datasets are enclosed in curly braces `{}`. The curly braces are meant to indicate that the elements are dictionary-like objects that support access by string field name.

A bit more concretely, the following code snippet demonstrates reading the mean of the second normal variable, `nuv_2`.

```python
import h5py

with h5py.File("dakota_results.h5") as h:
    model = h["/models/simulation/tb_model/"]
    nu_vars = model["variable_parameters/normal_uncertain"]
    nuv_2_mu = nu_vars[1]["mean"]
    nuv_2_mu now contains 1.0.
```

The feature in HDF5 that underlies this name-based storage of fields is compound datatypes, which are similar to C/C++ structs or Python dictionaries. Further information about how to work with compound datatypes is available in the h5py documentation.

### 3.5.1 Naming Conventions and Layout

In most cases, datasets for storing parameters have names that match their variable types. The `normal_uncertain` and `uniform_uncertain` datasets illustrated above are examples. Exceptions include types such as `discrete_design_set`, which has string, integer, and real subtypes. For these, the dataset name is the top-level type with `_string`, `_int`, or `_real` appended: `discrete_design_set_string`, `discrete_design_set_int`, and `discrete_design_set_real`.

Most Dakota variable types have scalar parameters. For these, the names of the parameters are generally the singular form of the associated Dakota keyword. For example, `triangular_uncertain` variables are characterized in Dakota input using the plural keywords `modes`, `lower_bounds`, and `upper_bounds`. The singular field names are, respectively, "mode", "lower_bound", and "upper_bound". In this case, all three parameters are real-valued and stored as floating point numbers, but variable types/fields can also be integer-valued (e.g. `binomial_uncertain/num_trials`) or string-valued.

Some variable/parameter fields contain 1D arrays or vectors of information. Consider `histogram_bin_uncertain` variables, for which the user specifies not just one value, but an ordered collection of abscissas and corresponding values.
ordinates or counts. Dakota stores the abscissas in the "abscissas" field, which is a 1D dataset of floating-point numbers. It similarly stores the counts in the "counts" field. (In this case, only the normalized counts are stored, regardless of whether the user provided counts or ordinates.)

When the user specifies more than one histogram_bin_uncertain variable, it often is also necessary to include the pairs_per_variable keyword to divide the abscissa/count pairs among the variables. This raises the question of how lists of parameters that vary in length across the variables ought to be stored.

Although HDF5 supports variable-length datasets, for simplicity (and due to limitations in h5py at the time of the 6.11 release), Dakota stores vector parameter fields in conventional fixed-length datasets. The lengths of these datasets are determined at runtime in the following way: For a particular variable type and field, the field for all variables is sized to be large enough to accommodate the variable with the longest list of parameters. Any unused space for a particular variable is filled with NaN (if the parameter is real-valued), INTMAX (integer-valued), or an empty string (string-valued). In addition, each variable has an additional field, "num_elements", that reports the number of elements in the fields that contain actual data and not fill values.

Consider this example, in which the user has specified a pair of histogram_bin_uncertain variables. The first has 3 pairs, and the second has 4.

```
variables
    histogram_bin_uncertain 2
    pairs_per_variable 2 3
    abscissas 0.0 0.5 1.0
    -1.0 -0.5 0.5 1.0
    counts 0.25 0.75 0.0
    0.2 0.4 0.2 0.0
```

For this specification, Dakota will write a dataset named histogram_bin_uncertain to the metadata/variable_parameters/ subgroup for the model. It will be of length 2, one element for each variable, and contain the following:

```
[{
    "num_elements": 3,
    "abscissas": [0.0, 0.5, 1.0, NaN],
    "counts": [0.25, 0.75, 0.0, NaN]
},
{
    "num_elements": 4,
    "abscissas": [-1.0, -0.5, 0.5, 1.0],
    "counts": [0.2, 0.4, 0.2, 0.0]
}]
```

### 3.5.2 h5py Examples

The fields available for a variable parameters dataset can be determined in h5py by examining the datatype of the dataset.

```
1 import h5py
2 with h5py.File("dakota_results.h5") as h:
3    model = h["/models/simulation/NO_MODEL_ID/*"]
4    md = model["metadata/variable_parameters"]
5    nu = md["normal_uncertain"]
6    nu_param_names = nu.dtype.names
7    # nu_param_names is a tuple of strings: ('mean', 'std_deviation',
8    # 'lower_bound', 'upper_bound')
```

### 3.5.3 Known Limitations

h5py has a known bug that prevents parameters for some types of variables from being accessed (the Python interpreter crashes with a segfault). These include:

- histogram_point_uncertain string
- discrete_uncertain_set string
3.5 Distribution Parameters

3.5.4 Metadata

The variable parameter datasets have two dimension scales. The first (index 0) contains the variable descriptors, and the second (index 1) contains variable Ids. Available Parameters

3.5.5 Parameter Listing for All Types

The table below lists all Dakota variables and parameters that can be stored.
Chapter 4

Test Problems

This page contains additional information about two test problems that are used in Dakota examples throughout the Dakota manuals Textbook and Rosenbrock.

Many of these examples are also used as code verification tests. The examples are run periodically and the results are checked against known solutions. This ensures that the algorithms are correctly implemented.

Additional test problems are described in the User’s Manual.

4.1 Textbook

The two-variable version of the “textbook” test problem provides a nonlinearly constrained optimization test case. It is formulated as:

\[
\begin{align*}
\text{minimize} & \quad f = (x_1 - 1)^4 + (x_2 - 1)^4 \\
\text{subject to} & \quad g_1 = x_1^2 - \frac{x_2}{2} \leq 0 \\
& \quad g_2 = x_2^2 - \frac{x_1}{2} \leq 0 \\
& \quad 0.5 \leq x_1 \leq 5.8 \\
& \quad -2.9 \leq x_2 \leq 2.9
\end{align*}
\]

Contours of this test problem are illustrated in the next two figures.

---

**Figure 4.1:** Contours of the textbook problem on the [-3,4] x [-3,4] domain. The feasible region lies at the intersection of the two constraints \( g_1 \) (solid) and \( g_2 \) (dashed).
Figure 4.2: Contours of the textbook problem zoomed into an area containing the constrained optimum point \((x_1, x_2) = (0.5, 0.5)\). The feasible region lies at the intersection of the two constraints \(g_1\) (solid) and \(g_2\) (dashed).

For the textbook test problem, the unconstrained minimum occurs at \((x_1, x_2) = (1, 1)\). However, the inclusion of the constraints moves the minimum to \((x_1, x_2) = (0.5, 0.5)\). Equation \(\text{textbookform}\) presents the 2-dimensional form of the textbook problem. An extended formulation is stated as

\[
\begin{align*}
\text{minimize} & \quad \sum_{i=1}^{n} (x_i - 1)^4 \\
\text{subject to} & \quad g_1 = x_1^2 - x_2^2 \leq 0 \\
& \quad g_2 = x_2^2 - x_1^2 \leq 0 \\
& \quad 0.5 \leq x_1 \leq 5.8 \\
& \quad -2.9 \leq x_2 \leq 2.9
\end{align*}
\tag{tbe}
\]

where \(n\) is the number of design variables. The objective function is designed to accommodate an arbitrary number of design variables in order to allow flexible testing of a variety of data sets. Contour plots for the \(n = 2\) case have been shown previously.

For the optimization problem given in Equation \(\text{tbe}\), the unconstrained solution \((\text{num\_nonlinear\_inequality\_constraints set to zero})\) for two design variables is:

\[x_1 = 1.0\]
\[x_2 = 1.0\]

with

\[f^* = 0.0\]

The solution for the optimization problem constrained by \(g_1\) \((\text{num\_nonlinear\_inequality\_constraints set to one})\) is:

\[x_1 = 0.763\]
\[x_2 = 1.16\]

with

\[f^* = 0.00388\]
\[g_1^* = 0.0\ (\text{active})\]
The solution for the optimization problem constrained by \( g_1 \) and \( g_2 \) (num_nonlinear_inequality_-constraints set to two) is:

\[
\begin{align*}
  x_1 &= 0.500 \\
  x_2 &= 0.500
\end{align*}
\]

with

\[
\begin{align*}
  f^* &= 0.125 \\
  g_1^* &= 0.0 \text{ (active)} \\
  g_2^* &= 0.0 \text{ (active)}
\end{align*}
\]

Note that as constraints are added, the design freedom is restricted (the additional constraints are active at the solution) and an increase in the optimal objective function is observed.

## 4.2 Rosenbrock

The Rosenbrock function \([34]\) is a well-known test problem for optimization algorithms. The standard formulation includes two design variables, and computes a single objective function. This problem can also be posed as a least-squares optimization problem with two residuals to be minimized because the objective function is the sum of squared terms.

### Standard Formulation

The standard two-dimensional formulation can be stated as

\[
\text{minimize } f = 100(x_2 - x_1^2)^2 + (1 - x_1)^2 \quad \text{(rosenstd)}
\]

Surface and contour plots for this function are shown in the Dakota User’s Manual.

The optimal solution is:

\[
\begin{align*}
  x_1 &= 1.0 \\
  x_2 &= 1.0
\end{align*}
\]

with

\[
  f^* = 0.0
\]

### A Least-Squares Optimization Formulation

This test problem may also be used to exercise least-squares solution methods by recasting the standard problem formulation into:

\[
\text{minimize } f = (f_1)^2 + (f_2)^2 \quad \text{(rosenls)}
\]

where

\[
  f_1 = 10(x_2 - x_1^2) \quad \text{(rosenr1)}
\]

and

\[
  f_2 = 1 - x_1 \quad \text{(rosenr2)}
\]

are residual terms.

The included analysis driver can handle both formulations. In the dakota/share/dakota/test directory, the rosenbrock executable (compiled from Dakota_Source/test/rosenbrock.cpp) checks the number of response functions passed in the parameters file and returns either an objective function (as computed from Equation rosenstd) for use with optimization methods or two least squares terms (as computed from Equations rosenr1 -rosenr2 ) for use with least squares methods. Both cases support analytic gradients of the function set with respect to the design variables. See the User’s Manual for examples of both cases (search for Rosenbrock).
Chapter 5

Dakota Input Specification

Dakota input is specified in a text file, e.g., dakota_uq.in containing blocks of keywords that control program behavior. This section describes the format and admissible elements of an input file.

5.1 Dakota Keywords

Valid Dakota input keywords are dictated by dakota.xml, included in source and binary distributions of Dakota. This specification file is used with the NIDR [30] parser to validate user input and is therefore the definitive source for input syntax, capability options, and optional and required capability sub-parameters for any given Dakota version. A more readable variant of the specification dakota.input.summary is also distributed.

While complete, users may find dakota.input.summary overwhelming or confusing and will likely derive more benefit from adapting example input files to a particular problem. Some examples can be found here: Sample Input Files. Advanced users can master the many input specification possibilities by understanding the structure of the input specification file.

5.2 Input Spec Overview

Refer to the dakota.input.summary file, in Input Spec Summary, for all current valid input keywords.

• The summary describes every keyword including:
  – Whether it is required or optional
  – Whether it takes ARGUMENTS (always required) Additional notes about ARGUMENTS can be found here: Specifying Arguments.
  – Whether it has an ALIAS, or synonym
  – Which additional keywords can be specified to change its behavior
• Additional details and descriptions are described in Keywords Area
• For additional details on NIDR specification logic and rules, refer to [30] (Gay, 2008).

5.2.1 Common Specification Mistakes

Spelling mistakes and omission of required parameters are the most common errors. Some causes of errors are more obscure:

• Documentation of new capability sometimes lags its availability in source and executables, especially stable releases. When parsing errors occur that the documentation cannot explain, reference to the particular input
specification dakota.input.summary used in building the executable, which is installed alongside the executable, will often resolve the errors.

- If you want to compare results with those obtained using an earlier version of Dakota (prior to 4.1), your input file for the earlier version must use backslashes to indicate continuation lines for Dakota keywords. For example, rather than

```plaintext
# Comment about the following "responses" keyword...
responses,
  objective_functions = 1
# Comment within keyword "responses"
analytic_gradients
# Another comment within keyword "responses"
no_hessians
```

you would need to write

```plaintext
# Comment about the following "responses" keyword...
responses, \  
  objective_functions = 1 \  
# Comment within keyword "responses" \  
  analytic_gradients \  
# Another comment within keyword "responses" \  
  no_hessians
```

with no white space (blanks or tabs) after the \ character.

In most cases, the Dakota parser provides error messages that help the user isolate errors in input files. Running `dakota -input dakota_study.in -check` will validate the input file without running the study.

### 5.2.2 Specifying Arguments

Some keywords, such as those providing bounds on variables, have an associated list of values or strings, referred to as arguments.

When the same value should be repeated several times in a row, you can use the notation N*value instead of repeating the value N times.

For example

```plaintext
lower_bounds -2.0 -2.0 -2.0
upper_bounds 2.0 2.0 2.0
```

could also be written

```plaintext
lower_bounds 3*-2.0
upper_bounds 3* 2.0
```

(with optional spaces around the *).

Another possible abbreviation is for sequences: L:S:U (with optional spaces around the : ) is expanded to L L+S L+2+S ... U, and L:U (with no second colon) is treated as L:1:U.

For example, in one of the test examples distributed with Dakota (test case 2 of test/dakota_uq_textbook-sop_lhs.in),

```plaintext
histogram_point = 2
  abscissas = 50. 60. 70. 80. 90.
  30. 40. 50. 60. 70.
  counts = 10 20 30 20 10
          10 20 30 20 10
```

could also be written

```plaintext
histogram_point = 2
  abscissas = 50 : 10 : 90
  30 : 10 : 70
  counts = 10:10:30 20 10
          10:10:30 20 10
```
Count and sequence abbreviations can be used together. For example

```
response_levels =
    0.0 0.1 0.2 0.3 0.4 0.5 0.6 0.7 0.8 0.9 1.0
    0.0 0.1 0.2 0.3 0.4 0.5 0.6 0.7 0.8 0.9 1.0
```
can be abbreviated

```
response_levels =
    2*0.0:0.1:1.0
```

### 5.3 Sample Input Files

A Dakota input file is a collection of fields from the dakota.input.summary file that describe the problem to be solved by Dakota. Several brief examples follow below.

Dakota 6.14 and newer include a refreshed Examples Library, ranging from examples of Dakota input files and basic studies through complete case studies. These can be found in binary distributions in dakota/share/dakota/examples/official (dakota/dakota-examples in source distributions). Legacy examples, including many from the Dakota software manuals appear in other directories in dakota/share/dakota/examples (dakota/examples for source).

#### Sample 1: Optimization

The following sample input file shows single-method optimization of the Textbook Example (see Textbook) using DOT’s modified method of feasible directions. A similar file is available as dakota/share/dakota/examples/users/textbook_opt_conmin.in.

```bash
# Dakota Input File: textbook_opt_conmin.in
environment
tabular_data
tabular_data_file = 'textbook_opt_conmin.dat'
method
    # dot_mmfd #DOT performs better but may not be available
conmin_mfd
    max_iterations = 50
    convergence_tolerance = 1e-4

variables
    continuous_design = 2
    initial_point 0.9 1.1
    upper_bounds 5.8 2.9
    lower_bounds 0.5 -2.9
descriptors 'x1' 'x2'

interface
direct
    analysis_driver = 'text_book'

responses
    objective_functions = 1
    nonlinear_inequality_constraints = 2
    numerical_gradients
        method_source dakota
        interval_type central
        fd_gradient_step_size = 1.e-4
    no_hessians
```

#### Sample 2: Least Squares (Calibration)

The following sample input file shows a nonlinear least squares (calibration) solution of the Rosenbrock Example (see Rosenbrock) using the NL2SOL method. A similar file is available as dakota/share/dakota/examples/users/rosen_opt_nls.in.

```bash
# Dakota Input File: rosen_opt_nls.in
```
environment
tabular_data
tabular_data_file = 'rosen_opt_nls.dat'

method
max_iterations = 100
convergence_tolerance = 1e-4
nl2sol

model

sample_type lhs

variables,
  normal_uncertain = 2
  means = 248.89, 593.33
  std_deviations = 12.4, 29.7
  descriptors = 'TF1n' 'TF2n'
  uniform_uncertain = 2
  lower_bounds = 199.3, 474.63
  upper_bounds = 298.5, 712.
  descriptors = 'TF1u' 'TF2u'
  weibull_uncertain = 2
  alphas = 12., 30.
  betas = 250., 590.
  descriptors = 'TF1w' 'TF2w'
  histogram_bin_uncertain = 2
  num_pairs = 3 4
  abscissas = 5 8 10 .1 .2 .3 .4
  counts = 17 21 0 12 24 12 0
  descriptors = 'TF1h' 'TF2h'
  histogram_point_uncertain = 1
  num_pairs = 2
  abscissas = 3 4
  counts = 11
  descriptors = 'TF3h'

interface,
  fork async evalutation_concurrency = 5
  analysis_driver = 'text_book'

responses,
  response_functions = 3
Sample 4: Parameter Study

The following sample input file shows a 1-D vector parameter study using the Textbook Example (see Textbook). It makes use of the default environment and model specifications, so they can be omitted. A similar file is available in the test directory as dakota/share/dakota/examples/users/rosen_ps_vector.in.

```dakota
# Dakota Input File: rosen_ps_vector.in
environment
tabular_data
tabular_data_file = 'rosen_ps_vector.dat'
method
vector_parameter_study
final_point = 1.1 1.3

Additional example input files, as well as the corresponding output, are provided in the Tutorial chapter of the Users Manual [5].

5.4 Input Spec Summary

This file is derived automatically from dakota.xml, which is used in the generation of parser system files that are compiled into the Dakota executable. Therefore, these files are the definitive source for input syntax, capability options, and associated data inputs. Refer to the Developers Manual information on how to modify the input specification and propagate the changes through the parsing system.

Key features of the input specification and the associated user input files include:

- In the input specification, required individual specifications simply appear, optional individual and group specifications are enclosed in [], required group specifications are enclosed in (), and either-or relationships are denoted by the | symbol. These symbols only appear in dakota.input.summary; they must not appear in actual user input files.

- Keyword specifications (i.e., environment, method, model, variables, interface, and responses) begin with the keyword possibly preceded by white space (blanks, tabs, and newlines) both in the input specifications and in user input files. For readability, keyword specifications may be spread across several lines. Earlier versions of Dakota (prior to 4.1) required a backslash character (\) at the ends of intermediate lines of a keyword. While such backslashes are still accepted, they are no longer required.
• Some of the keyword components within the input specification indicate that the user must supply INTEGER, REAL, STRING, INTEGERLIST, REALLIST, or STRINGLIST data as part of the specification. In a user input file, the "=" is optional, data in a LIST can be separated by commas or whitespace, and the STRING data are enclosed in single or double quotes (e.g., 'text_book' or "text_book").

• In user input files, input is largely order-independent (except for entries in lists of data), case insensitive, and white-space insensitive. Although the order of input shown in the Sample Input Files generally follows the order of options in the input specification, this is not required.

• In user input files, specifications may be abbreviated so long as the abbreviation is unique. For example, the npsol_sqp specification within the method keyword could be abbreviated as npsol, but dot_sqp should not be abbreviated as dot since this would be ambiguous with other DOT method specifications.

• In both the input specification and user input files, comments are preceded by #.

• ALIAS refers to synonymous keywords, which often exist for backwards compatibility. Users are encouraged to use the most current keyword.

Chapter 6

Topics Area

This page introduces the user to the topics used to organize keywords.

- admin
- dakota_IO
- dakota_concepts
- models
- variables
- responses
- interface
- methods
- advanced_topics
- packages

6.1 admin

Description

This is only for management while ref man is under construction

Related Topics

- empty
- problem
- not_yet_reviewed

Related Keywords

6.1.1 empty

Description

This topic tracks the keywords which do not have content in the reference manual
Related Topics

Related Keywords

6.1.2 problem

Description

empty

Related Topics

Related Keywords

6.1.3 not_yet_reviewed

Description

Not yet reviewed.

Related Topics

Related Keywords

6.2 dakota_IO

Description

Keywords and Concepts relating inputs to Dakota and outputs from Dakota

Related Topics

• dakota_inputs
• dakota_output
• file Formats

Related Keywords

• error_file : Base filename for error redirection
• output_file : Base filename for output redirection
• input : Base filename for post-run mode data input
• output : Base filename for post-run mode data output
• input : Base filename for pre-run mode data input
• output : Base filename for pre-run mode data output
• read_restart : Base filename for restart file read
• stop_restart : Restart record number at which to stop reading the restart file.
6.2 dakota_IO

- **input**: Base filename for run mode data input
- **output**: Base filename for run mode data output
- **write_restart**: Base filename for restart file write

### 6.2.1 dakota_inputs

**Description**

eempty

**Related Topics**

- **block**
- **data_import_capabilities**

**Related Keywords**

### 6.2.1.1 block

**Description**

A block is the highest level of keyword organization in Dakota. There are currently 6 blocks in the Dakota input spec:

**Related Topics**

- **block_identifier**
- **block_pointer**

**Related Keywords**

- **environment**: Top-level settings for Dakota execution
- **interface**: Specifies how function evaluations will be performed in order to map the variables into the responses.
- **method**: Begins Dakota method selection and behavioral settings.
- **model**: Specifies how variables are mapped into a set of responses
- **responses**: Description of the model output data returned to Dakota upon evaluation of an interface.
- **variables**: Specifies the parameter set to be iterated by a particular method.

### 6.2.1.2 block_identifier

**Description**

eempty
Related Topics

Related Keywords

- **id_interface**: Name the interface block; helpful when there are multiple
- **id_method**: Name the method block; helpful when there are multiple
- **id_model**: Give the model block an identifying name, in case of multiple model blocks
- **id_responses**: Name the responses block; helpful when there are multiple
- **id_variables**: Name the variables block; helpful when there are multiple

6.2.1.3 block_pointer

Description

See **block_pointer** for details about pointers.

Related Topics

Related Keywords

- **top_method_pointer**: Identify which method leads the Dakota study
- **model_pointer**: Identifier for model block to be used by a method
- **model_pointer**: Identifier for model block to be used by a method
- **model_pointer**: Identifier for model block to be used by a method
- **model_pointer**: Identifier for model block to be used by a method
- **method_pointer**: Pointer to sub-method to apply to a surrogate or branch-and-bound sub-problem
- **model_pointer**: Identifier for model block to be used by a method
- **model_pointer**: Identifier for model block to be used by a method
- **model_pointer**: Identifier for model block to be used by a method
- **model_pointer**: Identifier for model block to be used by a method
- **model_pointer**: Identifier for model block to be used by a method
- **model_pointer**: Identifier for model block to be used by a method
- **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer_list**: Associate models with method names
• **method_pointer_list**: Pointers to methods to execute sequentially or collaboratively
• **global_model_pointer**: Pointer to model used by global method
• **global_method_pointer**: Pointer to global method
• **local_model_pointer**: Pointer to model used by local method
• **local_method_pointer**: Pointer to local method
• **model_pointer_list**: Associate models with method names
• **method_pointer_list**: Pointers to methods to execute sequentially or collaboratively
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **method_pointer**: Pointer to sub-method to run from each starting point
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method

• **model_pointer**: Identifier for model block to be used by a method

• **model_pointer**: Identifier for model block to be used by a method

• **model_pointer**: Identifier for model block to be used by a method

• **model_pointer**: Identifier for model block to be used by a method

• **model_pointer**: Identifier for model block to be used by a method

• **model_pointer**: Identifier for model block to be used by a method

• **method_pointer**: Pointer to optimization or least-squares sub-method

• **model_pointer**: Identifier for model block to be used by a method

• **model_pointer**: Identifier for model block to be used by a method

• **model_pointer**: Identifier for model block to be used by a method

• **model_pointer**: Identifier for model block to be used by a method

• **model_pointer**: Identifier for model block to be used by a method

• **model_pointer**: Identifier for model block to be used by a method

• **model_pointer**: Identifier for model block to be used by a method

• **model_pointer**: Identifier for model block to be used by a method

• **method_pointer**: Pointer to sub-method to apply to a surrogate or branch-and-bound sub-problem

• **model_pointer**: Identifier for model block to be used by a method

• **method_pointer**: Pointer to sub-method to apply to a surrogate or branch-and-bound sub-problem

• **model_pointer**: Identifier for model block to be used by a method

• **model_pointer**: Identifier for model block to be used by a method

• **model_pointer**: Identifier for model block to be used by a method

• **model_pointer**: Identifier for model block to be used by a method

• **truth_model_pointer**: Pointer to specify a full-space model, from which to construct a lower dimensional surrogate

• **truth_model_pointer**: Pointer to specify a “truth” model, from which to construct a surrogate
• **optional_interface_pointer**: Pointer to interface that provides non-nested responses

• **optional_interface_responses_pointer**: Pointer to responses block that defines non-nested responses

• **sub_method_pointer**: The `sub_method_pointer` specifies the method block for the sub-iterator

• **responses_pointer**: Specify which responses block will be used by this model block

• **interface_pointer**: Interface block pointer for the single model type

• **dace_method_pointer**: Specify a method to gather training data

• **truth_model_pointer**: Pointer to specify a “truth” model, from which to construct a surrogate

• **truth_model_pointer**: Pointer to specify a “truth” model, from which to construct a surrogate

• **truth_model_pointer**: Pointer to specify a “truth” model, from which to construct a surrogate

• **variables_pointer**: Specify which variables block will be included with this model block

### 6.2.1.4 data_import_capabilities

**Description**

empty

**Related Topics**

**Related Keywords**

### 6.2.2 dakota_output

**Description**

empty

**Related Topics**

**Related Keywords**

• **graphics**: (DEPRECATED) Display plots of variables and responses

• **output_precision**: Control the output precision

• **results_output**: (Experimental) Write a summary file containing the final results

• **hdf5**: Write results to file in HDF5 format

• **interface_selection**: Select the models that write evaluation data to HDF5

• **all**: Write evaluation data for all interfaces to HDF5

• **none**: Write evaluation data for no interfaces to HDF5

• **simulation**: Write evaluation data only for simulation interfaces to HDF5

• **model_selection**: Select the models that write evaluation data to HDF5

• **all**: Write evaluation data to HDF5 for all models

• **all_methods**: Write evaluation data to HDF5 for all models that belong directly to methods
• **none**: Write evaluation data for no models to HDF5
• **top_method**: Write evaluation data only for the top-level method's model to HDF5
• **results_output_file**: The base file name of the results file
• **text**: Write results to file in text format
• **tabular_data**: Write a tabular results file with variable and response history
• **tabular_data_file**: File name for tabular data output
• **output**: Control how much method information is written to the screen and output file

### 6.2.3 file_formats

**Description**

See sections “Inputs to Dakota” and “Outputs from Dakota” in the Dakota User's Manual [5].

**Related Topics**

**Related Keywords**

• **annotated**: Selects annotated tabular file format
• **custom_annotated**: Selects custom-annotated tabular file format
• **freeform**: Selects freeform file format
• **annotated**: Selects annotated tabular file format

- `pointers`

Related Keywords

6.3.1 `method_independent_controls`

Description

The `<method independent controls>` are those controls which are valid for a variety of methods. In some cases, these controls are abstractions which may have slightly different implementations from one method to the next. While each of these controls is not valid for every method, the controls are valid for enough methods that it was reasonable to consolidate the specifications.

Related Topics

Related Keywords

- `max_iterations`: Number of iterations allowed for optimizers and adaptive UQ methods
- `convergence_tolerance`: Stopping criterion based on relative error reduction
- `max_function_evaluations`: Stopping criterion based on maximum function evaluations
- `max_iterations`: Number of iterations allowed for optimizers and adaptive UQ methods
- `constraint_tolerance`: Maximum allowable constraint violation still considered feasible
- `max_function_evaluations`: Number of function evaluations allowed for optimizers
- `scaling`: Turn on scaling for variables, responses, and constraints
- `convergence_tolerance`: Stopping criterion based on objective function or statistics convergence
- `max_iterations`: Number of iterations allowed for optimizers and adaptive UQ methods
- `scaling`: Turn on scaling for variables, responses, and constraints
- `convergence_tolerance`: Stopping criterion based on objective function or statistics convergence
- `max_function_evaluations`: Number of function evaluations allowed for optimizers
- `max_iterations`: Number of iterations allowed for optimizers and adaptive UQ methods
- `scaling`: Turn on scaling for variables, responses, and constraints
- `convergence_tolerance`: Stopping criterion based on objective function or statistics convergence
- `max_function_evaluations`: Number of function evaluations allowed for optimizers
- `max_iterations`: Number of iterations allowed for optimizers and adaptive UQ methods
- **scaling**: Turn on scaling for variables, responses, and constraints
- **convergence_tolerance**: Stopping criterion based on objective function or statistics convergence
- **max_function_evaluations**: Number of function evaluations allowed for optimizers
- **max_iterations**: Number of iterations allowed for optimizers and adaptive UQ methods
- **scaling**: Turn on scaling for variables, responses, and constraints
- **convergence_tolerance**: Stopping criterion based on objective function or statistics convergence
- **max_function_evaluations**: Number of function evaluations allowed for optimizers
- **max_iterations**: Number of iterations allowed for optimizers and adaptive UQ methods
- **scaling**: Turn on scaling for variables, responses, and constraints
- **constraint_tolerance**: Maximum allowable constraint violation still considered feasible
- **convergence_tolerance**: Stopping criterion based on objective function or statistics convergence
- **max_function_evaluations**: Number of function evaluations allowed for optimizers
- **max_iterations**: Number of iterations allowed for optimizers and adaptive UQ methods
- **scaling**: Turn on scaling for variables, responses, and constraints
- **speculative**: Compute speculative gradients
- **constraint_tolerance**: Maximum allowable constraint violation still considered feasible
- **convergence_tolerance**: Stopping criterion based on objective function or statistics convergence
- **max_function_evaluations**: Number of function evaluations allowed for optimizers
- **max_iterations**: Number of iterations allowed for optimizers and adaptive UQ methods
- **scaling**: Turn on scaling for variables, responses, and constraints
- **speculative**: Compute speculative gradients
- **convergence_tolerance**: Stopping criterion based on objective function or statistics convergence
- **max_function_evaluations**: Number of function evaluations allowed for optimizers
- **max_iterations**: Number of iterations allowed for optimizers and adaptive UQ methods
- **max_function_evaluations**: Number of function evaluations allowed for optimizers
- **scaling**: Turn on scaling for variables, responses, and constraints
- **constraint_tolerance**: Maximum allowable constraint violation still considered feasible
- **convergence_tolerance**: Stopping criterion based on objective function or statistics convergence
• **max_function_evaluations**: Number of function evaluations allowed for optimizers

• **max_iterations**: Number of iterations allowed for optimizers and adaptive UQ methods

• **scaling**: Turn on scaling for variables, responses, and constraints

• **speculative**: Compute speculative gradients

• **constraint_tolerance**: Maximum allowable constraint violation still considered feasible

- **convergence_tolerance**: Stopping criterion based on objective function or statistics convergence
- **max_iterations**: Number of iterations allowed for optimizers and adaptive UQ methods
- **max_function_evaluations**: Stopping criterion based on maximum function evaluations
- **convergence_tolerance**: Stopping criterion based on objective function or statistics convergence
- **max_function_evaluations**: Number of function evaluations allowed for optimizers
- `max_iterations`: Number of iterations allowed for optimizers and adaptive UQ methods
- `scaling`: Turn on scaling for variables, responses, and constraints
- `convergence_tolerance`: Stopping criterion based on objective function or statistics convergence
- `max_function_evaluations`: Number of function evaluations allowed for optimizers
- `max_iterations`: Number of iterations allowed for optimizers and adaptive UQ methods
- `scaling`: Turn on scaling for variables, responses, and constraints
- `speculative`: Compute speculative gradients
- `convergence_tolerance`: Stopping criterion based on objective function or statistics convergence
- `max_function_evaluations`: Number of function evaluations allowed for optimizers
- `max_iterations`: Number of iterations allowed for optimizers and adaptive UQ methods
- `scaling`: Turn on scaling for variables, responses, and constraints
- `speculative`: Compute speculative gradients
- `convergence_tolerance`: Stopping criterion based on objective function or statistics convergence
- `max_function_evaluations`: Number of function evaluations allowed for optimizers
- `max_iterations`: Number of iterations allowed for optimizers and adaptive UQ methods
- `scaling`: Turn on scaling for variables, responses, and constraints
- `speculative`: Compute speculative gradients
- `convergence_tolerance`: Stopping criterion based on objective function or statistics convergence
- `max_function_evaluations`: Number of function evaluations allowed for optimizers
- `max_iterations`: Number of iterations allowed for optimizers and adaptive UQ methods
- `scaling`: Turn on scaling for variables, responses, and constraints
- `speculative`: Compute speculative gradients
- `convergence_tolerance`: Stopping criterion based on objective function or statistics convergence
- `max_function_evaluations`: Number of function evaluations allowed for optimizers
- `max_iterations`: Number of iterations allowed for optimizers and adaptive UQ methods
- `scaling`: Turn on scaling for variables, responses, and constraints
- `speculative`: Compute speculative gradients
- `convergence_tolerance`: Stopping criterion based on objective function or statistics convergence
• max_function_evaluations : Number of function evaluations allowed for optimizers
• max_iterations : Number of iterations allowed for optimizers and adaptive UQ methods
• scaling : Turn on scaling for variables, responses, and constraints
• speculative : Compute speculative gradients
• convergence_tolerance : Stopping criterion based on objective function or statistics convergence
• max_function_evaluations : Number of function evaluations allowed for optimizers
• max_iterations : Number of iterations allowed for optimizers and adaptive UQ methods
• scaling : Turn on scaling for variables, responses, and constraints
• speculative : Compute speculative gradients
• convergence_tolerance : Stopping criterion based on objective function or statistics convergence
• max_function_evaluations : Number of function evaluations allowed for optimizers
• max_iterations : Number of iterations allowed for optimizers and adaptive UQ methods
• scaling : Turn on scaling for variables, responses, and constraints
• speculative : Compute speculative gradients
• output : Control how much method information is written to the screen and output file
• convergence_tolerance : Stopping criterion based on objective function or statistics convergence
• convergence_tolerance : Stopping criterion based on objective function or statistics convergence
• max_iterations : Number of iterations allowed for optimizers and adaptive UQ methods
• constraint_tolerance : Maximum allowable constraint violation still considered feasible
• max_iterations : Number of iterations allowed for optimizers and adaptive UQ methods
• scaling : Turn on scaling for variables, responses, and constraints
• max_function_evaluations : Number of function evaluations allowed for optimizers
• max_iterations : Number of iterations allowed for optimizers and adaptive UQ methods
• scaling : Turn on scaling for variables, responses, and constraints
• convergence_tolerance : Stopping criterion based on objective function or statistics convergence
• max_function_evaluations : Number of function evaluations allowed for optimizers
• max_iterations : Number of iterations allowed for optimizers and adaptive UQ methods
• scaling : Turn on scaling for variables, responses, and constraints
• convergence_tolerance : Stopping criterion based on objective function or statistics convergence
• max_function_evaluations : Number of function evaluations allowed for optimizers
• max_iterations : Number of iterations allowed for optimizers and adaptive UQ methods
• constraint_tolerance : Maximum allowable constraint violation still considered feasible
• convergence_tolerance : Stopping criterion based on objective function or statistics convergence
• max_iterations : Number of iterations allowed for optimizers and adaptive UQ methods
• max_function_evaluations : Number of function evaluations allowed for optimizers
• max_iterations : Number of iterations allowed for optimizers and adaptive UQ methods
• max_function_evaluations : Number of function evaluations allowed for optimizers
6.3.2 block

Description

A block is the highest level of keyword organization in Dakota. There are currently 6 blocks in the Dakota input spec:

Related Topics

- block_identifier
- block_pointer

Related Keywords

- environment: Top-level settings for Dakota execution
- interface: Specifies how function evaluations will be performed in order to map the variables into the responses.
- model: Specifies how variables are mapped into a set of responses
- responses: Description of the model output data returned to Dakota upon evaluation of an interface.
- variables: Specifies the parameter set to be iterated by a particular method.

6.3.2.1 block_identifier

Description

empty

Related Topics

Related Keywords

- id_interface: Name the interface block; helpful when there are multiple
- id_method: Name the method block; helpful when there are multiple
- id_model: Give the model block an identifying name, in case of multiple model blocks
- id_responses: Name the responses block; helpful when there are multiple
- id_variables: Name the variables block; helpful when there are multiple

6.3.2.2 block_pointer

Description

See block_pointer for details about pointers.
Related Topics

Related Keywords

- `top_method_pointer`: Identify which method leads the Dakota study
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `method_pointer`: Pointer to sub-method to apply to a surrogate or branch-and-bound sub-problem
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
- `model_pointer`: Identifier for model block to be used by a method
• model_pointer_list : Associate models with method names
• method_pointer_list : Pointers to methods to execute sequentially or collaboratively
• global_model_pointer : Pointer to model used by global method
• global_method_pointer : Pointer to global method
• local_model_pointer : Pointer to model used by local method
• local_method_pointer : Pointer to local method
• model_pointer_list : Associate models with method names
• method_pointer_list : Pointers to methods to execute sequentially or collaboratively
• model_pointer : Identifier for model block to be used by a method
• model_pointer : Identifier for model block to be used by a method

• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **method_pointer**: Pointer to optimization or least-squares sub-method
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **method_pointer**: Pointer to sub-method to apply to a surrogate or branch-and-bound sub-problem
• **model_pointer**: Identifier for model block to be used by a method
• **method_pointer**: Pointer to sub-method to apply to a surrogate or branch-and-bound sub-problem
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **model_pointer**: Identifier for model block to be used by a method
• **truth_model_pointer**: Pointer to specify a full-space model, from which to construct a lower dimensional surrogate
• **truth_model_pointer**: Pointer to specify a "truth" model, from which to construct a surrogate
• **optional_interface_pointer**: Pointer to interface that provides non-nested responses
• **optional_interface_responses_pointer**: Pointer to responses block that defines non-nested responses
• **sub_method_pointer**: The **sub_method_pointer** specifies the method block for the sub-iterator
• **responses_pointer**: Specify which responses block will be used by this model block
• **interface_pointer**: Interface block pointer for the single model type
• **dace_method_pointer**: Specify a method to gather training data
• **truth_model_pointer**: Pointer to specify a "truth" model, from which to construct a surrogate
• **truth_model_pointer**: Pointer to specify a "truth" model, from which to construct a surrogate
• **truth_model_pointer**: Pointer to specify a "truth" model, from which to construct a surrogate
• **variables_pointer**: Specify which variables block will be included with this model block
6.3.3 strategies

Description
empty

Related Topics
- advanced_strategies

Related Keywords

6.3.3.1 advanced_strategies

Description
empty

Related Topics

Related Keywords

6.3.4 command_line_options

Description
empty

Related Topics

Related Keywords

- check : Invoke Dakota in input check mode
- error_file : Base filename for error redirection
- output_file : Base filename for output redirection
- post_run : Invoke Dakota with post-run mode active
- pre_run : Invoke Dakota with pre-run mode active
- read_restart : Base filename for restart file read
- run : Invoke Dakota with run mode active
- write_restart : Base filename for restart file write

6.3.5 restarts

Description
empty
Related Topics

Related Keywords

6.3.6 pointers

Description

For all pointer specifications, if a pointer string is specified and no corresponding id string is available, Dakota will exit with an error message.

If the pointer is optional and no pointer string is specified, then the last specification parsed will be used.

It is appropriate to omit optional cross-referencing whenever the relationships are unambiguous due to the presence of only one specification.

6.5.2 continuous_variables

Description

This page collects information related to the topic of continuous design, uncertain, and state variables.
6.5.3 discrete_variables

Description

This page discusses discrete design, uncertain, and state variables (which have discrete in their keyword name) as they have similar specifications. These include:

1. Integer ranges
2. Sets of integers
3. Sets of reals
4. Sets of strings and each is described below.

In addition, some aleatory uncertain variables, e.g., binomial_uncertain, are discrete integer-valued random variables specified using parameters. These are described on their individual keyword pages.

Sets

Sets of integers, reals, and strings have similar specifications, though different value types.

The variables are specified using three keywords:

- Variable declaration keyword - specifies the number of variables being defined
- elements_per_variable - a list of positive integers specifying how many set members each variable admits
  - Length = # of variables
• elements - a list of the permissible integer values in ALL sets, concatenated together.
  – Length = sum of elements_per_variable, or an integer multiple of number of variables
  – The order is very important here.
  – The list is partitioned according to the values of elements_per_variable, and each partition is
    assigned to a variable.

• The ordering of elements_per_variable, and the partitions of elements must match the strings
  from descriptors

For string variables, each string element value must be quoted and may contain alphanumeric, dash, underscore,
and colon. White space, quote characters, and backslash/metacharacters are not permitted.

Examples are given on the pages:

• discrete design set integer
• discrete design set real
• discrete design set string
• discrete uncertain set integer
• discrete uncertain set real
• discrete uncertain set string

Range
For discrete variables defined by range(s), the lower_bounds and upper_bounds restrict the permissible
values. For design variables, this constrains the feasible design space and is frequently used to prevent nonphysical
designs. This is a discrete interval variable that may take any integer value within bounds (e.g., \([1, 4]\), allowing values
of 1, 2, 3, or 4). For some variable types, each variable is can be defined by multiple ranges.

Examples are given on the pages:

• discrete_interval_uncertain

### 6.5.4 linear_constraints

**Description**

Many methods can make use of linear equality or inequality constraints. As the name implies, linear constraints are constraints that are linear functions of the variables. Constraints that are nonlinear functions of variables are specified using the `nonlinear_constraints` family of keywords. From a Dakota usage point of view, the most important difference between linear and nonlinear constraints is that the former are specified entirely within the Dakota input file and calculated by Dakota itself, while the latter must be calculated by the user's simulation and returned as responses to Dakota.

The Optimization chapter of the User's Manual states which methods support linear constraints. Of those methods, a subset strictly obey linear constraints; that is, no candidate points are generated by the optimizer that violate the constraints. These include `asynch_pattern_search`, the `optpp_` family of optimizers (with the exception of `optpp_fd_newton`), and `npsol_sqp`. The other methods seek feasible solutions (i.e. solutions that satisfy the linear constraints), but may violate the constraints as they run. Linear constraints may also be violated, even when using an optimizer that itself strictly respects them, if `numerical_gradients` are used. In this case, Dakota may request evaluations that lie outside of the feasible region when computing a gradient near the boundary.

One final limitation that bears mentioning is that linear constraints are compatible only with continuous variables. No discrete types are permitted when using linear constraints.

6.5.5  variable_type

Description

Dakota variables can be grouped their type: design, uncertain (further sub-divided into aleatory and epistemic), and state. These distinctions are useful in situations where the user may want to explicitly control the subset of variables that is considered active for a certain Dakota method, overriding the default active variable type.

- **weibull_uncertain**: Aleatory uncertain variable - Weibull

6.5.8 **epistemic_uncertain_variables**

Description

Epistemic uncertainty is uncertainty due to lack of knowledge.

In Dakota, epistemic uncertainty can be characterized by interval- or set-valued variables (see relevant keywords below) that are propagated to calculate bounding intervals on simulation output using interval analysis methods. These epistemic variable types can optionally include basic probability assignments for use in Dempster-Shafer theory of evidence methods. Epistemic uncertainty can alternately be modeled with probability density functions, although results from UQ studies are then typically interpreted as possibilities or bounds, as opposed to a probability distribution of responses.

Through nested models, Dakota can perform combined aleatory / epistemic analyses such as second-order probability or probability of frequency. For example, a variable can be assumed to have a lognormal distribution with specified variance, with its mean expressed as an epistemic uncertainty lying in an expert-specified interval.
6.6 responses

Related Topics

- response_types
- nonlinear_constraints

6.5.9 state_variables

Description

State variables provide a convenient mechanism for managing additional model parameterizations such as mesh density, simulation convergence tolerances, and time step controls. These are typically fixed parameters for a given Dakota run.

By default, only parameter studies and design of experiments methods will vary state variables. This can be overridden for other methods by specifying active state or active all.

When a state variable is held fixed, the specified initial_state is used as its sole value. If the state variable is defined only by its bounds, then the initial_state will be inferred from the variable bounds or valid set values.

If a method iterates on a state variable, the variable is treated as a design variable with the given bounds, or as a uniform uncertain variable with the given bounds.

6.6.1 response_types

Description

The specification must be one of three types:

1. objective and constraint functions
2. calibration (least squares) terms and constraint functions
3. a generic response functions specification.

These correspond to (a) optimization, (b) deterministic (least squares) or stochastic (Bayesian) inversion, and (c) general-purpose analyzer methods such as parameter studies, DACE, and UQ methods, respectively. Refer to responses for additional details and examples.

- optimization_and_calibration

Related Keywords

6.8.1 parameter_studies

Description

Parameter studies employ deterministic designs to explore the effect of parametric changes within simulation models, yielding one form of sensitivity analysis. They can help assess simulation characteristics such as smoothness, multi-modality, robustness, and nonlinearity, which affect the choice of algorithms and controls in follow-on optimization and UQ studies.

Dakota's parameter study methods compute response data sets at a selection of points in the parameter space. These points may be specified as a vector, a list, a set of centered vectors, or a multi-dimensional grid. Capability overviews and examples of the different types of parameter studies are provided in the Users Manual [5].
With the exception of output verbosity (a setting of silent will suppress some parameter study diagnostic output), Dakota’s parameter study methods do not make use of the method independent controls. Therefore, the parameter study documentation which follows is limited to the method dependent controls for the vector, list, centered, and multidimensional parameter study methods.

6.8.4 sampling

Description

Sampling techniques are selected using the sampling method selection. This method generates sets of samples according to the probability distributions of the uncertain variables and maps them into corresponding sets of response functions, where the number of samples is specified by the samples integer specification. Means, standard deviations, coefficients of variation (COVs), and 95% confidence intervals are computed for the response functions. Probabilities and reliabilities may be computed for response_levels specifications, and response levels may be computed for either probability_levels or reliability_levels specifications (refer to the Method Commands chapter in the Dakota Reference Manual [4] for additional information).

Currently, traditional Monte Carlo (MC) and Latin hypercube sampling (LHS) are supported by Dakota and are chosen by specifying sample_type as random or lhs. In Monte Carlo sampling, the samples are selected randomly according to the user-specified probability distributions. Latin hypercube sampling is a stratified sampling technique for which the range of each uncertain variable is divided into \( N_s \) segments of equal probability, where \( N_s \) is the number of samples requested. The relative lengths of the segments are determined by the nature of the specified probability distribution (e.g., uniform has segments of equal width, normal has small segments near the mean and larger segments in the tails). For each of the uncertain variables, a sample is selected randomly from each of these equal probability segments. These \( N_s \) values for each of the individual parameters are then combined in a shuffling operation to create a set of \( N_s \) parameter vectors with a specified correlation structure. A feature of the resulting sample set is that every row and column in the hypercube of partitions has exactly one sample. Since the total number of samples is exactly equal to the number of partitions used for each uncertain variable, an arbitrary number of desired samples is easily accommodated (as compared to less flexible approaches in which the total number of samples is a product or exponential function of the number of intervals for each variable, i.e., many classical design of experiments methods).

Advantages of sampling-based methods include their relatively simple implementation and their independence from the scientific disciplines involved in the analysis. The main drawback of these techniques is the large number of function evaluations needed to generate converged statistics, which can render such an analysis computationally very expensive, if not intractable, for real-world engineering applications. LHS techniques, in general, require fewer samples than traditional Monte Carlo for the same accuracy in statistics, but they still can be prohibitively expensive. For further information on the method and its relationship to other sampling techniques, one is referred to the works by McKay, et al. [61], Iman and Shortencarier [54], and Helton and Davis [47]. Note that under certain separability conditions associated with the function to be sampled, Latin hypercube sampling provides a more accurate estimate of the mean value than does random sampling. That is, given an equal number of samples, the LHS estimate of the mean will have less variance than the mean value obtained through random sampling.

6.8.5 uncertainty_quantification

Description

Dakota provides a variety of methods for propagating both aleatory and epistemic uncertainty.

At a high level, uncertainty quantification (UQ) or nondeterministic analysis is the process of characterizing input uncertainties, forward propagating these uncertainties through a computational model, and performing statistical or interval assessments on the resulting responses. This process determines the effect of uncertainties and assumptions on model outputs or results. In Dakota, uncertainty quantification methods specifically focus on the forward propagation part of the process, where probabilistic or interval information on parametric inputs are mapped through
the computational model to assess statistics or intervals on outputs. For an overview of these approaches for engineering applications, consult [43].

UQ is related to sensitivity analysis in that the common goal is to gain an understanding of how variations in the parameters affect the response functions of the engineering design problem. However, for UQ, some or all of the components of the parameter vector, are considered to be uncertain as specified by particular probability distributions (e.g., normal, exponential, extreme value), or other uncertainty structures. By assigning specific distributional structure to the inputs, distributional structure for the outputs (i.e., response statistics) can be inferred. This migrates from an analysis that is more \{qualitative\} in nature, in the case of sensitivity analysis, to an analysis that is more rigorously \{quantitative\}.

UQ methods are often distinguished by their ability to propagate aleatory or epistemic input uncertainty characterizations, where aleatory uncertainties are irreducible variabilities inherent in nature and epistemic uncertainties are reducible uncertainties resulting from a lack of knowledge. Since sufficient data is generally available for aleatory uncertainties, probabilistic methods are commonly used for computing response distribution statistics based on input probability distribution specifications. Conversely, for epistemic uncertainties, any use of probability distributions is based on subjective knowledge rather than objective data, and we may alternatively explore nonprobabilistic methods based on interval specifications.

Dakota contains capabilities for performing nondeterministic analysis with both types of input uncertainty. These UQ methods have been developed by Sandia Labs, in conjunction with collaborators in academia [31], [32], [21], [82].

The aleatory UQ methods in Dakota include various sampling-based approaches (e.g., Monte Carlo and Latin Hypercube sampling), local and global reliability methods, and stochastic expansion (polynomial chaos expansions and stochastic collocation) approaches. The epistemic UQ methods include local and global interval analysis and Dempster-Shafer evidence theory. These are summarized below and then described in more depth in subsequent sections of this chapter. Dakota additionally supports mixed aleatory/epistemic UQ via interval-valued probability, second-order probability, and Dempster-Shafer theory of evidence. These involve advanced model recursions and are described in Section.

Dakota contains capabilities for performing nondeterministic analysis with both types of input uncertainty. These UQ methods have been developed by Sandia Labs, in conjunction with collaborators in academia [31], [32], [21], [82].

The epistemic UQ methods include local and global interval analysis and Dempster-Shafer evidence theory. These are summarized below and then described in more depth in subsequent sections of this chapter. Dakota additionally supports mixed aleatory/epistemic UQ via interval-valued probability, second-order probability, and Dempster-Shafer theory of evidence. These involve advanced model recursions and are described in Section.

The choice of uncertainty quantification method depends on how the input uncertainty is characterized, the computational budget, and the desired output accuracy. The recommendations for UQ methods are summarized in Table and are discussed in the remainder of the section.

6.8.7 sampling

**Description**

Sampling techniques are selected using the sampling method selection. This method generates sets of samples according to the probability distributions of the uncertain variables and maps them into corresponding sets of response functions, where the number of samples is specified by the samples integer specification. Means, standard deviations, coefficients of variation (COVs), and 95% confidence intervals are computed for the response functions. Probabilities and reliabilities may be computed for response_levels specifications, and response levels may be computed for either probability_levels or reliability_levels specifications (refer to the Method Commands chapter in the Dakota Reference Manual [4] for additional information).

Currently, traditional Monte Carlo (MC) and Latin hypercube sampling (LHS) are supported by Dakota and are chosen by specifying sample_type as random or lhs. In Monte Carlo sampling, the samples are selected randomly according to the user-specified probability distributions. Latin hypercube sampling is a stratified sampling technique for which the range of each uncertain variable is divided into \( N_i \) segments of equal probability, where \( N_i \) is the number of samples requested. The relative lengths of the segments are determined by the nature of the specified probability distribution (e.g., uniform has segments of equal width, normal has small segments near the mean and larger segments in the tails). For each of the uncertain variables, a sample is selected randomly from...
each of these equal probability segments. These \( N \) values for each of the individual parameters are then combined in a shuffling operation to create a set of \( N \) parameter vectors with a specified correlation structure. A feature of the resulting sample set is that every row and column in the hypercube of partitions has exactly one sample. Since the total number of samples is exactly equal to the number of partitions used for each uncertain variable, an arbitrary number of desired samples is easily accommodated (as compared to less flexible approaches in which the total number of samples is a product or exponential function of the number of intervals for each variable, i.e., many classical design of experiments methods).

Advantages of sampling-based methods include their relatively simple implementation and their independence from the scientific disciplines involved in the analysis. The main drawback of these techniques is the large number of function evaluations needed to generate converged statistics, which can render such an analysis computationally very expensive, if not intractable, for real-world engineering applications. LHS techniques, in general, require fewer samples than traditional Monte Carlo for the same accuracy in statistics, but they still can be prohibitively expensive. For further information on the method and its relationship to other sampling techniques, one is referred to the works by McKay, et al. [61], Iman and Shortencarier [54], and Helton and Davis [47]. Note that under certain separability conditions associated with the function to be sampled, Latin hypercube sampling provides a more accurate estimate of the mean value than does random sampling. That is, given an equal number of samples, the LHS estimate of the mean will have less variance than the mean value obtained through random sampling.

6.8.8 reliability_methods

Description

Reliability methods provide an alternative approach to uncertainty quantification which can be less computationally demanding than sampling techniques. Reliability methods for uncertainty quantification are based on probabilistic approaches that compute approximate response function distribution statistics based on specified uncertain variable distributions. These response statistics include response mean, response standard deviation, and cumulative or complementary cumulative distribution functions (CDF/CCDF). These methods are often more efficient at computing statistics in the tails of the response distributions (events with low probability) than sampling based approaches since the number of samples required to resolve a low probability can be prohibitive.

The methods all answer the fundamental question: “Given a set of uncertain input variables, \( \mathbf{X} \), and a scalar response function, \( g \), what is the probability that the response function is below or above a certain level, \( z \)?” The former can be written as \( P[g(\mathbf{X}) \leq z] = F_g(z) \) where \( F_g(z) \) is the cumulative distribution function (CDF) of the uncertain response \( g(\mathbf{X}) \) over a set of response levels. The latter can be written as \( P[g(\mathbf{X}) > z] \) and defines the complementary cumulative distribution function (CCDF).

This probability calculation involves a multi-dimensional integral over an irregularly shaped domain of interest, \( \mathbf{D} \), where \( g(\mathbf{X}) < z \) as displayed in Figure figUQ05 for the case of two variables. The reliability methods all involve the transformation of the user-specified uncertain variables, \( \mathbf{X} \), with probability density function, \( p(x_1, x_2) \), which can be non-normal and correlated, to a space of independent Gaussian random variables, \( \mathbf{u} \), possessing a mean value of zero and unit variance (i.e., standard normal variables). The region of interest, \( \mathbf{D} \), is also mapped to the transformed space to yield, \( \mathbf{D}_u \), where \( g(\mathbf{U}) < z \) as shown in Figure figUQ06. The Nataf transformation [17], which is identical to the Rosenblatt transformation [75] in the case of independent random variables, is used in Dakota to accomplish this mapping. This transformation is performed to make the probability calculation more tractable. In the transformed space, probability contours are circular in nature as shown in Figure figUQ06 unlike in the original uncertain variable space, Figure figUQ05. Also, the multi-dimensional integrals can be approximated by simple functions of a single parameter, \( \beta \), called the reliability index. \( \beta \) is the minimum Euclidean distance from the origin in the transformed space to the response surface. This point is also known as the most probable point (MPP) of failure. Note, however, the methodology is equally applicable for generic functions, not simply those corresponding
6.8 methods

to failure criteria; this nomenclature is due to the origin of these methods within the disciplines of structural safety and reliability. Note that there are local and global reliability methods. The majority of the methods available are local, meaning that a local optimization formulation is used to locate one MPP. In contrast, global methods can find multiple MPPs if they exist.

6.8.9 stochastic_expansion_methods

Description

The development of these techniques mirrors that of deterministic finite element analysis utilizing the notions of projection, orthogonality, and weak convergence [31], [32]. Rather than estimating point probabilities, they form an approximation to the functional relationship between response functions and their random inputs, which provides a more complete uncertainty representation for use in multi-code simulations. Expansion methods include polynomial chaos expansions (PCE), which employ multivariate orthogonal polynomials that are tailored to representing particular input probability distributions, and stochastic collocation (SC), which employs multivariate interpolation polynomials. For PCE, expansion coefficients may be evaluated using a spectral projection approach (based on sampling, tensor-product quadrature, Smolyak sparse grid, or cubature methods for numerical integration) or a regression approach (least squares or compressive sensing). For SC, interpolants are formed over tensor-product or sparse grids and may be local or global, value-based or gradient-enhanced, and nodal or hierarchical. In global value-based cases (Lagrange polynomials), the barycentric formulation is used [9], [57], [50] to improve numerical efficiency and stability. Both sets of methods provide analytic response moments and variance-based metrics; however, CDF/CCDF probabilities are evaluated numerically by sampling on the expansion.

6.8.10 epistemic_uncertainty_quantification_methods

Description

Epistemic uncertainty is uncertainty due to lack of knowledge.

In Dakota, epistemic uncertainty analysis is performed using interval analysis or Dempster-Shafer theory of evidence.

Note that epistemic uncertainty can also be modeled probabilistically. It would be more accurate to call this class of method, non-probabilistic uncertainty quantification, but the name persists for historical reasons.

6.8.11 interval_estimation

Description

In interval analysis, one assumes that nothing is known about an epistemic uncertain variable except that its value lies somewhere within an interval. In this situation, it is NOT assumed that the value has a uniform probability of
occurring within the interval. Instead, the interpretation is that any value within the interval is a possible value or a potential realization of that variable. In interval analysis, the uncertainty quantification problem is one of determining the resulting bounds on the output (defining the output interval) given interval bounds on the inputs. Again, any output response that falls within the output interval is a possible output with no frequency information assigned to it.

We have the capability to perform interval analysis using either global_interval_est or local_interval_est. In the global approach, one uses either a global optimization method or a sampling method to assess the bounds. global_interval_est allows the user to specify either lhs, which performs Latin Hypercube Sampling and takes the minimum and maximum of the samples as the bounds (no optimization is performed) or ego. In the case of ego, the efficient global optimization method is used to calculate bounds. The ego method is described in Section . If the problem is amenable to local optimization methods (e.g. can provide derivatives or use finite difference method to calculate derivatives), then one can use local methods to calculate these bounds. local_interval_est allows the user to specify either sqp which is sequential quadratic programming, or nip which is a nonlinear interior point method.

Note that when performing interval analysis, it is necessary to define interval uncertain variables as described in Section . For interval analysis, one must define only one interval per input variable, in contrast with Dempster-Shafer evidence theory, where an input can have several possible intervals. Interval analysis can be considered a special case of Dempster-Shafer evidence theory where each input is defined by one interval input with a basic probability assignment of one. In Dakota, however, the methods are separate and semantic differences exist in the output presentation. If you are performing a pure interval analysis, we recommend using either global_interval_est or local_interval_est instead of global_evidence or local_evidence, for reasons of simplicity. An example of interval estimation is found in the dakota/share/dakota/examples/users/cantilever_uq_global_interval.in, and also in Section .

Note that we have kept separate implementations of interval analysis and Dempster-Shafer evidence theory because our users often want to couple interval analysis on an outer loop with an aleatory, probabilistic analysis on an inner loop for nested, second-order probability calculations. See Section for additional details on these nested approaches. These interval methods can also be used as the outer loop within an interval-valued probability analysis for propagating mixed aleatory and epistemic uncertainty – refer to Section for additional details.

Interval analysis is often used to model epistemic uncertainty. In interval analysis, the uncertainty quantification problem is one of determining the resulting bounds on the output (defining the output interval) given interval bounds on the inputs.

We can do interval analysis using either global_interval_est or local_interval_est. In the global approach, one uses either a global optimization method or a sampling method to assess the bounds, whereas the local method uses gradient information in a derivative-based optimization approach.

An example of interval estimation is shown in Figure , with example results in Figure . This example is a demonstration of calculating interval bounds for three outputs of the cantilever beam problem. The cantilever beam problem is described in detail in Section . Given input intervals of [1,10] on beam width and beam thickness, we can see that the interval estimate of beam weight is approximately [1,100].

Min and Max estimated values for each response function:
weight: Min = 1.0000369352e+00 Max = 9.99999948e+01
stress: Min = -9.7749994284e-01 Max = 2.1499428450e+01
displ: Min = -9.9315672724e-01 Max = 6.7429714485e+01

Dakota Version 6.16 Reference Manual generated on May 12, 2022
6.8.12 evidence_theory

Description

This section discusses Dempster-Shafer evidence theory. In this approach, one does not assign a probability distribution to each uncertain input variable. Rather, one divides each uncertain input variable into one or more intervals. The input parameters are only known to occur within intervals: nothing more is assumed.

Each interval is defined by its upper and lower bounds, and a Basic Probability Assignment (BPA) associated with that interval. The BPA represents a probability of that uncertain variable being located within that interval.

The intervals and BPAs are used to construct uncertainty measures on the outputs called "belief" and "plausibility." Belief represents the smallest possible probability that is consistent with the evidence, while plausibility represents the largest possible probability that is consistent with the evidence. For more information about the Dempster-Shafer theory of evidence, see [69] and [48].

Similar to the interval approaches, one may use global or local methods to determine plausibility and belief measures for the outputs.

Usage Notes

Note that to calculate the plausibility and belief cumulative distribution functions, one has to look at all combinations of intervals for the uncertain variables. Within each interval cell combination, the minimum and maximum value of the objective function determine the belief and plausibility, respectively. In terms of implementation, global methods use LHS sampling or global optimization to calculate the minimum and maximum values of the objective function within each interval cell, while local methods use gradient-based optimization methods to calculate these minima and maxima.

Finally, note that many non-deterministic keywords apply to the evidence methods, but one needs to be careful about the interpretation and translate probabilistic measures to epistemic ones. For example, if the user specifies distribution of type complementary, a complementary plausibility and belief function will be generated for the evidence methods (as opposed to a complementary distribution function in the sampling case). If the user specifies a set of responses levels, both the belief and plausibility will be calculated for each response level. Likewise, if the user specifies a probability level, the probability level will be interpreted both as a belief and plausibility, and response levels corresponding to the belief and plausibility levels will be calculated. Finally, if generalized reliability levels are specified, either as inputs (gen_reliability_levels) or outputs (response_levels with compute gen_reliabilities), then these are directly converted to/from probability levels and the same probability-based mappings described above are performed.

6.8.13 variable_support

Description

Different nondeterministic methods have differing support for uncertain variable distributions. Tables 5.37, 5.38, and 5.39 summarize the uncertain variables that are available for use by the different methods, where a "-" indicates that the distribution is not supported by the method, a "U" means the uncertain input variables of this type must be uncorrelated, a "C" denotes that correlations are supported involving uncertain input variables of this type, and an "A" means the appropriate variables must be specified as active in the variables specification block. For example, if one wants to support sampling or a stochastic expansion method over both continuous uncertain and continuous state variables, the specification active all must be listed in the variables specification block. Additional notes include:
• we have four variants for stochastic expansions (SE), listed as Wiener, Askey, Extended, and Piecewise which draw from different sets of basis polynomials. The term stochastic expansion indicates polynomial chaos and stochastic collocation collectively, although the Piecewise option is only currently supported for stochastic collocation. Refer to polynomial_chaos and stoch_collocation for additional information on these three options.

• methods supporting the epistemic interval distributions have differing approaches: sampling and the lhs option of global_interval_est model the interval basic probability assignments (BPAs) as continuous histogram bin distributions for purposes of generating samples; local_interval_est and the ego option of global_interval_est ignore the BPA details and models these variables as simple bounded regions defined by the cell extremes; and local_evidence and global_evidence model the interval specifications as true BPAs.

6.8.14  optimization_and_calibration

Description

Optimization algorithms work to minimize (or maximize) an objective function, typically calculated by the user simulation code, subject to constraints on design variables and responses. Available approaches in Dakota include well-tested, proven gradient-based, derivative-free local, and global methods for use in science and engineering design applications. Dakota also offers more advanced algorithms, e.g., to manage multi-objective optimization or perform surrogate-based minimization. This chapter summarizes optimization problem formulation, standard algorithms available in Dakota (mostly through included third-party libraries, see Section 6.5 of [5]), some advanced capabilities, and offers usage guidelines.

6.8.14.1  Optimization Formulations

This section provides a basic introduction to the mathematical formulation of optimization, problems. The primary goal of this section is to introduce terms relating to these topics. and is not intended to be a description of theory or numerical algorithms. For further details, consult [7], [34], [42], [67], and [87].

A general optimization problem is formulated as follows:

where vector and matrix terms are marked in bold typeface. In this formulation, \( x = [x_1, x_2, \ldots, x_n] \) is an \( n \)-dimensional vector of real-valued design variables or design parameters. The \( n \)-dimensional vectors, \( x_L \) and \( x_U \), are the lower and upper bounds, respectively, on the design parameters. These bounds define the allowable values for the elements of \( x \), and the set of all allowable values is termed the design space or the parameter space. A design point or a sample point is a particular set of values within the parameter space.

The optimization goal is to minimize the objective function, \( f(x) \), while satisfying the constraints. Constraints can be categorized as either linear or nonlinear and as either inequality or equality. The nonlinear inequality constraints, \( g(x) \), are “2-sided,” in that they have both lower and upper bounds, \( g_L \) and \( g_U \), respectively. The nonlinear equality constraints, \( h(x) \), have target values specified by \( h_t \). The linear inequality constraints create a linear system \( A_x x \), where \( A_i \) is the coefficient matrix for the linear system. These constraints are also 2-sided as they have lower and upper bounds, \( a_L \) and \( a_U \), respectively. The linear equality constraints create a linear system \( A_e x \), where \( A_e \) is the
The optimization problem type can be characterized both by the types of constraints present in the problem and by the linearity or nonlinearity of the objective and constraint functions. For constraint categorization, a hierarchy of complexity exists for optimization algorithms, ranging from simple bound constraints, through linear constraints, to full nonlinear constraints. By the nature of this increasing complexity, optimization problem categorizations are inclusive of all constraint types up to a particular level of complexity. That is, an unconstrained problem has no constraints, a bound-constrained problem has only lower and upper bounds on the design parameters, a linearly-constrained problem has both linear and bound constraints, and a nonlinearly-constrained problem may contain the full range of nonlinear, linear, and bound constraints. If all of the linear and nonlinear constraints are equality constraints, then this is referred to as an equality-constrained problem, and if all of the linear and nonlinear constraints are inequality constraints, then this is referred to as an inequality-constrained problem. Further categorizations can be made based on the linearity of the objective and constraint functions. A problem where the objective function and all constraints are linear is called a linear programming (LP) problem. These types of problems commonly arise in scheduling, logistics, and resource allocation applications. Likewise, a problem where at least some of the objective and constraint functions are nonlinear is called a nonlinear programming (NLP) problem. These NLP problems predominate in engineering applications and are the primary focus of Dakota.

The search goal refers to the ultimate objective of the optimization algorithm, i.e., either global or local optimization. In global optimization, the goal is to find the design point that gives the lowest feasible objective function value over the entire parameter space. In contrast, in local optimization, the goal is to find a design point that is lowest relative to a “nearby” region of the parameter space. In almost all cases, global optimization will be more computationally expensive than local optimization. Thus, the user must choose an optimization algorithm with an appropriate search scope that best fits the problem goals and the computational budget.

The search method refers to the approach taken in the optimization algorithm to locate a new design point that has a lower objective function or is more feasible than the current design point. The search method can be classified as either gradient-based or nongradient-based. In a gradient-based algorithm, gradients of the response functions are computed to find the direction of improvement. Gradient-based optimization is the search method that underlies many efficient local optimization methods. However, a drawback to this approach is that gradients can be computationally expensive, inaccurate, or even nonexistent. In such situations, nongradient-based search methods may be useful. There are numerous approaches to nongradient-based optimization. Some of the more well known of these include pattern search methods (nongradient-based local techniques) and genetic algorithms (nongradient-based global techniques).

Because of the computational cost of running simulation models, surrogate-based optimization (SBO) methods are often used to reduce the number of actual simulation runs. In SBO, a surrogate or approximate model is constructed based on a limited number of simulation runs. The optimization is then performed on the surrogate model. Dakota has an extensive framework for managing a variety of local, multipoint, global, and hierarchical surrogates for use in optimization. Finally, sometimes there are multiple objectives that one may want to optimize simultaneously instead of a single scalar objective. In this case, one may employ multi-objective methods that are described in Section 6.3.1 of [5].

This overview of optimization approaches underscores that no single optimization method or algorithm works best for all types of optimization problems. Section 6.4 of [5] offers guidelines for choosing a Dakota optimization algorithm best matched to your specific optimization problem.

6.8.14.1.1 Constraint Considerations

Dakota’s input commands permit the user to specify two-sided nonlinear inequality constraints of the form \( g_i(t) \leq g_t, \) as well as nonlinear equality constraints of the form \( h_j(x) = h_t. \) Some optimizers (e.g., npsol, optpp, soga, and moga methods) can handle these constraint forms directly, whereas other optimizers (e.g., async_pattern_search, dot, and conmin, mesh_adaptive_search) require Dakota to perform
an internal conversion of all constraints to one-sided inequality constraints of the form \( g_i(x) \leq 0 \). In the latter case, the two-sided inequality constraints are treated as \( g_i(x) - g_{i,j} \leq 0 \) and \( g_{i,j} - g_i(x) \leq 0 \) and the equality constraints are treated as \( h_j(x) - h_{j,j} \leq 0 \) and \( h_{j,j} - h_j(x) \leq 0 \). The situation is similar for linear constraints: \( \text{async, pattern_search, npsol, optpp, soga, and moga methods support them directly, whereas dot and conmin methods do not.} \) For linear inequalities of the form \( a_i^T x \leq a_i \), the nonlinear constraint arrays in \( \text{dot and conmin methods} \) are further augmented to include \( a_i^T x - a_i \leq 0 \) and \( a_i \). The situation is similar for linear constraints:

\[
\begin{align*}
    x_i^T \leq a_i & \quad \text{for linear constraints} \\
    x_i \leq a_i & \quad \text{for linear inequalities}
\end{align*}
\]

Constraint mappings are used with NLPQL for both linear and nonlinear cases. Most \( \text{coliny} \) methods now support two-sided nonlinear inequality constraints and nonlinear constraints with targets, but do not natively support linear constraints.

When gradient and Hessian information is used in the optimization, derivative components are most commonly computed with respect to the active continuous variables, which in this case are the \textit{continuous design variables}. This differs from parameter study methods (for which all continuous variables are active) and from nondeterministic analysis methods (for which the uncertain variables are active). Refer to Chapter 11 of [5] for additional information on derivative components and active continuous variables.

6.8.14.2 Optimizing with Dakota: Choosing a Method

This section summarizes the optimization methods available in Dakota. We group them according to search method and search goal and establish their relevance to types of problems. For a summary of this discussion, see Section 6.4 of [5].

6.8.14.2.1 Gradient-Based Local Methods

Gradient-based optimizers are best suited for efficient navigation to a local minimum in the vicinity of the initial point. They are not intended to find global optima in nonconvex design spaces. For global optimization methods, see Section 6.2.3 of [5]. Gradient-based optimization methods are highly efficient, with the best convergence rates of all of the local optimization methods, and are the methods of choice when the problem is smooth, unimodal, and well-behaved. However, these methods can be among the least robust when a problem exhibits nonsmooth, discontinuous, or multimodal behavior. The derivative-free methods described in Section 6.2.2 of [5] are more appropriate for problems with these characteristics.

Gradient accuracy is a critical factor for gradient-based optimizers, as inaccurate derivatives will often lead to failures in the search or pre-mature termination of the method. Analytic gradients and Hessians are ideal but often unavailable. If analytic gradient and Hessian information can be provided by an application code, a full Newton method will achieve quadratic convergence rates near the solution. If only gradient information is available and the Hessian information is approximated from an accumulation of gradient data, the superlinear convergence rates can be obtained. It is most often the case for engineering applications, however, that a finite difference method will be used by the optimization algorithm to estimate gradient values. Dakota allows the user to select the step size for these calculations, as well as choose between forward-difference and central-difference algorithms. The finite difference step size should be selected as small as possible, to allow for local accuracy and convergence, but not so small that the steps are “in the noise.” This requires an assessment of the local smoothness of the response functions using, for example, a parameter study method. Central differencing will generally produce more reliable gradients than forward differencing but at roughly twice the expense.

Gradient-based methods for nonlinear optimization problems can be described as iterative processes in which a sequence of subproblems, usually which involve an approximation to the full nonlinear problem, are solved until the solution converges to a local optimum of the full problem. The optimization methods available in Dakota fall into several categories, each of which is characterized by the nature of the subproblems solved at each iteration.

6.8.15.3 sequential_quadratic_programming

Description

Sequential Quadratic Programming (SQP) algorithms are a class of mathematical programming problems used to solve nonlinear optimization problems with nonliner constraints. These methods are a generalization of Newton's method: each iteration involves minimizing a quadratic model of the problem. These subproblems are formulated as minimizing a quadratic approximation of the Lagrangian subject to linearized constraints. Only gradient information is required; Hessians are approximated by low-rank updates defined by the step taken at each iteration. It is important to note that while the solution found by an SQP method will respect the constraints, the intermediate iterates may not. SQP methods available in Dakota are dot_sqp, nlpql_sqp, nlssol_sqp, and npsol_sqp. The particular implementation in nlpql_sqp uses a variant with distributed and non-monotone line search. Thus, this variant is designed to be more robust in the presence of inaccurate or noisy gradients common in many engineering applications.

6.8.18 nonlinear_least_squares

Description

Dakota’s least squares branch currently contains three methods for solving nonlinear least squares problems:

- **NL2SOL**, a trust-region method that adaptively chooses between two Hessian approximations (Gauss-Newton and Gauss-Newton plus a quasi-Newton approximation to the rest of the Hessian)
- **NLSSOL**, a sequential quadratic programming (SQP) approach that is from the same algorithm family as NPSOL
- **Gauss-Newton**, which supplies the Gauss-Newton Hessian approximation to the full-Newton optimizers from OPT++.

The important difference of these algorithms from general-purpose optimization methods is that the response set is defined by calibration terms (e.g., separate terms for each residual), rather than an objective function. Thus, a finer granularity of data is used by least squares solvers as compared to that used by optimizers. This allows the exploitation of the special structure provided by a sum of squares objective function.

6.10.1 package_coliny

Description

SCOLIB (formerly known as COLINY) is a collection of nongradient-based optimizers that support the Common Optimization Library Interface (COLIN). SCOLIB optimizers currently include coliny_cobyla, coliny_direct, coliny_ea, coliny_pattern_search and coliny_solis_wets. (Yes, the input spec still has “coliny” prepended to the method name.) Additional SCOLIB information is available from https://software.sandia.gov/trac/acro.

SCOLIB solvers now support bound constraints and general nonlinear constraints. Supported nonlinear constraints include both equality and two-sided inequality constraints. SCOLIB solvers do not yet support linear constraints. Most SCOLIB optimizers treat constraints with a simple penalty scheme that adds constraint_penalty times the sum of squares of the constraint violations to the objective function. Specific exceptions to this method for handling constraint violations are noted below. (The default value of constraint_penalty is 1000.0, except for methods that dynamically adapt their constraint penalty, for which the default value is 1.0.)

The method independent controls for max_iterations and max_function_evaluations limit the number of major iterations and the number of function evaluations that can be performed during a SCOLIB optimization, respectively. The convergence_tolerance control defines the threshold value on relative change in the objective function that indicates convergence. The output verbosity specification controls the amount of information generated by SCOLIB: the silent, quiet, and normal settings correspond to minimal reporting from SCOLIB, whereas the verbose setting corresponds to a higher level of information, and debug outputs method initialization and a variety of internal SCOLIB diagnostics. The majority of SCOLIB’s methods perform independent function evaluations that can directly take advantage of Dakota’s parallel capabilities. Only coliny_solis_wets, coliny_cobyla, and certain configurations of coliny_pattern_search are inherently serial. The parallel methods automatically utilize parallel logic when the Dakota configuration supports parallelism. Lastly, neither speculative gradients nor linear constraints are currently supported with SCOLIB.

Some SCOLIB methods exploit parallelism through the use of Dakota’s concurrent function evaluations. The nature of the algorithms, however, limits the amount of concurrency that can be exploited. The maximum amount of evaluation concurrency that can be leveraged by the various methods is as follows:

- COBYLA: one
- DIRECT: twice the number of variables
- Evolutionary Algorithms: size of the population
- Pattern Search: size of the search pattern
- Solis-Wets: one
All SCOLIB methods support the `show_misc_options` optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The `misc_options` optional specification provides a means for inputting additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

Each of the SCOLIB methods supports the `solution_target` control, which defines a convergence criterion in which the optimizer will terminate if it finds an objective function value lower than the specified target.

### 6.10.2 package_conmin

**Description**

The CONMIN library [86] is a public domain library of nonlinear programming optimizers, specifically the Fletcher-Reeves conjugate gradient (`conmin_frcg`) method for unconstrained optimization, and the method of feasible directions (`conmin_mfd`) for constrained optimization. As CONMIN was a predecessor to the DOT commercial library, the algorithm controls are very similar.

**Related Topics**

**Related Keywords**

- `conmin_mfd`: CONMIN method of feasible directions

### 6.10.3 package_ddace

**Description**

The Distributed Design and Analysis of Computer Experiments (DDACE) library provides the following DACE techniques: grid sampling (`grid`), pure random sampling (`random`), orthogonal array sampling (`oas`), latin hypercube sampling (`lhs`), orthogonal array latin hypercube sampling (`oa_lhs`), Box-Behnken (`box_behnken`), and central composite design (`central_composite`).

It is worth noting that there is some overlap in sampling techniques with those available from the nondeterministic branch. The current distinction is that the nondeterministic branch methods are designed to sample within a variety of probability distributions for uncertain variables, whereas the design of experiments methods treat all variables as having uniform distributions. As such, the design of experiments methods are well-suited for performing parametric studies and for generating data sets used in building global approximations, but are not currently suited for
assessing the effect of uncertainties characterized with probability distribution. If a design of experiments over both design/state variables (treated as uniform) and uncertain variables (with probability distributions) is desired, then sampling can support this with active all specified in the Variables specification block.

Related Topics

Related Keywords

- dace: Design and Analysis of Computer Experiments

6.10.4 package_dot

Description

The DOT library [88] contains nonlinear programming optimizers, specifically the Broyden-Fletcher-Goldfarb-Shanno (dot_bfgs) and Fletcher-Reeves conjugate gradient (dot_frcg) methods for unconstrained optimization, and the modified method of feasible directions (dot_mmfd), sequential linear programming (dot_slp), and sequential quadratic programming (dot_sqp) methods for constrained optimization. To use DOT, one of these methods must be specified.

Specialized handling of linear constraints is supported with DOT; linear constraint coefficients, bounds, and targets can be provided to DOT at start-up and tracked internally.

Method Independent Controls - Stopping Criteria

Stopping criteria are set by: max_iterations, max_function_evaluations, convergence_tolerance, and constraint_tolerance

Note: The convergence_tolerance criterion must be satisfied for two consecutive iterations before DOT will terminate.

Method Independent Controls - Output

The output verbosity specification controls the amount of information generated by DOT: the silent and quiet settings result in header information, final results, and objective function, constraint, and parameter information on each iteration; whereas the verbose and debug settings add additional information on gradients, search direction, one-dimensional search results, and parameter scaling factors.

Concurrency

DOT contains no parallel algorithms which can directly take advantage of concurrent evaluations. However, if numerical_gradients with method_source dakota is specified, then the finite difference function evaluations can be performed concurrently (using any of the parallel modes described in the Users Manual [5]). In addition, if speculative is specified, then gradients (dakota numerical or analytic gradients) will be computed on each line search evaluation in order to balance the load and lower the total run time in parallel optimization studies.

6.10.6  package_hopspack

Description

The HOPSPACK software [72] contains the asynchronous parallel pattern search (APPS) algorithm [38]. It can handle unconstrained problems as well as those with bound constraints, linear constraints, and general nonlinear constraints.

HOPSPACK is available to the public under the GNU LGPL and the source code is included with Dakota. HOPSPACK-specific software documentation is available from https://software.sandia.gov/trac/hopspack.

Related Topics

Related Keywords

- **asynch_pattern_search**: Pattern search, derivative free optimization method

6.10.7  package_jega

Description

The JEGA library [19] contains two global optimization methods. The first is a Multi-objective Genetic Algorithm (MOGA) which performs Pareto optimization. The second is a Single-objective Genetic Algorithm (SOGA) which performs optimization on a single objective function. Both methods support general constraints and a mixture of real and discrete variables. The JEGA library was written by John Eddy, currently a member of the technical staff in the System Readiness and Sustainment Technologies department at Sandia National Laboratories in Albuquerque. These algorithms are accessed as moga and soga within Dakota.
Related Topics

Related Keywords

6.10.8  **package_nlpql**

Description

The NLPQL library includes a sequential quadratic programming (SQP) optimizer, specified as Dakota's `nlpql-sqp` method, for constrained optimization. The particular implementation used is NLPQLP [77], a variant with distributed and non-monotone line search. NLPQL is commercially licensed (available from the author) and not distributed with public versions of Dakota.

Related Topics

Related Keywords

- **nlpql_sqp**: NLPQL Sequential Quadratic Program

6.10.9  **package_npsol**

Description

The NPSOL library [33] contains a sequential quadratic programming (SQP) implementation (the `npsol_sqp` method). SQP is a nonlinear programming optimizer for constrained minimization.

Related Topics

Related Keywords

- **npsol_sqp**: NPSOL Sequential Quadratic Program

6.10.10  **package_optpp**

Description

The conjugate gradient method is strictly unconstrained, and each of the Newton-based methods are automatically bound to the appropriate OPT++ algorithm based on the user constraint specification (unconstrained, bound-constrained, or generally-constrained). In the generally-constrained case, the Newton methods use a nonlinear interior-point approach to manage the constraints. The library also contains a direct search algorithm, PDS (parallel direct search, Dakota's `optpp_pds` method), which supports bound constraints.

Controls

1. max_iterations
2. max_function_evaluations
3. convergence_tolerance
4. output
5. speculative

Concurrency

OPT++’s gradient-based methods are not parallel algorithms and cannot directly take advantage of concurrent function evaluations. However, if numerical_gradients with method_source dakota is specified, a parallel Dakota configuration can utilize concurrent evaluations for the finite difference gradient computations.

Constraints

Linear constraint specifications are supported by each of the Newton methods (optpp_newton, optpp_q_newton, optpp_fd_newton, and optpp_g_newton)

optpp_cg must be unconstrained
optpp_pds can be, at most, bound-constrained.

Chapter 7

Keywords Area

This page summarizes the overall input file structure, syntax, and the six types of blocks that may appear in Dakota input. Some are optional and some may appear multiple times:

- **environment** (optional; 0 or 1 may appear)
- **method** (required; 1 or more may appear)
- **model** (optional; 0 or more may appear)
- **variables** (required; 1 or more may appear)
- **interface** (required; 1 or more may appear)
- **responses** (required; 1 or more may appear)

**Introduction to Dakota Keywords**

In Dakota, the *environment* manages execution modes and I/O streams and defines the top-level iterator. Generally speaking, an iterator contains a model and a model contains a set of *variables*, an *interface*, and a set of *responses*. An iterator repeatedly operates on the model to map the variables into responses using the interface. Each of these six components (environment, method, model, variables, interface, and responses) are separate specifications in the user's input file, and as a whole, determine the study to be performed during an execution of the Dakota software.

A Dakota execution is limited to a single environment, but may involve multiple methods and multiple models. In particular, advanced iterators (i.e., meta- and component-based iterators) and advanced models (i.e., nested and surrogate models) may specialize to include recursions with additional sub-iterators and sub-models. Since each model may contain its own variables, interface, and responses, there may be multiple specifications of the method, model, variables, interface, and responses sections.

**Keyword Pages**

Every Dakota keyword has its own page in this manual. The page describes:

- Whether the keyword takes **ARGUMENTS**, and the data type Additional notes about ARGUMENTS can be found here: Specifying Arguments.
- Whether it has an **ALIAS**
- Which additional keywords can be specified to change its behavior
- Which of these additional keywords are required or optional
- Additional information about how to use the keyword in an input file

</tr>
</tbody>
</table>
### Description

The environment section in a Dakota input file is optional. It specifies the top-level solution environment, optionally including run modes, output controls, and identification of the primary iterative method (`top_method_pointer`). The output-related keywords address generation of tabular and results data, and precision of numerical output.

### Run Mode Defaults

**Dakota run phases** include `check`, `pre_run`, `run`, and `post_run`. The default behavior is to `pre_run`, `run`, and `post_run`, though any or all of these may be specified to select specific run phases. Specifying `check` will cause Dakota to exit before any selected run modes.

### 7.1.1 tabular_data

| | | annotated | Selects annotated tabular file format |
| | | freeform | Selects freeform file format |

**Description**

Specifying the `tabular_data` flag writes to a data file the same variable and response function history data plotted when using the (deprecated) `graphics` flag. Within the generated data file, the variables and response functions appear as columns and each function evaluation provides a new table row. This capability is most useful for post-processing of Dakota results with third-party graphics tools such as MatLab, Excel, Tecplot, etc.

There is no dependence between the `graphics` flag and the `tabular_data` flag; they may be used independently or concurrently.

Dakota exports tabular data in one of three formats:

- annotated *(default)*
- custom_annotated
- freeform

**See Also**

These keywords may also be of interest:

File name for tabular data output
Topics

This keyword is related to the topics:

- dakota_output

Specification

**Alias:** tabular_graphics_file

**Argument(s):** STRING

**Default:** dakota_tabular.dat

Description

Specifies a name to use for the tabular data file, overriding the default dakota_tabular.dat.

7.1.1.2 custom_annotated

- **Keywords Area**
- environment
- tabular_data
- custom_annotated

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- file_formats

Specification

**Alias:** none

**Argument(s):** none

**Default:** annotated format

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>header</td>
<td></td>
<td>Enable header row in custom-annotated tabular file</td>
</tr>
</tbody>
</table>
Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

Usage Tips

• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```ini
environment
  tabular_data
  tabular_data_file = 'dakota_summary.dat'
  custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id  x1   x2   obj_fn nln_ineq_con_1 nln_ineq_con_2
1  0.9  1.1  0.0002  0.26  0.76
2  0.90009  1.1  0.0001996404857  0.2601620081  0.759955
3  0.89991  1.1  0.0002003604863  0.2598380081  0.760045
...
```

7.1.1.2.1 header

• Keywords Area

• environment

• tabular_data

• custom_annotated

• header

Enable header row in custom-annotated tabular file
7.1 environment

Specification

Alias: none
Argument(s): none

Description

See description of parent custom_annotated

7.1.1.2.2 eval_id

- Keywords Area
- environment
- tabular_data
- custom_annotated
- eval_id

Enable evaluation ID column in custom-annotated tabular file

Specification

Alias: none
Argument(s): none
Default: no eval_id column

Description

See description of parent custom_annotated

7.1.1.2.3 interface_id

- Keywords Area
- environment
- tabular_data
- custom_annotated
- interface_id

Enable interface ID column in custom-annotated tabular file

Specification

Alias: none
Argument(s): none
Default: no interface_id column
Description

See description of parent custom.annotated

7.1.1.3 annotated

- Keywords Area
- environment
- tabular_data
- annotated

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom.annotated header eval_id

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.
7.1 environment

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```plaintext
environment
tabular_data
  tabular_data_file = 'dakota_summary.dat'
  annotated
```

Resulting tabular file:

```plaintext
%eval_id interface    x1    x2    obj_fn nln_ineq_con_1 nln_ineq_con_2
1     NO_ID 0.9    1.1    0.0002  0.26    0.76
2     NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3     NO_ID 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...
```

7.1.1.4 freeform

- Keywords Area
- environment
- tabular_data
- freeform

Selects freeform file format

Topics

This keyword is related to the topics:

- file_formats

Specification

**Alias:** none

**Argument(s):** none

**Default:** annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.
• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
  tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

```plaintext
0.9  1.1  0.0002  0.26  0.76
0.90009  1.1  0.0001996404857  0.2601620081  0.759955
0.89991  1.1  0.0002003604863  0.2598380081  0.760045
```

7.1.2 output_file

• Keywords Area
• environment
• output_file

Base filename for output redirection

Topics

This keyword is related to the topics:

• dakota_IO
• command_line_options

Specification

Alias: none

Argument(s): STRING

Default: output to console, not file

Description

Specify a base filename to which Dakota output will be directed. Output will (necessarily) be redirected after the input file is parsed. This option is overridden by any command-line -output option.

Default Behavior

Output to console (screen).
7.1 environment

7.1.3 error_file

- Keywords Area
- environment
- error_file

Base filename for error redirection

Topics

This keyword is related to the topics:

- dakota_IO
- command_line_options

Specification

Alias: none
Argument(s): STRING
Default: errors to console, not file

Description

Specify a base filename to which Dakota errors will be directed. Errors will (necessarily) be redirected after the input file is parsed. This option is overridden by any command-line -error option.

Default Behavior

Errors to console (screen).

7.1.4 read_restart

- Keywords Area
- environment
- read_restart

Base filename for restart file read

Topics

This keyword is related to the topics:

- dakota_IO
- command_line_options
Specification

**Alias:** none

**Argument(s):** STRING

**Default:** no restart read

**Child Keywords:**
### 7.1.4.1 stop_restart

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>stop_restart</td>
<td>Restart record number at which to stop reading the restart file.</td>
</tr>
</tbody>
</table>

**Description**

Specify a base filename for the restart file Dakota should read. This option is overridden by any command-line -read_restart option.

**Default Behavior**

No restart file is read.

**7.1.5 write_restart**

- **Keywords Area**
- **environment**
- **read_restart**
- **stop_restart**

Base filename for restart file write.
This keyword is related to the topics:

- dakota_IO
- command_line_options

**Specification**

**Alias:** none  
**Argument(s):** STRING  
**Default:** dakota.rst

**Description**

Specify a base filename for the restart file Dakota should write. This option is overridden by any command-line -write_restart option.

### 7.1.6 output_precision

- Keywords Area  
- environment  
- output_precision

Control the output precision

**Topics**

This keyword is related to the topics:

- dakota_output

**Specification**

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** 10

**Description**

The precision of numeric output precision can be set with `output_precision`, with an upper limit of 16. When not specified, most Dakota output will default to a precision of 10, though filesystem interfaces and pre-run output use higher precision for accuracy and better results reproducibility.
7.1 environment

7.1.7 results_output

• Keywords Area
  • environment
  • results_output

(Experimental) Write a summary file containing the final results

Topics

This keyword is related to the topics:

  • dakota_output

Specification

Alias: none

Argument(s): none

Default: no results output

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>results_output_file</td>
<td></td>
<td>The base file name of the results file</td>
</tr>
<tr>
<td>Optional</td>
<td>text</td>
<td></td>
<td>Write results to file in text format</td>
</tr>
<tr>
<td>Optional</td>
<td>hdf5</td>
<td></td>
<td>Write results to file in HDF5 format</td>
</tr>
</tbody>
</table>

Description

(Experimental)

Dakota writes final results for most methods to the screen (console). This keyword enables experimental support for writing them to disk, as well. By default, they are written in a structured text format to a file named dakota_-results.txt. Text format can be explicitly selected using the text sub-keyword. If Dakota was built with HDF5 enabled, the sub-keyword hdf5 causes results to be written in HDF5 format, as well.

The name of the results file can be changed using the results_output_file keyword.

Text output eventually will be deprecated, and HDF5 will be enabled in all distributed builds of Dakota. The layout of the HDF5 file is described in the Dakota HDF5 Output section of this manual. The contents, organization, and format of results files are all under active development and are subject to change.

7.1.7.1 results_output_file

• Keywords Area
  • environment
  • results_output
• results_output_file

The base file name of the results file

Topics

This keyword is related to the topics:

• dakota_output

Specification

Alias: none
Argument(s): STRING
Default: dakota_results

Description

The default filename is dakota_results.txt for text output and dakota_results.h5 for HDF5. The dakota_results stem can be changed using this keyword. Do not include the extension; these will be added by Dakota.

7.1.7.2 text

• Keywords Area

• environment

• results_output

• text

Write results to file in text format

Topics

This keyword is related to the topics:

• dakota_output

Specification

Alias: none
Argument(s): none
Default: text output
Description

When this keyword is present, Dakota will right (some) final method results to disk in a custom structured text format instead of just to the console. Support for text format results output will be deprecated in a future release, and the contents and organization of the output file is subject to change.

The default name of the file is `dakota_results.txt`. This can be changed using the `results_output_file` keyword.

Examples

```plaintext
environment
  results_output
text
  results_output_file 'my_results'  # The .txt extension will be added
```

7.1.7.3 hdf5

- Keywords Area
- environment
- results_output
- hdf5

Write results to file in HDF5 format

Topics

This keyword is related to the topics:

- dakota_output

Specification

Alias: none

Argument(s): none

Default: no HDF5 output

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>model_selection</td>
<td>Select the models that write evaluation data to HDF5</td>
</tr>
</tbody>
</table>
Description

When this keyword is present, Dakota will right (some) final method results to disk in HDF5 format instead of just to the console. This is an experimental feature, and the contents and organization of the output file is subject to change. The current organization and a brief explanation of HDF5 is provided in the Dakota HDF5 Output section of this manual.

With hdf5 selected, the default name of the output file is dakota_results.h5. This can be changed using the results_output_file keyword.

Examples

```bash
environment
    results_output
        hdf5
            results_output_file 'my_results'  # The .h5 extension will be added
```

Topics

This keyword is related to the topics:

- dakota_output

Specification

7.1.7.3.1.1 top_method
  • Keywords Area
  • environment
  • results_output
  • hdf5
  • model_selection
  • top_method

Write evaluation data only for the top-level method’s model to HDF5

Topics
This keyword is related to the topics:
  • dakota_output

Specification
Alias: none
Argument(s): none
Default: top_method

Description
When this option is selected, evaluation data only for the model that belongs to the top-level method will be written to HDF5.

HDF5 output is an experimental feature, and the contents and organization of the output file is subject to change. The current organization and a brief explanation of HDF5 is provided in the Dakota HDF5 Output section of this manual.
Examples

For the example input in the parent keyword, the following model groups would be written:

- `/models/recast/RECAST_surr_RECAST_1/

The recast model, in this case, is automatically generated by Dakota to handle summing the pair of objective functions. It is the model that belongs directly to the method 'opt', which is the top-level method. See Sources of Evaluation Data for further explanation.

The following links would be added to methods and models sources groups:

- `/methods/opt/sources/RECAST_surr_RECAST_1 → /models/recast/RECAST_surr_RECAST_1/`

7.1.7.3.1.2 none

- Keywords Area
- environment
- results_output
- hdf5
- model_selection
- none

Write evaluation data for no models to HDF5

Topics

This keyword is related to the topics:

- dakota_output

Specification

Alias: none
Argument(s): none
Default: top_method

Description

When this option is selected, no model evaluation data is written to HDF5, and the /models group itself is not created.

HDF5 output is an experimental feature, and the contents and organization of the output file is subject to change. The current organization and a brief explanation of HDF5 is provided in the Dakota HDF5 Output section of this manual.
7.1.7.3.1.3 all_methods

- Keywords Area
- environment
- results_output
- hdf5
- model_selection
- all_methods

Write evaluation data to HDF5 for all models that belong directly to methods

Topics

This keyword is related to the topics:

- dakota_output

Specification

Alias: none
Argument(s): none
Default: top_method

Description

When this option is selection, evaluation data for all models that belong directly to methods will be written to HDF5. Models that belong to other models (e.g. wrapped models in a recast relationship) are not stored.

By default, when HDF5 output is enabled, Dakota writes evaluation data only for the model that belongs to the top-level method. This keyword group is used to override the default.

HDF5 output is an experimental feature, and the contents and organization of the output file is subject to change. The current organization and a brief explanation of HDF5 is provided in the Dakota HDF5 Output section of this manual.

Examples

For the example input in the parent keyword, the following model groups would be written:

- /models/recast/RECAST_surr_RECAST_1/
- /models/simulation/truth_m/

The recast model, in this case, is automatically generated by Dakota to handle summing the pair of objective functions. It is the model that belongs directly to the method 'opt'. See Sources of Evaluation Data for further explanation.

The following links would be added to methods and models sources groups:

- /methods/opt/sources/RECAST_surr_RECAST_1 → /models/recast/RECAST_surr_RECAST_1/
7.1 environment

- /methods/training/sources/truth_m → /models/simulation/truth_m/

Depending on interface_selection, the following links may also be added to model sources groups:

- /models/simulation/truth_m/sources/truth → /interfaces/truth/truth_m/

7.1.7.3.1.4 all

- Keywords Area
- environment
- results_output
- hdf5
- model_selection
- all

Write evaluation data to HDF5 for all models

Topics

This keyword is related to the topics:

- dakota_output

Specification

Alias: none
Argument(s): none
Default: top_method

Description

When this option is selected, evaluation for all models will be written to HDF5.

HDF5 output is an experimental feature, and the contents and organization of the output file is subject to change. The current organization and a brief explanation of HDF5 is provided in the Dakota HDF5 Output section of this manual.

Examples

For the example input in the parent keyword, the following model groups would be written:

- /models/recast/RECAST_surr_RECAST_1/
- /models/simulation/truth_m/
- /models/surrogate/surr/

The recast model, in this case, is automatically generated by Dakota to handle summing the pair of objective functions. See Sources of Evaluation Data for further explanation.

The following links would be added to methods and models sources groups:
Depending on interface_selection, the following links may also be added to model sources groups:

- /models/surrogate/surr/sources/APPROX_INTERFACE_1 → /interfaces/APPROX_INTERFACE_1/surr/
- /models/simulation/truth_m/sources/truth → /interfaces/truth/truth_m/

Write evaluation data for no interfaces to HDF5

Topics

This keyword is related to the topics:

- dakota_output

Specification

Alias: none
Argument(s): none
Default: simulation

Description

When this option is selected, no interface evaluation data is written to HDF5, and the /interfaces group is not created.

HDF5 output is an experimental feature, and the contents and organization of the output file is subject to change. The current organization and a brief explanation of HDF5 is provided in the Dakota HDF5 Output section of this manual.

Write evaluation data only for simulation interfaces to HDF5

Topics

This keyword is related to the topics:

- dakota_output
7.1 environment

Specification

Alias: none
Argument(s): none
Default: simulation

Description

When this option is selected, evaluation data only for simulation interfaces will be written to HDF5. Simulation interfaces include fork, system, direct, matlab, python, scilab, and grid interfaces, but not approximation interfaces, which are automatically generated by Dakota to be used by surrogate models.

HDF5 output is an experimental feature, and the contents and organization of the output file is subject to change. The current organization and a brief explanation of HDF5 is provided in the Dakota HDF5 Output section of this manual.

Examples

For the example input in the parent keyword, the following interface groups would be written:

• /interfaces/truth/truth_m/

Depending on the model_selection, the following links may be added to model sources groups.

• /models/simulation/truth_m/sources/truth → /interfaces/truth/truth_m/

7.1.7.3.2.3 all

• Keywords Area
  • environment
  • results_output
  • hdf5
  • interface_selection
  • all

Write evaluation data for all interfaces to HDF5

Topics

This keyword is related to the topics:

• dakota_output

Specification

Alias: none
Argument(s): none
Default: top_simulation
Description

When this option is selected, evaluation data for all interfaces, including both simulations and approximations, will be written to HDF5.

HDF5 output is an experimental feature, and the contents and organization of the output file is subject to change. The current organization and a brief explanation of HDF5 is provided in the Dakota HDF5 Output section of this manual.

Examples

For the example input in the parent keyword, the following interface groups would be written:

- /interfaces/truth/truth_m/
- /interfaces/APPROX_INTERFACE_1/surr/

Depending on the model_selection, the following links may be added to model sources groups.

- /models/simulation/truth_m/sources/truth → /interfaces/truth/truth_m/
- /models/surrogate/surr/sources/APPROX_INTERFACE_1 → /interfaces/APPROX_INTERFACE_1/surr/

7.1.8 graphics

- Keywords Area
- environment
- graphics

(DEPRECATED) Display plots of variables and responses

Topics

This keyword is related to the topics:

- dakota_output

Specification

Alias: none

Argument(s): none

Default: graphics off

Description

Activate Dakota’s legacy X Windows-based graphics feature. Dakota plotting and visualization capabilities are increasingly available in the Dakota graphical user interface (GUI); see the Dakota GUI User Manual in the documentation section of the Dakota website for additional details.

The graphics flag activates a 2D graphics window containing history plots for the variables and response functions in the study. This window is updated approximately every two seconds. Some study types such as surrogate-based optimization or local reliability specialize the use of the graphics window.
There is no dependence between the `graphics flag` and the `tabular_data flag`; they may be used independently or concurrently.

**See Also**

These keywords may also be of interest:

- `tabular_data`

### 7.1.9 check

- Keywords Area
- environment
- check

Invoke Dakota in input check mode

**Topics**

This keyword is related to the topics:

- `command_line_options`

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** no check; proceed to run

**Description**

When specified, Dakota input will be parsed and the problem instantiated. Dakota will exit reporting whether any errors were found.

### 7.1.10 pre_run

- Keywords Area
- environment
- `pre_run`

Invoke Dakota with pre-run mode active

**Topics**

This keyword is related to the topics:

- `command_line_options`
Specification

**Alias:** none

**Argument(s):** none

**Default:** pre-run, run, post-run all executed

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>input</td>
<td>Base filename for pre-run mode data input</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>output</td>
<td>Base filename for pre-run mode data output</td>
</tr>
</tbody>
</table>

**Description**

When specified, Dakota execution will include the pre-run mode, which sets up methods and often generates parameter sets to evaluate. This mode is currently useful for parameter study, DACE, and Monte Carlo sampling methods.

**Default Behavior**

When no run modes are specified, Dakota will perform pre-run, run, and post-run phases.

7.1.10.1 input

- **Keywords Area**

- **environment**

- **pre_run**

- **input**

Base filename for pre-run mode data input

**Topics**

This keyword is related to the topics:

- **dakota_IO**

**Specification**

**Alias:** none

**Argument(s):** STRING

**Default:** no pre-run specific input read

---

Dakota Version 6.16 Reference Manual generated on May 12, 2022
Description

(For future expansion; not currently used by any methods.) Specify a base filename from which Dakota will read any pre-run input data. This option is overridden by any command-line -pre_run arguments.

7.1.10.2 output

- Keywords Area
- environment
- pre_run
- output

Base filename for pre-run mode data output

Topics

This keyword is related to the topics:

- dakota_IO

Specification

Alias: none

Argument(s): STRING

Default: no pre-run specific output written

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group Tabular Format (Group 1)</th>
<th>Dakota Keyword custom_annotated</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>

<td>annotated</td>
<td>Selects annotated tabular file format</td>
<td></td>
</tr>
<tr>
<td></td>
<td>freeform</td>
<td>Selects freeform file format</td>
<td></td>
</tr>
</tbody>
</table>

Description

Specify a base filename to which Dakota will write any pre-run output data (typically parameter sets to be evaluated). This option is overridden by any command-line -pre_run arguments.

Usage Tips

Dakota exports tabular data in one of three formats:

- annotated (default)
- custom_annotated
- freeform
7.1.10.2.1 custom.annotated

- Keywords Area
- environment
- pre_run
- output
- custom.annotated

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>header</td>
<td>custom.annotated format</td>
<td>Enable header row in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td>eval_id</td>
<td>custom.annotated format</td>
<td>Enable evaluation ID column in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td>interface_id</td>
<td>custom.annotated format</td>
<td>Enable interface ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom.annotated, followed by options, in the relevant export/import context.

Usage Tips
Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```plaintext
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id  x1  x2  obj_fn  nln_ineq_con_1  nln_ineq_con_2
1  0.9  1.1  0.0002  0.26  0.76
2  0.90009  1.1  0.0001996404857  0.2601620081  0.759955
3  0.89991  1.1  0.0002003604863  0.2598380081  0.760045
...```

7.1.10.2.1.1 header

- Keywords Area
- environment

**Argument(s):** none

**Default:** no header

Description

See description of parent custom_annotated

7.1.10.2.1.2 eval_id

- Keywords Area
- environment
- pre_run
Enable evaluation ID column in custom-annotated tabular file

**Specification**

**Alias**: none

**Argument(s)**: none

**Default**: no eval_id column

**Description**

See description of parent `custom_annotated`  

7.1.10.2.1.3 interface_id

Enable interface ID column in custom-annotated tabular file

**Specification**

**Alias**: none

**Argument(s)**: none

**Default**: no interface_id column

**Description**

See description of parent `custom_annotated`  

7.1.10.2.2 annotated

Selects annotated tabular file format
7.1 environment

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
annotated
```

Resulting tabular file:

```
%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 NO_ID 0.9 1.1 0.0002 0.26 0.76
2 NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 NO_ID 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...```
7.1.10.2.3 freeform

- Keywords Area
- environment
- pre_run
- output
- freeform

Selects freeform file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none
Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:
environment
tabular_data
  tabular_data_file = 'dakota_summary.dat'
freeform

Resulting tabular file:

<p>| | | | | |</p>
<table>

Default: see discussion

Description

An optional top_method_pointer specification may be used to point to a particular method specification that will lead the Dakota analysis. The associated string must be a method identifier specified via id_method. If top_method_pointer is not used, then it will be inferred as described below (no top_method_pointer within an environment specification is treated the same as no environment specification).

Default Behavior

The top_method_pointer keyword is typically used in Dakota studies consisting of more than one method block to clearly indicate which is the leading method. This method provides the starting point for the iteration. The corresponding method specification may recurse with additional sub-method pointers in the case of "meta-iteration" (see method) or may specify a single method without recursion. Either case will ultimately result in identification
of one or more model specifications using `model_pointer`, which again may or may not involve further recursion (see `nested` and `surrogate` for recursion cases). Each of the model specifications identify the variables and responses specifications (using `variables_pointer` and `responses_pointer`) that are used to build the model, and depending on the type of model, may also identify an interface specification (for example, using `interface_pointer`). If one of these specifications does not provide an optional pointer, then that component will be constructed using the last specification parsed.

When the environment block is omitted, the top level method will be inferred as follows: When a single method is specified, there is no ambiguity and the sole method will be the top method. When multiple methods are specified, the top level method will be deduced from the hierarchical relationships implied by method pointers. If this inference is not well defined (e.g., there are multiple method specifications without any pointer relationship), then the default behavior is to employ the last method specification parsed.

### Examples

Specify that the optimization method is the outermost method in an optimization under uncertainty study

```plaintext
environment
  top_method_pointer 'OPTIMIZATION_METHOD'
method
  id_method 'UQ_METHOD'
...
method
  id_method 'OPTIMIZATION_METHOD'
...
```

**Description**

The `method` keyword signifies the start of a block in the Dakota input file. A method block contains the various keywords necessary to select a method and to control its behavior.

**Method Block Requirements**

At least one `method` block must appear in the Dakota input file. Multiple `method` blocks may be needed to fully define advanced analysis approaches.

Each `method` block must specify one method and, optionally, any associated keywords that govern the behavior of the method.

**The Methods**

Each `method` block must select one method.

Starting with Dakota v6.0, the methods are grouped into two types: standard methods and multi-component methods.

The standard methods are stand-alone and self-contained in the sense that they only require a model to perform a study. They do not call other methods. While methods such as `polynomial_chaos` and `efficient_global` internally utilize multiple iterator and surrogate model components, these components are generally hidden from user control due to restrictions on modularity; thus, these methods are stand-alone.

The multi-component group of methods provides a higher level "meta-algorithm" that points to other methods and models that support sub-iteration. For example, in a sequential hybrid method, the `hybrid` method specification must identify a list of subordinate methods, and the "meta-algorithm" executes these methods in sequence and transfers information between them. Surrogate-based minimizers provide another example in that they point both to other methods (e.g., what optimization method is used to solve the approximate subproblem) as well as to models (e.g., what type of surrogate model is employed). Multi-component methods generally provide some level of "plug and play" modularity, through their flexible support of a variety of method and model selections.

**Component-Based Iterator Commands**

Component-based iterator specifications include hybrid, multi-start, pareto set, surrogate-based local, surrogate-based global, and branch and bound methods. Whereas a standard iterator specification only needs an optional model pointer string (specified with `model_pointer`), component-based iterator specifications can include method pointer, method name, and model pointer specifications in order to define the components employed in the "meta-iteration." In particular, these specifications identify one or more methods (by pointer or by name) to specify the subordinate iterators that will be used in the top-level algorithm. Identifying a sub-iterator by name instead of by pointer is a lightweight option that relaxes the need for a separate method specification for the sub-iterator; however, a model pointer may be required in this case to provide the specification connectivity normally supported by the method pointer. Refer to these individual method descriptions for specific requirements for these advanced methods.

**Method Independent Controls**

In addition to the method, there are 10 optional keywords, which are referred to as method independent controls. These controls are valid for enough methods that it was reasonable to pull them out of the method dependent blocks.
and consolidate the specifications, however, they are NOT universally respected by all methods.

Examples

Several examples follow. The first example shows a minimal specification for an optimization method.

```
method
dot_sqp
```

This example uses all of the defaults for this method.

A more sophisticated example would be

```
method,  
id_method = 'NLP1'  
dot_sqp
    max_iterations = 50  
    convergence_tolerance = 1e-4  
    output verbose
    model_pointer = 'M1'
```

This example demonstrates the use of identifiers and pointers as well as some method independent and method dependent controls for the sequential quadratic programming (SQP) algorithm from the DOT library. The `max_iterations`, `convergence_tolerance`, and `output` settings are method independent controls, in that they are defined for a variety of methods.

The next example shows a specification for a least squares method.

```
method
    optpp_g_newton
        max_iterations = 10
        convergence_tolerance = 1.e-8
        search_method trust_region
        gradient_tolerance = 1.e-6
```

Some of the same method independent controls are present along with several method dependent controls (`search_method` and `gradient_tolerance`) which are only meaningful for OPT++ methods (see `package_optpp`).

The next example shows a specification for a nondeterministic method with several method dependent controls (refer to `sampling`).

```
method
    sampling
        samples = 100
        seed = 12345
        sample_type lhs
        response_levels = 1000. 500.
```

The last example shows a specification for a parameter study method where, again, each of the controls are method dependent (refer to `vector_parameter_study`).

```
method
    vector_parameter_study
        step_vector = 1. 1. 1.
        num_steps = 10
```

7.2.1 id_method

- Keywords Area
- method
- id_method

Name the method block; helpful when there are multiple
7.2 method

Topics

This keyword is related to the topics:

- block_identifier
- method_independent_controls

Specification

Alias: none

Argument(s): STRING

Default: strategy use of last method parsed

Description

The method identifier string is supplied with id_method and is used to provide a unique identifier string for use with environment or meta-iterator specifications (refer to environment). It is appropriate to omit a method identifier string if only one method is included in the input file, since the single method to use is unambiguous in this case.

7.2.2 output

- Keywords Area
- method
- output

Control how much method information is written to the screen and output file

Topics

This keyword is related to the topics:

- dakota_output
- method_independent_controls

Specification

Alias: none

Argument(s): none

Default: normal

<td>Group 1</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Dakota Version 6.16 Reference Manual generated on May 12, 2022
## Description

Choose from a total of five output levels during the course of a Dakota study. If there is no user specification for output verbosity, then the default setting is **normal**.

Specific mappings are as follows:

- **silent** (i.e., really quiet): silent iterators, silent model, silent interface, quiet approximation, quiet file operations
- **quiet**: quiet iterators, quiet model, quiet interface, quiet approximation, quiet file operations
- **normal**: normal iterators, normal model, normal interface, quiet approximation, quiet file operations
- **verbose**: verbose iterators, normal model, verbose interface, verbose approximation, verbose file operations
- **debug** (i.e., really verbose): debug iterators, normal model, debug interface, verbose approximation, verbose file operations

Note that iterators and interfaces utilize the full granularity in verbosity, whereas models, approximations, and file operations do not. With respect to iterator verbosity, different iterators implement this control in slightly different ways (as described below in the method independent controls descriptions for each iterator), however the meaning is consistent.

For models, interfaces, approximations, and file operations, **quiet** suppresses parameter and response set reporting and **silent** further suppresses function evaluation headers and scheduling output. Similarly, **verbose** adds file management, approximation evaluation, and global approximation coefficient details, and **debug** further adds diagnostics from nonblocking schedulers.

### 7.2.2.1 debug

- **Keywords Area**
- **method**
- **output**
- **debug**

**Level 5 of 5 - maximum**

### Specification

**Alias**: none

### 7.2.3 final_solutions

- **Keywords Area**
- **method**
- **final_solutions**

Number of designs returned as the best solutions

Topics

This keyword is related to the topics:

- **method_independent_controls**

Specification

**Alias:** none  
**Argument(s):** INTEGER

**Default:** 1
7.2 method

Description

The `final_solutions` controls the number of final solutions returned by the iterator as the best solutions. For most optimizers, this is one, but some optimizers can produce multiple solutions (e.g. genetic algorithms). When using a `hybrid` strategy, the number of final solutions dictates how many solutions are passed from one method to another.

Examples

In the case of sampling methods, if one specifies 100 samples (for example) but also specifies `final_solutions = 5`, the five best solutions (in order of lowest response function value) are returned.

7.2.4 hybrid

- Keywords Area
  - method
  - hybrid

Strategy in which a set of methods synergistically seek an optimal design

Specification

Alias: none

Argument(s): none

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required (Choose One)</td>
<td>Hybrid Method Type (Group 1)</td>
<td>sequential</td>
<td>Methods are run one at a time, in sequence</td>
</tr>
<tr>
<td></td>
<td></td>
<td>embedded</td>
<td>A subordinate local method provides periodic refinements to a top-level global method</td>
</tr>
<tr>
<td></td>
<td></td>
<td>collaborative</td>
<td>Multiple methods run concurrently and share information</td>
</tr>
</tbody>
</table>

Description

In a hybrid minimization method (`hybrid`), a set of methods synergistically seek an optimal design. The relationships among the methods are categorized as:

- collaborative
- embedded
- sequential
The goal in each case is to exploit the strengths of different optimization and nonlinear least squares algorithms at different stages of the minimization process. Global + local hybrids (e.g., genetic algorithms combined with nonlinear programming) are a common example in which the desire for identification of a global optimum is balanced with the need for efficient navigation to a local optimum.

7.2.4.1 sequential

- **Keywords Area**
- **method**
- **hybrid**
- **sequential**

Methods are run one at a time, in sequence

**Specification**

**Alias:** uncoupled

**Argument(s):** none

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required (Choose One)</td>
<td>Sub-method Selection (Group 1)</td>
<td>method_name_list</td>
<td>List of Dakota methods to sequentially or collaboratively run</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>method_pointer_list</td>
<td>Pointers to methods to execute sequentially or collaboratively</td>

</tr>
<tr>
<td>Optional</td>
<td></td>
<td>processors_per_iterator</td>
<td>Specify the number of processors per iterator server when Dakota is run in parallel</td>
</tr>
</tbody>
</table>

**Description**

In the **sequential** approach, methods are run one at a time, in sequence. The best solutions from one method are used to initialize the next method.

The sequence of methods (i.e., iterators) to run are specified using either a method_pointer_list or a method_name_list (with optional model_pointer_list). Any number of iterators may be specified.

Method switching is managed through the separate convergence controls of each method. The number of solutions transferred between methods is specified by the particular method through its final_solutions method control.
For example, if one sets up a two-level study with a first method that generates multiple solutions such as a genetic algorithm, followed by a second method that is initialized only at a single point such as a gradient-based algorithm, it is possible to take the multiple solutions generated by the first method and create several instances of the second method, each one with a different initial starting point.

The logic governing the transfer of multiple solutions between methods is as follows:

- if one solution is returned from method A, then one solution is transferred to method B.
- If multiple solutions are returned from method A, and method B can accept multiple solutions as input (for example, as a genetic algorithm population), then one instance of method B is initialized with multiple solutions.
- If multiple solutions are returned from method A but method B only can accept one initial starting point, then method B is run several times, each one with a separate starting point from the results of method A.

7.2.4.1.1 method_name_list

- Keywords Area
- method
- hybrid
- sequential
- method_name_list

List of Dakota methods to sequentially or collaboratively run

Specification

Alias: none

Argument(s): STRINGLIST

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>model_pointer_list</td>
<td></td>
<td>Associate models with method names</td>
</tr>
</tbody>
</table>

Description

method_name_list specifies a list of Dakota methods (e.g. soga, conmin_frcg) that will be run by a hybrid sequential or hybrid collaborative method. The methods are executed with default options. The optional model_pointer_list may be used to associate a model with each method.

7.2.4.1.1.1 model_pointer_list

- Keywords Area
- method
- hybrid
- sequential
- method_name_list
- model_pointer_list

Associate models with method names
Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none

Argument(s): STRINGLIST

Description

Using the optional keyword model_pointer_list, models can be assigned to methods specified in the method_name_list. Models are referred to by name (i.e. by their id_model labels). The length of the model_pointer_list must be either 1 or match the length of the method_name_list. If the former, the same model will be used for all methods, and if the latter, methods and models will be paired in the order that they appear in the two lists.

7.2.4.1.2 method_pointer_list

- Keywords Area

- method

- hybrid

- sequential

- method_pointer_list

Pointers to methods to execute sequentially or collaboratively

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none

Argument(s): STRINGLIST

Description

method_pointer_list specifies by name the methods that are to be executed by a hybrid sequential or hybrid collaborative method. Its argument is a list of strings that refer to method blocks by name (i.e. to their id_method labels).
### 7.2.4.1.3 iterator_servers

- **Keywords Area**
- **method**
- **hybrid**
- **sequential**
- **iterator_servers**

Specify the number of iterator servers when Dakota is run in parallel.

**Topics**

This keyword is related to the topics:

- **concurrency_and_parallelism**

**Specification**

**Alias:** none  
**Argument(s):** INTEGER

**Description**

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional `iterator_servers` specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, `hybrid`, `multi_start`, and `pareto_set` component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [5] for additional information.

### 7.2.4.1.4 iterator_scheduling

- **Keywords Area**
- **method**
- **hybrid**
- **sequential**
- **iterator_scheduling**

Specify the scheduling of concurrent iterators when Dakota is run in parallel.

**Topics**

This keyword is related to the topics:

- **concurrency_and_parallelism**
Specification

Alias: none
Argument(s): none
Child Keywords:
<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group Scheduling Mode (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>

<td>peer</td>
<td>Specify a peer partition for parallel iterator scheduling</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional `iterator_scheduling` specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, `hybrid`, `multi_start`, and `pareto_set` component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [5] for additional information.

#### 7.2.4.1.4.1 master

- **Keywords Area**
- **method**
- **hybrid**
- **sequential**
- **iterator_scheduling**
- **master**

Specify a dedicated master partition for parallel iterator scheduling

### Topics

This keyword is related to the topics:

- **concurrency_and_parallelism**

### Specification

**Alias**: none

**Argument(s)**: none

### Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a dedicated master partition. In a dedicated master partition, one processor (the "master") dynamically schedules work on the iterator servers. This reduces the number of processors available to create servers by 1.
7.2.4.1.4.2 peer

Specify a peer partition for parallel iterator scheduling

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none
Argument(s): none

Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a peer partition. In a peer partition, all processors are available to be assigned to iterator servers. Note that unlike the case of evaluation_scheduling, it is not possible to specify static or dynamic.

7.2.4.1.5 processors_per_iterator

Specify the number of processors per iterator server when Dakota is run in parallel

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none
Argument(s): INTEGER
7.2 method

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional processors_per_iterator specification supports user override of the automatic parallel configuration for the number of processors in each iterator server. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired server size at the iterator parallelism level. Currently, hybrid, multi_start, and pareto_set component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [5] for additional information.

7.2.4.2 embedded

- Keywords Area
- method
- hybrid
- embedded

A subordinate local method provides periodic refinements to a top-level global method

Specification

Alias: coupled

Argument(s): none

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required (Choose One)</td>

<td>Specify the number of iterator servers when Dakota is run in parallel</td>
<td></td>
</tr>
<tr>
<td>Optional</td>
<td>iterator_scheduling</td>
<td>Specify the scheduling of concurrent iterators when Dakota is run in parallel</td>
<td></td>
</tr>
</tbody>
</table>
Description

In the embedded approach, a tightly-coupled hybrid is employed in which a subordinate local method provides periodic refinements to a top-level global method.

Global and local method strings supplied with the `global_method_pointer` and `local_method_pointer` specifications identify the two methods to be used. Alternatively, Dakota method names (e.g. ‘soga’) can be supplied using the `global_method_name` and `local_method_name` keywords, which each have optional model pointer specifications. The `local_search_probability` setting is an optional specification for supplying the probability (between 0.0 and 1.0) of employing local search to improve estimates within the global search.

### 7.2.4.2.1 global_method_name

- **Keywords Area**
- **method**
- **hybrid**
- **embedded**
- **global_method_name**

Specify the global method by Dakota name

**Specification**

**Alias**: none

**Argument(s)**: STRING

**Child Keywords**:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>global_model_pointer</td>
<td>Pointer to model used by global method</td>
</tr>
</tbody>
</table>

**Description**

global_method_name is used to specify the global method in a hybrid embedded optimization by Dakota name (e.g. ‘soga’). The name of the method is provided as a string. The method is executed with default options.

### 7.2.4.2.1.1 global_model_pointer

- **Keywords Area**
- **method**
- **hybrid**
- **embedded**
7.2 method

- global_method_name
- global_model_pointer

Pointer to model used by global method

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none
Argument(s): STRING

Description

global_model_pointer can be used to specify a model for use with the Dakota method named by the global_method_name specification. The argument is a string that refers to the id_model label of the desired model.

7.2.4.2.2 global_method_pointer

- Keywords Area
- method
- hybrid
- embedded
- global_method_pointer

Pointer to global method

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none
Argument(s): STRING

Description

The global_method_pointer identifies the method block to use as the global method in a hybrid embedded optimization using its id_method label.
7.2.4.2.3 local_method_name

- Keywords Area
- method
- hybrid
- embedded
- local_method_name

Specify the local method by Dakota name

**Specification**

**Alias:** none

**Argument(s):** STRING

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>local_method_pointer</td>
<td></td>
<td>Pointer to model used by local method</td>
</tr>
</tbody>
</table>

**Description**

`local_method_name` is used to specify the local method in a hybrid embedded optimization by Dakota name (e.g. `conmin_mfd`). The name of the method is provided as a string. The method is executed with default options.

7.2.4.2.3.1 local_model_pointer

- Keywords Area
- method
- hybrid
- embedded
- local_method_name
- local_model_pointer

Pointer to model used by local method

**Topics**

This keyword is related to the topics:

- `block_pointer`

**Specification**

**Alias:** none

**Argument(s):** STRING
7.2 method

Description

`local_model_pointer` can be used to specify a model for use with the Dakota method named by the `local_method_name` specification. The argument is a string that refers to the `id_model` label of the desired model.

7.2.4.2.4 local_method_pointer

- Keywords Area
  - method
  - hybrid
  - embedded
  - local_method_pointer

Pointer to local method

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none

Argument(s): STRING

Description

The `local_method_pointer` identifies the method block to use as the local method in a hybrid embedded optimization using its `id_method`

7.2.4.2.5 local_search_probability

- Keywords Area
  - method
  - hybrid
  - embedded
  - local_search_probability

Probability of executing local searches

Specification

Alias: none

Argument(s): REAL
Description

The `local_search_probability` setting is an optional specification for supplying the probability (between 0.0 and 1.0) of employing local search to improve estimates within the global search. Its default value is 0.1.

7.2.4.2.6 iterator_servers

- Keywords Area
- method
- hybrid
- embedded
- iterator_servers

Specify the number of iterator servers when Dakota is run in parallel

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none

Argument(s): INTEGER

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional `iterator_servers` specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, hybrid, multi_start, and pareto_set component-based iterators support concurrency in their sub-iterations. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [5] for additional information.

7.2.4.2.7 iterator_scheduling

- Keywords Area
- method
- hybrid
- embedded
- iterator_scheduling

Specify the scheduling of concurrent iterators when Dakota is run in parallel

Topics

This keyword is related to the topics:

- concurrency_and_parallelism
7.2 method

Specification

**Alias:** none

**Argument(s):** none

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>

<td>master</td>
<td>Specify a dedicated master partition for parallel iterator scheduling</td>
</tr>
<tr>
<td>peer</td>
<td>Specify a peer partition for parallel iterator scheduling</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Description**

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional `iterator_scheduling` specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, `hybrid`, `multi_start`, and `pareto_set` component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [5] for additional information.

7.2.4.2.7.1 master

- Keywords Area
- method
- hybrid
- embedded
- `iterator_scheduling`
- `master`

Specify a dedicated master partition for parallel iterator scheduling

**Topics**

This keyword is related to the topics:

- `concurrency_and_parallelism`

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

This option overrides the Dakota parallel automatic configuration, forcing the use of a dedicated master partition. In a dedicated master partition, one processor (the "master") dynamically schedules work on the iterator servers. This reduces the number of processors available to create servers by 1.
7.2.4.2.7.2 peer

- Keywords Area
- method
- hybrid
- embedded
- iterator_scheduling
- peer

Specify a peer partition for parallel iterator scheduling

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none
Argument(s): none

Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a peer partition. In a peer partition, all processors are available to be assigned to iterator servers. Note that unlike the case of evaluation_scheduling, it is not possible to specify static or dynamic.

7.2.4.2.8 processors_per_iterator

- Keywords Area
- method
- hybrid
- embedded
- processors_per_iterator

Specify the number of processors per iterator server when Dakota is run in parallel

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none
Argument(s): INTEGER
Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional \texttt{processors\_per\_iterator} specification supports user override of the automatic parallel configuration for the number of processors in each iterator server. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired server size at the iterator parallelism level. Currently, \texttt{hybrid}, \texttt{multi\_start}, and \texttt{pareto\_set} component-based iterators support concurrency in their sub-iterators. Refer to \texttt{ParallelLibrary} and the Parallel Computing chapter of the Users Manual [5] for additional information.

### 7.2.4.3 collaborative

- **Keywords Area**
  - method
  - hybrid
  - collaborative

Multiple methods run concurrently and share information

**Specification**

**Alias:** none

**Argument(s):** none

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Required (Choose One)</strong></td>
<td>Sub-method Selection (Group 1)</td>
<td>\texttt{method_name_list} \texttt{method_pointer_list}</td>
<td>List of Dakota methods to sequentially or collaboratively run</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>\texttt{method_pointer_list}</td>
<td>Pointers to methods to execute sequentially or collaboratively</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>\texttt{iterator_servers}</td>
<td>Specify the number of iterator servers when Dakota is run in parallel</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>\texttt{iterator_scheduling}</td>
<td>Specify the scheduling of concurrent iterators when Dakota is run in parallel</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>\texttt{processors_per_iterator}</td>
<td>Specify the number of processors per iterator server when Dakota is run in parallel</td>
</tr>
</tbody>
</table>

**Description**

In the collaborative approach, multiple methods work together and share solutions while executing concurrently. A list of method strings specifies the pool of iterators to be used. Any number of iterators may be specified. The
method collaboration logic follows that of either the Agent-Based Optimization or HOPSPACK codes and is currently under development and not available at this time.

### 7.2.4.3.1 method_name_list

- **Keywords Area**
- **method**
- **hybrid**
- **collaborative**
- **method_name_list**

List of Dakota methods to sequentially or collaboratively run

**Specification**

**Alias:** none

**Argument(s):** STRINGLIST

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>model_pointer_list</td>
<td>Associate models with method names</td>
</tr>
</tbody>
</table>

**Description**

`method_name_list` specifies a list of Dakota methods (e.g. `soga, conmin_frcg`) that will be run by a hybrid sequential or hybrid collaborative method. The methods are executed with default options. The optional `model_pointer_list` may be used to associate a model with each method.

### 7.2.4.3.1.1 model_pointer_list

- **Keywords Area**
- **method**
- **hybrid**
- **collaborative**
- **method_name_list**
- **model_pointer_list**

Associate models with method names

**Topics**

This keyword is related to the topics:

- block_pointer
7.2 method

Specification

Alias: none
Argument(s): STRINGLIST

Description

Using the optional keyword model_pointer_list, models can be assigned to methods specified in the method_name_list. Models are referred to by name (i.e. by their id_model labels). The length of the model_pointer_list must be either 1 or match the length of the method_name_list. If the former, the same model will be used for all methods, and if the latter, methods and models will be paired in the order that they appear in the two lists.

7.2.4.3.2 method_pointer_list

• Keywords Area
  • method
  • hybrid
  • collaborative
  • method_pointer_list

Pointers to methods to execute sequentially or collaboratively

Topics

This keyword is related to the topics:

• block_pointer

Specification

Alias: none
Argument(s): STRINGLIST

Description

method_pointer_list specifies by name the methods that are to be executed by a hybrid sequential or hybrid collaborative method. Its argument is a list of strings that refer to method blocks by name (i.e. to their id_method labels).

7.2.4.3.3 iterator_servers

• Keywords Area
  • method
  • hybrid
  • collaborative
  • iterator_servers

Specify the number of iterator servers when Dakota is run in parallel
Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none

Argument(s): INTEGER

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional iterator_servers specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, hybrid, multi_start, and pareto_set component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [5] for additional information.

7.2.4.3.4 iterator_scheduling

- Keywords Area
- method
- hybrid
- collaborative
- iterator_scheduling

Specify the scheduling of concurrent iterators when Dakota is run in parallel

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none

Argument(s): none

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group Scheduling Mode (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required (Choose One)</td>
<td>master</td>
<td>master</td>
<td>Specify a dedicated master partition for parallel iterator scheduling</td>
</tr>
</tbody>
</table>
Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional `iterator_scheduling` specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, `hybrid`, `multi_start`, and `pareto_set` component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [5] for additional information.

7.2.4.3.4.1 master

**Keywords Area**

- method
- hybrid
- collaborative
- iterator_scheduling
- master

Specify a dedicated master partition for parallel iterator scheduling

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

**Alias:** none

**Argument(s):** none

Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a dedicated master partition. In a dedicated master partition, one processor (the "master") dynamically schedules work on the iterator servers. This reduces the number of processors available to create servers by 1.

7.2.4.3.4.2 peer

**Keywords Area**

- method
- hybrid
- collaborative
- iterator_scheduling
Specify a peer partition for parallel iterator scheduling

This keyword is related to the topics:

- concurrency_and_parallelism

### Specification

**Alias:** none

**Argument(s):** none

**Description**

This option overrides the Dakota parallel automatic configuration, forcing the use of a peer partition. In a peer partition, all processors are available to be assigned to iterator servers. Note that unlike the case of evaluation_scheduling, it is not possible to specify static or dynamic.

#### 7.2.4.3.5 processors_per_iterator

- Keywords Area
- method
- hybrid
- collaborative
- processors_per_iterator

Specify the number of processors per iterator server when Dakota is run in parallel

This keyword is related to the topics:

- concurrency_and_parallelism

### Specification

**Alias:** none

**Argument(s):** INTEGER

**Description**

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional processors_per_iterator specification supports user override of the automatic parallel configuration for the number of processors in each iterator server. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired server size at the iterator parallelism level. Currently, hybrid, multi_start, and pareto_set component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [5] for additional information.

</tr>
<tr>
<td>Optional</td>
<td></td>
<td>processors_per_iterator</td>
<td>Specify the number of processors per iterator server when Dakota is run in parallel</td>
</tr>
</tbody>
</table>

**Description**

In the multi-start iteration method (multi_start), a series of iterator runs are performed for different values of parameters in the model. A common use is for multi-start optimization (i.e., different local optimization runs from different starting points for the design variables), but the concept and the code are more general. Multi-start iteration is implemented within the MetaIterator branch of the Iterator hierarchy within the ConcurrentMetaIterator class. Additional information on the multi-start algorithm is available in the Users Manual [5].

The multi_start meta-iterator must specify a sub-iterator using either a method_pointer or a method_name plus optional model_pointer. This iterator is responsible for completing a series of iterative analyses from a set of different starting points. These starting points can be specified as follows: (1) using random_starts, for which the specified number of starting points are selected randomly within the variable bounds, (2)
using `starting_points`, in which the starting values are provided in a list, or (3) using both `random_starts` and `starting_points`, for which the combined set of points will be used. In aggregate, at least one starting point must be specified. The most common example of a multi-start algorithm is multi-start optimization, in which a series of optimizations are performed from different starting values for the design variables. This can be an effective approach for problems with multiple minima.

**Expected HDF5 Output**

If Dakota was built with HDF5 support and run with the `hdf5` keyword, this method writes the starting points for each sub-iterator it runs, as well as the best parameters and responses returned by each sub-iterator. See the Multistart and Pareto Set documentation for details.

### 7.2.5.1 `method_name`

- **Keywords Area**
- **method**
- **multi_start**
- **method_name**

Specify sub-method by name

**Specification**

**Alias:** none

**Argument(s):** STRING

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td><code>model_pointer</code></td>
<td>Identifier for model block to be used by a method</td>
</tr>
</tbody>
</table>

**Description**

The `method_name` keyword is used to specify a sub-method by Dakota method name (e.g. `npsol_sqp`) rather than block pointer. The method will be executed using its default settings. The optional `model_pointer` specification can be used to associate a model block with the method.

### 7.2.5.1.1 `model_pointer`

- **Keywords Area**
- **method**
- **multi_start**
- **method_name**
- **model_pointer**

Identifier for model block to be used by a method
Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.

See block_pointer for details about pointers.

Examples

```dakota
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
      0.1 0.2 0.6
      0.1 0.2 0.6
    sample_type lhs
    distribution cumulative

model
  id_model = 'SURR'
    surrogate global,
    dace_method_pointer = 'DACE'
    polynomial quadratic

method
  id_method = 'DACE'
  model_pointer = 'DACE_M'
  sampling sample_type lhs
    samples = 121 seed = 5034 rng rnum2

model
  id_model = 'DACE_M'
    single
    interface_pointer = 'I1'
```
variables
uniform_uncertain = 2
lower_bounds = 0. 0.
upper_bounds = 1. 1.
descriptors = 'x1' 'x2'

no_hessians

7.2.5.2 method_pointer

- Keywords Area
- method
- multi_start
- method_pointer

Pointer to sub-method to run from each starting point

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none
Argument(s): STRING

Description

The method_pointer keyword is used to specify a pointer to the sub-method block that will be run from each starting point.

7.2.5.3 random_starts

- Keywords Area
- method
- multi_start
- random_starts

Number of random starting points
7.2 method

Specification

**Alias:** none

**Argument(s):** INTEGER

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional Group</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>seed</td>
<td>Seed of the random number generator</td>
</tr>
</tbody>
</table>

Description

The `multi_start` meta-iterator must specify a sub-iterator using either a `method_pointer` or a `method_name` plus optional `model_pointer`. This iterator is responsible for completing a series of iterative analyses from a set of different starting points. These starting points can be specified as follows: (1) using `random_starts`, for which the specified number of starting points are selected randomly within the variable bounds, (2) using `starting_points`, in which the starting values are provided in a list, or (3) using both `random_starts` and `starting_points`, for which the combined set of points will be used.

7.2.5.3.1 seed

- Keywords Area
- method
- `multi_start`
- `random_starts`
- `seed`

Seed of the random number generator

Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** system-generated (non-repeatable)

Description

The random `seed` control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

**Default Behavior**

If not specified, the seed is randomly generated.

**Expected Output**

If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

**Usage Tips**

If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Dakota Version 6.16 Reference Manual generated on May 12, 2022
Examples

```
method
    sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

7.2.5.4 starting_points

- Keywords Area
- method
- multi_start
- starting_points

List of user-specified starting points

Specification

**Alias**: none

**Argument(s)**: REALLIST

**Description**

The `multi_start` meta-iterator must specify a sub-iterator using either a `method_pointer` or a `method_name` plus optional `model_pointer`. This iterator is responsible for completing a series of iterative analyses from a set of different starting points. These starting points can be specified as follows: (1) using `random_starts`, for which the specified number of starting points are selected randomly within the variable bounds, (2) using `starting_points`, in which the starting values are provided in a list, or (3) using both `random_starts` and `starting_points`, for which the combined set of points will be used.

7.2.5.5 iterator_servers

- Keywords Area
- method
- multi_start
- iterator_servers

Specify the number of iterator servers when Dakota is run in parallel

**Topics**

This keyword is related to the topics:

- `concurrency_and_parallelism`

**Specification**

**Alias**: none

**Argument(s)**: INTEGER
Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional `iterator_servers` specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, `hybrid`, `multi_start`, and `pareto_set` component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [5] for additional information.

7.2.5.6 `iterator_scheduling`

- **Keywords Area**
  - `method`
  - `multi_start`
  - `iterator_scheduling`

Specify the scheduling of concurrent iterators when Dakota is run in parallel

**Topics**

This keyword is related to the topics:

- `concurrency_and_parallelism`

**Specification**

**Alias**: none

**Argument(s)**: none

**Child Keywords**:

<table>
<thead>
<tr>
<th>Required/Optional Required <em>(Choose One)</em></th>
<th>Description of Group Scheduling Mode <em>(Group 1)</em></th>

<td></td>
<td><code>peer</code></td>
<td>Specify a peer partition for parallel iterator scheduling</td>
</tr>
</tbody>
</table>

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional `iterator_scheduling` specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, `hybrid`, `multi_start`, and `pareto_set` component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [5] for additional information.
7.2.5.6.1 master

- Keywords Area
- method
- multi_start
- iterator_scheduling
- master

Specify a dedicated master partition for parallel iterator scheduling

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none

Argument(s): none

Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a dedicated master partition. In a dedicated master partition, one processor (the "master") dynamically schedules work on the iterator servers. This reduces the number of processors available to create servers by 1.

7.2.5.6.2 peer

- Keywords Area
- method
- multi_start
- iterator_scheduling
- peer

Specify a peer partition for parallel iterator scheduling

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none

Argument(s): none
7.2 method

Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a peer partition. In a peer partition, all processors are available to be assigned to iterator servers. Note that unlike the case of evaluation_scheduling, it is not possible to specify static or dynamic.

7.2.5.7 processors_per_iterator

- Keywords Area
- method
- multi_start
- processors_per_iterator

Specify the number of processors per iterator server when Dakota is run in parallel

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none

Argument(s): INTEGER

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional processors_per_iterator specification supports user override of the automatic parallel configuration for the number of processors in each iterator server. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired server size at the iterator parallelism level. Currently, hybrid, multi_start, and pareto_set component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [5] for additional information.

7.2.6 pareto_set

- Keywords Area
- method
- pareto_set

Pareto set optimization

Specification

Alias: none

Argument(s): none

Child Keywords:
### Description

In the pareto set minimization method (pareto_set), a series of optimization or least squares calibration runs are performed for different weightings applied to multiple objective functions. This set of optimal solutions defines a "Pareto set," which is useful for investigating design trade-offs between competing objectives. The code is similar enough to the multi_start technique that both algorithms are implemented in the same ConcurrentMetaIterator class.

The pareto_set specification must identify an optimization or least squares calibration method using either a method_pointer or a method_name plus optional model_pointer. This minimizer is responsible for computing a set of optimal solutions from a set of response weightings (multi-objective weights or least squares term weights). These weightings can be specified as follows: (1) using random_weight_sets, in which case weightings are selected randomly within [0,1] bounds, (2) using weight_sets, in which the weighting sets are specified in a list, or (3) using both random_weight_sets and weight_sets, for which the combined set of weights will be used. In aggregate, at least one set of weights must be specified. The set of optimal solutions is called the "pareto set," which can provide valuable design trade-off information when there are competing objectives.

### Expected HDF5 Output

If Dakota was built with HDF5 support and run with the hdf5 keyword, this method writes the best parameters and responses returned by each sub-iterator. The weights are provided as metadata. See the Multistart and Pareto Set documentation for details.

#### 7.2.6.1 method_name

- Keywords Area
- method
- pareto_set
7.2 method

- method_name

Specify sub-method by name

Specification

Alias: opt_method_name

Argument(s): STRING

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>model_pointer</td>
<td>Identifier for model block to be used by a method</td>
</tr>
</tbody>
</table>

Description

The method_name keyword is used to specify a sub-method by Dakota method name (e.g. ‘npsol_sqp’) rather than block pointer. The method will be executed using its default settings. The optional model_pointer specification can be used to associate a model block with the method.

7.2.6.1.1 model_pointer

- Keywords Area
- method
- pareto_set
- method_name
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: opt_model_pointer

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.
Default Behavior
If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips
When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.

See block_pointer for details about pointers.

Examples

```plaintext
environment
  tabular_data
  method_pointer = 'UQ'
method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling, samples = 10
  seed = 98765 rng rnum2
  response_levels = 0.1 0.2 0.6
                   0.1 0.2 0.6
                   0.1 0.2 0.6
  sample_type lhs
  distribution cumulative
model
  id_model = 'SURR'
  surrogate global,
  dace_method_pointer = 'DACE'
  polynomial quadratic
method
  id_method = 'DACE'
  model_pointer = 'DACE_M'
  sampling sample_type lhs
  samples = 121 seed = 5034 rng rnum2
model
  id_model = 'DACE_M'
  single
  interface_pointer = 'I1'
variables
  uniform_uncertain = 2
  lower_bounds = 0. 0.0.
  upper_bounds = 1. 1.
  descriptors = 'x1' 'x2'
interface
  id_interface = 'I1'
  system asynch evaluation_concurrency = 5
  analysis_driver = 'text_book'
responses
  response_functions = 3
  no_gradients
  no_hessians
```

7.2.6.2 method_pointer

- Keywords Area
- method
- pareto_set
• **method_pointer**

Pointer to optimization or least-squares sub-method

**Topics**

This keyword is related to the topics:

• **block_pointer**

**Specification**

**Alias**: opt_method_pointer

**Argument(s)**: STRING

**Description**

The `method_pointer` keyword is used to specify a pointer to an optimization or least-squares sub-method that is responsible for computing a set of optimal solutions for a set of response weightings.

7.2.6.3 **random_weight_sets**

• **Keywords Area**

• **method**

• **pareto_set**

• **random_weight_sets**

Number of random weighting sets

**Specification**

**Alias**: none

**Argument(s)**: INTEGER

**Child Keywords**: Required/Optional

<table>
<thead>
<tr>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>seed</td>
<td>Seed of the random number generator</td>
</tr>
</tbody>
</table>

**Description**

The `pareto_set` specification must identify an optimization or least squares calibration method using either a `method_pointer` or a `method_name` plus optional `model_pointer`. This minimizer is responsible for computing a set of optimal solutions from a set of response weightings (multi-objective weights or least squares term weights). These weightings can be specified as follows: (1) using `random_weight_sets`, in which case weightings are selected randomly within [0,1] bounds, (2) using `weight_sets`, in which the weighting sets are specified in a list, or (3) using both `random_weight_sets` and `weight_sets`, for which the combined set of weights will be used. In aggregate, at least one set of weights must be specified. The set of optimal solutions is called the "pareto set," which can provide valuable design trade-off information when there are competing objectives.
7.2.6.3.1 seed

- Keywords Area
- method
- pareto_set
- random_weight_sets
- seed

Seed of the random number generator

Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** system-generated (non-repeatable)

Description

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

**Default Behavior**

If not specified, the seed is randomly generated.

**Expected Output**

If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

**Usage Tips**

If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

**Examples**

```dakota
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

7.2.6.4 weight_sets

- Keywords Area
- method
- pareto_set
- weight_sets

List of user-specified weighting sets
7.2 method

Specification

Alias: multi_objective_weight_sets
Argument(s): REALLIST

Description

The pareto_set specification must identify an optimization or least squares calibration method using either a method_pointer or a method_name plus optional model_pointer. This minimizer is responsible for computing a set of optimal solutions from a set of response weightings (multi-objective weights or least squares term weights). These weightings can be specified as follows: (1) using random_weight_sets, in which case weightings are selected randomly within $[0,1]$ bounds, (2) using weight_sets, in which the weighting sets are specified in a list, or (3) using both random_weight_sets and weight_sets, for which the combined set of weights will be used. In aggregate, at least one set of weights must be specified. The set of optimal solutions is called the “pareto set,” which can provide valuable design trade-off information when there are competing objectives.

7.2.6.5 iterator_servers

- Keywords Area
- method
- pareto_set
- iterator_servers

Specify the number of iterator servers when Dakota is run in parallel

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none
Argument(s): INTEGER

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional iterator_servers specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, hybrid, multi_start, and pareto_set component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [5] for additional information.

7.2.6.6 iterator_scheduling

- Keywords Area
- method
Specify the scheduling of concurrent iterators when Dakota is run in parallel

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none

Argument(s): none

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group Scheduling Mode (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required (Choose One)</td>
<td>peer</td>
<td>master</td>
<td>Specify a dedicated master partition for parallel iterator scheduling</td>
</tr>
</tbody>
</table>

Description

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional iterator_scheduling specification supports user override of the automatic parallel configuration for the number of iterator servers. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired number of partitions at the iterator parallelism level. Currently, hybrid, multi_start, and pareto_set component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [5] for additional information.

7.2.6.6.1 master

- Keywords Area

- method

- pareto_set

- iterator_scheduling

- master

Specify a dedicated master partition for parallel iterator scheduling

Topics

This keyword is related to the topics:

- concurrency_and_parallelism
7.2 method

Specification

Alias: none
Argument(s): none

Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a dedicated master partition. In a dedicated master partition, one processor (the "master") dynamically schedules work on the iterator servers. This reduces the number of processors available to create servers by 1.

7.2.6.6.2 peer

- Keywords Area
- method
- pareto_set
- iterator_scheduling
- peer

Specify a peer partition for parallel iterator scheduling

Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

Alias: none
Argument(s): none

Description

This option overrides the Dakota parallel automatic configuration, forcing the use of a peer partition. In a peer partition, all processors are available to be assigned to iterator servers. Note that unlike the case of evaluation_scheduling, it is not possible to specify static or dynamic.

7.2.6.7 processors_per_iterator

- Keywords Area
- method
- pareto_set
- processors_per_iterator

Specify the number of processors per iterator server when Dakota is run in parallel
Topics

This keyword is related to the topics:

- concurrency_and_parallelism

Specification

**Alias:** none

**Argument(s):** INTEGER

**Description**

An important feature for component-based iterators is that execution of sub-iterator runs may be performed concurrently. The optional `processors_per_iterator` specification supports user override of the automatic parallel configuration for the number of processors in each iterator server. That is, if the automatic configuration is undesirable for some reason, the user can enforce a desired server size at the iterator parallelism level. Currently, hybrid, multi_start, and pareto_set component-based iterators support concurrency in their sub-iterators. Refer to ParallelLibrary and the Parallel Computing chapter of the Users Manual [5] for additional information.

7.2.7 branch_and_bound

- Keywords Area
- method
- branch_and_bound

(Experimental Capability) Solves a mixed integer nonlinear optimization problem

Specification

**Alias:** none

**Argument(s):** none

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Required</strong> <em>(Choose One)</em></td>
<td>Local Optimizer Selection (Group 1)</td>
<td>method_pointer</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pointer to sub-method to apply to a surrogate or branch-and-bound sub-problem</td>
</tr>
</tbody>
</table>
Description

The branch-and-bound optimization methods solves mixed integer nonlinear optimization problems. It does so by partitioning the parameter space according to some criteria along the integer or discrete variables. It then relaxes (i.e., treats all variables as continuous) the sub-problems created by the partitions and solves each sub-problem with a continuous nonlinear optimization method. Results of the sub-problems are combined in such a way that yields the solution to the original optimization problem.

Default Behavior

Branch-and-bound expects all discrete variables to be relaxable. If your problem has categorical or otherwise non-relaxable discrete variables, then this is not the optimization method you are looking for.

Expected Output

The optimal solution and associated parameters will be printed to the screen output.

Usage Tips

The user must choose a nonlinear optimization method to solve the sub-problems. We recommend choosing a method that would be chosen to solve a continuous problem that has similar form to the mixed integer problem.

Examples

```dakota
environment
  method_pointer = 'BandB'

method
  id_method = 'BandB'
  branch_and_bound
    output verbose
    method_pointer = 'SubNLP'

method
  id_method = 'SubNLP'
  coliny_ea
    seed = 12345
    max_iterations = 100
    max_function_evaluations = 100

variables,
  continuous_design = 3
    initial_point -1.0 1.5 2.0
    upper_bounds 10.0 10.0 10.0
    lower_bounds -10.0 -10.0 -10.0
    descriptors 'x1' 'x2' 'x3'
  discrete_design_range = 2
    initial_point 2 2
    lower_bounds 1 1
    upper_bounds 4 9
    descriptors 'y1' 'y2'

interface,
  fork
    analysis_driver = 'text_book'

responses,
  objective_functions = 1
```
nonlinear_inequality_constraints = 2
numerical_gradients
no_hessians

7.2.7.1 method_pointer

- Keywords Area
- method
- branch_and_bound
- method_pointer

Pointer to sub-method to apply to a surrogate or branch-and-bound sub-problem

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none
Argument(s): STRING

Description

The method_pointer keyword is used to specify a pointer to an optimization or least-squares sub-method to apply in the context of what could be described as hierarchical methods. In surrogate-based methods, the sub-method is applied to the surrogate model. In the branch-and-bound method, the sub-method is applied to the relaxed sub-problems.

Any model_pointer identified in the sub-method specification is ignored. Instead, the parent method is responsible for selecting the appropriate model to use as specified by its model_pointer. In surrogate-based methods, it is a surrogate model defined using its model_pointer. In branch-and-bound methods, it is the relaxed model that is constructed internally from the original model.

7.2.7.2 method_name

- Keywords Area
- method
- branch_and_bound
- method_name

Specify sub-method by name

Specification

Alias: none
Argument(s): STRING
Child Keywords:
### Description

The `method_name` keyword is used to specify a sub-method by Dakota method name (e.g. 'npsol_sqp') rather than block pointer. The method will be executed using its default settings. The optional `model_pointer` specification can be used to associate a model block with the method.

#### 7.2.7.2.1 `model_pointer`

- Keywords Area
  - `method`
  - `branch_and_bound`
  - `method_name`
  - `model_pointer`

Identifier for model block to be used by a method

### Topics

This keyword is related to the topics:

- `block_pointer`

### Specification

**Alias:** none  
**Argument(s):** STRING  
**Default:** method use of last model parsed (or use of default model if none parsed)

### Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

### Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

### Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.
Examples

```plaintext
environment
tabular_data
method_pointer = 'UQ'

method
id_method = 'UQ'
model_pointer = 'SURR'
sampling,
samples = 10
seed = 98765 rng rnum2
response_levels = 0.1 0.2 0.6 0.1 0.2 0.6
sample_type lhs
distribution cumulative

model
id_model = 'SURR'
surrogate global,
dace_method_pointer = 'DACE'
polynomial quadratic

method
id_method = 'DACE'
model_pointer = 'DACE_M'
sampling sample_type lhs
samples = 121 seed = 5034 rng rnum2

model
id_model = 'DACE_M'
single
interface_pointer = 'I1'

variables
uniform_uncertain = 2
lower_bounds = 0. 0.
upper_bounds = 1. 1.
descriptors = 'x1' 'x2'

interface
id_interface = 'I1'
system asynch evaluation_concurrency = 5
analysis_driver = 'text_book'

responses
response_functions = 3
no_gradients
no_hessians

7.2.7.3 scaling

- Keywords Area
- method
- branch_and_bound
- scaling

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- method_independent_controls
```
Specification

Alias: none
Argument(s): none
Default: no scaling

Description

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the scaling keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords scale_types and/or *scales in the variables and responses blocks. When the scaling keyword is omitted from method, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

- a *scales keyword, which gives characteristic values (divisors)
- a *scale_types keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in responses for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are three scale types:

1. value - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.

2. auto - automatic scaling
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   - two-sided bounds scaled into the interval [0,1];
   - one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
   - no bounds or targets: no automatic scaling possible, therefore no scaling for this component

   Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

3. log - logarithmic scaling
   First, any characteristic values from the optional *_scales specification are applied. Then logarithm base 10 scaling is applied.
   Logarithmic scaling is not available for linear constraints.
   When continuous design variables are log scaled, linear constraints are not allowed.
Scales

The `scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `scale_types`, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- `auto`, `log` - optional
- `value` - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than `1.0e10*DBL_MN`. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```plaintext
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100

responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

7.2.8 surrogate_based_local

- Keywords Area
- method

Description

In surrogate-based optimization (SBO) and surrogate-based nonlinear least squares (SBNLS), minimization occurs using a set of one or more approximations, defined from a surrogate model, that are built and periodically updated using data from a "truth" model. The surrogate model can be a global data fit (e.g., regression or interpolation of data generated from a design of computer experiments), a multipoint approximation, a local Taylor Series expansion, or a model hierarchy approximation (e.g., a low-fidelity simulation model), whereas the truth model involves a high-fidelity simulation model. The goals of surrogate-based methods are to reduce the total number of truth model simulations and, in the case of global data fit surrogates, to smooth noisy data with an easily navigated analytic function.

In the surrogate-based local method, a trust region approach is used to manage the minimization process to maintain acceptable accuracy between the surrogate model and the truth model (by limiting the range over which the surrogate model is trusted). The process involves a sequence of minimizations performed on the surrogate model and bounded by the trust region. At the end of each approximate minimization, the candidate optimum point is validated using the truth model. If sufficient decrease has been obtained in the truth model, the trust region is re-centered around the candidate optimum point and the trust region will either shrink, expand, or remain the same size depending on the accuracy with which the surrogate model predicted the truth model decrease. If sufficient decrease has not been attained, the trust region center is not updated and the entire trust region shrinks by a user-specified factor. The cycle then repeats with the construction of a new surrogate model, a minimization, and another test for sufficient decrease in the truth model. This cycle continues until convergence is attained.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the hdf5 keyword, this method writes the following results to HDF5:

- Best Parameters
- Best Objective Functions (when objective_functions are specified)
- Best Nonlinear Constraints
- Calibration (when calibration_terms are specified)

Theory

For surrogate_based_local problems with nonlinear constraints, a number of algorithm formulations exist as described in [23] and as summarized in the Advanced Examples section of the Models chapter of the Users Manual [5].

7.2 method

7.2.8.1 method_pointer

- Keywords Area
- method
- surrogate_based_local
- method_pointer

Pointer to sub-method to apply to a surrogate or branch-and-bound sub-problem

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: approx_method_pointer

Argument(s): STRING

Description

The method_pointer keyword is used to specify a pointer to an optimization or least-squares sub-method to apply in the context of what could be described as hierarchical methods. In surrogate-based methods, the sub-method is applied to the surrogate model. In the branch-and-bound method, the sub-method is applied to the relaxed sub-problems.

Any model_pointer identified in the sub-method specification is ignored. Instead, the parent method is responsible for selecting the appropriate model to use as specified by its model_pointer. In surrogate-based methods, it is a surrogate model defined using its model_pointer. In branch-and-bound methods, it is the relaxed model that is constructed internally from the original model.

7.2.8.2 method_name

- Keywords Area
- method
- surrogate_based_local
- method_name

Specify sub-method by name

Specification

Alias: approx_method_name

Argument(s): STRING
Description

The *method_name* keyword is used to specify a sub-method by Dakota method name (e.g. 'npsol_sqp') rather than block pointer. The method will be executed using its default settings. The optional *model_pointer* specification can be used to associate a model block with the method.

### 7.2.8.3 model_pointer

- Keywords Area
- method
- surrogate_based_local
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

**Alias:** approx_model_pointer

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)

Description

The *model_pointer* is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding *id_model* with the same name.

**Usage Tips**

When doing advanced analyses that involve using multiple methods and multiple models, defining a *model_pointer* for each method is imperative.

See *block_pointer* for details about pointers.

**Examples**

```plaintext
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
```

7.2.8.4 soft_convergence_limit

- Keywords Area
- method
- surrogate_based_local
- soft_convergence_limit

Limit number of iterations w/ little improvement

Specification

Alias: none
Argument(s): INTEGER
Default: 5

Description

soft_convergence_limit (a soft convergence control for the surrogate_based_local iterations which limits
the number of consecutive iterations with improvement less than the convergence tolerance). soft_convergence>1
counts an iteration in which a design point was rejected as an iteration with no improvement. Setting soft_-convergence=1 ignores iterations involving rejected points, instead comparing only consecutive iterations of accepted points.

### 7.2.8.5 truth_surrogate_bypass

- **Keywords Area**
- **method**
- **surrogate_based_local**
- **truth_surrogate_bypass**

Bypass lower level surrogates when performing truth verifications on a top level surrogate

**Specification**

**Alias**: none

**Argument(s)**: none

**Default**: no bypass

**Description**

truth_surrogate_bypass (a flag for bypassing all lower level surrogates when performing truth verifications on a top level surrogate).

### 7.2.8.6 approx_subproblem

- **Keywords Area**
- **method**
- **surrogate_based_local**

### Description

First, the "primary" functions (that is, the objective functions or calibration terms) in the approximate subproblem can be selected to be surrogates of the original primary functions (`original_primary`), a single objective function (`single_objective`) formed from the primary function surrogates, or either an augmented Lagrangian merit function (`augmented_lagrangian_objective`) or a Lagrangian merit function (`lagrangian_objective`) formed from the primary and secondary function surrogates. The former option may imply the use of a nonlinear least squares method, a multiobjective optimization method, or a single objective optimization method to solve the approximate subproblem, depending on the definition of the primary functions. The latter three options all imply the use of a single objective optimization method regardless of primary function definition. Second, the surrogate constraints in the approximate subproblem can be selected to be surrogates of the original constraints (`original_constraints`) or linearized approximations to the surrogate constraints (`linearized_constraints`), or constraints can be omitted from the subproblem (`no_constraints`).

#### 7.2.8.6.1 original_primary

</tr>
</tbody>
</table>

Description

Following calculation of the merit function for the new iterate, the iterate is accepted or rejected and the trust region size is adjusted for the next surrogate_based_local iteration. Iterate acceptance is governed either by a trust region ratio (tr_ratio) formed from the merit function values or by a filter method (filter); however, trust region resizing logic is currently based only on the trust region ratio. For infeasible iterates, constraint relaxation can be used for balancing constraint satisfaction and progress made toward an optimum.

</tbody>
</table>

Description

The trust_region optional group specification can be used to specify the initial size of the trust region (using initial_size) relative to the total variable bounds, the minimum size of the trust region (using minimum_size), the contraction factor for the trust region size (using contraction_factor) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using expansion_factor) used when the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using contract_threshold) and the trust region size expansion threshold (using expand_threshold). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command contract_threshold sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next surrogate_based_local iteration. The command expand_threshold determines the trust region value above which the trust region will expand for the next surrogate_based_local iteration.

Each of these specifications are REAL scalars, with the exception of initial_size, which is a REALLIST.

7.2.8.10.1 initial_size

- Keywords Area
Trust region initial size (relative to bounds)

**Specification**

**Alias:** none

**Argument(s):** REALIST

**Description**

The `trust_region` optional group specification can be used to specify the initial size of the trust region (using `initial_size`), the minimum size of the trust region (using `minimum_size`), the contraction factor for the trust region size (using `contraction_factor`) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using `expansion_factor`) used when the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using `contract_threshold`) and the trust region size expansion threshold (using `expand_threshold`). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command `contract_threshold` sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command `expand_threshold` determines the trust region value above which the trust region will expand for the next SBL iteration.

All of these specifications are REAL scalars, with the exception of the specification of `initial_size`, which is a REALIST. This array corresponds to the case when there are more than 2 model forms or discretizations within a model hierarchy. The default `initial_size` involves a recursive halving of the global bounds for each trust region in the hierarchy: e.g., a scalar value of .5 for a single trust region managing two model forms/discretizations, or an array of (.125, .25, .5) for four model forms/discretizations (three trust regions ordered from the lowest to highest fidelity surrogate, with model four as truth).

7.2.8.10.2 minimum_size

- Keywords Area
- method
- surrogate_based_local
- trust_region
- initial_size

Trust region minimum size

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 1.e-6
Description

The `trust_region` optional group specification can be used to specify the initial size of the trust region (using `initial_size`) relative to the total variable bounds, the minimum size of the trust region (using `minimum_size`), the contraction factor for the trust region size (using `contraction_factor`) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using `expansion_factor`) used when the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using `contract_threshold`) and the trust region size expansion threshold (using `expand_threshold`). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command `contract_threshold` sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command `expand_threshold` determines the trust region value above which the trust region will expand for the next SBL iteration.

7.2.8.10.3 `contract_threshold`

- **Keywords Area**
- **method**
- **surrogate_based_local**
- **trust_region**
- **contract_threshold**

Shrink trust region if trust region ratio is below this value

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 0.25

**Description**

The `trust_region` optional group specification can be used to specify the initial size of the trust region (using `initial_size`) relative to the total variable bounds, the minimum size of the trust region (using `minimum_size`), the contraction factor for the trust region size (using `contraction_factor`) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using `expansion_factor`) used when the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using `contract_threshold`) and the trust region size expansion threshold (using `expand_threshold`). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command `contract_threshold` sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command `expand_threshold` determines the trust region value above which the trust region will expand for the next SBL iteration.

7.2.8.10.4 `expand_threshold`

- **Keywords Area**
- **method**
- **surrogate_based_local**
- **trust_region**
- **expand_threshold**
Expand trust region if trust region ratio is above this value

**Specification**

**Alias:** none  
**Argument(s):** REAL  
**Default:** 0.75

**Description**

The trust_region optional group specification can be used to specify the initial size of the trust region (using initial_size) relative to the total variable bounds, the minimum size of the trust region (using minimum_size), the contraction factor for the trust region size (using contraction_factor) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using expansion_factor) used when the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using contract_threshold) and the trust region size expansion threshold (using expand_threshold). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command contract_threshold sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command expand_threshold determines the trust region value above which the trust region will expand for the next SBL iteration.

7.2.8.10.5 contraction_factor

- Keywords Area  
- method  
- surrogate_based_local  
- trust_region  
- contraction_factor

Amount by which step length is rescaled

**Specification**

**Alias:** none  
**Argument(s):** REAL  
**Default:** 0.25

**Description**

For pattern search methods, contraction_factor specifies the amount by which step length is rescaled after unsuccessful iterates, must be strictly between 0 and 1.

For methods that can expand the step length, the expansion is \(1/\text{contraction\_factor}\)

7.2.8.10.6 expansion_factor

- Keywords Area  
- method  
- surrogate_based_local
7.2 method

- **trust_region**
  - expansion_factor

Trust region expansion factor

**Specification**

**Alias:** none
**Argument(s):** REAL
**Default:** 2.0

**Description**

The trust_region optional group specification can be used to specify the initial size of the trust region (using initial_size) relative to the total variable bounds, the minimum size of the trust region (using minimum_size), the contraction factor for the trust region size (using contraction_factor) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using expansion_factor) used when the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using contract_threshold) and the trust region size expansion threshold (using expand_threshold). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command contract_threshold sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command expand_threshold determines the trust region value above which the trust region will expand for the next SBL iteration.

7.2.8.11 max_iterations

- Keywords Area
- method
- surrogate_based_local
- max_iterations

Number of iterations allowed for optimizers and adaptive UQ methods

**Topics**

This keyword is related to the topics:

- method_independent_controls

**Specification**

**Alias:** none
**Argument(s):** INTEGER
**Default:** 100 (exceptions: fsu_cvt, local_reliability: 25; global_(reliability, interval_est, evidence) / efficient_global: 25*n)
Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed \( \text{max\_iterations} \) iterations. In cases where there are multiple nested iterations to be controlled, \( \text{max\_iterations} \) generally controls the outer-most context.

Default Behavior

Default value is 100.

See Also

These keywords may also be of interest:

- \( \text{max\_function\_evaluations} \)

7.2.8.12 convergence_tolerance

- Keywords Area
- method
- surrogate_based_local
- convergence_tolerance

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- \( \text{method\_independent\_controls} \)

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The \( \text{convergence\_tolerance} \) specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by \( \text{convergence\_tolerance} \), then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.
Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See nl2sol
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

7.2.8.13 **constraint_tolerance**

- **Keywords** Area
- method
- surrogate_based_local
- constraint_tolerance

Maximum allowable constraint violation still considered feasible

**Topics**

This keyword is related to the topics:

- method_independent_controls

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** Library default

**Description**

Sets the maximum allowable value of infeasibility that any constraint in an optimization problem may possess and still be considered to be satisfied.

If a constraint's violation is greater than this value then it is considered to be violated by the optimization algorithm. This specification gives some control over how tightly the constraints will be satisfied at convergence of the algorithm. However, if the value is set too small the algorithm may terminate with one or more constraints being violated.

**Defaults**

Defaults vary depending on the method.

Description

The `surrogate_based_global` method iteratively performs optimization on a global surrogate using the same bounds during each iteration.
• In one iteration, optimal solutions are found on the surrogate model, and a subset of these are passed to the next iteration.

• At the next iteration, these surrogate-optimal variable sets are evaluated with the “truth” model, and added to the set of points over which the next surrogate is constructed.

In this way, the optimization operates on a more accurate surrogate during each iteration, presumably driving to optimality quickly. In contrast to surrogate_based_local, this approach has no guarantee of convergence.

Usage Tips

Attention: This adaptive method is not recommended for “build-once” surrogates trained from (static) imported data or trained online using a single Dakota design of experiments. Instead, any Dakota optimization method can be used with a (build-once) global surrogate by specifying the id_model of a global surrogate model with the optimizer’s model_pointer keyword.

Configuring the method:

• The sub-method, specified with either method_pointer or method_name should typically be an optimizer that returns multiple final solutions, such as moga or soga.

• The model_pointer keyword must identify a surrogate model which includes an underlying truth model, typically via truth_model_pointer or dace_method_pointer

Workflow:

• One might first try a single minimization method coupled with a surrogate model prior to using this surrogate-based global method. This is essentially equivalent to setting max_iterations to 1 and will allow one to get a sense of what surrogate types are the most accurate to use for the problem.

• Consider starting with a small number of maximum iterations, such as 3–5, to get a sense of how the optimization evolves as the surrogate gets updated. If it is still changing significantly, then a larger number (used in combination with restart) may be needed.

• Surrogates can be built for all primary functions and constraints or for only a subset of these functions and constraints. This allows one to use a “truth” model directly for some of the response functions, perhaps due to them being much less expensive than other functions.

Known Issue: When using discrete variables, there have been sometimes significant differences in surrogate behavior observed across computing platforms in some cases. The cause has not yet been fully diagnosed and is currently under investigation. In addition, guidance on appropriate construction and use of surrogates with discrete variables is under development. In the meantime, users should therefore be aware that there is a risk of inaccurate results when using surrogates with discrete variables.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the hdf5 keyword, this method writes the following results to HDF5:

• Best Parameters

• Best Objective Functions (when objective_functions are specified)

• Best Nonlinear Constraints

• Calibration (when calibration_terms are specified)
Theory

In surrogate-based optimization (SBO) and surrogate-based nonlinear least squares (SBNLS), minimization occurs using a set of one or more approximations, defined from a surrogate model, that are built and periodically updated using data from a "truth" model. The surrogate model can be a global data fit (e.g., regression or interpolation of data generated from a design of computer experiments), a multipoint approximation, a local Taylor Series expansion, or a model hierarchy approximation (e.g., a low-fidelity simulation model), whereas the truth model involves a high-fidelity simulation model. The goals of surrogate-based methods are to reduce the total number of truth model simulations and, in the case of global data fit surrogates, to smooth noisy data with an easily navigated analytic function.

The surrogate_based_global method was originally designed for MOGA (a multi-objective genetic algorithm). Since genetic algorithms often need thousands or tens of thousands of points to produce optimal or near-optimal solutions, the use of surrogates can be helpful for reducing the truth model evaluations. Instead of creating one set of surrogates for the individual objectives and running the optimization algorithm on the surrogate once, the idea is to select points along the (surrogate) Pareto frontier, which can be used to supplement the existing points.

In this way, one does not need to use many points initially to get a very accurate surrogate. The surrogate becomes more accurate as the iterations progress.

These keywords may also be of interest:

- efficient_global
- surrogate_based_local

7.2.9.1 method_pointer

- Keywords Area
- method
- surrogate_based_global
- method_pointer

Pointer to sub-method to apply to a surrogate or branch-and-bound sub-problem

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: approx_method_pointer

Argument(s): STRING

Description

The method_pointer keyword is used to specify a pointer to an optimization or least-squares sub-method to apply in the context of what could be described as hierarchical methods. In surrogate-based methods, the sub-method is applied to the surrogate model. In the branch-and-bound method, the sub-method is applied to the relaxed sub-problems.
Any `model_pointer` identified in the sub-method specification is ignored. Instead, the parent method is responsible for selecting the appropriate model to use as specified by its `model_pointer`. In surrogate-based methods, it is a surrogate model defined using its `model_pointer`. In branch-and-bound methods, it is the relaxed model that is constructed internally from the original model.

### 7.2.9.2 method_name

- **Keywords Area**
- **method**
- **surrogate_based_global**
- **method_name**

Specify sub-method by name

**Specification**

**Alias:** `approx_method_name`

**Argument(s):** STRING

**Description**

The `method_name` keyword is used to specify a sub-method by Dakota method name (e.g., 'npsol_sqp') rather than block pointer. The method will be executed using its default settings. The optional `model_pointer` specification can be used to associate a model block with the method.

### 7.2.9.3 model_pointer

- **Keywords Area**
- **method**
- **surrogate_based_global**
- **model_pointer**

Identifier for model block to be used by a method

**Topics**

This keyword is related to the topics:

- **block_pointer**

**Specification**

**Alias:** `approx_model_pointer`

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)
Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

Examples

```plaintext
environment
  tabular_data
  method_pointer = 'UQ'
method
  id_method = 'UQ'
  model_pointer = 'SURR'
sampling,
  samples = 10
  seed = 98765 rng rnum2
  response_levels = 0.1 0.2 0.6
                  0.1 0.2 0.6
                  0.1 0.2 0.6
  sample_type lhs

  response_functions = 3
  no_gradients
  no_hessians
```
7.2.9.4 replace_points

- Keywords Area
  - method
  - surrogate_based_global
  - replace_points

(Recommended) Replace points in the surrogate training set, instead of appending

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** Points appended, not replaced

**Description**

The user has the option of appending the optimal points from the surrogate model to the current set of truth points or using the optimal points from the surrogate model to replace the optimal set of points from the previous iteration. Although appending to the set is the default behavior, at this time we strongly recommend using the option `replace_points` because it appears to be more accurate and robust.

7.2.9.5 max_iterations

- Keywords Area
  - method
  - surrogate_based_global
  - max_iterations

Number of iterations allowed for optimizers and adaptive UQ methods

**Topics**

This keyword is related to the topics:

- method_independent_controls

**Specification**

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** 100 (exceptions: fsu_cvt, local_reliability: 25; global_(reliability, interval_est, evidence) / efficient_global: 25*n)
Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed \( \text{max}\_\text{iterations} \) iterations. In cases where there are multiple nested iterations to be controlled, \( \text{max}\_\text{iterations} \) generally controls the outer-most context.

Default Behavior

Default value is 100.

### Description

DOT library [88] implementation of Fletcher-Reeves conjugate gradient method for unconstrained optimization.

See package dot for information common to all DOT methods.

**DOT requires a separate software license and therefore may not be available in all versions of Dakota. CONMIN or OPT++ methods may be suitable alternatives.**

**Caution regarding dot_frcg.** In DOT Version 4.20, we have noticed inconsistent behavior of this algorithm across different versions of Linux. Our best assessment is that it is due to different treatments of uninitialized variables. As we do not know the intention of the code authors and maintaining DOT source code is outside of the Dakota project scope, we have not made nor are we recommending any code changes to address this. However, all users who use dot_frcg in DOT Version 4.20 should be aware that results may not be reliable.

### Expected HDF5 Output

If Dakota was built with HDF5 support and run with the hdf5 keyword, this method writes the following results to HDF5:

- Best Parameters
- Best Objective Functions (when objective_functions are specified)
- Calibration (when calibration_terms are specified)

### 7.2.10.1 max_iterations

- Keywords Area
- method
- dot_frcg
- max_iterations

Number of iterations allowed for optimizers and adaptive UQ methods

---

**Dakota Version 6.16 Reference Manual generated on May 12, 2022**
Topics

This keyword is related to the topics:

• method_independent_controls

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: fsu_cvt, local_reliability: 25; global_(reliability, interval_est, evidence) / efficient_global: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed max_iterations iterations. In cases where there are multiple nested iterations to be controlled, max_iterations generally controls the outer-most context.

Default Behavior

Default value is 100.

• max_function_evaluations

7.2.10.2 convergence_tolerance

• Keywords Area
• method
• dot_frcg
• convergence_tolerance

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

• method_independent_controls

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4
Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See `nl2sol`
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

### 7.2.10.3 constraint_tolerance

- **Keywords** Area
- **method**
- **dot_frcg**
- **constraint_tolerance**

Maximum allowable constraint violation still considered feasible

Topics

This keyword is related to the topics:

- **method_independent_controls**

Specification

**Alias:** none

**Argument(s):** REAL

**Default:** Library default

Description

Sets the maximum allowable value of infeasibility that any constraint in an optimization problem may possess and still be considered to be satisfied.
If a constraint’s violation is greater than this value then it is considered to be violated by the optimization algorithm. This specification gives some control over how tightly the constraints will be satisfied at convergence of the algorithm. However, if the value is set too small the algorithm may terminate with one or more constraints being violated.

**Defaults**

Defaults vary depending on the method.

- CONMIN optimizers: 1.0e-3
- DOT constrained optimizers: 3.0e-3
- surrogate_based_local: 1.0e-4

### 7.2.10.4 speculative

Compute speculative gradients

**Topics**

This keyword is related to the topics:

- method_independent_controls

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** no speculation

**Description**

When performing gradient-based optimization in parallel, speculative gradients can be selected to address the load imbalance that can occur between gradient evaluation and line search phases. In a typical gradient-based optimization, the line search phase consists primarily of evaluating the objective function and any constraints at a trial point, and then testing the trial point for a sufficient decrease in the objective function value and/or constraint violation. If a sufficient decrease is not observed, then one or more additional trial points may be attempted sequentially. However, if the trial point is accepted then the line search phase is complete and the gradient evaluation phase begins. By speculating that the gradient information associated with a given line search trial point will be used later, additional coarse grained parallelism can be introduced by computing the gradient information (either by finite difference or analytically) in parallel, at the same time as the line search phase trial-point function values. This balances the total amount of computation to be performed at each design point and allows for efficient utilization of multiple processors. While the total amount of work performed will generally increase (since some speculative gradients will not be used when a trial point is rejected in the line search phase), the run time will usually decrease (since gradient evaluations needed at the start of each new optimization cycle were already performed in parallel during the line search phase). Refer to [13] for additional details. The speculative specification is implemented for the gradient-based optimizers in the DOT, CONMIN, and OPT++ libraries, and it can be used with dakota numerical
or analytic gradient selections in the responses specification (refer to responses gradient section for information
on these specifications). It should not be selected with vendor numerical gradients since vendor internal finite
difference algorithms have not been modified for this purpose. In full-Newton approaches, the Hessian is also
computed speculatively. NPSOL and NLSSOL do not support speculative gradients, as their gradient-based line search
in user-supplied gradient mode (dakota numerical or analytic gradients) is a superior approach for load-balanced
parallel execution.

The speculative specification enables speculative computation of gradient and/or Hessian information, where
applicable, for parallel optimization studies. By speculating that the derivative information at the current point will
be used later, the complete data set (all available gradient/Hessian information) can be computed on every function
evaluation. While some of these computations will be wasted, the positive effects are a consistent parallel load
balance and usually shorter wall clock time. The speculative specification is applicable only when parallelism
in the gradient calculations can be exploited by Dakota (it will be ignored for vendor numerical gradients).

7.2.10.5 max_function_evaluations

- Keywords Area
- method
- dot_frcg
- max_function_evaluations

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached
any other stopping criteria first, the optimizer will stop after it has performed max_function_evaluations
evaluations. See also max_iterations.

Some optimizers (e.g. ncsu_direct) may run past this limit in the course of an iteration step that began before
max_function_evaluations was exceeded.

Default Behavior

Default value is 1000.

7.2.10.6 scaling

- Keywords Area
- method
Turn on scaling for variables, responses, and constraints

Topics
This keyword is related to the topics:

• method_independent_controls

Specification
Alias: none
Argument(s): none
Default: no scaling

Description
Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the scaling keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords scale_types and/or *scales in the variables and responses blocks. When the scaling keyword is omitted from method, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled:

• a *scales keyword, which gives characteristic values (divisors)
• a *scale_types keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in responses for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types
There are three scale types:

1. value - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.

2. auto - automatic scaling
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   • two-sided bounds scaled into the interval [0,1];
• one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;

• no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

3. **log** - logarithmic scaling

First, any characteristic values from the optional *scales specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

**Scales**

The *scales keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding *scale_types, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

• auto, log - optional

• value - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10*DBL_MIN$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

**Examples**

The two examples below are equivalent:

```
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100
```

```
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

7.2.10.7 **model_pointer**

• Keywords Area

• method

• dot_frcg

• model_pointer

Identifier for model block to be used by a method
Topics

This keyword is related to the topics:

• block_pointer

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.

See block_pointer for details about pointers.

Examples

environment

### Description

DOT library [88] implementation of the modified method of feasible directions for constrained optimization.

See package_dot for information common to all DOT methods.

**DOT requires a separate software license and therefore may not be available in all versions of Dakota. CONMIN or OPT++ methods may be suitable alternatives.**

#### Expected HDF5 Output

If Dakota was built with HDF5 support and run with the hdf5 keyword, this method writes the following results to HDF5:

- Best Parameters
- Best Objective Functions (when objective_functions are specified)
- Best Nonlinear Constraints
- Calibration (when calibration_terms are specified)

#### 7.2.11.1 max_iterations

- Keywords Area
- method
- dot_mmfd
- max_iterations

Number of iterations allowed for optimizers and adaptive UQ methods.

#### Topics

This keyword is related to the topics:

- method_independent_controls
Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: fsu_cvt, local_reliability: 25; global_(reliability, interval_est, evidence) / efficient_global: 25+n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed \( \text{max\_iterations} \) iterations. In cases where there are multiple nested iterations to be controlled, \( \text{max\_iterations} \) generally controls the outer-most context.

Default Behavior

Default value is 100.

See Also

These keywords may also be of interest:

- \text{max\_function\_evaluations}

7.2.11.2 convergence_tolerance

- Keywords Area
- method
- dot_mmfd
- convergence_tolerance

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- \text{method\_independent\_controls}

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The \( \text{convergence\_tolerance} \) specification provides a real value for controlling the termination of iteration.
For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by convergence_tolerance, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

**Behavior Varies by Package/Library**

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See nl2sol
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

7.2.11.3 constraint_tolerance

- Keywords Area
- method
- dot_mmfd
- constraint_tolerance

Maximum allowable constraint violation still considered feasible

**Topics**

This keyword is related to the topics:

- method-independent_controls

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** Library default

**Description**

Sets the maximum allowable value of infeasibility that any constraint in an optimization problem may possess and still be considered to be satisfied.

If a constraint's violation is greater than this value then it is considered to be violated by the optimization algorithm. This specification gives some control over how tightly the constraints will be satisfied at convergence of the algorithm. However, if the value is set too small the algorithm may terminate with one or more constraints being violated.
7.2 method

Defaults

Defaults vary depending on the method.

- CONMIN optimizers: 1.0e-3
- DOT constrained optimizers: 3.0e-3
- surrogate_based_local : 1.0e-4

7.2.11.4 speculative

- Keywords Area
- method
- dot_mmfd
- speculative

Compute speculative gradients

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none
Argument(s): none
Default: no speculation

Description

When performing gradient-based optimization in parallel, speculative gradients can be selected to address the load imbalance that can occur between gradient evaluation and line search phases. In a typical gradient-based optimization, the line search phase consists primarily of evaluating the objective function and any constraints at a trial point, and then testing the trial point for a sufficient decrease in the objective function value and/or constraint violation. If a sufficient decrease is not observed, then one or more additional trial points may be attempted sequentially. However, if the trial point is accepted then the line search phase is complete and the gradient evaluation phase begins. By speculating that the gradient information associated with a given line search trial point will be used later, additional coarse grained parallelism can be introduced by computing the gradient information (either by finite difference or analytically) in parallel, at the same time as the line search phase trial-point function values. This balances the total amount of computation to be performed at each design point and allows for efficient utilization of multiple processors. While the total amount of work performed will generally increase (since some speculative gradients will not be used when a trial point is rejected in the line search phase), the run time will usually decrease (since gradient evaluations needed at the start of each new optimization cycle were already performed in parallel during the line search phase). Refer to [13] for additional details. The speculative specification is implemented for the gradient-based optimizers in the DOT, CONMIN, and OPT++ libraries, and it can be used with dakota numerical or analytic gradient selections in the responses specification (refer to responses gradient section for information on these specifications). It should not be selected with vendor numerical gradients since vendor internal finite difference algorithms have not been modified for this purpose. In full-Newton approaches, the Hessian is also computed speculatively. NPSOL and NLSSOL do not support speculative gradients, as their gradient-based line search
in user-supplied gradient mode (dakota numerical or analytic gradients) is a superior approach for load-balanced parallel execution.

The speculative specification enables speculative computation of gradient and/or Hessian information, where applicable, for parallel optimization studies. By speculating that the derivative information at the current point will be used later, the complete data set (all available gradient/Hessian information) can be computed on every function evaluation. While some of these computations will be wasted, the positive effects are a consistent parallel load balance and usually shorter wall clock time. The speculative specification is applicable only when parallelism in the gradient calculations can be exploited by Dakota (it will be ignored for vendor numerical gradients).

7.2.11.5 max_function_evaluations

- Keywords Area
- method
- dot_mmfd
- max_function_evaluations

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed max_function_evaluations evaluations. See also max_iterations.

Some optimizers (e.g. ncsu_direct) may run past this limit in the course of an iteration step that began before max_function_evaluations was exceeded.

Default Behavior

Default value is 1000.

7.2.11.6 scaling

- Keywords Area
- method
- dot_mmfd
- scaling

Turn on scaling for variables, responses, and constraints
Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none
Argument(s): none
Default: no scaling

Description

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the scaling keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords scale_types and/or scales in the variables and responses blocks. When the scaling keyword is omitted from method, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

- a *scales keyword, which gives characteristic values (divisors)
- a *scale_types keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in responses for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are three scale types:

1. value - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.

2. auto - automatic scaling
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   - two-sided bounds scaled into the interval [0,1];
   - one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
   - no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].
3. **log**-logarithmic scaling

   First, any characteristic values from the optional *_scales specification are applied. Then logarithm base 10 scaling is applied.

   Logarithmic scaling is not available for linear constraints.

   When continuous design variables are log scaled, linear constraints are not allowed.

### Scales

The *scales keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding *scale_types, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- **auto, log** - optional
- **value** - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0\times 10^{-10}$.*DBL_MIN*. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

### Examples

The two examples below are equivalent:

```plaintext
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100

responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

### 7.2.11.7 model_pointer

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- \texttt{method\_independent\_controls}

Specification

\texttt{Alias: none}

\texttt{Argument(s): REAL}

\texttt{Default: 1.e-4}

Description

The \texttt{convergence\_tolerance} specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by \texttt{convergence\_tolerance}, then this convergence criterion is satisfied on the current iteration. Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.
Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See nl2sol
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

7.2.12.3 constraint_tolerance

- Keywords Area
- method
- dot_bfgs
- constraint_tolerance

Maximum allowable constraint violation still considered feasible

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): REAL

Default: Library default

Description

Sets the maximum allowable value of infeasibility that any constraint in an optimization problem may possess and still be considered to be satisfied.

If a constraint's violation is greater than this value then it is considered to be violated by the optimization algorithm. This specification gives some control over how tightly the constraints will be satisfied at convergence of the algorithm. However, if the value is set too small the algorithm may terminate with one or more constraints being violated.

Compute speculative gradients

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none
Argument(s): none
Default: no speculation

Description

When performing gradient-based optimization in parallel, speculative gradients can be selected to address the load imbalance that can occur between gradient evaluation and line search phases. In a typical gradient-based optimization, the line search phase consists primarily of evaluating the objective function and any constraints at a trial point, and then testing the trial point for a sufficient decrease in the objective function value and/or constraint violation. If a sufficient decrease is not observed, then one or more additional trial points may be attempted sequentially. However, if the trial point is accepted then the line search phase is complete and the gradient evaluation phase begins. By speculating that the gradient information associated with a given line search trial point will be used later, additional coarse grained parallelism can be introduced by computing the gradient information (either by finite difference or analytically) in parallel, at the same time as the line search phase trial-point function values. This balances the total amount of computation to be performed at each design point and allows for efficient utilization of multiple processors. While the total amount of work performed will generally increase (since some speculative gradients will not be used when a trial point is rejected in the line search phase), the run time will usually decrease (since gradient evaluations needed at the start of each new optimization cycle were already performed in parallel during the line search phase). Refer to [13] for additional details. The speculative specification is implemented for the gradient-based optimizers in the DOT, CONMIN, and OPT++ libraries, and it can be used with dakota numerical or analytic gradient selections in the responses specification (refer to responses gradient section for information on these specifications). It should not be selected with vendor numerical gradients since vendor internal finite difference algorithms have not been modified for this purpose. In full-Newton approaches, the Hessian is also computed speculatively. NPSOL and NLSSOL do not support speculative gradients, as their gradient-based line search in user-supplied gradient mode (dakota numerical or analytic gradients) is a superior approach for load-balanced parallel execution.

The speculative specification enables speculative computation of gradient and/or Hessian information, where applicable, for parallel optimization studies. By speculating that the derivative information at the current point will be used later, the complete data set (all available gradient/Hessian information) can be computed on every function evaluation. While some of these computations will be wasted, the positive effects are a consistent parallel load balance and usually shorter wall clock time. The speculative specification is applicable only when parallelism in the gradient calculations can be exploited by Dakota (it will be ignored for vendor numerical gradients).

• max_function_evaluations

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

• method_independent_controls

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed max_function_evaluations evaluations. See also max_iterations.

Some optimizers (e.g. ncsu_direct) may run past this limit in the course of an iteration step that began before max_function_evaluations was exceeded.

Default Behavior

Default value is 1000.

7.2.12.6 scaling

• Keywords Area
• method
• dot_bfgs
• scaling

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

• method_independent_controls
Specification

**Alias:** none

**Argument(s):** none

**Default:** no scaling

Description

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords `scale_types` and/or `scales` in the `variables` and `responses` blocks. When the `scaling` keyword is omitted from `method`, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

- a `scales` keyword, which gives characteristic values (divisors)
- a `scale_types` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in `responses` for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are three scale types:

1. **value** - characteristic value scaling
   
   The target quantity will be scaled (divided) by the specified characteristic value.

2. **auto** - automatic scaling
   
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   
   - two-sided bounds scaled into the interval \([0,1]\);
   - one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
   - no bounds or targets: no automatic scaling possible, therefore no scaling for this component

   Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into \([0,1]\).

3. **log** - logarithmic scaling
   
   First, any characteristic values from the optional `*_scales` specification are applied. Then logarithm base 10 scaling is applied.

   Logarithmic scaling is not available for linear constraints.

   When continuous design variables are log scaled, linear constraints are not allowed.
Scales

The *scales* keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding *scale_types*, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- auto, log - optional
- value - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0 \times 10^{10}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```plaintext
responses
    objective_functions 3
    sense "maximize"
    primary_scale_types = "value"
    primary_scales = 1 1 100

responses
    objective_functions 3
    sense "maximize"
    primary_scale_types = "value" "value" "value"
    primary_scales = 1 1 100
```

**Description**

DOT library [88] implementation of sequential linear programming for constrained optimization.

See package_dot for information common to all DOT methods.
**DOT requires a separate software license and therefore may not be available in all versions of Dakota. CONMIN or OPT++ methods may be suitable alternatives.**

**Expected HDF5 Output**

If Dakota was built with HDF5 support and run with the **hdf5** keyword, this method writes the following results to HDF5:

- Best Parameters
- Best Objective Functions (when **objective_functions**) are specified)
- Best Nonlinear Constraints
- Calibration (when **calibration_terms** are specified)

### 7.2.13.1 max_iterations

- **Keywords Area**
- **method**
- **dot_slp**
- **max_iterations**

Number of iterations allowed for optimizers and adaptive UQ methods

**Topics**

This keyword is related to the topics:

- **method_independent_controls**

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 100 (exceptions: fsu_cvt, local_reliability: 25; global_(reliability, interval_est, evidence) / efficient_global: 25*n)

**Description**

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed **max_iterations** iterations. In cases where there are multiple nested iterations to be controlled, **max_iterations** generally controls the outer-most context.

**Default Behavior**

Default value is 100.

**See Also**

These keywords may also be of interest:

- **max_function_evaluations**
7.2.13.2 convergence_tolerance

- Keywords Area
- method
- dot_slp
- convergence_tolerance

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none
Argument(s): REAL
Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration. Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See `nl2sol`
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

7.2.13.3 constraint_tolerance

- Keywords Area
- method
Maximum allowable constraint violation still considered feasible

Topics
This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none
Argument(s): REAL
Default: Library default

Description

Sets the maximum allowable value of infeasibility that any constraint in an optimization problem may possess and still be considered to be satisfied.

If a constraint's violation is greater than this value then it is considered to be violated by the optimization algorithm. This specification gives some control over how tightly the constraints will be satisfied at convergence of the algorithm. However, if the value is set too small the algorithm may terminate with one or more constraints being violated.

Defaults

Defaults vary depending on the method.

- CONMIN optimizers: 1.0e-3
- DOT constrained optimizers: 3.0e-3
- surrogate_based_local : 1.0e-4

Compute speculative gradients

Topics

This keyword is related to the topics:

- method_independent_controls
Specification

Alias: none
Argument(s): none
Default: no speculation

Description

When performing gradient-based optimization in parallel, speculative gradients can be selected to address the load imbalance that can occur between gradient evaluation and line search phases. In a typical gradient-based optimization, the line search phase consists primarily of evaluating the objective function and any constraints at a trial point, and then testing the trial point for a sufficient decrease in the objective function value and/or constraint violation. If a sufficient decrease is not observed, then one or more additional trial points may be attempted sequentially. However, if the trial point is accepted then the line search phase is complete and the gradient evaluation phase begins. By speculating that the gradient information associated with a given line search trial point will be used later, additional coarse grained parallelism can be introduced by computing the gradient information (either by finite difference or analytically) in parallel, at the same time as the line search phase trial-point function values. This balances the total amount of computation to be performed at each design point and allows for efficient utilization of multiple processors. While the total amount of work performed will generally increase (since some speculative gradients will not be used when a trial point is rejected in the line search phase), the run time will usually decrease (since gradient evaluations needed at the start of each new optimization cycle were already performed in parallel during the line search phase). Refer to [13] for additional details. The speculative specification is implemented for the gradient-based optimizers in the DOT, CONMIN, and OPT++ libraries, and it can be used with dakota numerical or analytic gradient selections in the responses specification (refer to responses gradient section for information on these specifications). It should not be selected with vendor numerical gradients since vendor internal finite difference algorithms have not been modified for this purpose. In full-Newton approaches, the Hessian is also computed speculatively. NPSOL and NLSSOL do not support speculative gradients, as their gradient-based line search in user-supplied gradient mode (dakota numerical or analytic gradients) is a superior approach for load-balanced parallel execution.

The speculative specification enables speculative computation of gradient and/or Hessian information, where applicable, for parallel optimization studies. By speculating that the derivative information at the current point will be used later, the complete data set (all available gradient/Hessian information) can be computed on every function evaluation. While some of these computations will be wasted, the positive effects are a consistent parallel load balance and usually shorter wall clock time. The speculative specification is applicable only when parallelism in the gradient calculations can be exploited by Dakota (it will be ignored for vendor numerical gradients).

7.2.13.5 max_function_evaluations

- Keywords Area

- method

- dot_slp

- max_function_evaluations

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- method_independent_controls
 Specification

 Alias: none
 Argument(s): INTEGER
 Default: 1000

 Description

 The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed \texttt{max\_function\_evaluations} evaluations. See also \texttt{max\_iterations}.

 Some optimizers (e.g. \texttt{ncsu\_direct}) may run past this limit in the course of an iteration step that began before \texttt{max\_function\_evaluations} was exceeded.

 Default Behavior

 Default value is 1000.

 7.2.13.6 scaling

 - Keywords Area
 - method
 - dot_slp
 - scaling

 Turn on scaling for variables, responses, and constraints

 Topics

 This keyword is related to the topics:

 - \texttt{method\_independent\_controls}

 Specification

 Alias: none
 Argument(s): none
 Default: no scaling

 Description

 Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the \texttt{scaling} keyword. Discrete variable scaling is not supported.

 When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.
Scaling also requires the specification of additional keywords `scale_types` and/or `*scales` in the `variables` and `responses` blocks. When the `scaling` keyword is omitted from `method`, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

- A `*scales` keyword, which gives characteristic values (divisors)
- A `*scale_types` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in `responses` for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

**Scale Types**

There are three scale types:

1. **value** - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.

2. **auto** - automatic scaling
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   - two-sided bounds scaled into the interval [0,1];
   - one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
   - no bounds or targets: no automatic scaling possible, therefore no scaling for this component

   Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

3. **log** - logarithmic scaling
   First, any characteristic values from the optional `*_scales` specification are applied. Then logarithm base 10 scaling is applied.
   Logarithmic scaling is not available for linear constraints.
   When continuous design variables are log scaled, linear constraints are not allowed.

**Scales**

The `*_scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*_scale_types`, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- `auto`, `log` - optional
- `value` - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than `1.0e10*DBL_MIN`. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.
Examples

The two examples below are equivalent:

```
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100
```

```
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

7.2.13.7 model_pointer

- Keywords Area
- method
- dot_slp
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

**Usage Tips**

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

7.2.14.2 convergence_tolerance

- Keywords Area
- method
- dot_sqp
- convergence_tolerance

Stopping criterion based on objective function or statistics convergence
Keywords Area

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration. Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See `nl2sol`
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

7.2.14.3 constraint_tolerance

- Keywords Area
- method
- dot_sqp
- constraint_tolerance

Maximum allowable constraint violation still considered feasible

Topics

This keyword is related to the topics:

- method_independent_controls
Specification

Alias: none
Argument(s): REAL
Default: Library default

Description

Sets the maximum allowable value of infeasibility that any constraint in an optimization problem may possess and still be considered to be satisfied.

If a constraint's violation is greater than this value then it is considered to be violated by the optimization algorithm. This specification gives some control over how tightly the constraints will be satisfied at convergence of the algorithm. However, if the value is set too small the algorithm may terminate with one or more constraints being violated.

Defaults

Defaults vary depending on the method.

7.2.14.4 speculative

- Keywords Area
  - method
  - dot_sqp
  - speculative

Compute speculative gradients

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none
Argument(s): none
Default: no speculation

Description

When performing gradient-based optimization in parallel, speculative gradients can be selected to address the load imbalance that can occur between gradient evaluation and line search phases. In a typical gradient-based optimization, the line search phase consists primarily of evaluating the objective function and any constraints at a
trial point, and then testing the trial point for a sufficient decrease in the objective function value and/or constraint violation. If a sufficient decrease is not observed, then one or more additional trial points may be attempted sequentially. However, if the trial point is accepted then the line search phase is complete and the gradient evaluation phase begins. By speculating that the gradient information associated with a given line search trial point will be used later, additional coarse grained parallelism can be introduced by computing the gradient information (either by finite difference or analytically) in parallel, at the same time as the line search phase trial-point function values. This balances the total amount of computation to be performed at each design point and allows for efficient utilization of multiple processors. While the total amount of work performed will generally increase (since some speculative gradients will not be used when a trial point is rejected in the line search phase), the run time will usually decrease (since gradient evaluations needed at the start of each new optimization cycle were already performed in parallel during the line search phase). Refer to [13] for additional details. The speculative specification is implemented for the gradient-based optimizers in the DOT, CONMIN, and OPT++ libraries, and it can be used with dakota numerical or analytic gradient selections in the responses specification (refer to responses gradient section for information on these specifications). It should not be selected with vendor numerical gradients since vendor internal finite difference algorithms have not been modified for this purpose. In full-Newton approaches, the Hessian is also computed speculatively. NPSOL and NLSSOL do not support speculative gradients, as their gradient-based line search in user-supplied gradient mode (dakota numerical or analytic gradients) is a superior approach for load-balanced parallel execution.

The speculative specification enables speculative computation of gradient and/or Hessian information, where applicable, for parallel optimization studies. By speculating that the derivative information at the current point will be used later, the complete data set (all available gradient/Hessian information) can be computed on every function evaluation. While some of these computations will be wasted, the positive effects are a consistent parallel load balance and usually shorter wall clock time. The speculative specification is applicable only when parallelism in the gradient calculations can be exploited by Dakota (it will be ignored for vendor numerical gradients).

7.2.14.5 max_function_evaluations

- Keywords Area
- method
- dot_sap
- max_function_evaluations

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed max_function_evaluations evaluations. See also max_iterations.
Some optimizers (e.g., ncsu_direct) may run past this limit in the course of an iteration step that began before max_function_evaluations was exceeded.

**Default Behavior**

Default value is 1000.

### 7.2.14.6 scaling

- **Keywords Area**
- **method**
- **dot_sqp**
- **scaling**

Turn on scaling for variables, responses, and constraints

**Topics**

This keyword is related to the topics:

- **method_independent_controls**

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** no scaling

**Description**

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords `scale_types` and/or `*scales` in the `variables` and `responses` blocks. When the `scaling` keyword is omitted from `method`, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

- a `*scales` keyword, which gives characteristic values (divisors)
- a `*scale_types` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in `responses` for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

**Scale Types**

There are three scale types:
1. value - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.

2. auto - automatic scaling
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   - two-sided bounds scaled into the interval [0,1];
   - one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
   - no bounds or targets: no automatic scaling possible, therefore no scaling for this component

   Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

3. log - logarithmic scaling
   First, any characteristic values from the optional *scales specification are applied. Then logarithm base 10 scaling is applied.
   Logarithmic scaling is not available for linear constraints.
   When continuous design variables are log scaled, linear constraints are not allowed.

Scales
The *scales keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding *scale_types, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

   • auto, log - optional
   • value - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than 1.0e10*DBL_MIN. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples
The two examples below are equivalent:

```
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100

responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

**Default:** 1.e-4
Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLQPLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See nl2sol
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

7.2.15.3 `constraint_tolerance`

- Keywords Area
- method
- conmin_frcg
- constraint_tolerance

Maximum allowable constraint violation still considered feasible

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none
Argument(s): REAL
Default: Library default

Description

Sets the maximum allowable value of infeasibility that any constraint in an optimization problem may possess and still be considered to be satisfied.
If a constraint’s violation is greater than this value then it is considered to be violated by the optimization algorithm. This specification gives some control over how tightly the constraints will be satisfied at convergence of the algorithm. However, if the value is set too small the algorithm may terminate with one or more constraints being violated.

**Defaults**

Defaults vary depending on the method.

- **CONMIN optimizers**: 1.0e-3
- **DOT constrained optimizers**: 3.0e-3
- **surrogate_based_local**: 1.0e-4

### 7.2.15.4 speculative

- **Keywords Area**
- **method**
- **conmin_frcg**
- **speculative**

Compute speculative gradients

**Topics**

This keyword is related to the topics:

- **method_independent_controls**

**Specification**

**Alias**: none

**Argument(s)**: none

**Default**: no speculation

**Description**

When performing gradient-based optimization in parallel, speculative gradients can be selected to address the load imbalance that can occur between gradient evaluation and line search phases. In a typical gradient-based optimization, the line search phase consists primarily of evaluating the objective function and any constraints at a trial point, and then testing the trial point for a sufficient decrease in the objective function value and/or constraint violation. If a sufficient decrease is not observed, then one or more additional trial points may be attempted sequentially. However, if the trial point is accepted then the line search phase is complete and the gradient evaluation phase begins. By speculating that the gradient information associated with a given line search trial point will be used later, additional coarse grained parallelism can be introduced by computing the gradient information (either by finite difference or analytically) in parallel, at the same time as the line search phase trial-point function values. This balances the total amount of computation to be performed at each design point and allows for efficient utilization of multiple processors. While the total amount of work performed will generally increase (since some speculative gradients will not be used when a trial point is rejected in the line search phase), the run time will usually decrease (since gradient evaluations needed at the start of each new optimization cycle were already performed in parallel during the line search phase). Refer to [13] for additional details. The speculative specification is implemented for the gradient-based optimizers in the DOT, CONMIN, and OPT++ libraries, and it can be used with dakota numerical...
or analytic gradient selections in the responses specification (refer to responses gradient section for information on these specifications). It should not be selected with vendor numerical gradients since vendor internal finite difference algorithms have not been modified for this purpose. In full-Newton approaches, the Hessian is also computed speculatively. NPSOL and NLSSOL do not support speculative gradients, as their gradient-based line search in user-supplied gradient mode (dakota numerical or analytic gradients) is a superior approach for load-balanced parallel execution.

The speculative specification enables speculative computation of gradient and/or Hessian information, where applicable, for parallel optimization studies. By speculating that the derivative information at the current point will be used later, the complete data set (all available gradient/Hessian information) can be computed on every function evaluation. While some of these computations will be wasted, the positive effects are a consistent parallel load balance and usually shorter wall clock time. The speculative specification is applicable only when parallelism in the gradient calculations can be exploited by Dakota (it will be ignored for vendor numerical gradients).

7.2.15.5 max_function_evaluations

- Keywords Area
- method
- conmin_frcg
- max_function_evaluations

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed max_function_evaluations evaluations. See also max_iterations.

Some optimizers (e.g. ncsu_direct) may run past this limit in the course of an iteration step that began before max_function_evaluations was exceeded.

Default Behavior

Default value is 1000.

7.2.15.6 scaling

- Keywords Area
- method
• conmin_frcg
• scaling

Turn on scaling for variables, responses, and constraints

Topics
This keyword is related to the topics:

• method_independent_controls

Specification

Alias: none
Argument(s): none
Default: no scaling

Description

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the *scaling* keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords *scale_types* and/or *scales* in the *variables* and *responses* blocks. When the *scaling* keyword is omitted from *method*, these scaling type and value specifications are ignored in the *variables* and *responses* sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

• a *scales* keyword, which gives characteristic values (divisors)

• a *scale_types* keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in *responses* for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types
There are three scale types:

1. value - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.

2. auto - automatic scaling
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   • two-sided bounds scaled into the interval [0,1];
7.2 method

- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0, 1].

3. log - logarithmic scaling

First, any characteristic values from the optional *
_scales specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints. When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The *
scales keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding *
scale_types, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- auto, log - optional
- value - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than 1.0e10*DBL_MIN. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```plaintext
responses
 objective_functions 3
 sense "maximize"
 primary_scale_types = "value"
 primary_scales = 1 1 100

responses
 objective_functions 3
 sense "maximize"
 primary_scale_types = "value" "value" "value"
 primary_scales = 1 1 100
```

7.2.15.7 model_pointer

- Keywords Area
- method
- conmin_frcg
- model_pointer

Identifier for model block to be used by a method
Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.

See block_pointer for details about pointers.

Examples

```dakota
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
      0.1 0.2 0.6
        0.1 0.2 0.6
    sample_type lhs
    distribution cumulative

model
  id_model = 'SURR'
  surrogate global,
  dace_method_pointer = 'DACE'
  polynomial quadratic

method
  id_method = 'DACE'
  model_pointer = 'DACE_M'
  sampling sample_type lhs
    samples = 121 seed = 5034 rng rnum2

model
  id_model = 'DACE_M'
  single
  interface_pointer = 'I1'
```
variables
  uniform_uncertain = 2
  lower_bounds = 0. 0.
  upper_bounds = 1. 1.
  descriptors = 'x1' 'x2'

interface
  id_interface = 'I1'
  system asynch evaluation_concurrency = 5
  analysis_driver = 'text_book'

responses
  response_functions = 3
  no_gradients
  no_hessians

7.2.16 conmin_mfd

  • Keywords Area
  • method
  • conmin_mfd

CONMIN method of feasible directions

Topics

This keyword is related to the topics:

### Description

The interpretations of the method independent controls for CONMIN are essentially identical to those for DOT. See [package_dot](https://package_dot) for information related to CONMIN methods, specifically [dot_mmfd](https://dot_mmfd).

### Expected HDF5 Output

If Dakota was built with HDF5 support and run with the hdf5 keyword, this method writes the following results to HDF5:

- **Best Parameters**
- **Best Objective Functions** (when objective_functions are specified)
- **Best Nonlinear Constraints**
- **Calibration** (when calibration_terms are specified)

### See Also

These keywords may also be of interest:

- [dot_mmfd](https://dot_mmfd)

### 7.2.16.1 max_iterations

- **Keywords Area**
- **method**
- **conmin_mfd**
- **max_iterations**

Number of iterations allowed for optimizers and adaptive UQ methods
7.2 method

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: fsu_cvt, local_reliability: 25; global_(reliability, interval_est, evidence) / efficient_global: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed \( \text{max_iterations} \) iterations. In cases where there are multiple nested iterations to be controlled, \( \text{max_iterations} \) generally controls the outer-most context.

Default Behavior

Default value is 100.

7.2.16.2 convergence_tolerance

Keywords Area

- method

convergence_tolerance

Keywords Area

- method

convergence_tolerance

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4
Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See `nl2sol`
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

7.2.16.3 constraint_tolerance

- Keywords Area
- method
- conmin_mfd
- constraint_tolerance

Maximum allowable constraint violation still considered feasible

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): REAL

Default: Library default

Description

Sets the maximum allowable value of infeasibility that any constraint in an optimization problem may possess and still be considered to be satisfied.
If a constraint's violation is greater than this value then it is considered to be violated by the optimization algorithm. This specification gives some control over how tightly the constraints will be satisfied at convergence of the algorithm. However, if the value is set too small the algorithm may terminate with one or more constraints being violated.

**Defaults**

Defaults vary depending on the method.

- conmin_mfd
- speculative

Compute speculative gradients

**Topics**

This keyword is related to the topics:

- method_independent_controls

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** no speculation

**Description**

When performing gradient-based optimization in parallel, speculative gradients can be selected to address the load imbalance that can occur between gradient evaluation and line search phases. In a typical gradient-based optimization, the line search phase consists primarily of evaluating the objective function and any constraints at a trial point, and then testing the trial point for a sufficient decrease in the objective function value and/or constraint violation. If a sufficient decrease is not observed, then one or more additional trial points may be attempted sequentially. However, if the trial point is accepted then the line search phase is complete and the gradient evaluation phase begins. By speculating that the gradient information associated with a given line search trial point will be used later, additional coarse grained parallelism can be introduced by computing the gradient information (either by finite difference or analytically) in parallel, at the same time as the line search phase trial-point function values. This balances the total amount of computation to be performed at each design point and allows for efficient utilization of multiple processors. While the total amount of work performed will generally increase (since some speculative gradients will not be used when a trial point is rejected in the line search phase), the run time will usually decrease (since gradient evaluations needed at the start of each new optimization cycle were already performed in parallel during the line search phase). Refer to [13] for additional details. The speculative specification is implemented for the gradient-based optimizers in the DOT, CONMIN, and OPT++ libraries, and it can be used with dakota numerical...
or analytic gradient selections in the responses specification (refer to responses gradient section for information on these specifications). It should not be selected with vendor numerical gradients since vendor internal finite difference algorithms have not been modified for this purpose. In full-Newton approaches, the Hessian is also computed speculatively. NPSOL and NLSSOL do not support speculative gradients, as their gradient-based line search in user-supplied gradient mode (dakota numerical or analytic gradients) is a superior approach for load-balanced parallel execution.

The speculative specification enables speculative computation of gradient and/or Hessian information, where applicable, for parallel optimization studies. By speculating that the derivative information at the current point will be used later, the complete data set (all available gradient/Hessian information) can be computed on every function evaluation. While some of these computations will be wasted, the positive effects are a consistent parallel load balance and usually shorter wall clock time. The speculative specification is applicable only when parallelism in the gradient calculations can be exploited by Dakota (it will be ignored for vendor numerical gradients).

- max_function_evaluations

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed max_function_evaluations evaluations. See also max_iterations.

Some optimizers (e.g. ncsu_direct) may run past this limit in the course of an iteration step that began before max_function_evaluations was exceeded.

Default Behavior

Default value is 1000.

7.2.16.6 scaling

- Keywords Area
- method
Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the scaling keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords scale_types and/or $\ast$scales in the variables and responses blocks. When the scaling keyword is omitted from method, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled:

- a $\ast$scales keyword, which gives characteristic values (divisors)
- a $\ast$scale_types keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in responses for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are three scale types:

1. value - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.

2. auto - automatic scaling
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   - two-sided bounds scaled into the interval $[0,1]$;
• one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
• no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

3. **log** - logarithmic scaling

First, any characteristic values from the optional *_scales specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

**Scales**

The *scales keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding *scale_types, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

• auto, log - optional
• value - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than 1.0e10*DBL_MIN. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

**Examples**

The two examples below are equivalent:

```dakota
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100

responses

- **Keywords Area**
- **method**
- **dl_solver**
- **scaling**

Turn on scaling for variables, responses, and constraints

**Topics**

This keyword is related to the topics:

- **method_independent_controls**
Specification

Alias: none
Argument(s): none
Default: no scaling

Description

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords `scale_types` and/or `*_scales` in the `variables` and `responses` blocks. When the `scaling` keyword is omitted from `method`, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled:

- a `*_scales` keyword, which gives characteristic values (divisors)
- a `*_scale_types` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in `responses` for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are three scale types:

1. value - characteristic value scaling
   
   The target quantity will be scaled (divided) by the specified characteristic value.

2. auto - automatic scaling
   
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   
   - two-sided bounds scaled into the interval [0,1];
   - one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
   - no bounds or targets: no automatic scaling possible, therefore no scaling for this component

   Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

3. log - logarithmic scaling
   
   First, any characteristic values from the optional `_scales` specification are applied. Then logarithm base 10 scaling is applied.

   Logarithmic scaling is not available for linear constraints.

   When continuous design variables are log scaled, linear constraints are not allowed.
Scales

The *scales* keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding *scale_types*, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- auto, log - optional
- value - required

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0 \times 10^{10}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```plaintext

7.2.17.3 model_pointer

- Keywords Area
- method
- dl_solver
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)
Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
    0.1 0.2 0.6
    0.1 0.2 0.6
    sample_type lhs
    distribution cumulative

model
  id_model = 'SURR'
  surrogate global,
  dace_method_pointer = 'DACE'
  polynomial quadratic

method
  id_method = 'DACE'
  model_pointer = 'DACE_M'
  sampling sample_type lhs
  samples = 121 seed = 5034 rng rnum2

model
  id_model = 'DACE_M'
  single
  interface_pointer = 'I1'

variables
  uniform_uncertain = 2
  lower_bounds = 0. 0.
  upper_bounds = 1. 1.
  descriptors = 'x1' 'x2'

interface
  id_interface = 'I1'
  system asynch evaluation_concurrency = 5
  analysis_driver = 'text_book'

responses
  response_functions = 3
  no_gradients
  no_hessians
```
7.2.18  npsol_sqp

### Description

Sequential quadratic programming optimizer.

*NPSOL requires a separate software license and therefore may not be available in all versions of Dakota. CONMIN or OPT++ methods may be suitable alternatives.*

### Stopping Criteria

The method independent controls for `max_iterations` and `max_function_evaluations` limit the number of major SQP iterations and the number of function evaluations that can be performed during an NPSOL optimization. The `convergence_tolerance` control defines NPSOL’s internal optimality tolerance which is used in evaluating if an iterate satisfies the first-order Kuhn-Tucker conditions for a minimum. The magnitude of `convergence_tolerance` approximately specifies the number of significant digits of accuracy desired in the final objective function (e.g., `convergence_tolerance = 1.e-6` will result in approximately six digits of accuracy in the final objective function). The `constraint_tolerance` control defines how tightly the constraint functions are satisfied at convergence. The default value is dependent upon the machine precision of the platform in use, but is typically on the order of 1.e-8 for double precision computations. Extremely small values for `constraint_tolerance` may not be attainable. The output verbosity setting controls the amount of information generated at each major SQP iteration: the `silent` and `quiet` settings result in only one line of diagnostic output for each major iteration and print the final optimization solution, whereas the `verbose` and `debug` settings add additional information on the objective function, constraints, and variables at each major iteration.

### Concurrency

*NPSOL is not a parallel algorithm and cannot directly take advantage of concurrent evaluations. However, if numerical_gradients with method_source dakota is specified, then the finite difference evaluations can be performed concurrently (using any of the parallel modes described in the Users Manual [5]).*  

An important related observation is the fact that NPSOL uses two different line searches depending on how gradients are computed. For either analytic_gradients or numerical_gradients with method_source dakota, NPSOL is placed in user-supplied gradient mode (NPSOLs “Derivative Level” is set to 3) and it uses a gradient-based line search (the assumption is that user-supplied gradients are inexpensive). On the other hand, if numerical_gradients are selected with method_source vendor, then NPSOL is computing finite differences internally and it will use a value-based line search (the assumption is that finite differencing on each line search evaluation is too expensive). The ramifications of this are: (1) performance will vary between method_source dakota and method_source vendor for numerical_gradients, and (2) gradient speculation is unnecessary when performing optimization in parallel since the gradient-based line search in user-supplied gradient mode is already load balanced for parallel execution. Therefore, a speculative specification will be ignored.
by NPSOL, and optimization with numerical gradients should select method_source dakota for load balanced parallel operation and method_source vendor for efficient serial operation.

Linear constraints

Lastly, NPSOL supports specialized handling of linear inequality and equality constraints. By specifying the coefficients and bounds of the linear inequality constraints and the coefficients and targets of the linear equality constraints, this information can be provided to NPSOL at initialization and tracked internally, removing the need for the user to provide the values of the linear constraints on every function evaluation.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the hdf5 keyword, this method writes the following results to HDF5:

- Best Parameters
- Best Objective Functions (when objective_functions) are specified
- Best Nonlinear Constraints
- Calibration (when calibration_terms are specified)

7.2.18.1 verify_level

- Keywords Area
- method
- npsol_sqp
- verify_level

Verify the quality of analytic gradients

Specification

Alias: none

Argument(s): INTEGER

Default: -1 (no gradient verification)

Description

verify_level instructs the NPSOL and NLSSOL algorithms to perform their own finite difference verification of the gradients provided by Dakota. Typically these are used to verify analytic_gradients produced by a simulation code, though the option can be used with other Dakota-supplied gradient types including numerical or mixed.

Level 1 will verify the objective gradients, level 2, the nonlinear constraint gradients, and level 3, both. See the Optional Input Parameters section of the NPSOL manual [33] for additional information, including options to verify at the user-supplied initial point vs. first feasible point.

7.2.18.2 function_precision

- Keywords Area
- method
- npsol_sqp
• function_precision

Specify the maximum precision of the analysis code responses

Specification

Alias: none
Argument(s): REAL
Default: 1.0e-10

Description

The function_precision control provides the algorithm with an estimate of the accuracy to which the problem functions can be computed. This is used to prevent the algorithm from trying to distinguish between function values that differ by less than the inherent error in the calculation.

7.2.18.3 linesearch_tolerance

• Keywords Area
• method
• npsol_sqp
• linesearch_tolerance

Choose how accurately the algorithm will compute the minimum in a line search

Specification

Alias: none
Argument(s): REAL
Default: 0.9 (inaccurate line search)

Description

The linesearch_tolerance setting controls the accuracy of the line search. The smaller the value (between 0 and 1), the more accurately the algorithm will attempt to compute a precise minimum along the search direction.

7.2.18.4 convergence_tolerance

• Keywords Area
• method
• npsol_sqp
• convergence_tolerance

Stopping criterion based on objective function convergence
7.2 method

Specification

Alias: none
Argument(s): REAL
Default: 1.e-4

Description

The convergence_tolerance specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by convergence_tolerance, then this convergence criterion is satisfied on the current iteration. Therefore, permissible values are between 0 and 1, non-inclusive.

NPSOL defines an internal optimality tolerance which is used in evaluating if an iterate satisfies the first-order Kuhn-Tucker conditions for a minimum. The magnitude of convergence_tolerance approximately specifies the number of significant digits of accuracy desired in the final objective function (e.g., convergence_tolerance = 1.0e-6 will result in approximately six digits of accuracy in the final objective function).

7.2.18.5 max_iterations

- Keywords Area
- method
- npsol_sqp
- max_iterations

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none
Argument(s): INTEGER
Default: 100 (exceptions: fsu_cvt, local_reliability: 25; global_(reliability, interval_est, evidence) / efficient_global: 25+n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed max_iterations iterations. In cases where there are multiple nested iterations to be controlled, max_iterations generally controls the outer-most context.

Default Behavior

Default value is 100.
See Also

These keywords may also be of interest:

- max_function_evaluations

7.2.18.6 constraint_tolerance

- Keywords Area
- method
- npsol_sqp
- constraint_tolerance

Maximum allowable constraint violation still considered feasible

Specification

Alias: none

Argument(s): REAL

Default: Library default

Description

Sets the maximum allowable value of infeasibility that any constraint in an optimization problem may possess and still be considered to be satisfied.

If a constraint’s violation is greater than this value then it is considered to be violated by the optimization algorithm. This specification gives some control over how tightly the constraints will be satisfied at convergence of the algorithm. However, if the value is set too small the algorithm may terminate with one or more constraints being violated.

Dakota’s constraint_tolerance settings maps to NPSOL’s feasibility tolerance which is an absolute tolerance on the constraints.

7.2.18.7 speculative

- Keywords Area
- method
- npsol_sqp
- speculative

Compute speculative gradients

Topics

This keyword is related to the topics:

- method_independent_controls
### Specification

**Alias:** none  
**Argument(s):** none  
**Default:** no speculation

#### Description

When performing gradient-based optimization in parallel, speculative gradients can be selected to address the load imbalance that can occur between gradient evaluation and line search phases. In a typical gradient-based optimization, the line search phase consists primarily of evaluating the objective function and any constraints at a trial point, and then testing the trial point for a sufficient decrease in the objective function value and/or constraint violation. If a sufficient decrease is not observed, then one or more additional trial points may be attempted sequentially. However, if the trial point is accepted then the line search phase is complete and the gradient evaluation phase begins. By speculating that the gradient information associated with a given line search trial point will be used later, additional coarse grained parallelism can be introduced by computing the gradient information (either by finite difference or analytically) in parallel, at the same time as the line search phase trial-point function values. This balances the total amount of computation to be performed at each design point and allows for efficient utilization of multiple processors. While the total amount of work performed will generally increase (since some speculative gradients will not be used when a trial point is rejected in the line search phase), the run time will usually decrease (since gradient evaluations needed at the start of each new optimization cycle were already performed in parallel during the line search phase). Refer to [13] for additional details. The speculative specification is implemented for the gradient-based optimizers in the DOT, CONMIN, and OPT++ libraries, and it can be used with dakota numerical or analytic gradient selections in the responses specification (refer to responses gradient section for information on these specifications). It should not be selected with vendor numerical gradients since vendor internal finite difference algorithms have not been modified for this purpose. In full-Newton approaches, the Hessian is also computed speculatively. NPSOL and NLSSOL do not support speculative gradients, as their gradient-based line search in user-supplied gradient mode (dakota numerical or analytic gradients) is a superior approach for load-balanced parallel execution.

The speculative specification enables speculative computation of gradient and/or Hessian information, where applicable, for parallel optimization studies. By speculating that the derivative information at the current point will be used later, the complete data set (all available gradient/Hessian information) can be computed on every function evaluation. While some of these computations will be wasted, the positive effects are a consistent parallel load balance and usually shorter wall clock time. The speculative specification is applicable only when parallelism in the gradient calculations can be exploited by Dakota (it will be ignored for vendor numerical gradients).

#### 7.2.18.8 max_function_evaluations

- **Keywords Area**
- **method**
- **npsol_sqp**
- **max_function_evaluations**

Number of function evaluations allowed for optimizers

#### Topics

This keyword is related to the topics:

- **method_independent_controls**
Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** 1000

**Description**

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed max\_function\_evaluations evaluations. See also max\_iterations.

Some optimizers (e.g. ncsu\_direct) may run past this limit in the course of an iteration step that began before max\_function\_evaluations was exceeded.

**Default Behavior**

Default value is 1000.

7.2.18.9 scaling

- Keywords Area
- method
- npsol_sqp
- scaling

Turn on scaling for variables, responses, and constraints

**Topics**

This keyword is related to the topics:

- method\_independent\_controls

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** no scaling

**Description**

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the scaling keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.
Scaling also requires the specification of additional keywords \texttt{scale\_types} and/or \texttt{*scales} in the \texttt{variables} and \texttt{responses} blocks. When the \texttt{scaling} keyword is omitted from \texttt{method}, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

- a \texttt{*scales} keyword, which gives characteristic values (divisors)
- a \texttt{*scale\_types} keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in \texttt{responses} for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

**Scale Types**

There are three scale types:

1. \texttt{value} - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.

2. \texttt{auto} - automatic scaling
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   - two-sided bounds scaled into the interval [0,1];
   - one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
   - no bounds or targets: no automatic scaling possible, therefore no scaling for this component

   Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

3. \texttt{log} - logarithmic scaling
   First, any characteristic values from the optional \texttt{*_scales} specification are applied. Then logarithm base 10 scaling is applied.

   Logarithmic scaling is not available for linear constraints.

   When continuous design variables are log scaled, linear constraints are not allowed.

**Scales**

The \texttt{*scales} keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding \texttt{*scale\_types}, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- \texttt{auto, log} - optional
- \texttt{value} - required

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10\times\text{DBL\_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.
Examples

The two examples below are equivalent:

```
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100
```

```
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

7.2.18.10  model_pointer

- Keywords Area
- method
- npsol_sqp
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

**Usage Tips**

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.
### Examples

```dakota
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
  sample_type lhs
distribution cumulative

model
  id_model = 'SURR'
  surrogate global,
    dace_method_pointer = 'DACE'
    polynomial quadratic

method
  id_method = 'DACE'
  model_pointer = 'DACE_M'
  sampling sample_type lhs
    samples = 121 seed = 5034 rng rnum2

model
  id_model = 'DACE_M'
  single
  interface_pointer = 'I1'

variables
  uniform_uncertain = 2
    lower_bounds = 0. 0.
    upper_bounds = 1. 1.
  descriptors = 'x1' 'x2'

interface
  id_interface = 'I1'
  system asynch evaluation_concurrency = 5
  analysis_driver = 'text_book'

responses
  response_functions = 3
  no_gradients
  no_hessians
```

NLSSOL supports unconstrained, bound-constrained, and generally-constrained least-squares calibration problems. It exploits the structure of a least squares objective function through the periodic use of Gauss-Newton Hessian approximations to accelerate the SQP algorithm.

NLSSOL requires a separate software license and therefore may not be available in all versions of Dakota. nl2sol or optpp_g_newton may be suitable alternatives.

Stopping Criteria
The method independent controls for max_iterations and max_function_evaluations limit the number of major SQP iterations and the number of function evaluations that can be performed during an NPSOL optimization. The convergence_tolerance control defines NPSOL's internal optimality tolerance which is used in evaluating if an iterate satisfies the first-order Kuhn-Tucker conditions for a minimum. The magnitude of convergence_tolerance approximately specifies the number of significant digits of accuracy desired in the final objective function (e.g., convergence_tolerance = 1.e-6 will result in approximately six digits of accuracy in the final objective function). The constraint_tolerance control defines how tightly the constraint functions are satisfied at convergence. The default value is dependent upon the machine precision of the platform in use, but is typically on the order of 1.e-8 for double precision computations. Extremely small values for constraint_tolerance may not be attainable.

Expected HDF5 Output
If Dakota was built with HDF5 support and run with the hdf5 keyword, this method writes the following results to HDF5:

- Best Parameters
- Best Nonlinear Constraints
- Calibration (when calibration_terms are specified)
- Parameter Confidence Intervals (when num_experiments equals 1)

See Also
These keywords may also be of interest:

7.2.19.1 verify_level

- Keywords Area
- method
- nlssol_sqp
- verify_level

Verify the quality of analytic gradients
Specification

Alias: none

Argument(s): INTEGER

Default: -1 (no gradient verification)

Description

verify_level instructs the NPSOL and NLSSOL algorithms to perform their own finite difference verification of the gradients provided by Dakota. Typically these are used to verify analytic_gradients produced by a simulation code, though the option can be used with other Dakota-supplied gradient types including numerical or mixed.

Level 1 will verify the objective gradients, level 2, the nonlinear constraint gradients, and level 3, both. See the Optional Input Parameters section of the NPSOL manual [33] for additional information, including options to verify at the user-supplied initial point vs. first feasible point.

7.2.19.2 function_precision

- Keywords Area
- method
- nlssol_sqp
- function_precision

Specify the maximum precision of the analysis code responses

Specification

Alias: none

Argument(s): REAL

Default: 1.0e-10

Description

The function_precision control provides the algorithm with an estimate of the accuracy to which the problem functions can be computed. This is used to prevent the algorithm from trying to distinguish between function values that differ by less than the inherent error in the calculation.

7.2.19.3 linesearch_tolerance

- Keywords Area
- method
- nlssol_sqp
- linesearch_tolerance

Choose how accurately the algorithm will compute the minimum in a line search
7.2 method

Specification

Alias: none
Argument(s): REAL
Default: 0.9 (inaccurate line search)

Description

The linesearch_tolerance setting controls the accuracy of the line search. The smaller the value (between 0 and 1), the more accurately the algorithm will attempt to compute a precise minimum along the search direction.

7.2.19.4 convergence_tolerance

- Keywords Area
- method
- nlssol_sqp
- convergence_tolerance

Stopping criterion based on objective function convergence

Specification

Alias: none
Argument(s): REAL
Default: 1.e-4

Description

The convergence_tolerance specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by convergence_tolerance, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

NPSOL defines an internal optimality tolerance which is used in evaluating if an iterate satisfies the first-order Kuhn-Tucker conditions for a minimum. The magnitude of convergence_tolerance approximately specifies the number of significant digits of accuracy desired in the final objective function (e.g., convergence_tolerance = 1.0e-6 will result in approximately six digits of accuracy in the final objective function).

7.2.19.5 max_iterations

- Keywords Area
- method
- nlssol_sqp
- max_iterations

Number of iterations allowed for optimizers and adaptive UQ methods
Topics

This keyword is related to the topics:

- method_independent_controls

Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** 100 (exceptions: fsu_cvt, local_reliability: 25; global_(reliability, interval_est, evidence) / efficient_global: 25*n)

**Description**

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed \( \text{max\_iterations} \) iterations. In cases where there are multiple nested iterations to be controlled, \( \text{max\_iterations} \) generally controls the outer-most context.

**Default Behavior**

Default value is 100.

**See Also**

These keywords may also be of interest:

- max_function_evaluations

7.2.19.6 constraint_tolerance

**Keyword(s):**

- Keywords Area
- method
- nlssol_sqp
- constraint_tolerance

Maximum allowable constraint violation still considered feasible

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** Library default

**Description**

Sets the maximum allowable value of infeasibility that any constraint in an optimization problem may possess and still be considered to be satisfied.
If a constraint’s violation is greater than this value then it is considered to be violated by the optimization algorithm. This specification gives some control over how tightly the constraints will be satisfied at convergence of the algorithm. However, if the value is set too small the algorithm may terminate with one or more constraints being violated.

Dakota’s `constraint_tolerance` settings maps to NPSOL’s feasibility tolerance which is an absolute tolerance on the constraints.

7.2.19.7 speculative

- **Keywords Area**
- **method**
- **nlssol_sqp**
- **speculative**

Compute speculative gradients

**Topics**

This keyword is related to the topics:

- **method_independent_controls**

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** no speculation

**Description**

When performing gradient-based optimization in parallel, speculative gradients can be selected to address the load imbalance that can occur between gradient evaluation and line search phases. In a typical gradient-based optimization, the line search phase consists primarily of evaluating the objective function and any constraints at a trial point, and then testing the trial point for a sufficient decrease in the objective function value and/or constraint violation. If a sufficient decrease is not observed, then one or more additional trial points may be attempted sequentially. However, if the trial point is accepted then the line search phase is complete and the gradient evaluation phase begins. By speculating that the gradient information associated with a given line search trial point will be used later, additional coarse grained parallelism can be introduced by computing the gradient information (either by finite difference or analytically) in parallel, at the same time as the line search phase trial-point function values. This balances the total amount of computation to be performed at each design point and allows for efficient utilization of multiple processors. While the total amount of work performed will generally increase (since some speculative gradients will not be used when a trial point is rejected in the line search phase), the run time will usually decrease (since gradient evaluations needed at the start of each new optimization cycle were already performed in parallel during the line search phase). Refer to [13] for additional details. The speculative specification is implemented for the gradient-based optimizers in the DOT, CONMIN, and OPT++ libraries, and it can be used with dakota numerical or analytic gradient selections in the responses specification (refer to responses gradient section for information on these specifications). It should not be selected with vendor numerical gradients since vendor internal finite difference algorithms have not been modified for this purpose. In full-Newton approaches, the Hessian is also computed speculatively. NPSOL and NLSSOL do not support speculative gradients, as their gradient-based line search in user-supplied gradient mode (dakota numerical or analytic gradients) is a superior approach for load-balanced parallel execution.
The speculative specification enables speculative computation of gradient and/or Hessian information, where applicable, for parallel optimization studies. By speculating that the derivative information at the current point will be used later, the complete data set (all available gradient/Hessian information) can be computed on every function evaluation. While some of these computations will be wasted, the positive effects are a consistent parallel load balance and usually shorter wall clock time. The speculative specification is applicable only when parallelism in the gradient calculations can be exploited by Dakota (it will be ignored for vendor numerical gradients).

7.2.19.8 max_function_evaluations

- Keywords Area
- method
- nlssol_sqp
- max_function_evaluations

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed max_function_evaluations evaluations. See also max_iterations.

Some optimizers (e.g. ncsu_direct) may run past this limit in the course of an iteration step that began before max_function_evaluations was exceeded.

Default Behavior

Default value is 1000.

7.2.19.9 scaling

- Keywords Area
- method
- nlssol_sqp
- scaling

Turn on scaling for variables, responses, and constraints
### Topics

This keyword is related to the topics:

- method\_independent\_controls

### Specification

**Alias:** none  
**Argument(s):** none  
**Default:** no scaling

### Description

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords `scale_types` and/or `*scales` in the variables and responses blocks. When the `scaling` keyword is omitted from `method`, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

- a `*scales` keyword, which gives characteristic values (divisors)
- a `*scale_types` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in `responses` for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

### Scale Types

There are three scale types:

1. **value** - characteristic value scaling
   
   The target quantity will be scaled (divided) by the specified characteristic value.

2. **auto** - automatic scaling
   
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   
   - two-sided bounds scaled into the interval $[0,1]$;
   - one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
   - no bounds or targets: no automatic scaling possible, therefore no scaling for this component

   Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into $[0,1]$. 

---

Dakota Version 6.16 Reference Manual generated on May 12, 2022
3. log - logarithmic scaling

   First, any characteristic values from the optional \_scales specification are applied. Then logarithm base 10 scaling is applied.

   Logarithmic scaling is not available for linear constraints.

   When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The scales keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding \scales, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- auto, log - optional
- value - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than 1.0e10*DBL_MIN. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```plaintext
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100

responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

7.2.19.10 model_pointer

- Keywords Area
- method
- nlssol_sqp
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer
7.2 method

Specification

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

**Usage Tips**

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

**Examples**

```plaintext
evironment
tabular_data
method_pointer = 'UQ'

method
id_method = 'UQ'
model_pointer = 'SURR'
sampling,
samples = 10
seed = 98765 rng rnum2

**Description**

NLPQL implementation of sequential quadratic programming. The particular SQP implementation in nlpql_sqp uses a variant with distributed and non-monotone line search. Thus, this variant is designed to be more robust in the presence of inaccurate or noisy gradients common in many engineering applications.

NLPQL requires a separate software license and therefore may not be available in all versions of Dakota. CONMIN or OPT++ methods may be suitable alternatives.

The method independent controls for maximum iterations and output verbosity are mapped to NLPQL controls MAXIT and IPRINT, respectively. The maximum number of function evaluations is enforced within the NLPQLPOptimizer class.

**Expected HDF5 Output**

If Dakota was built with HDF5 support and run with the hdf5 keyword, this method writes the following results to HDF5:

- Best Parameters
- Best Objective Functions (when objective_functions) are specified
- Best Nonlinear Constraints
- Calibration (when calibration_terms are specified)

7.2.20.1 max_iterations

- Keywords Area
- method
- nlpql_sqp
- max_iterations

Number of iterations allowed for optimizers and adaptive UQ methods

**Topics**

This keyword is related to the topics:

- method_independent_controls

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 100 (exceptions: fsu_cvt, local_reliability: 25; global_{reliability, interval_est, evidence} / efficient_global: 25+n)
Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed \( \text{max\_iterations} \) iterations. In cases where there are multiple nested iterations to be controlled, \( \text{max\_iterations} \) generally controls the outer-most context.

Default Behavior

Default value is 100.

See Also

These keywords may also be of interest:

- \( \text{max\_function\_evaluations} \)

7.2.20.2 convergence_tolerance

- \( \text{Keywords Area} \)
- \( \text{method} \)
- \( \text{nlpql\_sqp} \)
- \( \text{convergence\_tolerance} \)

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- \( \text{method\_independent\_controls} \)

Specification

**Alias:** none

**Argument(s):** REAL

**Default:** 1.e-4

Description

The **convergence_tolerance** specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by **convergence\_tolerance**, then this convergence criterion is satisfied on the current iteration. Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.
Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See nl2sol
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

7.2.20.3 max_function_evaluations

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none
Argument(s): INTEGER
Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed max_function_evaluations evaluations. See also max_iterations.

Some optimizers (e.g. ncsu_direct) may run past this limit in the course of an iteration step that began before max_function_evaluations was exceeded.

Default Behavior

Default value is 1000.
• scaling

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

• method_independent_controls

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the scaling keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords scale_types and/or scales in the variables and responses blocks. When the scaling keyword is omitted from method, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

• a *scales keyword, which gives characteristic values (divisors)

• a *scale_types keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in responses for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are three scale types:

1. value - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.

2. auto - automatic scaling
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   • two-sided bounds scaled into the interval [0,1];
   • one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

3. log - logarithmic scaling
First, any characteristic values from the optional *_scales specification are applied. Then logarithm base 10 scaling is applied.
Logarithmic scaling is not available for linear constraints.
When continuous design variables are log scaled, linear constraints are not allowed.

Scales
The *scales keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding *scale_types, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.
Depending on the scale type, the characteristic values may be required or optional.

• auto, log - optional

7.2.21.1 max_step

- Keywords Area
- method
- optpp_cg
- max_step

Max change in design point
7.2 method

Specification

Alias: none
Argument(s): REAL
Default: 1000.

Description

The max_step control specifies the maximum step that can be taken when computing a change in the current design point (e.g., limiting the Newton step computed from current gradient and Hessian information). It is equivalent to a move limit or a maximum trust region size. The gradient_tolerance control defines the threshold value on the L2 norm of the objective function gradient that indicates convergence to an unconstrained minimum (no active constraints). The gradient_tolerance control is defined for all gradient-based optimizers.

7.2.21.2 gradient_tolerance

- Keywords Area
- method
- optpp_cg
- gradient_tolerance

Stopping criteria based on L2 norm of gradient

Specification

Alias: none
Argument(s): REAL
Default: 1.e-4

Description

The gradient_tolerance control defines the threshold value on the L2 norm of the objective function gradient (for unconstrained minimum or no active constraints) or the Lagrangian gradient (for constrained minimum) that indicates convergence to a stationary point. The gradient_tolerance control is currently defined only for the OPT++ and ROL libraries.

7.2.21.3 max_iterations

- Keywords Area
- method
- optpp_cg
- max_iterations

Number of iterations allowed for optimizers and adaptive UQ methods
Topics

This keyword is related to the topics:

- method_independent_controls

Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** 100 (exceptions: fsu_cvt, local_reliability: 25; global_{reliability, interval_est, evidence} / efficient_global: 25*n)

**Description**

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed \( \text{max_iterations} \) iterations. In cases where there are multiple nested iterations to be controlled, \( \text{max_iterations} \) generally controls the outer-most context.

**Default Behavior**

Default value is 100.

7.2.21.4 convergence_tolerance

- Keywords Area
- method
- optpp_cg
- convergence_tolerance

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

**Alias:** none

**Argument(s):** REAL

**Default:** 1.e-4
### Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

### Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See `nl2sol`
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

#### 7.2.21.5 speculative

- **Keywords Area**
- **method**
- **optpp_cg**
- **speculative**

Compute speculative gradients

### Topics

This keyword is related to the topics:

- method_independent_controls

### Specification

**Alias:** none  
**Argument(s):** none  
**Default:** no speculation

### Description

When performing gradient-based optimization in parallel, speculative gradients can be selected to address the load imbalance that can occur between gradient evaluation and line search phases. In a typical gradient-based
optimization, the line search phase consists primarily of evaluating the objective function and any constraints at a trial point, and then testing the trial point for a sufficient decrease in the objective function value and/or constraint violation. If a sufficient decrease is not observed, then one or more additional trial points may be attempted sequentially. However, if the trial point is accepted then the line search phase is complete and the gradient evaluation phase begins. By speculating that the gradient information associated with a given line search trial point will be used later, additional coarse grained parallelism can be introduced by computing the gradient information (either by finite difference or analytically) in parallel, at the same time as the line search phase trial-point function values. This balances the total amount of computation to be performed at each design point and allows for efficient utilization of multiple processors. While the total amount of work performed will generally increase (since some speculative gradients will not be used when a trial point is rejected in the line search phase), the run time will usually decrease (since gradient evaluations needed at the start of each new optimization cycle were already performed in parallel during the line search phase). Refer to [13] for additional details. The speculative specification is implemented for the gradient-based optimizers in the DOT, CONMIN, and OPT++ libraries, and it can be used with dakota numerical or analytic gradient selections in the responses specification (refer to responses gradient section for information on these specifications). It should not be selected with vendor numerical gradients since vendor internal finite difference algorithms have not been modified for this purpose. In full-Newton approaches, the Hessian is also computed speculatively. NPSOL and NLSSOL do not support speculative gradients, as their gradient-based line search in user-supplied gradient mode (dakota numerical or analytic gradients) is a superior approach for load-balanced parallel execution.

The speculative specification enables speculative computation of gradient and/or Hessian information, where applicable, for parallel optimization studies. By speculating that the derivative information at the current point will be used later, the complete data set (all available gradient/Hessian information) can be computed on every function evaluation. While some of these computations will be wasted, the positive effects are a consistent parallel load balance and usually shorter wall clock time. The speculative specification is applicable only when parallelism in the gradient calculations can be exploited by Dakota (it will be ignored for vendor numerical gradients).

7.2.21.6 max_function_evaluations

- Keywords Area
- method
- optpp_cg
- max_function_evaluations

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed max_function_evaluations evaluations. See also max_iterations.
Some optimizers (e.g. ncsu_direct) may run past this limit in the course of an iteration step that began before max_function_evaluations was exceeded.

Default Behavior
Default value is 1000.

7.2.21.7 scaling

- Keywords Area
- method
- optpp_cg
- scaling

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none
Argument(s): none
Default: no scaling

Description

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the scaling keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords scale_types and/or *scales in the variables and responses blocks. When the scaling keyword is omitted from method, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

- a *scales keyword, which gives characteristic values (divisors)
- a *scale_types keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in responses for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are three scale types:
1. **value** - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.

2. **auto** - automatic scaling
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   - two-sided bounds scaled into the interval [0,1];
   - one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
   - no bounds or targets: no automatic scaling possible, therefore no scaling for this component

   Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

3. **log** - logarithmic scaling
   First, any characteristic values from the optional *scales specification are applied. Then logarithm base 10 scaling is applied.
   Logarithmic scaling is not available for linear constraints.
   When continuous design variables are log scaled, linear constraints are not allowed.

### Scales

The *scales keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding *scale_types, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- **auto, log** - optional
- **value** - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than 1.0e10*DBL_MIN. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

### Examples

The two examples below are equivalent:

```
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = *value*
  primary_scales = 1 1 100

responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = *value* *value* *value*
  primary_scales = 1 1 100
```

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.

See block_pointer for details about pointers.

**Description**

This is a Newton method that expects a gradient and computes a low-rank approximation to the Hessian. Each of the Newton-based methods are automatically bound to the appropriate OPT++ algorithm based on the user constraint specification (unconstrained, bound-constrained, or generally-constrained). In the generally-constrained case, the Newton methods use a nonlinear interior-point approach to manage the constraints.

See package_optpp for info related to all optpp methods.

**Expected HDF5 Output**
If Dakota was built with HDF5 support and run with the hdf5 keyword, this method writes the following results to HDF5:

- Best Parameters
- Best Objective Functions (when objective_functions are specified)
- Best Nonlinear Constraints
- Calibration (when calibration_terms are specified)

7.2.22.1 search_method

- Keywords Area
- method
- optpp_q_newton
- search_method

Select a search method for Newton-based optimizers

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The search_method control is defined for all Newton-based optimizers and is used to select between trust_region, gradient_based_line_search, and value_based_line_search methods. The gradient_based_line_search option uses the line search method proposed by [63]. This option satisfies sufficient decrease and curvature conditions; whereas, value_based_line_search only satisfies the sufficient decrease condition. At each line search iteration, the gradient_based_line_search method computes the function and gradient at the trial point. Consequently, given expensive function evaluations, the value_based_line_search method is preferred to the gradient_based_line_search method. Each of these Newton methods additionally supports the tr_pds selection for unconstrained problems. This option performs a robust trust region search using pattern search techniques. Use of a line search is the default for bound-constrained and generally-constrained problems, and use of a trust_region search method is the default for unconstrained problems.
7.2.22.1.1 value_based_line_search

- Keywords Area
- method
- optpp_q_newton
- search_method
- value_based_line_search

Use only function values for line search

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** trust_region (unconstrained), value_based_line_search (bound/general constraints)

**Description**

The `search_method` control is defined for all Newton-based optimizers and is used to select between trust_region, gradient_based_line_search, and value_based_line_search methods. The gradient_based_line_search option uses the line search method proposed by [63]. This option satisfies sufficient decrease and curvature conditions; whereas, value_base_line_search only satisfies the sufficient decrease condition. At each line search iteration, the gradient_based_line_search method computes the function and gradient at the trial point. Consequently, given expensive function evaluations, the value_based_line_search method is preferred to the gradient_based_line_search method. Each of these Newton methods additionally supports the tr_pds selection for unconstrained problems. This option performs a robust trust region search using pattern search techniques. Use of a line search is the default for bound-constrained and generally-constrained problems, and use of a trust_region search method is the default for unconstrained problems.

7.2.22.1.2 gradient_based_line_search

- Keywords Area
- method
- optpp_q_newton
- search_method
- gradient_based_line_search

Set the search method to use the gradient

**Specification**

**Alias:** none

**Argument(s):** none
Description

The search_method control is defined for all Newton-based optimizers and is used to select between trust_region, gradient_based_line_search, and value_based_line_search methods. The gradient_based_line_search option uses the line search method proposed by [63]. This option satisfies sufficient decrease and curvature conditions; whereas, value_based_line_search only satisfies the sufficient decrease condition. At each line search iteration, the gradient_based_line_search method computes the function and gradient at the trial point. Consequently, given expensive function evaluations, the value_based_line_search method is preferred to the gradient_based_line_search method. Each of these Newton methods additionally supports the tr_pds selection for unconstrained problems. This option performs a robust trust region search using pattern search techniques. Use of a line search is the default for bound-constrained and generally-constrained problems, and use of a trust_region search method is the default for unconstrained problems.

7.2.22.1.3 trust_region

- Keywords Area
- method
- optpp_q_newton
- search_method
- trust_region

Use trust region as the globalization strategy.

Specification

Alias: none
Argument(s): none

Description

The trust_region optional group specification can be used to specify the initial size of the trust region (using initial_size) relative to the total variable bounds, the minimum size of the trust region (using minimum_size), the contraction factor for the trust region size (using contraction_factor) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using expansion_factor) used when the the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using contract_threshold) and the trust region size expansion threshold (using expand_threshold). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command contract_threshold sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command expand_threshold determines the trust region value above which the trust region will expand for the next SBL iteration.

7.2.22.1.4 tr_pds

- Keywords Area
- method
- optpp_q_newton
- search_method
- tr_pds

Use direct search as the local search in a trust region method.
### 7.2 Method

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

The `search_method` control is defined for all Newton-based optimizers and is used to select between `trust_region`, `gradient_based_line_search`, and `value_based_line_search` methods. The `gradient_based_line_search` option uses the line search method proposed by [63]. This option satisfies sufficient decrease and curvature conditions; whereas, `value_base_line_search` only satisfies the sufficient decrease condition. At each line search iteration, the `gradient_based_line_search` method computes the function and gradient at the trial point. Consequently, given expensive function evaluations, the `value_based_line_search` method is preferred to the `gradient_based_line_search` method. Each of these Newton methods additionally supports the `tr_pds` selection for unconstrained problems. This option performs a robust trust region search using pattern search techniques. Use of a line search is the default for bound-constrained and generally-constrained problems, and use of a `trust_region` search method is the default for unconstrained problems.

#### 7.2.22.2 merit_function

- **Keywords Area**
  - method
  - optpp_q_newton
  - merit_function

**Description**

A merit function is a function in constrained optimization that attempts to provide joint progress toward reducing the objective function and satisfying the constraints.
7.2.22.2.1 el_bakry

- Keywords Area
- method
- optpp_q_newton
- merit_function
- el_bakry

El-Bakry merit function

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The "el_bakry" merit function is the L2-norm of the first order optimality conditions for the nonlinear programming problem. The cost per linesearch iteration is $n+1$ function evaluations. For more information, see [20].

7.2.22.2.2 argaez_tapia

- Keywords Area
- method
- optpp_q_newton
- merit_function
- argaez_tapia

The merit function by Tapia and Argaez

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The "argaez_tapia" merit function can be classified as a modified augmented Lagrangian function. The augmented Lagrangian is modified by adding to its penalty term a potential reduction function to handle the perturbed complementarity condition. The cost per linesearch iteration is one function evaluation. For more information, see [83].

If the function evaluation is expensive or noisy, set the **merit_function** to "argaez_tapia" or "van_shanno".
7.2 method

7.2.22.3 van_shanno

- Keywords Area
- method
- optpp_q_newton
- merit_function
- van_shanno

The merit function by Vanderbei and Shanno

Specification

Alias: none
Argument(s): none

Description

The "van_shanno" merit function can be classified as a penalty function for the logarithmic barrier formulation of the nonlinear programming problem. The cost per linesearch iteration is one function evaluation. For more information see [85].

If the function evaluation is expensive or noisy, set the merit_function to "argaez_tapia" or "van_shanno".

7.2.22.3 steplength_to_boundary

- Keywords Area
- method
- optpp_q_newton
- steplength_to_boundary

Controls how close to the boundary of the feasible region the algorithm is allowed to move

Specification

Alias: none
Argument(s): REAL

Default: Merit function dependent: 0.8 (el_bakry), 0.99995 (argaez_tapia), 0.95 (van_shanno)

Description

The steplength_to_boundary specification is a parameter (between 0 and 1) that controls how close to the boundary of the feasible region the algorithm is allowed to move. A value of 1 means that the algorithm is allowed to take steps that may reach the boundary of the feasible region. If the user wishes to maintain strict feasibility of the design parameters this value should be less than 1. Default values are .8, .99995, and .95 for the el_bakry, argaez_tapia, and van_shanno merit functions, respectively.
7.2.22.4 centering_parameter

- Keywords Area
- method
- optpp_q_newton
- centering_parameter

Controls how closely the algorithm should follow the "central path"

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** Merit function dependent: 0.2 (el_bakry), 0.2 (argaez_tapia), 0.1 (van_shanno)

**Description**

The centering_parameter specification is a parameter (between 0 and 1) that controls how closely the algorithm should follow the "central path". See [92] for the definition of central path. The larger the value, the more closely the algorithm follows the central path, which results in small steps. A value of 0 indicates that the algorithm will take a pure Newton step. Default values are .2, .2, and .1 for the el_bakry, argaez_tapia, and van_shanno merit functions, respectively.

7.2.22.5 max_step

- Keywords Area
- method
- optpp_q_newton
- max_step

Max change in design point

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 1000.

**Description**

The max_step control specifies the maximum step that can be taken when computing a change in the current design point (e.g., limiting the Newton step computed from current gradient and Hessian information). It is equivalent to a move limit or a maximum trust region size. The gradient_tolerance control defines the threshold value on the L2 norm of the objective function gradient that indicates convergence to an unconstrained minimum (no active constraints). The gradient_tolerance control is defined for all gradient-based optimizers.
7.2.22.6 gradient_tolerance

- Keywords Area
- method
- optpp_q_newton
- gradient_tolerance

Stopping criteria based on L2 norm of gradient

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `gradient_tolerance` control defines the threshold value on the L2 norm of the objective function gradient (for unconstrained minimum or no active constraints) or the Lagrangian gradient (for constrained minimum) that indicates convergence to a stationary point. The `gradient_tolerance` control is currently defined only for the OPT++ and ROL libraries.

7.2.22.7 max_iterations

- Keywords Area
- method
- optpp_q_newton
- max_iterations

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: fsu_cvt, local_reliability: 25; global_(reliability, interval_est, evidence) / efficient_global: 25*n)
Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed max_iterations iterations. In cases where there are multiple nested iterations to be controlled, max_iterations generally controls the outer-most context.

Default Behavior

Default value is 100.

See Also

These keywords may also be of interest:

- max_function_evaluations

7.2.22.8 convergence_tolerance

- Keywords Area
- method
- optpp_q_newton
- convergence_tolerance

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The convergence_tolerance specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by convergence_tolerance, then this convergence criterion is satisfied on the current iteration. Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.
7.2 method

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See nl2sol
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

7.2.22.9 speculative

- Keywords Area
- method
- optpp_q_newton
- speculative

Compute speculative gradients

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none
Argument(s): none
Default: no speculation

Description

When performing gradient-based optimization in parallel, speculative gradients can be selected to address the load imbalance that can occur between gradient evaluation and line search phases. In a typical gradient-based optimization, the line search phase consists primarily of evaluating the objective function and any constraints at a trial point, and then testing the trial point for a sufficient decrease in the objective function value and/or constraint violation. If a sufficient decrease is not observed, then one or more additional trial points may be attempted sequentially. However, if the trial point is accepted then the line search phase is complete and the gradient evaluation phase begins. By speculating that the gradient information associated with a given line search trial point will be used later, additional coarse grained parallelism can be introduced by computing the gradient information (either by finite difference or analytically) in parallel, at the same time as the line search phase trial-point function values. This balances the total amount of computation to be performed at each design point and allows for efficient utilization of multiple processors. While the total amount of work performed will generally increase (since some speculative gradients will not be used when a trial point is rejected in the line search phase), the run time will usually decrease (since gradient evaluations needed at the start of each new optimization cycle were already performed in parallel during the line search phase). Refer to [13] for additional details. The speculative specification is implemented for the gradient-based optimizers in the DOT, CONMIN, and OPT++ libraries, and it can be used with dakota numerical or analytic gradient selections in the responses specification (refer to responses gradient section for information...
on these specifications). It should not be selected with vendor numerical gradients since vendor internal finite
difference algorithms have not been modified for this purpose. In full-Newton approaches, the Hessian is also com-
puted speculatively. NPSOL and NLSSOL do not support speculative gradients, as their gradient-based line search
in user-supplied gradient mode (dakota numerical or analytic gradients) is a superior approach for load-balanced
parallel execution.

The speculative specification enables speculative computation of gradient and/or Hessian information, where
applicable, for parallel optimization studies. By speculating that the derivative information at the current point
will be used later, the complete data set (all available gradient/Hessian information) can be computed on every function
evaluation. While some of these computations will be wasted, the positive effects are a consistent parallel load
balance and usually shorter wall clock time. The speculative specification is applicable only when parallelism
in the gradient calculations can be exploited by Dakota (it will be ignored for vendor numerical gradients).

7.2.22.10 max_function_evaluations

- Keywords Area
- method
- optpp_q_newton
- max_function_evaluations

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none
Argument(s): INTEGER
Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached
any other stopping criteria first, the optimizer will stop after it has performed \texttt{max-function_evaluations}
evaluations. See also \texttt{max_iterations}.

Some optimizers (e.g. ncsu_direct) may run past this limit in the course of an iteration step that began before
\texttt{max-function_evaluations} was exceeded.

Default Behavior

Default value is 1000.
7.2 method

- **scaling**

Turn on scaling for variables, responses, and constraints

**Topics**

This keyword is related to the topics:

- **method_independent_controls**

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** no scaling

**Description**

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the **scaling** keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords **scale_types** and/or **scales** in the **variables** and **responses** blocks. When the **scaling** keyword is omitted from **method**, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

- A **scales** keyword, which gives characteristic values (divisors)
- A **scale_types** keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in **responses** for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

**Scale Types**

There are three scale types:

1. **value** - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.

2. **auto** - automatic scaling
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   - two-sided bounds scaled into the interval [0,1];
   - one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into \([0,1]\).

3. log - logarithmic scaling
   
   First, any characteristic values from the optional \(*_scales\) specification are applied. Then logarithm base 10 scaling is applied.
   
   Logarithmic scaling is not available for linear constraints.

   When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The \(*scales\) keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding \(*scale_types\), as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- auto, log - optional
- value - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than \(1.0e10*DBL_MIN\). User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
 objective_functions 3
 sense "maximize"
 primary_scale_types = "value"
 primary_scales = 1 1 100

responses
 objective_functions 3
 sense "maximize"
 primary_scale_types = "value" "value" "value"
 primary_scales = 1 1 100
```

7.2.22.12 model_pointer

- Keywords Area
- method
- optpp_q_newton
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer
Specification

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

Examples

```plaintext
environment
tabular_data
method_pointer = 'UQ'

method
id_method = 'UQ'
model_pointer = 'SURR'
sampling,
samples = 10
seed = 98765 rng rnum2

**Description**

This is a Newton method that expects a gradient and computes a finite-difference approximation to the Hessian. Each of the Newton-based methods are automatically bound to the appropriate OPT++ algorithm based on the user constraint specification (unconstrained, bound-constrained, or generally-constrained). In the generally-constrained case, the Newton methods use a nonlinear interior-point approach to manage the constraints.

See package_optpp for info related to all optpp methods.

**Expected HDF5 Output**

If Dakota was built with HDF5 support and run with the hdf5 keyword, this method writes the following results to HDF5:

- Best Parameters
- Best Objective Functions (when objective_functions are specified)
- Best Nonlinear Constraints
- Calibration (when calibration_terms are specified)

**Description**

The search_method control is defined for all Newton-based optimizers and is used to select between trust_region, gradient_based_line_search, and value_based_line_search methods. The gradient_based_line_search option uses the line search method proposed by [63]. This option satisfies sufficient decrease and curvature conditions; whereas, value_based_line_search only satisfies the sufficient decrease condition. At each line search iteration, the gradient_based_line_search method computes the function and gradient at the trial point. Consequently, given expensive function evaluations, the value_based_line_search method is preferred to the gradient_based_line_search method. Each of these Newton methods additionally supports the tr_pds selection for unconstrained problems. This option performs a robust trust region search using pattern search techniques. Use of a line search is the default for bound-constrained and generally-constrained problems, and use of a trust_region search method is the default for unconstrained problems.

7.2.23.1.3 trust_region

Use trust region as the globalization strategy.

Specification

Alias: none

Argument(s): none

Description

The trust_region optional group specification can be used to specify the initial size of the trust region (using initial_size) relative to the total variable bounds, the minimum size of the trust region (using minimum_size), the contraction factor for the trust region size (using contraction_factor) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using expansion_factor) used when the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using contract_threshold) and the trust region size expansion threshold (using expand_threshold). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command contract_threshold sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command expand_threshold determines the trust region value above which the trust region will expand for the next SBL iteration.

7.2.23.1.4 tr_pds

Use direct search as the local search in a trust region method.
### 7.2 method

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

The `search_method` control is defined for all Newton-based optimizers and is used to select between `trust_region`, `gradient_based_line_search`, and `value_based_line_search` methods. The `gradient_based_line_search` option uses the line search method proposed by [63]. This option satisfies sufficient decrease and curvature conditions; whereas, `value_based_line_search` only satisfies the sufficient decrease condition. At each line search iteration, the `gradient_based_line_search` method computes the function and gradient at the trial point. Consequently, given expensive function evaluations, the `value_based_line_search` method is preferred to the `gradient_based_line_search` method. Each of these Newton methods additionally supports the `tr_pds` selection for unconstrained problems. This option performs a robust trust region search using pattern search techniques. Use of a line search is the default for bound-constrained and generally-constrained problems, and use of a `trust_region` search method is the default for unconstrained problems.

#### 7.2.23.2 merit_function

- **Keywords Area**
- **method**
- **optpp_fd_newton**
- **merit_function**

Balance goals of reducing objective function and satisfying constraints

**Specification**

**Alias:** none  
**Argument(s):** none

**Default:** argaez_tapia

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>

</tr>
</tbody>
</table>

**Description**

A `merit_function` is a function in constrained optimization that attempts to provide joint progress toward reducing the objective function and satisfying the constraints.
7.2.23.2.1  el_bakry

- Keywords Area
- method
- optpp_fd_newton
- merit_function
- el_bakry

El-Bakry merit function

Specification

Alias: none
Argument(s): none

Description

The "el_bakry" merit function is the L2-norm of the first order optimality conditions for the nonlinear programming problem. The cost per linesearch iteration is n+1 function evaluations. For more information, see [20].

7.2.23.2.2  argaez_tapia

- Keywords Area
- method
- optpp_fd_newton
- merit_function
- argaez_tapia

The merit function by Tapia and Argaez

Specification

Alias: none
Argument(s): none

Description

The "argaez_tapia" merit function can be classified as a modified augmented Lagrangian function. The augmented Lagrangian is modified by adding to its penalty term a potential reduction function to handle the perturbed complementarity condition. The cost per linesearch iteration is one function evaluation. For more information, see [83].

If the function evaluation is expensive or noisy, set the merit_function to "argaez_tapia" or "van_shanno".
The merit function by Vanderbei and Shanno

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

The "van_shanno" merit function can be classified as a penalty function for the logarithmic barrier formulation of the nonlinear programming problem. The cost per linesearch iteration is one function evaluation. For more information see [85].

If the function evaluation is expensive or noisy, set the `merit_function` to "argaez_tapia" or "van_shanno".

**steplength_to_boundary**

**Specification**

**Alias:** none  
**Argument(s):** REAL  
**Default:** Merit function dependent: 0.8 (el_bakry), 0.99995 (argaez_tapia), 0.95 (van_shanno)

**Description**

The `steplength_to_boundary` specification is a parameter (between 0 and 1) that controls how close to the boundary of the feasible region the algorithm is allowed to move. A value of 1 means that the algorithm is allowed to take steps that may reach the boundary of the feasible region. If the user wishes to maintain strict feasibility of the design parameters this value should be less than 1. Default values are .8, .99995, and .95 for the `el_bakry`, `argaez_tapia`, and `van_shanno` merit functions, respectively.
7.2.23.4 centering_parameter

- Keywords Area
- method
- optpp_fd_newton
- centering_parameter

Controls how closely the algorithm should follow the "central path"

**Specification**

**Alias:** none
**Argument(s):** REAL
**Default:** Merit function dependent: 0.2 (el_bakry), 0.2 (argaez_tapia), 0.1 (van_shanno)

**Description**

The `centering_parameter` specification is a parameter (between 0 and 1) that controls how closely the algorithm should follow the "central path". See [92] for the definition of central path. The larger the value, the more closely the algorithm follows the central path, which results in small steps. A value of 0 indicates that the algorithm will take a pure Newton step. Default values are .2, .2, and .1 for the el_bakry, argaez_tapia, and van_shanno merit functions, respectively.

7.2.23.5 max_step

- Keywords Area
- method
- optpp_fd_newton
- max_step

Max change in design point

**Specification**

**Alias:** none
**Argument(s):** REAL
**Default:** 1000.

**Description**

The `max_step` control specifies the maximum step that can be taken when computing a change in the current design point (e.g., limiting the Newton step computed from current gradient and Hessian information). It is equivalent to a move limit or a maximum trust region size. The `gradient_tolerance` control defines the threshold value on the L2 norm of the objective function gradient that indicates convergence to an unconstrained minimum (no active constraints). The `gradient_tolerance` control is defined for all gradient-based optimizers.
7.2.23.6 gradient_tolerance

- Keywords Area
- method
- optpp_fd_newton
- gradient_tolerance

Stopping criteria based on L2 norm of gradient

Specification

Alias: none
Argument(s): REAL
Default: 1.e-4

Description

The gradient_tolerance control defines the threshold value on the L2 norm of the objective function gradient (for unconstrained minimum or no active constraints) or the Lagrangian gradient (for constrained minimum) that indicates convergence to a stationary point. The gradient_tolerance control is currently defined only for the OPT++ and ROL libraries.

7.2.23.7 max_iterations

- Keywords Area
- method
- optpp_fd_newton
- max_iterations

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none
Argument(s): INTEGER
Default: 100 (exceptions: fsu_cv , local_reliability: 25; global_(reliability , interval_est , evidence) / efficient_global: 25*n)
Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_iterations` iterations. In cases where there are multiple nested iterations to be controlled, `max_iterations` generally controls the outer-most context.

Default Behavior

Default value is 100.

See Also

These keywords may also be of interest:

- `max_function_evaluations`

7.2.23.8 convergence_tolerance

- Keywords Area
- method
- optpp_fd_newton
- convergence_tolerance

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- `method_independent_controls`

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.
Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See nl2sol
- NLPLQP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

7.2.23.9 speculative

- Keywords Area
- method
- optpp_fd_newton
- speculative

Compute speculative gradients

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

**Alias:** none

**Argument(s):** none

**Default:** no speculation

Description

When performing gradient-based optimization in parallel, speculative gradients can be selected to address the load imbalance that can occur between gradient evaluation and line search phases. In a typical gradient-based optimization, the line search phase consists primarily of evaluating the objective function and any constraints at a trial point, and then testing the trial point for a sufficient decrease in the objective function value and/or constraint violation. If a sufficient decrease is not observed, then one or more additional trial points may be attempted sequentially. However, if the trial point is accepted then the line search phase is complete and the gradient evaluation phase begins. By speculating that the gradient information associated with a given line search trial point will be used later, additional coarse grained parallelism can be introduced by computing the gradient information (either by finite difference or analytically) in parallel, at the same time as the line search phase trial-point function values. This balances the total amount of computation to be performed at each design point and allows for efficient utilization of multiple processors. While the total amount of work performed will generally increase (since some speculative gradients will not be used when a trial point is rejected in the line search phase), the run time will usually decrease (since gradient evaluations needed at the start of each new optimization cycle were already performed in parallel during the line search phase). Refer to [13] for additional details. The speculative specification is implemented for the gradient-based optimizers in the DOT, CONMIN, and OPT++ libraries, and it can be used with dakota numerical or analytic gradient selections in the responses specification (refer to responses gradient section for information...
on these specifications). It should not be selected with vendor numerical gradients since vendor internal finite difference algorithms have not been modified for this purpose. In full-Newton approaches, the Hessian is also computed speculatively. NPSOL and NLSSOL do not support speculative gradients, as their gradient-based line search in user-supplied gradient mode (dakota numerical or analytic gradients) is a superior approach for load-balanced parallel execution.

The **speculative** specification enables speculative computation of gradient and/or Hessian information, where applicable, for parallel optimization studies. By speculating that the derivative information at the current point will be used later, the complete data set (all available gradient/Hessian information) can be computed on every function evaluation. While some of these computations will be wasted, the positive effects are a consistent parallel load balance and usually shorter wall clock time. The speculative specification is applicable only when parallelism in the gradient calculations can be exploited by Dakota (it will be ignored for vendor numerical gradients).

### 7.2.23.10 max_function_evaluations

- **Keywords Area**
- **method**
- **optpp_fd_newton**
- **max_function_evaluations**

Number of function evaluations allowed for optimizers

**Topics**

This keyword is related to the topics:

- **method_independent_controls**

**Specification**

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** 1000

**Description**

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

**Default Behavior**

Default value is 1000.

### 7.2.23.11 scaling

- **Keywords Area**
- **method**
- **optpp_fd_newton**
• scaling

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

• method_independent_controls

Specification

Alias: none
Argument(s): none
Default: no scaling

Description

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the scaling keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords scale_types and/or scales in the variables and responses blocks. When the scaling keyword is omitted from method, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

• a *scales keyword, which gives characteristic values (divisors)
• a *scale_types keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in responses for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are three scale types:

1. value - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.

2. auto - automatic scaling
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:

   • two-sided bounds scaled into the interval [0,1];
   • one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
• no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into $[0,1]$.

3. log - logarithmic scaling
First, any characteristic values from the optional *scales specification are applied. Then logarithm base 10 scaling is applied.
Logarithmic scaling is not available for linear constraints.
When continuous design variables are log scaled, linear constraints are not allowed.

Scales
The *scales keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding *scale_types, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.
Depending on the scale type, the characteristic values may be required or optional.

• auto, log - optional
• value - required.
A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10*DBL_MIN$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples
The two examples below are equivalent:

```
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100
```

```
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

7.2.23.12 model_pointer

• Keywords Area
• method
• optpp_fd_newton
• model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

• block_pointer
7.2 method

Specification

Alias: none
Argument(s): STRING
Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.

See block_pointer for details about pointers.

Examples

environment

**Description**

The Gauss-Newton algorithm is available as `optpp_g_newton` and supports unconstrained, bound-constrained, and generally-constrained problems. When interfaced with the unconstrained, bound-constrained, and nonlinear interior point full-Newton optimizers from the OPT++ library, it provides a Gauss-Newton least squares capability which – on zero-residual test problems – can exhibit quadratic convergence rates near the solution. (Real problems almost never have zero residuals, i.e., perfect fits.)

See `package_optpp` for info related to all `optpp` methods.

**Expected HDF5 Output**

If Dakota was built with HDF5 support and run with the `hdf5` keyword, this method writes the following results to HDF5:

- **Best Parameters**
- **Best Nonlinear Constraints**
- **Calibration** (when `calibration_terms` are specified)
- **Parameter Confidence Intervals** (when `num_experiments` equals 1)

**See Also**

These keywords may also be of interest:
Select a search method for Newton-based optimizers

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

The `search_method` control is defined for all Newton-based optimizers and is used to select between `trust_region`, `gradient_based_line_search`, and `value_based_line_search` methods. The `gradient_based_line_search` option uses the line search method proposed by [63]. This option satisfies sufficient decrease and curvature conditions; whereas, `value_based_line_search` only satisfies the sufficient decrease condition. At each line search iteration, the `gradient_based_line_search` method computes the function and gradient at the trial point. Consequently, given expensive function evaluations, the `value_based_line_search` method is preferred to the `gradient_based_line_search` method. Each of these Newton methods additionally supports the `tr_pds` selection for unconstrained problems. This option performs a robust trust region search using pattern search techniques. Use of a line search is the default for bound-constrained and generally-constrained problems, and use of a `trust_region` search method is the default for unconstrained problems.
7.2.24.1.1 value_based_line_search

The gradient_based_line_search option uses the line search method proposed by [63]. This option satisfies sufficient decrease and curvature conditions; whereas, value_based_line_search only satisfies the sufficient decrease condition. At each line search iteration, the gradient_based_line_search method computes the function and gradient at the trial point. Consequently, given expensive function evaluations, the value_based_line_search method is preferred to the gradient_based_line_search method. Each of these Newton methods additionally supports the tr_pds selection for unconstrained problems. This option performs a robust trust region search using pattern search techniques. Use of a line search is the default for bound-constrained and generally-constrained problems, and use of a trust_region search method is the default for unconstrained problems.

7.2.24.1.3 trust_region

- Keywords Area
- method
- optpp_g_newton
- search_method
- trust_region

Use trust region as the globalization strategy.

Specification

Alias: none

Argument(s): none

Description

The trust_region optional group specification can be used to specify the initial size of the trust region (using initial_size) relative to the total variable bounds, the minimum size of the trust region (using minimum_size), the contraction factor for the trust region size (using contraction_factor) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using expansion_factor) used when the the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using contract_threshold) and the trust region size expansion threshold (using expand_threshold). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command contract_threshold sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command expand_threshold determines the trust region value above which the trust region will expand for the next SBL iteration.

7.2.24.1.4 tr_pds

- Keywords Area
- method
- optpp_g_newton
- search_method
- tr_pds

Use direct search as the local search in a trust region method.
7.2 method

Specification

Alias: none
Argument(s): none

Description

The `search_method` control is defined for all Newton-based optimizers and is used to select between `trust_region`, `gradient_based_line_search`, and `value_based_line_search` methods. The `gradient_based_line_search` option uses the line search method proposed by [63]. This option satisfies sufficient decrease and curvature conditions; whereas, `value_based_line_search` only satisfies the sufficient decrease condition. At each line search iteration, the `gradient_based_line_search` method computes the function and gradient at the trial point. Consequently, given expensive function evaluations, the `value_based_line_search` method is preferred to the `gradient_based_line_search` method. Each of these Newton methods additionally supports the `tr_pds` selection for unconstrained problems. This option performs a robust trust region search using pattern search techniques. Use of a line search is the default for bound-constrained and generally-constrained problems, and use of a `trust_region` search method is the default for unconstrained problems.

7.2.24.2 merit_function

- Keywords Area
- method
- optpp_g_newton
- merit_function

Balance goals of reducing objective function and satisfying constraints

Specification

Alias: none
Argument(s): none
Default: argaez_tapia

Child Keywords:

<table>

</tbody>
</table>

Description

A `merit_function` is a function in constrained optimization that attempts to provide joint progress toward reducing the objective function and satisfying the constraints.
7.2.24.2.1  el_bakry

- Keywords Area
- method
- optpp_g_newton
- merit_function
- el_bakry

El-Bakry merit function

Specification

**Alias:** none
**Argument(s):** none

**Description**

The "el_bakry" merit function is the L2-norm of the first order optimality conditions for the nonlinear programming problem. The cost per linesearch iteration is n+1 function evaluations. For more information, see [20].

7.2.24.2.2  argaez_tapia

- Keywords Area
- method
- optpp_g_newton
- merit_function
- argaez_tapia

The merit function by Tapia and Argaez

Specification

**Alias:** none
**Argument(s):** none

**Description**

The "argaez_tapia" merit function can be classified as a modified augmented Lagrangian function. The augmented Lagrangian is modified by adding to its penalty term a potential reduction function to handle the perturbed complementarity condition. The cost per linesearch iteration is one function evaluation. For more information, see [83].

If the function evaluation is expensive or noisy, set the **merit_function** to "argaez_tapia" or "van_shanno".
7.2.24.2.3 van_shanno

- Keywords Area
- method
- optpp_g_newton
- merit_function
- van_shanno

The merit function by Vanderbei and Shanno

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

The "van_shanno" merit function can be classified as a penalty function for the logarithmic barrier formulation of the nonlinear programming problem. The cost per linesearch iteration is one function evaluation. For more information see [85].

If the function evaluation is expensive or noisy, set the `merit_function` to "argaez_tapia" or "van_shanno".

7.2.24.3 steplength_to_boundary

- Keywords Area
- method
- optpp_g_newton
- steplength_to_boundary

Controls how close to the boundary of the feasible region the algorithm is allowed to move

**Specification**

**Alias:** none 
**Argument(s):** REAL  
**Default:** Merit function dependent: 0.8 (el_bakry), 0.99995 (argaez_tapia), 0.95 (van_shanno)

**Description**

The `steplength_to_boundary` specification is a parameter (between 0 and 1) that controls how close to the boundary of the feasible region the algorithm is allowed to move. A value of 1 means that the algorithm is allowed to take steps that may reach the boundary of the feasible region. If the user wishes to maintain strict feasibility of the design parameters this value should be less than 1. Default values are .8, .99995, and .95 for the el_bakry, argaez_tapia, and van_shanno merit functions, respectively.
7.2.24.4 centering_parameter

- Keywords Area
- method
- optpp_g_newton
- centering_parameter

Controls how closely the algorithm should follow the "central path"

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** Merit function dependent: 0.2 (el_bakry), 0.2 (argaez_tapia), 0.1 (van_shanno)

**Description**

The `centering_parameter` specification is a parameter (between 0 and 1) that controls how closely the algorithm should follow the "central path". See [92] for the definition of central path. The larger the value, the more closely the algorithm follows the central path, which results in small steps. A value of 0 indicates that the algorithm will take a pure Newton step. Default values are .2, .2, and .1 for the `el_bakry`, `argaez_tapia`, and `van_shanno` merit functions, respectively.

7.2.24.5 max_step

- Keywords Area
- method
- optpp_g_newton
- max_step

Max change in design point

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 1000.

**Description**

The `max_step` control specifies the maximum step that can be taken when computing a change in the current design point (e.g., limiting the Newton step computed from current gradient and Hessian information). It is equivalent to a move limit or a maximum trust region size. The `gradient_tolerance` control defines the threshold value on the L2 norm of the objective function gradient that indicates convergence to an unconstrained minimum (no active constraints). The `gradient_tolerance` control is defined for all gradient-based optimizers.
7.2.24.6 gradient_tolerance

- Keywords Area
- method
- optpp_g_newton
- gradient_tolerance

Stopping criteria based on L2 norm of gradient

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 1.e-4

**Description**

The `gradient_tolerance` control defines the threshold value on the L2 norm of the objective function gradient (for unconstrained minimum or no active constraints) or the Lagrangian gradient (for constrained minimum) that indicates convergence to a stationary point. The `gradient_tolerance` control is currently defined only for the OPT++ and ROL libraries.

7.2.24.7 max_iterations

- Keywords Area
- method
- optpp_g_newton
- max_iterations

Number of iterations allowed for optimizers and adaptive UQ methods

**Topics**

This keyword is related to the topics:

- method_independent_controls

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 100 (exceptions: fsu_cvt, local_reliability: 25; global_(reliability, interval_est, evidence) / efficient_global: 25+n)
Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed \( \text{max\_iterations} \) iterations. In cases where there are multiple nested iterations to be controlled, \( \text{max\_iterations} \) generally controls the outer-most context.

Default Behavior

Default value is 100.

See Also

These keywords may also be of interest:

- \text{max\_function\_evaluations}

7.2.24.8 convergence\_tolerance

- Keywords Area
- method
- optpp\_g\_newton
- convergence\_tolerance

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- \text{method\_independent\_controls}

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The \text{convergence\_tolerance} specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by convergence\_tolerance, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.
Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See nl2sol
- NLPOPL: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

7.2.24 speculative

- Keywords Area
  - method
  - optpp_g_newton
  - speculative

Compute speculative gradients

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): none

Default: no speculation

Description

When performing gradient-based optimization in parallel, speculative gradients can be selected to address the load imbalance that can occur between gradient evaluation and line search phases. In a typical gradient-based optimization, the line search phase consists primarily of evaluating the objective function and any constraints at a trial point, and then testing the trial point for a sufficient decrease in the objective function value and/or constraint violation. If a sufficient decrease is not observed, then one or more additional trial points may be attempted sequentially. However, if the trial point is accepted then the line search phase is complete and the gradient evaluation phase begins. By speculating that the gradient information associated with a given line search trial point will be used later, additional coarse grained parallelism can be introduced by computing the gradient information (either by finite difference or analytically) in parallel, at the same time as the line search phase trial-point function values. This balances the total amount of computation to be performed at each design point and allows for efficient utilization of multiple processors. While the total amount of work performed will generally increase (since some speculative gradients will not be used when a trial point is rejected in the line search phase), the run time will usually decrease (since gradient evaluations needed at the start of each new optimization cycle were already performed in parallel during the line search phase). Refer to [13] for additional details. The speculative specification is implemented for the gradient-based optimizers in the DOT, CONMIN, and OPT++ libraries, and it can be used with dakota numerical or analytic gradient selections in the responses specification (refer to responses gradient section for information.
on these specifications). It should not be selected with vendor numerical gradients since vendor internal finite difference algorithms have not been modified for this purpose. In full-Newton approaches, the Hessian is also computed speculatively. NPSOL and NLSSOL do not support speculative gradients, as their gradient-based line search in user-supplied gradient mode (dakota numerical or analytic gradients) is a superior approach for load-balanced parallel execution.

The speculative specification enables speculative computation of gradient and/or Hessian information, where applicable, for parallel optimization studies. By speculating that the derivative information at the current point will be used later, the complete data set (all available gradient/Hessian information) can be computed on every function evaluation. While some of these computations will be wasted, the positive effects are a consistent parallel load balance and usually shorter wall clock time. The speculative specification is applicable only when parallelism in the gradient calculations can be exploited by Dakota (it will be ignored for vendor numerical gradients).

7.2.24.10 max_function_evaluations

- Keywords Area
- method
- optpp_g_newton
- max_function_evaluations

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed max_function_evaluations evaluations. See also max_iterations.

Some optimizers (e.g. ncsu_direct) may run past this limit in the course of an iteration step that began before max_function_evaluations was exceeded.

Default Behavior

Default value is 1000.

7.2.24.11 scaling

- Keywords Area
- method
- optpp_g_newton
Turn on scaling for variables, responses, and constraints

Topics
This keyword is related to the topics:

- method_independent_controls

Specification

**Alias:** none

**Argument(s):** none

**Default:** no scaling

Description

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords `scale_types` and/or `scales` in the `variables` and `responses` blocks. When the `scaling` keyword is omitted from `method`, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

- a `*scales` keyword, which gives characteristic values (divisors)
- a `*scale_types` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in `responses` for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

**Scale Types**

There are three scale types:

1. `value` - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.

2. `auto` - automatic scaling
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   - two-sided bounds scaled into the interval [0,1];
   - one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
• no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound
constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not
affinely scaled into [0,1].

3. log - logarithmic scaling

First, any characteristic values from the optional *_scales specification are applied. Then logarithm base
10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The *scales keywords are used to specify the characteristic values. These must be non-zero real numbers. The
numbers are used according to the corresponding *scale_types, as described above. A value of 1.0 can be
used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

• auto, log - optional

• value - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than 1.0e10*DBL_MIN.
User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated
scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```plaintext
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100

responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

7.2.24.12 model_pointer

• Keywords Area

• method

• optpp_g_newton

• model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

• block_pointer
**Specification**

**Alias:** none  
**Argument(s):** STRING  
**Default:** method use of last model parsed (or use of default model if none parsed)

**Description**

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

**Usage Tips**

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative. See `block_pointer` for details about pointers.

**Examples**

```plaintext
evironment  
  tabular_data  
  method_pointer = ‘UQ’

method  
  id_method = ‘UQ’  
  model_pointer = ‘SURR’  
  sampling,  
    samples = 10  
    seed = 98765 rng rnum2  
    response_levels = 0.1 0.2 0.6  
      0.1 0.2 0.6  
      0.1 0.2 0.6  
  sample_type lhs  
  distribution cumulative

model  
  id_model = ‘SURR’  
  surrogate global,  
  dace_method_pointer = ‘DACE’  
  polynomial quadratic

method  
  id_method = ‘DACE’  
  model_pointer = ‘DACE_M’  
  sampling sample_type lhs  
    samples = 121 seed = 5034 rng rnum2

model  
  id_model = ‘DACE_M’  
  single  
  interface_pointer = ‘I1’

variables  
  uniform_uncertain = 2  
  lower_bounds = 0. 0.  
  upper_bounds = 1. 1.  
  descriptors = ‘x1’ ‘x2’

interface  
  id_interface = ‘I1’  
  system asynch evaluationConcurrency = 5
```
7.2.25  optpp_newton

- Keywords Area
- method
- optpp_newton

Newton method based optimization

Topics

This keyword is related to the topics:

- package_optpp

### Description

This is a full Newton method that expects a gradient and a Hessian. Each of the Newton-based methods are automatically bound to the appropriate OPT++ algorithm based on the user constraint specification (unconstrained, bound-constrained, or generally-constrained). In the generally-constrained case, the Newton methods use a nonlinear interior-point approach to manage the constraints.

See [package_optpp](https://www.openopt.org/Optpp) for info related to all optpp methods.

### Expected HDF5 Output

If Dakota was built with HDF5 support and run with the `hdf5` keyword, this method writes the following results to HDF5:

- **Best Parameters**
- **Best Objective Functions** (when `objective_functions` are specified)
- **Best Nonlinear Constraints**
- **Calibration** (when `calibration_terms` are specified)

7.2.25.1.3 trust_region

- Keywords Area
- method
- optpp_newton
- search_method
- trust_region

Use trust region as the globalization strategy.

Specification

Alias: none

Argument(s): none

Description

The `trust_region` optional group specification can be used to specify the initial size of the trust region (using `initial_size`) relative to the total variable bounds, the minimum size of the trust region (using `minimum_size`), the contraction factor for the trust region size (using `contraction_factor`) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using `expansion_factor`) used when the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using `contract_threshold`) and the trust region size expansion threshold (using `expand_threshold`). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command `contract_threshold` sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command `expand_threshold` determines the trust region value above which the trust region will expand for the next SBL iteration.

7.2.25.1.4 tr_pds

- Keywords Area
- method
- optpp_newton

Specification

Alias: none
Argument(s): none

Description

The "argaez_tapia" merit function can be classified as a modified augmented Lagrangian function. The augmented Lagrangian is modified by adding to its penalty term a potential reduction function to handle the perturbed complementarity condition. The cost per linesearch iteration is one function evaluation. For more information, see [83].

If the function evaluation is expensive or noisy, set the merit_function to "argaez_tapia" or "van_shanno".
7.25.2.3 van_shanno

- Keywords Area
- method
- optpp_newton
- merit_function
- van_shanno

The merit function by Vanderbei and Shanno

**Specification**

Alias: none  
Argument(s): none

**Description**

The "van_shanno" merit function can be classified as a penalty function for the logarithmic barrier formulation of the nonlinear programming problem. The cost per linesearch iteration is one function evaluation. For more information see [85].

If the function evaluation is expensive or noisy, set the **merit_function** to "argaez_tapia" or "van_shanno".

7.25.3 steplength_to_boundary

- Keywords Area
- method
- optpp_newton
- steplength_to_boundary

Controls how close to the boundary of the feasible region the algorithm is allowed to move

**Specification**

Alias: none  
Argument(s): REAL

Default: Merit function dependent: 0.8 (el_bakry), 0.99995 (argaez_tapia), 0.95 (van_shanno)

**Description**

The **steplength_to_boundary** specification is a parameter (between 0 and 1) that controls how close to the boundary of the feasible region the algorithm is allowed to move. A value of 1 means that the algorithm is allowed to take steps that may reach the boundary of the feasible region. If the user wishes to maintain strict feasibility of the design parameters this value should be less than 1. Default values are .8, .99995, and .95 for the el_bakry, argaez_tapia, and van_shanno merit functions, respectively.
7.2.25.4 centering_parameter

- Keywords Area
- method
- optpp_newton
- centering_parameter

Controls how closely the algorithm should follow the "central path"

Specification

Alias: none
Argument(s): REAL
Default:Merit function dependent: 0.2 (el_bakry), 0.2 (argaez_tapia), 0.1 (van_shanno)

Description

The centering_parameter specification is a parameter (between 0 and 1) that controls how closely the algorithm should follow the "central path". See [92] for the definition of central path. The larger the value, the more closely the algorithm follows the central path, which results in small steps. A value of 0 indicates that the algorithm will take a pure Newton step. Default values are .2, .2, and .1 for the el_bakry, argaez_tapia, and van_shanno merit functions, respectively.

7.2.25.5 max_step

- Keywords Area
- method
- optpp_newton
- max_step

Max change in design point

Specification

Alias: none
Argument(s): REAL
Default: 1000.

Description

The max_step control specifies the maximum step that can be taken when computing a change in the current design point (e.g., limiting the Newton step computed from current gradient and Hessian information). It is equivalent to a move limit or a maximum trust region size. The gradient_tolerance control defines the threshold value on the L2 norm of the objective function gradient that indicates convergence to an unconstrained minimum (no active constraints). The gradient_tolerance control is defined for all gradient-based optimizers.
7.2.25.6 gradient_tolerance

- Keywords Area
- method
- optpp_newton
- gradient_tolerance

Stopping criteria based on L2 norm of gradient

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `gradient_tolerance` control defines the threshold value on the L2 norm of the objective function gradient (for unconstrained minimum or no active constraints) or the Lagrangian gradient (for constrained minimum) that indicates convergence to a stationary point. The `gradient_tolerance` control is currently defined only for the OPT++ and ROL libraries.

7.2.25.7 max_iterations

- Keywords Area
- method
- optpp_newton
- max_iterations

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: fsu_cvt, local_reliability: 25; global_(reliability, interval_est, evidence) / efficient_global: 25*n)
Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed \texttt{max\_iterations} iterations. In cases where there are multiple nested iterations to be controlled, \texttt{max\_iterations} generally controls the outer-most context.

Default Behavior

Default value is 100.

See Also

These keywords may also be of interest:

- \texttt{max\_function\_evaluations}

7.2.25.8 convergence_tolerance

- Keywords Area
- method
- \texttt{optpp\_newton}
- convergence_tolerance

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- method\_independent\_controls

Specification

**Alias:** none

**Argument(s):** \texttt{REAL}

**Default:** 1.e-4

Description

The \texttt{convergence\_tolerance} specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a \textbf{relative convergence tolerance} for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by \texttt{convergence\_tolerance}, then this convergence criterion is satisfied on the current iteration. Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.
Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See nl2sol
- NLPLQP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

**7.2.25.9 speculative**

- Keywords Area
- method
- optpp_newton
- speculative

Compute speculative gradients

**Topics**

This keyword is related to the topics:

- method_independent_controls

**Specification**

Alias: none

Argument(s): none

Default: no speculation

**Description**

When performing gradient-based optimization in parallel, speculative gradients can be selected to address the load imbalance that can occur between gradient evaluation and line search phases. In a typical gradient-based optimization, the line search phase consists primarily of evaluating the objective function and any constraints at a trial point, and then testing the trial point for a sufficient decrease in the objective function value and/or constraint violation. If a sufficient decrease is not observed, then one or more additional trial points may be attempted sequentially. However, if the trial point is accepted then the line search phase is complete and the gradient evaluation phase begins. By speculating that the gradient information associated with a given line search trial point will be used later, additional coarse-grained parallelism can be introduced by computing the gradient information (either by finite difference or analytically) in parallel, at the same time as the line search phase trial-point function values. This balances the total amount of computation to be performed at each design point and allows for efficient utilization of multiple processors. While the total amount of work performed will generally increase (since some speculative gradients will not be used when a trial point is rejected in the line search phase), the run time will usually decrease (since gradient evaluations needed at the start of each new optimization cycle were already performed in parallel during the line search phase). Refer to [13] for additional details. The speculative specification is implemented for the gradient-based optimizers in the DOT, CONMIN, and OPT++ libraries, and it can be used with dakota numerical or analytic gradient selections in the responses specification (refer to responses gradient section for information...
on these specifications). It should not be selected with vendor numerical gradients since vendor internal finite
difference algorithms have not been modified for this purpose. In full-Newton approaches, the Hessian is also com-
puted speculatively. NPSOL and NLSSOL do not support speculative gradients, as their gradient-based line search
in user-supplied gradient mode (dakota numerical or analytic gradients) is a superior approach for load-balanced
parallel execution.

The speculative specification enables speculative computation of gradient and/or Hessian information, where
applicable, for parallel optimization studies. By speculating that the derivative information at the current point will
be used later, the complete data set (all available gradient/Hessian information) can be computed on every function
evaluation. While some of these computations will be wasted, the positive effects are a consistent parallel load
balance and usually shorter wall clock time. The speculative specification is applicable only when parallelism
in the gradient calculations can be exploited by Dakota (it will be ignored for vendor numerical gradients).

7.2.25.10 max_function_evaluations

- Keywords Area
- method
  - optpp_newton
- max_function_evaluations

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached
any other stopping criteria first, the optimizer will stop after it has performed max_function_evaluations
evaluations. See also max_iterations.

Some optimizers (e.g. ncsu_direct) may run past this limit in the course of an iteration step that began before
max_function_evaluations was exceeded.

Default Behavior

Default value is 1000.

7.2.25.11 scaling

- Keywords Area
- method
  - optpp_newton
7.2 method

• scaling

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

• method_independent_controls

Specification

Alias: none
Argument(s): none
Default: no scaling

Description

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the scaling keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords scale_types and/or scales in the variables and responses blocks. When the scaling keyword is omitted from method, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

• a *scales keyword, which gives characteristic values (divisors)
• a *scale_types keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in responses for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are three scale types:

1. value - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.

2. auto - automatic scaling
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   • two-sided bounds scaled into the interval [0,1];
   • one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into $[0,1]$.

3. log - logarithmic scaling

First, any characteristic values from the optional *scales specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The *scales keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding *scale_types, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- auto, log - optional
- value - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10*DBL_MIN$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```plaintext
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100

responses
objective_functions 3
sense "maximize"
primary_scale_types = "value" "value" "value"
primary_scales = 1 1 100
```

7.2.25.12 model_pointer

- Keywords Area
- method
- optpp_newton
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer
Specification

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

Examples

```plaintext
environment
    tabular_data
    method_pointer = 'UQ'
method
    id_method = 'UQ'
    model_pointer = 'SURR'
    sampling,
        samples = 10
        seed = 98765 rng rnum2
        response_levels = 0.1 0.2 0.6
                        0.1 0.2 0.6
                        0.1 0.2 0.6
        sample_type lhs
    distribution cumulative
model
    id_model = 'SURR'
    surrogate global,
    dace_method_pointer = 'DACE'
    polynomial quadratic
method
    id_method = 'DACE'
    model_pointer = 'DACE_M'
    sampling sample_type lhs
        samples = 121 seed = 5034 rng rnum2
model
    id_model = 'DACE_M'
    single
    interface_pointer = 'I1'
variables
    uniform_uncertain = 2
    lower_bounds = 0. 0.
    upper_bounds = 1. 1.
    descriptors = 'x1' 'x2'
interface
    id_interface = 'I1'
    system asynch evaluation_concurrency = 5
```
```
    analysis_driver = 'text_book'
```

```
    responses
    response_functions = 3
    no_gradients
    no_hessians
```

### 7.2.26 optpp_pds

7.2.26.3 convergence_tolerance

- Keywords Area
- method
- optpp_pds
- convergence_tolerance

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- `method_independent_controls`

Specification

**Alias:** none

**Argument(s):** REAL

**Default:** 1.e-4

**Description**

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by convergence_tolerance, then this convergence criterion is satisfied on the current iteration. Therefore, permissible values are between 0 and 1, non-inclusive.

**Behavior Varies by Package/Library**

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

**Notes on each library:**

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See nl2sol
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance
7.2.26.4 max_function_evaluations

- Keywords Area
- method
- optpp_pds
- max_function_evaluations

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed max_function_evaluations evaluations. See also max_iterations.

Some optimizers (e.g. ncsu_direct) may run past this limit in the course of an iteration step that began before max_function_evaluations was exceeded.

Default Behavior

Default value is 1000.

7.2.26.5 scaling

- Keywords Area
- method
- optpp_pds
- scaling

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- method_independent_controls
Specification

Alias: none
Argument(s): none
Default: no scaling

Description

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the scaling keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords scale_types and/or ∗scales in the variables and responses blocks. When the scaling keyword is omitted from method, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled:

- a ∗scales keyword, which gives characteristic values (divisors)
- a ∗scale_types keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in responses for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are three scale types:

1. value - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.

2. auto - automatic scaling
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   - two-sided bounds scaled into the interval [0,1];
   - one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
   - no bounds or targets: no automatic scaling possible, therefore no scaling for this component

   Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

3. log - logarithmic scaling
   First, any characteristic values from the optional ∗_scales specification are applied. Then logarithm base 10 scaling is applied.
   Logarithmic scaling is not available for linear constraints.
   When continuous design variables are log scaled, linear constraints are not allowed.
Scales

The *scales* keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding *scale_types*, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- **auto, log** - optional
- **value** - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0 \times 10^{10} \times \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100
```

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value" "value" "value"
primary_scales = 1 1 100
```

7.2.26.6 model_pointer

- Keywords Area
- method
- optpp_pds
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)
Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

**Description**

This is not a method that is intended for use. Rather it is part of a documented, functional example of how to integrate a third-party optimization library. It takes an initial point, generates a list of random parameter values, evaluates the function at each point in the list, and returns the point with the lowest function value.

Documented instructions on how to integrate a third-party library, working source code, and build infrastructure can be found in $dakotaSource/packages/external/demo_tpl. Additionally, integration instructions can be found in the Developers Manual.
7.2 method

7.2.27.1 max_function_evaluations

- Keywords Area
- method
- demo_tpl
- max_function_evaluations

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed max_function_evaluations evaluations. See also max_iterations.

Some optimizers (e.g. ncsu_direct) may run past this limit in the course of an iteration step that began before max_function_evaluations was exceeded.

Default Behavior

Default value is 1000.

7.2.27.2 max_iterations

- Keywords Area
- method
- demo_tpl
- max_iterations

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- method_independent_controls
Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: fsu_cvt, local_reliability: 25; global_(reliability, interval_est, evidence) / efficient_global: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed \( \text{max_iterations} \) iterations. In cases where there are multiple nested iterations to be controlled, \( \text{max_iterations} \) generally controls the outer-most context.

Default Behavior

Default value is 100.

See Also

These keywords may also be of interest:

- max_function_evaluations

7.2.27.3 convergence_tolerance

- Keywords Area
- method
- demo_tpl
- convergence_tolerance

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The \( \text{convergence_tolerance} \) specification provides a real value for controlling the termination of iteration.
For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by convergence_tolerance, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See nl2sol
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

7.2.27.4 variable_tolerance

- Keywords Area
- method
- demo_tpl
- variable_tolerance

Step length-based stopping criteria for derivative-free optimizers

Specification

Alias: none

Argument(s): REAL

Default: 0.01

Description

The variable_tolerance keyword defines the minimum step length allowed by the optimizer and is used to determine convergence. It is applicable to asynch_pattern_search, coliny_cobyla, coliny_pattern_search, coliny_solis_wets, and mesh_adaptive_search.

Default Behavior

The default value varies according to method as follows:

- asynch_pattern_search: 1.0e-2
- coliny_cobyla: 1.0e-4
- coliny_pattern_search: 1.0e-5
- coliny_solis_wets: 1.0e-6
- `mesh_adaptive_search: 1.0e-6`

**Usage Tips**

It is recommended that `variable_tolerance` be set to a value for which changes of that scale in parameter values cause negligible changes in the objective function.

**Examples**

Three example method input blocks appear below.

For `asynch_pattern_search`:

```plaintext
method
  asynch_pattern_search
  contraction_factor = 0.25
  variable_tolerance = 1.e-4
  solution_target = 1.e-6
  max_function_evaluations = 500
  constraint_tolerance = 1.e-6
```

For `coliny_pattern_search`:

```plaintext
method
  coliny_pattern_search
  initial_delta = .2
  variable_tolerance = 1.e-4
  max_iterations = 100
  solution_accuracy = 1.e-6
  seed = 1234
  max_function_evaluations = 1000
```

For `mesh_adaptive_search`:

```plaintext
method
  mesh_adaptive_search
  variable_tolerance = 0.01
  seed = 1234
```

7.2.27.5 `solution_target`

- Keywords Area
- method
- demo_tpl
- solution_target

Stopping criteria based on objective function value

**Specification**

*Alias*: `solution_accuracy`

**Argument(s):** REAL

**Default:** no target

**Description**

`solution_target` is a termination criterion. The algorithm will terminate when the function value falls below `solution_target`.
7.2.27.6 options_file

- Keywords Area
- method
- demo_tpl
- options_file

Filename for a YAML file that specifies Gaussian process options

Specification

Alias: none

Argument(s): STRING

Default: no advanced options file

Description

The YAML file contains configuration options that are used to populate a Teuchos ParameterList used by the Gaussian process that will override other keyword-specified parameters. Missing options in the YAML file are set to default values.

Examples

# FILE: gp_options.yaml

GP Parameters:
Sigma Bounds:
    lower bound: 1.0e-2
    upper bound: 1.0e2
scaler name: standardization
num restarts: 20
Nugget:
    fixed nugget: 0.0
    estimate nugget: true
Bounds:
    lower bound: 3.17e-8
    upper bound: 1.0e-2
gp seed: 42
standardize response: false
Trend:
    estimate trend: true
Options:
    max degree: 2
    reduced basis: false
    p-norm: 1.0
    scaler type: none
    regression solver type: SVD
    verbosity: 1
kernel type: squared exponential
Length-scale Bounds:
    lower bound: 1.0e-2
    upper bound: 1.0e2
    verbosity: 1

7.2.28 rol

- Keywords Area
Rapid Optimization Library (ROL) is a large-scale optimization package within Trilinos.

Topics

This keyword is related to the topics:

- local_optimization_methods

Specification

Alias: none

Argument(s): none

Child Keywords:

<table>

<td>scaling</td>
<td></td>
<td>Turn on scaling for variables, responses, and constraints</td>
</tr>
</tbody>
</table>
**Description**

ROL is used for the solution of optimal design, optimal control and inverse problems in large-scale engineering applications.

**Usage Tips**

ROL is a general gradient-based library designed to scale well to very large problem sizes. For large problem sizes (i.e. number of variables), ROLs trust region method and conjugate gradient methods exhibit good scalability for unconstrained problems. ROL handles equality constraints natively but converts inequality constraints into equality constraints with bounded slack variables. This has might degrade convergence for problems involving large number of inequality constraints. ROL has traditionally been applied to problems with analytic gradients (and Hessians) but can be used with Dakota-provided finite-differencing approximations to the gradient of both objective and constraints. However, a user employing these is advised to use alternative optimizers such as DOT until performance of ROL improves in future releases.

**Expected HDF5 Output**

If Dakota was built with HDF5 support and run with the hdf5 keyword, this method writes the following results to HDF5:

- Best Parameters
- Best Objective Functions (when objective_functions) are specified)
- Calibration (when calibration_terms are specified)

### 7.2.28.1 max_iterations

- Keywords Area
- method
- rol
- max_iterations

Number of iterations allowed for optimizers and adaptive UQ methods

**Topics**

This keyword is related to the topics:

- method_independent_controls

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 100 (exceptions: fsu_cvt, local_reliability: 25; global_(reliability, interval_est, evidence) / efficient_global: 25+n)
Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed \texttt{max\_iterations} iterations. In cases where there are multiple nested iterations to be controlled, \texttt{max\_iterations} generally controls the outer-most context.

Default Behavior

Default value is 100.

See Also

These keywords may also be of interest:

- \texttt{max\_function\_evaluations}

7.2.28.2 variable\_tolerance

- \texttt{Keywords Area}
- \texttt{method}
- \texttt{rol}
- \texttt{variable\_tolerance}

Step length-based stopping criteria for derivative-free optimizers

Specification

\texttt{Alias: none}

\texttt{Argument(s): REAL}

\texttt{Default: 0.01}

Description

The \texttt{variable\_tolerance} keyword defines the minimum step length allowed by the optimizer and is used to determine convergence. It is applicable to \texttt{asynch\_pattern\_search}, \texttt{coliny\_cobyla}, \texttt{coliny\_-pattern\_search}, \texttt{coliny\_solis\_wets}, and \texttt{mesh\_adaptive\_search}.

Default Behavior

The default value varies according to method as follows:

- \texttt{asynch\_pattern\_search}: 1.0e-2
- \texttt{coliny\_cobyla}: 1.0e-4
- \texttt{coliny\_pattern\_search}: 1.0e-5
- \texttt{coliny\_solis\_wets}: 1.0e-6
- \texttt{mesh\_adaptive\_search}: 1.0e-6

Usage Tips

It is recommended that \texttt{variable\_tolerance} be set to a value for which changes of that scale in parameter values cause negligible changes in the objective function.
Examples

Three example method input blocks appear below.

For `asynch_pattern_search`:

```dakota
method
  asynch_pattern_search
  contraction_factor = 0.25
  variable_tolerance = 1.e-4
  solution_target = 1.e-6
  max_function_evaluations 500
  constraint_tolerance 1.e-6
```

For `coliny_pattern_search`:

```dakota
method
  coliny_pattern_search
  initial_delta = .2
  variable_tolerance = 1.e-4
  max_iterations 100
  solution_accuracy = 1.e-6
  seed = 1234
  max_function_evaluations = 1000
```

For `mesh_adaptive_search`:

```dakota
method
  mesh_adaptive_search
  variable_tolerance = 0.01
  seed = 1234
```

7.2.28.3 gradient_tolerance

- Keywords Area
- method
- rol
- gradient_tolerance

Stopping critera based on L2 norm of gradient

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `gradient_tolerance` control defines the threshold value on the L2 norm of the objective function gradient (for unconstrained minimum or no active constraints) or the Lagrangian gradient (for constrained minimum) that indicates convergence to a stationary point. The `gradient_tolerance` control is currently defined only for the OPT++ and ROL libraries.
7.2.28.4  constraint_tolerance

- Keywords Area
- method
- rol
- constraint_tolerance

Maximum allowable constraint violation still considered feasible

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

**Alias:** none

**Argument(s):** REAL

**Default:** Library default

Description

Sets the maximum allowable value of infeasibility that any constraint in an optimization problem may possess and still be considered to be satisfied.

If a constraint’s violation is greater than this value then it is considered to be violated by the optimization algorithm. This specification gives some control over how tightly the constraints will be satisfied at convergence of the algorithm. However, if the value is set too small the algorithm may terminate with one or more constraints being violated.

**Defaults**

Defaults vary depending on the method.

- CONMIN optimizers: 1.0e-3
- DOT constrained optimizers: 3.0e-3
- surrogate_based_local : 1.0e-4

7.2.28.5  options_file

- Keywords Area
- method
- rol
- options_file

File containing advanced ROL options
7.2 method

Specification

Alias: none
Argument(s): STRING
Default: no advanced options file

Description

Allow power users to override default ROL options

Default Behavior  No advanced options used.

Usage Tips  The options_file offers a final override over other options settings, which are applied with the following precedence:

1. ROL library defaults
2. Dakota hard-coded defaults
3. Settings from Dakota input file
4. Settings from the advanced options_file

7.2.28.6 scaling

• Keywords Area
• method
• rol
• scaling

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

• method_independent_controls

Specification

Alias: none
Argument(s): none
Default: no scaling

Description

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the scaling keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are
performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords scale_types and/or *scales in the variables and responses blocks. When the scaling keyword is omitted from method, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

- a *scales keyword, which gives characteristic values (divisors)
- a *scale_types keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in responses for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types
There are three scale types:

1. value - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.

2. auto - automatic scaling
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   - two-sided bounds scaled into the interval [0,1];
   - one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
   - no bounds or targets: no automatic scaling possible, therefore no scaling for this component

   Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

3. log - logarithmic scaling
   First, any characteristic values from the optional *_scales specification are applied. Then logarithm base 10 scaling is applied.
   Logarithmic scaling is not available for linear constraints.
   When continuous design variables are log scaled, linear constraints are not allowed.

Scales
The *scales keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding *scale_types, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- auto, log - optional
- value - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than 1.0e10*DBL_MIN. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.
Examples

The two examples below are equivalent:

```
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100

responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

7.2.28.7 model_pointer

- **Keywords Area**
- **method**
- **rol**
- **model_pointer**

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- **block_pointer**

Specification

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)

Description

The **model_pointer** is used to specify which **model** block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a **model** block in the Dakota input file that has a corresponding **id_model** with the same name.

**Usage Tips**

When doing advanced analyses that involve using multiple methods and multiple models, defining a **model_pointer** for each method is imperative. See **block_pointer** for details about pointers.
Examples

method
id_method = ‘UQ’
model_pointer = ‘SURR’
sampling,
samples = 10
seed = 98765 rng rnum2
response_levels = 0.1 0.2 0.6
0.1 0.2 0.6
0.1 0.2 0.6
sample_type lhs
distribution cumulative

model
id_model = ‘SURR’
surrogate global,
dace_method_pointer = ‘DACE’
polynomial quadratic

method
id_method = ‘DACE’
model_pointer = ‘DACE_M’
sampling sample_type lhs
samples = 121 seed = 5034 rng rnum2

model
id_model = ‘DACE_M’
single
interface_pointer = ‘I1’

variables
uniform_uncertain = 2
lower_bounds = 0. 0.
upper_bounds = 1. 1.
descriptors = ‘x1’ ‘x2’

interface
id_interface = ‘I1’
system asynch evaluation_concurrency = 5
analysis_driver = ‘text_book’

responses
response_functions = 3
no_gradients
no_hessians

7.2.29 asynch_pattern_search

• Keywords Area
• method
• asynch_pattern_search

Pattern search, derivative free optimization method

Topics

This keyword is related to the topics:

• package_hopspack
• global_optimization_methods
### Specification

**Alias:** coliny_apps  
**Argument(s):** none

</tbody>
</table>
Description

The asynchronous parallel pattern search (APPS) algorithm [38] is a fully asynchronous pattern search technique in that the search along each offset direction continues without waiting for searches along other directions to finish. Currently, APPS only supports coordinate bases with a total of $2n$ function evaluations in the pattern, and these patterns may only contract.

Concurrency

APPS exploits parallelism through the use of Dakota's concurrent function evaluations. The variant of the algorithm that is currently exposed, however, limits the amount of concurrency that can be exploited. In particular, APPS can leverage an evaluation concurrency level of at most twice the number of variables. More options that allow for greater evaluation concurrency may be exposed in future releases.

Algorithm Behavior

- \texttt{initial\_delta}: the initial step length, must be positive
- \texttt{variable\_tolerance}: step length used to determine convergence, must be greater than or equal to $4.4e^{-16}$
- \texttt{contraction\_factor}: amount by which step length is rescaled after unsuccessful iterates, must be strictly between 0 and 1

Merit Functions

APPS solves nonlinearly constrained problems by solving a sequence of linearly constrained merit function-based subproblems. There are several exact and smoothed exact penalty functions that can be specified with the \texttt{merit\_function} control. The options are as follows:

- \texttt{merit\_max}: based on $\ell_\infty$ norm
- \texttt{merit\_max\_smooth}: based on smoothed $\ell_\infty$ norm
- \texttt{merit1}: based on $\ell_1$ norm
- \texttt{merit1\_smooth}: based on smoothed $\ell_1$ norm
- \texttt{merit2}: based on $\ell_2$ norm
- \texttt{merit2\_smooth}: based on smoothed $\ell_2$ norm
- \texttt{merit2\_squared}: based on $\ell_2^2$ norm

The user can also specify the following to affect the merit functions:

- \texttt{constraint\_penalty}
- \texttt{smoothing\_parameter}

Method Independent Controls

The only method independent controls that are currently mapped to APPS are:
• max_function_evaluations
• constraint_tolerance
• output

Note that while APPS treats the constraint tolerance separately for linear and nonlinear constraints, we apply the same value to both if the user specifies constraint_tolerance.

The APPS internal display level is mapped to the Dakota output settings as follows:

• debug: display final solution, all input parameters, variable and constraint info, trial points, search directions, and execution details
• verbose: display final solution, all input parameters, variable and constraint info, and trial points
• normal: display final solution, all input parameters, variable and constraint summaries, and new best points
• quiet: display final solution and all input parameters
• silent: display final solution

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the hdf5 keyword, this method writes the following results to HDF5:

• Best Parameters
• Best Objective Functions (when objective_functions are specified)
• Best Nonlinear Constraints
• Calibration (when calibration_terms are specified)

7.2.29.1 initial_delta

• Keywords Area
• method
• asynch_pattern_search
• initial_delta

Initial step size for derivative-free optimizers

Specification

Alias: none

Argument(s): REAL

Default: 1.0
Description

The `initial_delta` keyword defines the size of the first search step in derivative-free optimization methods, specifically `asynch_pattern_search`, `coliny_cobyla`, `coliny_pattern_search`, `coliny_solis_wets`, and `mesh_adaptive_search`. It is applied in an absolute sense to all search directions.

Default Behavior

The default value is 1.0.

Usage Tips

It is recommended that `initial_delta` be the approximate distance from the initial point to the solution. If this distance is unknown, it is advisable to err on the side of choosing an `initial_delta` that is too large or to not specify it. Relative application of `initial_delta` is not available unless the user scales the problem accordingly.

Examples

Three example method input blocks appear below.

For `asynch_pattern_search`:

```dakota
method
  asynch_pattern_search
  initial_delta = .5
  contraction_factor = 0.25
  merit_function merit1_smooth
  smoothing_factor = 1.0
  constraint_tolerance = 1.e-6
```

For `coliny_pattern_search`:

```dakota
method
  coliny_pattern_search
  initial_delta = .2
  variable_tolerance = 1.e-4
  max_iterations 100
  solution_accuracy = 1.e-6
  seed = 1234
  max_function_evaluations = 1000
```

For `mesh_adaptive_search`:

```dakota
method
  mesh_adaptive_search
  initial_delta = 2.0
  seed = 1234
```

7.2.29.2 `contraction_factor`

- Keywords Area
- method
- `asynch_pattern_search`
- `contraction_factor`

Amount by which step length is rescaled

Specification

Alias: none
Argument(s): REAL
Default: 0.5

Description
For pattern search methods, contraction_factor specifies the amount by which step length is rescaled after unsuccessful iterates, must be strictly between 0 and 1.

For methods that can expand the step length, the expansion is 1/contraction_factor

7.2.29.3 variable_tolerance

• Keywords Area
  • method
  • asynch_pattern_search
  • variable_tolerance

Step length-based stopping criteria for derivative-free optimizers

Specification

Alias: none
Argument(s): REAL
Default: 0.01

Description
The variable_tolerance keyword defines the minimum step length allowed by the optimizer and is used to determine convergence. It is applicable to asynch_pattern_search, coliny_cobyla, coliny_pattern_search, coliny_solis_wets, and mesh_adaptive_search.

Default Behavior
The default value varies according to method as follows:

• asynch_pattern_search: 1.0e-2
• coliny_cobyla: 1.0e-4
• coliny_pattern_search: 1.0e-5
• coliny_solis_wets: 1.0e-6
• mesh_adaptive_search: 1.0e-6

Usage Tips
It is recommended that variable_tolerance be set to a value for which changes of that scale in parameter values cause negligible changes in the objective function.
Examples

Three example method input blocks appear below.

For **asynch_pattern_search**:

```
method
  asynch_pattern_search
  contraction_factor = 0.25
  variable_tolerance = 1.e-4
  solution_target = 1.e-6
  max_function_evaluations 500
  constraint_tolerance 1.e-6
```

For **coliny_pattern_search**:

```
method
  coliny_pattern_search
  initial_delta = .2
  variable_tolerance = 1.e-4
  max_iterations 100
  solution_accuracy = 1.e-6
  seed = 1234
  max_function_evaluations = 1000
```

For **mesh_adaptive_search**

```
method
  mesh_adaptive_search
  variable_tolerance = 0.01
  seed = 1234
```

7.2.29.4  **solution_target**

- **Keywords Area**
- **method**
- **asynch_pattern_search**
- **solution_target**

Stopping criteria based on objective function value

**Specification**

**Alias:** solution_accuracy  
**Argument(s):** REAL  
**Default:** no target

**Description**

**solution_target** is a termination criterion. The algorithm will terminate when the function value falls below **solution_target**.

7.2.29.5  **synchronization**

- **Keywords Area**
- **method**
7.2 method

- **asynch_pattern_search**
- **synchronization**

Select how Dakota schedules a batch of concurrent function evaluations in a parallel algorithm

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** method specific

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Required (Choose One)</strong></td>
<td>Synchronization (Group 1)</td>
<td>blocking</td>
<td>Complete concurrent evaluation of all evaluations within a batch</td>
</tr>
</tbody>
</table>

**nonblocking**

A batch of concurrent evaluations are queried for completions and a partial set is returned to the algorithm

**Description**

The synchronization specification can be used to specify the use of either blocking or nonblocking schedulers, where the former must block until all evaluations are completed and the latter does not block, returning only the partial set that has been completed for a particular call to the scheduler.

**7.2.29.5.1 blocking**

- **Keywords Area**
- **method**
- **asynch_pattern_search**
- **synchronization**
- **blocking**

Complete concurrent evaluation of all evaluations within a batch

**Specification**

**Alias:** none

**Argument(s):** none
Description

In the **blocking** case, all of the concurrent evaluations in the batch must be completed and all results are returned together to the algorithm.

These runs are reproducible, assuming use of the same seed in cases with random number generation.

7.2.29.5.2 nonblocking

- **Keywords Area**
- **method**
- **async_pattern_search**
- **synchronization**
- **nonblocking**

A batch of concurrent evaluations are queried for completions and a partial set is returned to the algorithm

Specification

**Alias**: none

**Argument(s)**: none

Description

In the **nonblocking** case, the set of running evaluations is queried for completion and a partial set of results is returned to an asynchronous algorithm, which can then generate new evaluations based on these partial results.

In all cases, the algorithm steps will be subject to parallel timing variabilities / race conditions such that these runs will not generally be repeatable regardless of seed specification.

7.2.29.6 merit_function

- **Keywords Area**
- **method**
- **async_pattern_search**
- **merit_function**

Balance goals of reducing objective function and satisfying constraints

Specification

**Alias**: none

**Argument(s)**: none

**Default**: merit2_squared

**Child Keywords**: None
### Description

A merit function is a function in constrained optimization that attempts to provide joint progress toward reducing the objective function and satisfying the constraints.

7.2.29.7 constraint_penalty

- Keywords Area
- method
- asynch_pattern_search
- constraint_penalty

Multiplier for the penalty function

**Specification**

**Alias**: none

**Argument(s)**: REAL

**Default**: 1.0

**Description**

Most SCOLIB optimizers treat constraints with a simple penalty scheme that adds $\text{constraint\_penalty \times} \text{the sum of squares of the constraint violations}$ to the objective function. The default value of $\text{constraint\_penalty}$ is 1000.0, except for methods that dynamically adapt their constraint penalty, for which the default value is 1.0.
7.2.29.8 smoothing_factor

- Keywords Area
- method
- asynch_pattern_search
- smoothing_factor

Smoothing value for smoothed penalty functions

Specification

Alias: none
Argument(s): REAL
Default: 0.0

Description

- smoothing_parameter: initial smoothing value for smoothed penalty functions, must be between 0 and 1 (inclusive)

7.2.29.9 constraint_tolerance

- Keywords Area
- method
- asynch_pattern_search
- constraint_tolerance

Maximum allowable constraint violation still considered feasible

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none
Argument(s): REAL
Default: Library default
Description

Sets the maximum allowable value of infeasibility that any constraint in an optimization problem may possess and still be considered to be satisfied.

If a constraint's violation is greater than this value then it is considered to be violated by the optimization algorithm. This specification gives some control over how tightly the constraints will be satisfied at convergence of the algorithm. However, if the value is set too small the algorithm may terminate with one or more constraints being violated.

Defaults

Defaults vary depending on the method.

- CONMIN optimizers: 1.0e-3
- DOT constrained optimizers: 3.0e-3
- surrogate_based_local : 1.0e-4

7.2.29.10 max_function_evaluations

- Keywords Area
- method
- asynch_pattern_search
- max_function_evaluations

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none
Argument(s): INTEGER
Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed max_function_evaluations evaluations. See also max_iterations.

Some optimizers (e.g. ncsu_direct) may run past this limit in the course of an iteration step that began before max_function_evaluations was exceeded.

Default Behavior

Default value is 1000.
7.2.29.11 scaling

- Keywords Area
- method
- asynch_pattern_search
- scaling

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none
Argument(s): none
Default: no scaling

Description

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the scaling keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords scale_types and/or *scales in the variables and responses blocks. When the scaling keyword is omitted from method, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

- a *scales keyword, which gives characteristic values (divisors)
- a *scale_types keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in responses for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are three scale types:

1. value - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.
2. *auto* - automatic scaling

First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval \([0,1]\);
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into \([0,1]\).

3. *log* - logarithmic scaling

First, any characteristic values from the optional \(*scales\) specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

### Scales

The \(*scales\) keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding \(*scale\_types\), as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- *auto, log* - optional
- *value* - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than \(1.0e10*DBL\_MIN\). User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

### Examples

The two examples below are equivalent:

```
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100

responses
objective_functions 3
sense "maximize"
primary_scale_types = "value" "value" "value"
primary_scales = 1 1 100
```

7.2.29.12 model_pointer

- Keywords Area
- method
- asynch_pattern_search
- model_pointer

Identifier for model block to be used by a method
Topics

This keyword is related to the topics:

- block_pointer

Specification

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)

**Description**

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

**Usage Tips**

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

**Examples**

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
    0.1 0.2 0.6
    0.1 0.2 0.6
    sample_type lhs
    distribution cumulative

model
  id_model = 'SURR'
  surrogate global,
  dace_method_pointer = 'DACE'
  polynomial quadratic

method
  id_method = 'DACE'
  model_pointer = 'DACE_M'
  sampling sample_type lhs
    samples = 121 seed = 5034 rng rnum2

model
  id_model = 'DACE_M'
  single
  interface_pointer = 'I1'
```
variables
uniform_uncertain = 2
lower_bounds = 0. 0.
upper_bounds = 1. 1.
descriptors = 'x1' 'x2'

interface
id_interface = 'I1'
system asynch evaluation_concurrency = 5
analysis_driver = 'text_book'

responses
response_functions = 3
no_gradients
no_hessians

7.2.30 mesh_adaptive_search

- Keywords Area
- method
- mesh_adaptive_search

Finds optimal variable values using adaptive mesh-based search

Specification

Alias: none
Argument(s): none
Child Keywords:

<table>

<td>Optional</td>
<td>history_file</td>
<td></td>
<td>Name of file where mesh adaptive search records all evaluation points.</td>
</tr>
</tbody>
</table>
### Description

The mesh adaptive direct search algorithm \[8\] is a derivative-free generalized pattern search in which the set of points evaluated becomes increasingly dense, leading to good convergence properties. It can handle unconstrained problems as well as those with bound constraints and general nonlinear constraints. Furthermore, it can handle continuous, discrete, and categorical variables.

### Default Behavior

By default, `mesh_adaptive_search` operates on design variables. The types of variables can be expanded through the use of the `active` keyword in the `variables` block in the Dakota input file. Categorical variables, however, must be limited to design variables.

<table>
<thead>

<td>scaling</td>
<td>Turn on scaling for variables, responses, and constraints</td>
</tr>
<tr>
<td>Optional</td>
<td>model_pointer</td>
<td>Identifier for model block to be used by a method</td>
</tr>
</tbody>
</table>
**Expected Outputs**

The best objective function value achieved and associated parameter and constraint values can be found at the end of the Dakota output. The method's internally summarized iteration history will appear in the screen output by default, with the option to control the method's output through Dakota's output level. It also generates a history file containing a list of all function evaluations done.

**Expected HDF5 Output**

If Dakota was built with HDF5 support and run with the hdf5 keyword, this method writes the following results to HDF5:

- Best Parameters
- Best Objective Functions (when objective_functions are specified)
- Best Nonlinear Constraints
- Calibration (when calibration_terms are specified)

**Additional Discussion**

The mesh adaptive direct search method is made available in Dakota through the NOMAD software [2], available to the public under the GNU LGPL from http://www.gerad.ca/nomad.

**Examples**

The following is an example of a Dakota input file that makes use of mesh_adaptive_search to optimize the textbook function.

```plaintext
method,
  mesh_adaptive_search
  seed = 1234
variables,
  continuous_design = 3
  initial_point  -1.0  1.5  2.0
  upper_bounds   10.0  10.0  10.0
  lower_bounds   -10.0 -10.0 -10.0
  descriptors    'x1' 'x2' 'x3'
interface,
  direct
    analysis_driver = 'text_book'
responses,
  objective_functions = 1
  no_gradients
  no_hessians

The best function value and associated parameters are found at the end of the Dakota output.

<<<<<< Function evaluation summary: 674 total (674 new, 0 duplicate)
<<<<<< Best parameters =
  1.0000000000e+00 x1
  1.0000000000e+00 x2
  1.0000000000e+00 x3
<<<<<< Best objective function =
  1.0735377280e-52
<<<<<< Best evaluation ID: 658

A NOMAD-generated iteration summary is also printed to the screen.

7.2.30.1 initial_delta

- Keywords Area
- method
- mesh_adaptive_search
initial_delta

Initial step size for derivative-free optimizers

**Specification**

**Alias:** none  
**Argument(s):** REAL  
**Default:** 1.0

**Description**

The `initial_delta` keyword defines the size of the first search step in derivative-free optimization methods, specifically `asynch_pattern_search`, `coliny_cobyla`, `coliny_pattern_search`, `coliny_solis_wets`, and `mesh_adaptive_search`. It is applied in an absolute sense to all search directions.

**Default Behavior**

The default value is 1.0.

**Usage Tips**

It is recommended that `initial_delta` be the approximate distance from the initial point to the solution. If this distance is unknown, it is advisable to err on the side of choosing an `initial_delta` that is too large or to not specify it. Relative application of `initial_delta` is not available unless the user scales the problem accordingly.

**Examples**

Three example method input blocks appear below.

For `asynch_pattern_search`:

```
method
  asynch_pattern_search
    initial_delta = .5
    contraction_factor = 0.25
    merit_function merit1_smooth
    smoothing_factor = 1.0
    constraint_tolerance = 1.e-6
```

For `coliny_pattern_search`:

```
method
  coliny_pattern_search
    initial_delta = .2
    variable_tolerance = 1.e-4
    max_iterations 100
    solution_accuracy = 1.e-6
    seed = 1234
    max_function_evaluations = 1000
```

For `mesh_adaptive_search`:

```
method
  mesh_adaptive_search
    initial_delta = 2.0
    seed = 1234
```
Step length-based stopping criteria for derivative-free optimizers

**Specification**

Alias: none  
Argument(s): REAL  
Default: 1.0e-6

**Description**

The `variable_tolerance` keyword defines the minimum step length allowed by the optimizer and is used to determine convergence. It is applicable to `asynch_pattern_search`, `coliny_cobyla`, `coliny_pattern_search`, `coliny_solis_wets`, and `mesh_adaptive_search`.

**Default Behavior**

The default value varies according to method as follows:

- `asynch_pattern_search`: 1.0e-2
- `coliny_cobyla`: 1.0e-4
- `coliny_pattern_search`: 1.0e-5
- `coliny_solis_wets`: 1.0e-6
- `mesh_adaptive_search`: 1.0e-6

**Usage Tips**

It is recommended that `variable_tolerance` be set to a value for which changes of that scale in parameter values cause negligible changes in the objective function.

**Examples**

Three example method input blocks appear below.

For `asynch_pattern_search`:

```plaintext
method
  asynch_pattern_search
    contraction_factor = 0.25
    variable_tolerance = 1.e-4
    solution_target = 1.e-6
    max_function_evaluations = 500
    constraint_tolerance = 1.e-6
```

For `coliny_pattern_search`:

```plaintext
method
  coliny_pattern_search
    initial_delta = .2
    variable_tolerance = 1.e-4
    max_iterations = 100
    solution_accuracy = 1.e-6
    seed = 1234
    max_function_evaluations = 1000
```
For \texttt{mesh\_adaptive\_search}

\begin{verbatim}
method
  mesh_adaptive_search
    variable_tolerance = 0.01
    seed = 1234
\end{verbatim}

7.2.30.3 \texttt{function\_precision}

- Keywords Area
- \texttt{method}
- \texttt{mesh\_adaptive\_search}
- \texttt{function\_precision}

Specify the maximum precision of the analysis code responses

\textbf{Specification}

\textbf{Alias}: none

\textbf{Argument(s)}: REAL

\textbf{Default}: 1.0e-10

\textbf{Description}

The \texttt{function\_precision} control provides the algorithm with an estimate of the accuracy to which the problem functions can be computed. This is used to prevent the algorithm from trying to distinguish between function values that differ by less than the inherent error in the calculation.

7.2.30.4 \texttt{seed}

- Keywords Area
- \texttt{method}
- \texttt{mesh\_adaptive\_search}
- \texttt{seed}

Seed of the random number generator

\textbf{Specification}

\textbf{Alias}: none

\textbf{Argument(s)}: INTEGER

\textbf{Default}: system-generated (non-repeatable)
Description

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```dakota
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

7.2.30.5 history_file

- Keywords Area
- method
- mesh_adaptive_search
- history_file

Name of file where mesh adaptive search records all evaluation points.

Specification

Alias: none

Argument(s): STRING

Default: mads_history

Description

The history_file is used to specify the name of a file to which mesh adaptive direct search will write its own list of evaluated points.

Default Behavior

By default, mesh adaptive direct search will write the list of evaluation points in a file named mads_history.xxxx, where xxxx corresponds to a randomly generated number. Dakota's output level controls the method's level of output to file.
Examples

The example below shows the syntax for specifying the name of the history file.

```python
method
    mesh_adaptive_search
    history_file = 'output.log'
    seed = 1234
```

### 7.2.30.6 display_format

- **Keywords Area**
- **method**
- **mesh_adaptive_search**
- **display_format**

Information to be reported from mesh adaptive search’s internal records.

**Specification**

**Alias:** none  
**Argument(s):** STRING

**Description**

The `display_format` keyword is used to specify the set of information to be reported by the mesh adaptive direct search method. This is information mostly internal to the method and not reported via Dakota output.

**Default Behavior**

By default, only the number of function evaluations (bbe) and the objective function value (obj) are reported. The full list of options is as follows. Note that case does not matter.

- **BBE:** Blackbox evaluations.  
- **BBO:** Blackbox outputs.  
- **EVAL:** Evaluations (includes cache hits).  
- **MESH_INDEX:** Mesh index.  
- **MESH_SIZE:** Mesh size parameter.  
- **OBJ:** Objective function value.  
- **POLL_SIZE:** Poll size parameter.  
- **SOL:** Solution, with format iSOLj where i and j are two (optional) strings: i will be displayed before each coordinate, and j after each coordinate (except the last).  
- **STAT_AVG:** The AVG statistic.  
- **STAT_SUM:** The SUM statistic defined by argument.  
- **TIME:** Wall-clock time.  
- **VARi:** Value of variable i. The index 0 corresponds to the first variable.
Expected Outputs
A list of the requested information will be printed to the screen.

Usage Tips
This will most likely only be useful for power users who want to understand and/or report more detailed information on method behavior.

Examples
The following example shows the syntax for specifying display_format. Note that all desired information options should be listed within a single string.

```
method
    mesh_adaptive_search
    display_format 'bbe obj poll_size'
    seed = 1234
```

Below is the output reported for the above example.

```
MADS run {
    BBE OBJ POLL_SIZE
    1 17.0625000000 2.0000000000 2.0000000000 2.0000000000
    2 1.0625000000 2.0000000000 2.0000000000 2.0000000000

These keywords may also be of interest:

- display_all_evaluations

7.2.30.7 variable_neighborhood_search

- Keywords Area
- method
- mesh_adaptive_search
- variable_neighborhood_search

Percentage of evaluations to do to escape local minima.

Specification

Alias: none

Argument(s): REAL

Default: 0.0

Description

The variable_neighborhood_search keyword is used to set the percentage (in decimal form) of function evaluations used to escape local minima. The mesh adaptive direct search method will try to perform a maximum of that percentage of the function evaluations within this more extensive search.

Default Behavior

By default, variable_neighborhood_search is not used.

Usage Tips

Using variable_neighborhood_search results in an increased number of function evaluations. If the desired result is a local minimum, the added cost is of little or no value, so the recommendation is not to use it. If the desired result is the best local minimum possible within a computational budget, then there is value in setting this parameter. Note that the higher the value, the greater the computational cost. The value should be no greater than 1.0.
7.2 method

Examples

The following example shows the syntax used to set variable_neighborhood_search.

```
method
  mesh_adaptive_search
    seed = 1234
    variable_neighborhood_search = 0.1
```

7.2.30.8 neighbor_order

- Keywords Area
- method
- mesh_adaptive_search
- neighbor_order

Number of dimensions in which to perturb categorical variables.

Specification

Alias: none

Argument(s): INTEGER

Description

The neighbor_order keyword allows the user to specify the number of categorical dimensions to perturb when determining neighboring points that will be used by the mesh adaptive direct search method to augment its search. When greater than 1, the neighbors are defined from the tensor product of the admissible 1-dimensional perturbations.

Default Behavior

By default, the categorical neighbors will be defined by perturbing only one categorical variable at a time (according to the corresponding adjacency_matrix; see adjacency_matrix) while leaving the others fixed at their current values.

Usage Tips

The maximum meaningful value neighbor_order can take on is the number of categorical variables.

Examples

In this example, suppose we have the following categorical variables and associated adjacency matrices.

```
variables
discrete_design_set
  real = 2
  categorical ‘yes’ ‘yes’
  num_set_values = 3 5
  set_values = 1.2 2.3 3.4 5.5 7.7
  adjacency_matrix = 1 0 1 0 1
                   1 0 1 0 1
                   0 1 1
                   0 1 1
                   1 0 1 0 1
                   1 0 1 0 1
                   0 1 1
                   0 1 1
                   1 0 1 0 1
                   1 0 1 0 1
```
Also suppose that we have the following method specification.

```dakota
method
  mesh_adaptive_search
  seed = 1234
```

If the mesh adaptive direct search is at the point (1.2, 1.2), then the neighbors will be defined by the default 1-dimensional perturbations and would be the following:

(2.3, 1.2)
(1.2, 4.4)
(1.2, 7.7)

If, instead, the method specification is the following:

```dakota
method
  mesh_adaptive_search
  seed = 1234
  neighbor_order = 2
```

The neighbors will be defined by 2-dimensional perturbations defined from the tensor product of the 1-dimensional perturbation and would be the following:

(2.3, 1.2)
(2.3, 4.4)
(2.3, 7.7)
(1.2, 4.4)
(1.2, 7.7)

- `method`
- `mesh_adaptive_search`
- `display_all_evaluations`

Shows mesh adaptive search’s internally held list of all evaluations

Specification

Alias: none

Argument(s): none

Default: false
Description

If set, `display_all_evaluations` will instruct the mesh adaptive direct search method to print out its own record of all evaluations. The information reported may be controlled using `display_format`.

Default Behavior

By default, mesh adaptive direct search does not report information on all evaluations, only on those for which an improvement in the objective function is found.

Expected Outputs

The information specified by `display_format` will be reported to the screen for every function evaluation.

Usage Tips

This will most likely only be useful for power users who want to understand and/or report more detailed information on method behavior.

Examples

The following example shows the syntax for specifying `display_all_evaluations`.

```dakota
method
    mesh_adaptive_search
    display_all_evaluations
    max_function_evaluations=20
    seed = 1234

Note that the output below reports information (default for `display_format`) for all function evaluations.

MADS run {
    BBE OBJ
    1 17.0625000000
    2 1.0625000000
    3 1297.0625000000
    4 257.0625000000
    5 81.0625000000
    6 151.0625000000
    7 1051.0625000000
    8 40.0625000000
    9 17.0625000000
    10 40.0625000000
    11 1.0625000000
    12 102.0625000000
    13 0.0625000000
    14 231.0625000000
    15 16.0625000000
    16 5.0625000000
    17 16.0625000000
    18 71.0625000000
    19 0.0625000000
    20 1.0625000000
} end of run (max number of blackbox evaluations)

blackbox evaluations : 20
best feasible solution : ( 1 0.5 1 ) h=0 f=0.0625

That is in contrast with what would be reported by default.

MADS run {
    BBE OBJ
```
blackbox evaluations : 20
best feasible solution : ( 1 0.5 1 ) h=0 f=0.0625

7.2.30.10 use_surrogate

Surrogate model usage mode for mesh adaptive search

Specification

Alias: none

Argument(s): none

Default: optimize

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional Required (Choose One)</th>
<th>Description of Group Surrogate Purpose (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inform_search</td>
<td>Surrogate informs evaluation order in mesh adaptive search</td>
<td></td>
<td></td>
</tr>
<tr>
<td>optimize</td>
<td>Surrogate is used in lieu of true model for mesh adaptive search</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Description

The use_surrogate keyword is used to define how a surrogate model (if one is provided) is to be used by mesh_adaptive_search. There are two approaches available: inform_search uses the surrogate to sort list of trial points and subsequently the true function is evaluated on the most promising points first. Both true function and surrogate are used interchangeably within the method. optimize forces the use of a surrogate in lieu of the true model and thus the true function is never invoked except to construct the surrogate.
Known Issue: When using discrete variables, there have been sometimes significant differences in surrogate behavior observed across computing platforms in some cases. The cause has not yet been fully diagnosed and is currently under investigation. In addition, guidance on appropriate construction and use of surrogates with discrete variables is under development. In the meantime, users should therefore be aware that there is a risk of inaccurate results when using surrogates with discrete variables.

Default Behavior

By default, `mesh_adaptive_search` follows behavior provided by `optimize` option.

Examples

The following example shows the syntax used to set `use_surrogate`.

```dakota
method,
  mesh_adaptive_search
  model_pointer = 'SURROGATE'
  use_surrogate inform_search
model,
  id_model = 'SURROGATE'

```

**7.2.30.10.1 inform_search**

- **Keywords Area**
Surrogate informs evaluation order in mesh adaptive search

Specification

Alias: none
Argument(s): none

Description

When inform_search is specified with use_surrogate, mesh_adaptive_search uses the surrogate to sort list of trial points and subsequently the true function is evaluated on the most promising points first. Both true function and surrogate are used interchangeably within the method.

Default Behavior

inform_search is not the default surrogate usage mode.

Expected Output

The user can expect to see both the number of true model evaluations and the number of approximation (i.e., surrogate) evaluations reported in the Dakota screen output. The former captures the sum of truth evaluations done for the surrogate construction and for the optimization.

Usage Tips

When inform_search is specified, the maximum_function_evaluations keyword applies to only the optimization method and does not account for evaluations needed to construct the surrogate. If the user has a strict evaluation budget, they should set maximum_function_evaluations such that evaluation budget = number of evaluations to construct surrogate + maximum_function_evaluations.

Examples

The following example shows the syntax used to set use_surrogate to optimize.

```
method,
  mesh_adaptive_search
  model_pointer = 'SURROGATE'
  use_surrogate inform_search

model,
  id_model = 'SURROGATE'
  surrogate global
  polynomial quadratic
dace_method_pointer = 'SAMPLING'

variables,
  continuous_design = 3
    initial_point  -1.0  1.5  2.0
    upper_bounds  10.0  10.0  10.0
    lower_bounds  -10.0 -10.0 -10.0
descriptors     'x1' 'x2' 'x3'
  discrete_design_range = 2
    initial_point  2  2
    lower_bounds  1  1
    upper_bounds  4  9
```
7.2 method

```
descriptors 'y1' 'y2'
discrete_design_set
  real = 2
    elements_per_variable = 4 5
    elements = 1.2 2.3 3.4 4.5 1.2 3.3 4.4 5.5 7.7
  descriptors 'y3' 'y4'
  integer = 2
    elements_per_variable = 2 2
    elements = 4 7 8 9
  descriptors 'z1' 'z2'

method,
  id_method = 'SAMPLING'
  model_pointer = 'TRUTH'
  sampling
    samples = 55

model,
  id_model = 'TRUTH'
  single
    interface_pointer = 'TRUE_FN'

interface,
  id_interface = 'TRUE_FN'
  direct
    analysis_driver = 'text_book'

responses,
  objective_functions = 1
  no_gradients
  no_hessians
```

The following will appear toward the end of the screen output when Dakota is run on this example. The number of true function evaluations includes the 55 evaluations that were done to construct the surrogate (as specified in the SAMPLING method block) plus the number of truth evaluations done by mesh_adaptive_search.

```
<<<<<< Function evaluation summary (APPROX_INTERFACE): 1660 total (1660 new, 0 duplicate)
<<<<<< Function evaluation summary (TRUE_FN): 795 total (795 new, 0 duplicate)
```

7.2.30.10.2 optimize

- Keywords Area
- method
  - mesh_adaptive_search
- use_surrogate
- optimize

Surrogate is used in lieu of true model for mesh adaptive search

Specification

**Alias:** none
**Argument(s):** none

Description

When `optimize` is specified with `use_surrogate`, `mesh_adaptive_search` will use the surrogate in lieu of the true model and thus the true function is never invoked except to construct the surrogate.

Default Behavior
**Expected Output**

The user can expect to see both the number of true model evaluations and the number of approximation (i.e., surrogate) evaluations reported in the Dakota screen output. The former should equal the number of truth evaluations done for the surrogate construction.

**Examples**

The following example shows the syntax used to set `use_surrogate` to `optimize`.

```plaintext
method,
    mesh_adaptive_search
model_pointer = 'SURROGATE'
    use_surrogate optimize

model,
    id_model = 'SURROGATE'
surrogate global polynomial quadratic
dace_method_pointer = 'SAMPLING'

variables,
    continuous_design = 3
        initial_point -1.0 1.5 2.0
        lower_bounds -10.0 -10.0 -10.0
        upper_bounds 10.0 10.0 10.0
descriptors 'x1' 'x2' 'x3'

    discrete_design_range = 2
        initial_point 2 2
        lower_bounds 1 1
        upper_bounds 4 9
descriptors 'y1' 'y2'

    discrete_design_set
        real = 2
            elements_per_variable = 4 5
                descriptors 'y3' 'y4'
            integer = 2
                elements = 4 7 8 9
                descriptors 'z1' 'z2'

method,
    id_method = 'SAMPLING'
model_pointer = 'TRUTH'
sampling
    samples = 55

model,
    id_model = 'TRUTH'
single
    interface_pointer = 'TRUE_FN'

interface,
    id_interface = 'TRUE_FN'
    direct
    analysis_driver = 'text_book'

responses,
    objective_functions = 1
    no_gradients
    no_hessians

The following will appear toward the end of the screen output when Dakota is run on this example. The number of true function evaluations includes only the 55 evaluations that were done to construct the surrogate (as specified in the SAMPLING method block).

```````````````````````````````
<<<<<< Function evaluation summary (APPROX_INTERFACE): 221 total (221 new, 0 duplicate)```````````````````````````````````

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: fsu_cvt, local_reliability: 25; global_(reliability, interval_est, evidence) / efficient_global: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed max_iterations iterations. In cases where there are multiple nested iterations to be controlled, max_iterations generally controls the outer-most context.

Default Behavior

Default value is 100.

See Also

These keywords may also be of interest:

- max_function_evaluations

7.2.30.12 max_function_evaluations

- Keywords Area
- method
- mesh_adaptive_search
- max_function_evaluations

Number of function evaluations allowed for optimizers
Topics
This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed max_function_evaluations evaluations. See also max_iterations.

Some optimizers (e.g. ncsu_direct) may run past this limit in the course of an iteration step that began before max_function_evaluations was exceeded.

Default Behavior
Default value is 1000.

7.2.30.13 scaling

- Keywords Area
- method
- mesh_adaptive_search
- scaling

Turn on scaling for variables, responses, and constraints

Topics
This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the scaling keyword. Discrete variable scaling is not supported.
When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords *scale_types* and/or *scales* in the variables and responses blocks. When the *scaling* keyword is omitted from *method*, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

- a *scales* keyword, which gives characteristic values (divisors)
- a *scale_types* keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in responses for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

**Scale Types**

There are three scale types:

1. **value** - characteristic value scaling
   
   The target quantity will be scaled (divided) by the specified characteristic value.

2. **auto** - automatic scaling
   
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   
   - two-sided bounds scaled into the interval [0,1];
   - one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
   - no bounds or targets: no automatic scaling possible, therefore no scaling for this component

   Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

3. **log** - logarithmic scaling
   
   First, any characteristic values from the optional *_scales* specification are applied. Then logarithm base 10 scaling is applied.
   
   Logarithmic scaling is not available for linear constraints.
   
   When continuous design variables are log scaled, linear constraints are not allowed.

**Scales**

The *scales* keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding *scale_types*, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- **auto, log** - optional
- **value** - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10\times\text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.
Examples

The two examples below are equivalent:

```yaml
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100

responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

7.2.30.14 model_pointer

- Keywords Area
- method
- mesh_adaptive_search
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

7.2.31 nowpac

- Keywords Area
- method
- nowpac

Gradient-free inequality-constrained optimization using Nonlinear Optimization With Path Augmented Constraints (NOWPAC).

Specification

Alias: none
Argument(s): none
Child Keywords:
NOWPAC is a provably-convergent gradient-free optimization method from MIT that solves a series of trust region surrogate-based subproblems to generate improving steps. Due to its use of an interior penalty scheme and enforcement of strict feasibility, it does not support linear or nonlinear equality constraints. As opposed to the stochastic version (SNOWPAC), NOWPAC does not currently support a feasibility restoration mode, so it is necessary to start from a feasible design.

Note: (S)NOWPAC is not configured with Dakota by default and requires a separate installation of the NOWPAC distribution from MIT, combined with its TPLs of Eigen and NLOPT.

### Examples

```dakota
method nowpac
max_function_evaluations = 1000
convergence_tolerance = 1e-4
trust_region
  initial_size = 0.10
  minimum_size = 1.0e-6
  contract_threshold = 0.25
  expand_threshold = 0.75
  contraction_factor = 0.50
  expansion_factor = 1.50
```

### 7.2.31.1 trust_region

- Keywords Area
- method
- nowpac
- trust_region
Use trust region as the globalization strategy.

Specification

**Alias:** none

**Argument(s):** none

**Child Keywords:**

</tr>
<tr>
<td>Optional</td>
<td></td>
<td>expansion_factor</td>
<td>Trust region expansion factor</td>
</tr>
</tbody>
</table>

**Description**

The `trust_region` optional group specification can be used to specify the initial size of the trust region (using `initial_size`) relative to the total variable bounds, the minimum size of the trust region (using `minimum_size`), the contraction factor for the trust region size (using `contraction_factor`) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using `expansion_factor`) used when the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using `contract_threshold`) and the trust region size expansion threshold (using `expand_threshold`). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command `contract_threshold` sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command `expand_threshold` determines the trust region value above which the trust region will expand for the next SBL iteration.

7.2.31.1 `initial_size`

- **Keywords Area**
  - `method`
  - `nowpac`
  - `trust_region`
  - `initial_size`

Trust region initial size (relative to bounds)
The *trust_region* optional group specification can be used to specify the initial size of the trust region (using `initial_size`) relative to the total variable bounds, the minimum size of the trust region (using `minimum_size`), the contraction factor for the trust region size (using `contraction_factor`) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using `expansion_factor`) used when the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using `contract_threshold`) and the trust region size expansion threshold (using `expand_threshold`). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command `contract_threshold` sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command `expand_threshold` determines the trust region value above which the trust region will expand for the next SBL iteration.

All of these specifications are REAL scalars, with the exception of the specification of `initial_size`, which is a REALLIST. This array corresponds to the case when there are more than 2 model forms or discretizations within a model hierarchy. The default `initial_size` involves a recursive halving of the global bounds for each trust region in the hierarchy: e.g., a scalar value of .5 for a single trust region managing two model forms/discretizations, or an array of (.125, .25, .5) for four model forms/discretizations (three trust regions ordered from the lowest to highest fidelity surrogate, with model four as truth).

### 7.2.31.1.2 minimum_size

- Keywords Area
- method
- nowpac
- trust_region
- minimum_size

Trust region minimum size

**Specification**

**Alias:** none  
**Argument(s):** REAL  
**Default:** 1.e-6

**Description**

The *trust_region* optional group specification can be used to specify the initial size of the trust region (using `initial_size`) relative to the total variable bounds, the minimum size of the trust region (using `minimum_size`), the contraction factor for the trust region size (using `contraction_factor`) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using `expansion_factor`) used when the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using `contract_threshold`) and the trust region size expansion threshold (using `expand_threshold`). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The
command **contract_threshold** sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command **expand_threshold** determines the trust region value above which the trust region will expand for the next SBL iteration.

### 7.2.31.1.3 **contract_threshold**

- **Keywords Area**
- **method**
- **nowpac**
- **trust_region**
- **contract_threshold**

Shrink trust region if trust region ratio is below this value

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 0.25

**Description**

The **trust_region** optional group specification can be used to specify the initial size of the trust region (using **initial_size**) relative to the total variable bounds, the minimum size of the trust region (using **minimum_size**), the contraction factor for the trust region size (using **contraction_factor**) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using **expansion_factor**) used when the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using **contract_threshold**) and the trust region size expansion threshold (using **expand_threshold**). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command **contract_threshold** sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command **expand_threshold** determines the trust region value above which the trust region will expand for the next SBL iteration.

### 7.2.31.1.4 **expand_threshold**

- **Keywords Area**
- **method**
- **nowpac**
- **trust_region**
- **expand_threshold**

Expand trust region if trust region ratio is above this value

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 0.75
The trust_region optional group specification can be used to specify the initial size of the trust region (using initial_size) relative to the total variable bounds, the minimum size of the trust region (using minimum_size), the contraction factor for the trust region size (using contraction_factor) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using expansion_factor) used when the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using contract_threshold) and the trust region size expansion threshold (using expand_threshold). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command contract_threshold sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command expand_threshold determines the trust region value above which the trust region will expand for the next SBL iteration.

7.2.31.1.5 contraction_factor

- Keywords Area
- method
- nowpac
- trust_region
- contraction_factor

Amount by which step length is rescaled

Specification

Alias: none
Argument(s): REAL
Default: 0.25

Description

For pattern search methods, contraction_factor specifies the amount by which step length is rescaled after unsuccessful iterates, must be strictly between 0 and 1.

For methods that can expand the step length, the expansion is $1 / \text{contraction_factor}$

7.2.31.1.6 expansion_factor

- Keywords Area
- method
- nowpac
- trust_region
- expansion_factor

Trust region expansion factor
7.2 method

Specification

Alias: none
Argument(s): REAL
Default: 2.0

Description

The trust_region optional group specification can be used to specify the initial size of the trust region (using initial_size) relative to the total variable bounds, the minimum size of the trust region (using minimum_size), the contraction factor for the trust region size (using contraction_factor) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using expansion_factor) used when the the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using contract_threshold) and the trust region size expansion threshold (using expand_threshold). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command contract_threshold sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command expand_threshold determines the trust region value above which the trust region will expand for the next SBL iteration.

7.2.31.2 max_iterations

• Keywords Area
• method
• nowpac
• max_iterations

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

• method_independent_controls

Specification

Alias: none
Argument(s): INTEGER
Default: 100 (exceptions: fsu_cvt, local_reliability: 25; global_{reliability, interval_est, evidence} / efficient_global: 25+n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed max_iterations iterations. In cases where there are multiple nested iterations to be controlled, max_iterations generally controls the outer-most context.

Default Behavior

Default value is 100.
See Also

- max_function_evaluations

7.2.31.3 max_function_evaluations

- Keywords Area
- method
- nowpac
- max_function_evaluations

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

Default Behavior

Default value is 1000.

7.2.31.4 scaling

- Keywords Area
- method
- nowpac
- scaling

Turn on scaling for variables, responses, and constraints
Topics

This keyword is related to the topics:

- method_independent_controls

Specification

**Alias:** none

**Argument(s):** none

**Default:** no scaling

Description

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the scaling keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords `scale_types` and/or `*scales` in the variables and responses blocks. When the scaling keyword is omitted from method, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

- a `*scales` keyword, which gives characteristic values (divisors)
- a `*scale_types` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in responses for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are three scale types:

1. **value** - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.

2. **auto** - automatic scaling
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   - two-sided bounds scaled into the interval [0,1];
   - one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
   - no bounds or targets: no automatic scaling possible, therefore no scaling for this component

   Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Futher, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].
3. log-logarithmic scaling

First, any characteristic values from the optional \_scales specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The scales keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding scale_types, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- auto, log - optional
- value - required

A warning is issued if scaling would result in division by a value smaller in magnitude than \(1.0e10\cdot\text{DBL_MIN}\). User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100

responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

7.2.31.5 model_pointer

- Keywords Area
- method
- nowpac
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer
7.2 method

Specification

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

Examples

```plaintext
environment
tabular_data
method_pointer = 'UQ'

method
id_method = 'UQ'
model_pointer = 'SURR'
sampling,
  samples = 10
  seed = 98765 rng rnum2

</tr>
<tr>
<td>Optional</td>
<td></td>
<td>model_pointer</td>
<td>Identifier for model block to be used by a method</td>
</tr>
</tbody>
</table>

Description

NOWPAC is a provably-convergent gradient-free optimization method from MIT that solves a series of trust region surrogate-based subproblems to generate improving steps. The stochastic version is SNOWPAC, which incorporates noise estimates in its objective and inequality constraints. SNOWPAC modifies its trust region controls and
adds smoothing from a Gaussian process surrogate in order to mitigate noise. SNOWPAC also supports a feasibility restoration mode, so it is not necessary to start from a feasible design.

Note: (S)NOWPAC is not configured with Dakota by default and requires a separate installation of the NOWPAC distribution from MIT, combined with its TPLs of Eigen and NLOPT.

Examples

Relative to the NOWPAC specification, SNOWPAC supports a seed control for repeatability of runs and also requires the return of error estimates from the underlying evaluator (e.g., UQ method such as Monte Carlo sampling).

```plaintext
method,  
snowpac  
    seed = 2504  
    max_function_evaluations = 1000  
    convergence_tolerance = 1e-4  
    trust_region  
        initial_size = 0.10  
        minimum_size = 1.0e-6  
        contract_threshold = 0.25  
        expand_threshold = 0.75  
        contraction_factor = 0.50  
        expansion_factor = 1.50
```

7.2.32.1 seed

- Keywords Area
- method
- snowpac
- seed

Seed of the random number generator

Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** system-generated (non-repeatable)

Description

The random **seed** control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

**Default Behavior**

If not specified, the seed is randomly generated.

**Expected Output**

If **seed** is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

**Usage Tips**

If a stochastic study was run without **seed** specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.
Examples

```
method
    sampling
        sample_type: lhs
        samples = 10
        seed = 15347
```

**Description**

The `trust_region` optional group specification can be used to specify the initial size of the trust region (using `initial_size`) relative to the total variable bounds, the minimum size of the trust region (using `minimum_size`), the contraction factor for the trust region size (using `contraction_factor`) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using `expansion_factor`) used when the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using `contract_threshold`) and the trust region size expansion threshold (using `expand_threshold`). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command `contract_threshold` sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command `expand_threshold` determines the trust region value above which the trust region will expand for the next SBL iteration.

- trust_region
- initial_size

Trust region initial size (relative to bounds)

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Description**

The trust_region optional group specification can be used to specify the initial size of the trust region (using initial_size) relative to the total variable bounds, the minimum size of the trust region (using minimum_size), the contraction factor for the trust region size (using contraction_factor) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using expansion_factor) used when the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using contract_threshold) and the trust region size expansion threshold (using expand_threshold). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command contract_threshold sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command expand_threshold determines the trust region value above which the trust region will expand for the next SBL iteration.

All of these specifications are REAL scalars, with the exception of the specification of initial_size, which is a REALLIST. This array corresponds to the case when there are more than 2 model forms or discretizations within a model hierarchy. The default initial_size involves a recursive halving of the global bounds for each trust region in the hierarchy: e.g., a scalar value of .5 for a single trust region managing two model forms/discretizations, or an array of (.125, .25, .5) for four model forms/discretizations (three trust regions ordered from the lowest to highest fidelity surrogate, with model four as truth).

7.2.32.2 minimum_size

Shrink trust region if trust region ratio is below this value

Specification

**Alias**: none

**Argument(s)**: REAL

**Default**: 0.25

Description

The trust_region optional group specification can be used to specify the initial size of the trust region (using initial_size) relative to the total variable bounds, the minimum size of the trust region (using minimum_size), the contraction factor for the trust region size (using contraction_factor) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using expansion_factor) used when the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using contract_threshold) and the trust region size expansion threshold (using expand_threshold). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command contract_threshold sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command expand_threshold determines the trust region value above which the trust region will expand for the next SBL iteration.

7.2.32.2.4 expand_threshold

- Keywords Area
- method
- snowpac
- trust_region
- expand_threshold
Expand trust region if trust region ratio is above this value

Specification

Alias: none
Argument(s): REAL
Default: 0.75

Description

The trust_region optional group specification can be used to specify the initial size of the trust region (using initial_size) relative to the total variable bounds, the minimum size of the trust region (using minimum_size), the contraction factor for the trust region size (using contraction_factor) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using expansion_factor) used when the the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using contract_threshold) and the trust region size expansion threshold (using expand_threshold). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command contract_threshold sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command expand_threshold determines the trust region value above which the trust region will expand for the next SBL iteration.

7.2.32.2.5 contraction_factor

- Keywords Area
- method
- snowpac
- trust_region
- contraction_factor

Amount by which step length is rescaled

Specification

Alias: none
Argument(s): REAL
Default: 0.25

Description

For pattern search methods, contraction_factor specifies the amount by which step length is rescaled after unsuccessful iterates, must be strictly between 0 and 1.

For methods that can expand the step length, the expansion is 1 / contraction_factor

7.2.32.2.6 expansion_factor

- Keywords Factor
- method
- snowpac
• trust_region
• expansion_factor

Trust region expansion factor

Specification

Alias: none
Argument(s): REAL
Default: 2.0

Description

The trust_region optional group specification can be used to specify the initial size of the trust region (using initial_size) relative to the total variable bounds, the minimum size of the trust region (using minimum_size), the contraction factor for the trust region size (using contraction_factor) used when the surrogate model is performing poorly, and the expansion factor for the trust region size (using expansion_factor) used when the surrogate model is performing well. Two additional commands are the trust region size contraction threshold (using contract_threshold) and the trust region size expansion threshold (using expand_threshold). These two commands are related to what is called the trust region ratio, which is the actual decrease in the truth model divided by the predicted decrease in the truth model in the current trust region. The command contract_threshold sets the minimum acceptable value for the trust region ratio, i.e., values below this threshold cause the trust region to shrink for the next SBL iteration. The command expand_threshold determines the trust region value above which the trust region will expand for the next SBL iteration.

7.2.32.3 max_iterations

• Keywords Area
• method
• snowpac
• max_iterations

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

• method_independent_controls

Specification

Alias: none
Argument(s): INTEGER
Default: 100 (exceptions: fsu_cvt, local_reliability: 25; global_(reliability, interval_est, evidence) / efficient_global: 25∗n)
7.2 method

**Description**

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed \( \text{max\_iterations} \) iterations. In cases where there are multiple nested iterations to be controlled, \( \text{max\_iterations} \) generally controls the outer-most context.

**Default Behavior**

Default value is 100.

**See Also**

These keywords may also be of interest:

- \( \text{max\_function\_evaluations} \)

7.2.32.4 \( \text{max\_function\_evaluations} \)

- Keywords Area
- method
- snowpac
- \( \text{max\_function\_evaluations} \)

Number of function evaluations allowed for optimizers

**Topics**

This keyword is related to the topics:

- \( \text{method\_independent\_controls} \)

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 1000

**Description**

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed \( \text{max\_function\_evaluations} \) evaluations. See also \( \text{max\_iterations} \).

Some optimizers (e.g. ncsu\_direct) may run past this limit in the course of an iteration step that began before \( \text{max\_function\_evaluations} \) was exceeded.

**Default Behavior**

Default value is 1000.
7.2.32.5 scaling

- Keywords Area
- method
- snowpac
- scaling

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none
Argument(s): none
Default: no scaling

Description

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the scaling keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords scale_types and/or scales in the variables and responses blocks. When the scaling keyword is omitted from method, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

- a scales keyword, which gives characteristic values (divisors)
- a scale_types keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in responses for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are three scale types:

1. value - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.
2. **auto** - automatic scaling

First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval \([0,1]\);
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into \([0,1]\).

3. **log** - logarithmic scaling

First, any characteristic values from the optional *scales specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints. When continuous design variables are log scaled, linear constraints are not allowed.

**Scales**

The *scales keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding *scale_types, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- **auto, log** - optional
- **value** - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than \(1.0e10\) *DBL_MIN*. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

**Examples**

The two examples below are equivalent:

```plaintext
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100

responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

7.2.32.6 **model_pointer**

- Keywords Area
- method
- snowpac
- model_pointer

Identifier for model block to be used by a method
Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.

See block_pointer for details about pointers.

Examples

environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,

The genetic algorithm configurations are:

1. fitness
2. replacement
3. niching
4. convergence
5. postprocessor
6. initialization
7. crossover
8. mutation
9. population size

The steps followed by the algorithm are listed below. The configurations will effect how the algorithm completes each step.

**Stopping Criteria**

The moga method respects the max_iterations and max_function_evaluations method independent controls to provide integer limits for the maximum number of generations and function evaluations, respectively. The algorithm also stops when convergence is reached. This involves repeated assessment of the algorithm’s progress in solving the problem, until some criterion is met.

The specification for convergence in a moga can either be metric_tracker or can be omitted all together. If omitted, no convergence algorithm will be used and the algorithm will rely on stopping criteria only.

**Expected Outputs**

The moga method respects the output method independent control to vary the amount of information presented to the user during execution.

The final results are written to the Dakota tabular output. Additional information is also available - see the log_-file and print_each_pop keywords.

Note that moga and SOGA create additional output files during execution. “finaldata.dat” is a file that holds the final set of Pareto optimal solutions after any post-processing is complete. “discards.dat” holds solutions that were discarded from the population during the course of evolution.

It can often be useful to plot objective function values from these files to visually see the Pareto front and ensure that finaldata.dat solutions dominate discards.dat solutions. The solutions are written to these output files in the format “Input1...InputN..Output1...OutputM”.

**Expected HDF5 Output**

If Dakota was built with HDF5 support and run with the hdf5 keyword, this method writes the following results to HDF5:

- Best Parameters
- Best Objective Functions (when objective_functions are specified)
- Best Nonlinear Constraints
- Calibration (when calibration_terms are specified)

**Important Notes**

The pool of potential members is the current population and the current set of offspring.

Choice of fitness assessors is strongly related to the type of replacement algorithm being used and can have a profound effect on the solutions selected for the next generation.
If using the fitness types `layer_rank` or `domination_count`, it is strongly recommended that you use the `replacement_type below_limit` (although the roulette wheel selectors can also be used).

The functionality of the `domination_count` selector of JEGA v1.0 can now be achieved using the `domination_count` fitness type and `below_limit` replacement type.

Theory

The basic steps of the `moga` algorithm are as follows:

1. Initialize the population
2. Evaluate the population (calculate the values of the objective function and constraints for each population member)
3. Loop until converged, or stopping criteria reached
   - Perform crossover
   - Perform mutation
   - Evaluate the new population
   - Assess the fitness of each member in the population
   - Replace the population with members selected to continue in the next generation
   - Apply niche pressure to the population
   - Test for convergence
4. Perform post processing

If `moga` is used in a hybrid optimization method (which requires one optimal solution from each individual optimization method to be passed to the subsequent optimization method as its starting point), the solution in the Pareto set closest to the “utopia” point is given as the best solution. This solution is also reported in the Dakota output.

This “best” solution in the Pareto set has minimum distance from the utopia point. The utopia point is defined as the point of extreme (best) values for each objective function. For example, if the Pareto front is bounded by (1,100) and (90,2), then (1,2) is the utopia point. There will be a point in the Pareto set that has minimum L2-norm distance to this point, for example (10,10) may be such a point.

If `moga` is used in a method which may require passing multiple solutions to the next level (such as the surrogate_based_global method or hybrid methods), the orthogonal_distance postprocessor type may be used to specify the distances between each solution value to winnow down the solutions in the full Pareto front to a subset which will be passed to the next iteration.

- **layer_rank**

Assign each member to a layer, based on domination the rank based on layers

**Specification**

*Alias*: none

*Argument(s)*: none

**Default**: domination_count

**Description**

The two JEGA methods use different fitness types, which are described on their respective pages.

7.2.33.1.1 layer_rank

- **Keywords Area**
- **method**
- **moga**
- **fitness_type**
- **layer_rank**

Assign each member to a layer, based on domination the rank based on layers

**Description**

The fitness_type: layer_rank has been specifically designed to avoid problems with aggregating and scaling objective function values and transforming them into a single objective.

The layer_rank fitness assessor works by assigning all non-dominated designs a layer of 0, then from what remains, assigning all the non-dominated a layer of 1, and so on until all designs have been assigned a layer. The values are negated to follow the higher-is-better fitness convention.

Use of the below_limit selector with the layer_rank fitness assessor has the effect of keeping all those designs whose layer is below a certain threshold again subject to the shrinkage limit.
7.2.33.1.2 \textit{domination\_count}

  \item \textit{fitness\_type}
  \item \textit{domination\_count}
\end{itemize}

Rank each member by the number of members that dominate it

\textbf{Specification}

\textbf{Alias:} none
\textbf{Argument(s):} none

\textbf{Description}

The \textit{fitness\_type: domination\_count} has been specifically designed to avoid problems with aggregating and scaling objective function values and transforming them into a single objective.

Instead, the \textit{domination\_count} fitness assessor works by ordering population members by the negative of the number of designs that dominate them. The values are negated in keeping with the convention that higher fitness is better.

The \textit{layer\_rank} fitness assessor works by assigning all non-dominated designs a layer of 0, then from what remains, assigning all the non-dominated a layer of 1, and so on until all designs have been assigned a layer. Again, the values are negated for the higher-is-better fitness convention.

Use of the \textit{below\_limit} selector with the \textit{domination\_count} fitness assessor has the effect of keeping all designs that are dominated by fewer than a limiting number of other designs subject to the shrinkage limit.

Using it with the \textit{layer\_rank} fitness assessor has the effect of keeping all those designs whose layer is below a certain threshold again subject to the shrinkage limit.

\textbf{Argument(s):} none
\textbf{Default:} below\_limit
\textbf{Child Keywords:}
### Description

Replace the population with members selected to continue in the next generation. The pool of potential members is the current population and the current set of offspring. The replacement_type of roulette_wheel or unique_roulette_wheel may be used either with MOGA or SOGA problems however they are not recommended for use with MOGA. Given that the only two fitness assessors for MOGA are the layer_rank and domination_count, the recommended selector is the below_limit selector. The below_limit replacement will only keep designs that are dominated by fewer than a limiting number of other designs.

In roulette_wheel replacement, each design is conceptually allotted a portion of a wheel proportional to its fitness relative to the fitnesses of the other Designs. Then, portions of the wheel are chosen at random and the design occupying those portions are duplicated into the next population. Those Designs allotted larger portions of the wheel are more likely to be selected (potentially many times). unique_roulette_wheel replacement is the same as roulette_wheel replacement, with the exception that a design may only be selected once. The below_limit selector attempts to keep all designs for which the negated fitness is below a certain limit. The values are negated to keep with the convention that higher fitness is better. The inputs to the below_limit selector are the limit as a real value, and a shrinkage_percentage as a real value. The shrinkage_percentage defines the minimum amount of selections that will take place if enough designs are available. It is interpreted as a percentage of the population size that must go on to the subsequent generation. To enforce this, below_limit makes all the selections it would make anyway and if that is not enough, it takes the remaining that it needs from the best of what is left (effectively raising its limit as far as it must to get the minimum number of selections). It continues until it has made enough selections. The shrinkage_percentage is designed to prevent extreme decreases in the population size at any given generation, and thus prevent a big loss of genetic diversity in a very short time. Without a shrinkage limit, a small group of “super” designs may appear and quickly pull the population down to a size on the order of the limiting value. In this case, all the diversity of the population is lost and it is expensive to re-diversify and spread the population. The

The replacement_type for a SOGA may be roulette_wheel, unique_roulette_wheel, elitist, or favor_feasible. The elitist selector simply chooses the required number of designs taking the most fit. For example, if 100 selections are requested, then the top 100 designs as ranked by fitness will be selected and the remaining will be discarded. The favor_feasible replacement type first considers feasibility as a selection criteria. If that does not produce a “winner” then it moves on to considering fitness value. Because of this, any fitness assessor used with the favor_feasible selector must only account objectives in the creation of fitness. Therefore, there is such a fitness assessor and it’s use is enforced when the favor_feasible selector is chosen. In that case, and if the output level is set high enough, a message will be presented indicating that the weighted_sum_only fitness assessor will be used.

### 7.2.33.2.1 elitist

- Keywords Area
- method
- moga
- replacement_type
- elitist
Use the best designs to form a new population

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

The **elitist** (default) setting creates a new population using (a) the `replacement_size` best individuals from the current population, (b) and `population_size - replacement_size` individuals randomly selected from the newly generated individuals. It is possible in this case to lose a good solution from the newly generated individuals if it is not randomly selected for replacement; however, the default `new_solutions_generated` value is set such that the entire set of newly generated individuals will be selected for replacement.

7.2.33.2.2 **roulette_wheel**

- **Keywords Area**
- **method**
- **moga**
- **replacement_type**
- **roulette_wheel**

Replace population

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

Replace the population with members selected to continue in the next generation. The pool of potential members is the current population and the current set of offspring. The **replacement_type** of **roulette_wheel** or **unique_roulette_wheel** may be used either with MOGA or SOGA problems however they are not recommended for use with MOGA. Given that the only two fitness assessors for MOGA are the **layer_rank** and **domination_count**, the recommended selector is the **below_limit** selector. The **below_limit** replacement will only keep designs that are dominated by fewer than a limiting number of other designs. The **replacement_type** of **favor_feasible** is specific to a SOGA. This replacement operator will always prefer a more feasible design to a less feasible one. Beyond that, it favors solutions based on an assigned fitness value which must have been installed by the weighted sum only fitness assessor (see the discussion below).

7.2.33.2.3 **unique_roulette_wheel**

- **Keywords Area**
- **method**
- **moga**
- **replacement_type**
- **unique_roulette_wheel**
Replace population

Specification

Alias: none
Argument(s): none

Description

Replace the population with members selected to continue in the next generation. The pool of potential members is the current population and the current set of offspring. The replacement_type of roulette_wheel or unique_roulette_wheel may be used either with MOGA or SOGA problems however they are not recommended for use with MOGA. Given that the only two fitness assessors for MOGA are the layer_rank and domination_count, the recommended selector is the below_limit selector. The below_limit replacement will only keep designs that are dominated by fewer than a limiting number of other designs. The replacement_type of favor_feasible is specific to a SOGA. This replacement operator will always prefer a more feasible design to a less feasible one. Beyond that, it favors solutions based on an assigned fitness value which must have been installed by the weighted sum only fitness assessor (see the discussion below).

7.2.33.2.4 below_limit

- Keywords Area
- method
- moga
- replacement_type
- below_limit

Limit number of designs dominating those kept

Description

The below_limit replacement will only keep designs that are dominated by fewer than a limiting number of other designs.

7.2.33.2.4.1 shrinkage_fraction

- Keywords Area
- method
Decrease the population size by a percentage

Specification

**Alias:** shrinkage_percentage  
**Argument(s):** REAL  
**Default:** 0.9

Description

As of JEGA v2.0, all replacement types are common to both MOGA and SOGA. They include the roulette_wheel, unique_roulette_wheel, elitist, and below_limit selectors. In roulette_wheel replacement, each design is conceptually allotted a portion of a wheel proportional to its fitness relative to the fitnesses of the other Designs. Then, portions of the wheel are chosen at random and the design occupying those portions are duplicated into the next population. Those Designs allotted larger portions of the wheel are more likely to be selected (potentially many times). unique_roulette_wheel replacement is the same as roulette_wheel replacement, with the exception that a design may only be selected once. The below_limit selector attempts to keep all designs for which the negated fitness is below a certain limit. The values are negated to keep with the convention that higher fitness is better. The inputs to the below_limit selector are the limit as a real value, and a shrinkage_percentage as a real value. The shrinkage_percentage defines the minimum amount of selections that will take place if enough designs are available. It is interpreted as a percentage of the population size that must go on to the subsequent generation. To enforce this, below_limit makes all the selections it would make anyway and if that is not enough, it takes the remaining that it needs from the best of what is left (effectively raising its limit as far as it must to get the minimum number of selections). It continues until it has made enough selections. The shrinkage_percentage is designed to prevent extreme decreases in the population size at any given generation, and thus prevent a big loss of genetic diversity in a very short time. Without a shrinkage limit, a small group of "super" designs may appear and quickly cull the population down to a size on the order of the limiting value. In this case, all the diversity of the population is lost and it is expensive to re-diversify and spread the population. The elitist selector simply chooses the required number of designs taking the most fit. For example, if 100 selections are requested, then the top 100 designs as ranked by fitness will be selected and the remaining will be discarded.

Specify the type of niching pressure
7.2 method

Specification

**Alias:** none

**Argument(s):** none

**Default:** No niche pressure

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Radial</strong></td>
<td>Niching Type (Group 1)</td>

<td>distance</td>
<td></td>
<td>Enforce minimum Euclidean distance between designs</td>
</tr>
<tr>
<td></td>
<td>max_designs</td>
<td></td>
<td>Limit number of solutions to remain in the population</td>
</tr>
</tbody>
</table>

**Description**

The purpose of niching is to encourage differentiation along the Pareto frontier and thus a more even and uniform sampling.

This is typically accomplished by discouraging clustering of design points in the performance space. In JEGA, the application of niche pressure occurs as a secondary selection operation. The nicher is given a chance to perform a pre-selection operation prior to the operation of the selection (replacement) operator, and is then called to perform niching on the set of designs that were selected by the selection operator.

The radial nicher takes information input from the user to compute a minimum allowable distance between designs in the performance space and acts as a secondary selection operator whereby it enforces this minimum distance. The distance nicher requires that solutions must be separated from other solutions by a minimum distance in each dimension (vs. Euclidean distance for the radial niching). After niching is complete, all designs in the population will be at least the minimum distance from one another in all directions.

The radial niche pressure applicator works by enforcing a minimum Euclidean distance between designs in the performance space at each generation. The algorithm proceeds by starting at the (or one of the) extreme designs along objective dimension 0 and marching through the population removing all designs that are too close to the current design. One exception to the rule is that the algorithm will never remove an extreme design which is defined as a design that is maximal or minimal in all but 1 objective dimension (for a classical 2 objective problem, the extreme designs are those at the tips of the non-dominated frontier). The distance nicher enforces a minimum distance in each dimension.

The designs that are removed by the nicher are not discarded. They are buffered and re-inserted into the population during the next pre-selection operation. This way, the selector is still the only operator that discards designs and the algorithm will not waste time "re-filling" gaps created by the nicher.

The radial nicher requires as input a vector of fractions with length equal to the number of objectives. The elements of the vector are interpreted as percentages of the non-dominated range for each objective defining a minimum distance to all other designs. All values should be in the range (0, 1). The minimum allowable distance between any two designs in the performance space is the Euclidian (simple square-root-sum-of-squares calculation) distance defined by these percentages. The distance nicher has a similar input vector requirement, only the distance is the minimum distance in each dimension.

The max_designs niche pressure applicator is designed to choose a limited number of solutions to remain in the population. That number is specified by num_designs. It does so in order to balance the tendency for populations to grow very large and thus consuming too many computer resources. It operates by ranking designs according to their fitness standing and a computed count of how many other designs are too close to them. Too
close is a function of the supplied niche_vector, which specifies the minimum distance between any two points in
the performance space along each dimension individually. Once the designs are all ranked, the top c\num_designs
designs are kept in the population and the remaining ones are buffered or discarded. Note that like other niching
operators, this one will not discard an extreme design.

7.2.33.3.1 radial

- Keywords Area
- method
- moga
- niching_type
- radial

Set niching distance to percentage of non-dominated range

Specification

Alias: none
Argument(s): REALLIST
Default: 0.01 for all objectives

Description

The radial nicher requires as input a vector of fractions with length equal to the number of objectives. The
elements of the vector are interpreted as percentages of the non-dominated range for each objective defining a
minimum distance to all other designs. All values should be in the range (0, 1). The minimum allowable distance
between any two designs in the performance space is the Euclidian (simple square-root-sum-of-squares calculation)
distance defined by these percentages. The distance nicher has a similar input vector requirement, only the
distance is the minimum distance in each dimension.

7.2.33.3.2 distance

- Keywords Area
- method
- moga
- niching_type
- distance

Enforce minimum Euclidean distance between designs

Specification

Alias: none
Argument(s): REALLIST
Description

Currently, the only niche pressure operators available are the radial nicher, the distance nicher, and the max_designs nicher. The radial niche pressure applicator works by enforcing a minimum Euclidean distance between designs in the performance space at each generation. The algorithm proceeds by starting at the (or one of the) extreme designs along objective dimension 0 and marching through the population removing all designs that are too close to the current design. One exception to the rule is that the algorithm will never remove an extreme design which is defined as a design that is maximal or minimal in all but 1 objective dimension (for a classical 2 objective problem, the extreme designs are those at the tips of the non-dominated frontier). The distance nicher enforces a minimum distance in each dimension.

The designs that are removed by the nicher are not discarded. They are buffered and re-inserted into the population during the next pre-selection operation. This way, the selector is still the only operator that discards designs and the algorithm will not waste time "re-filling" gaps created by the nicher.

Description

The two JEGA methods use different convergence types, which are described on their respective pages. All the convergence types are modified by the optional keywords `percent_change` and `num_generations`.

7.2.33.4.1 metric_tracker

- Keywords Area
- method
- moga
- convergence_type
- metric_tracker

Track changes in the non-dominated frontier

Specification

Alias: none
Argument(s): none
Default: metric_tracker

Description

The moga converger (metric_tracker) operates by tracking various changes in the non-dominated frontier from generation to generation. When the changes occurring over a user specified number of generations fall below a user specified threshold, the algorithm stops.

If `metric_tracker` is specified, then a `percent_change` and `num_generations` must be supplied as well. These are listed as optional keywords in the input spec.

Theory

The `metric_tracker` converger tracks 3 metrics specific to the non-dominated frontier from generation to generation. All 3 of these metrics are computed as percent changes between the generations. In order to compute these metrics, the converger stores a duplicate of the non-dominated frontier at each generation for comparison to the non-dominated frontier of the next generation.

The first metric is one that indicates how the expanse of the frontier is changing. The expanse along a given objective is defined by the range of values existing within the non-dominated set. The expansion metric is computed by tracking the extremes of the non-dominated frontier from one generation to the next. Any movement of the extreme values is noticed and the maximum percentage movement is computed as:

\[
Em = \max_{j} \frac{\text{abs}(\text{range}(j, i) - \text{range}(j, i-1))}{\text{range}(j, i-1)}
\]

where \(Em\) is the max expansion metric, \(j\) is the objective function index, \(i\) is the current generation number, and \(nof\) is the total number of objectives. The range is the difference between the largest value along an objective and the smallest when considering only non-dominated designs.
The second metric monitors changes in the density of the non-dominated set. The density metric is computed as the number of non-dominated points divided by the hypervolume of the non-dominated region of space. Therefore, changes in the density can be caused by changes in the number of non-dominated points or by changes in size of the non-dominated space or both. The size of the non-dominated space is computed as:

\[ V_{ps}(i) = \prod_{j=1}^{nof} \text{range}(j, i) \]

where \( V_{ps}(i) \) is the hypervolume of the non-dominated space at generation \( i \) and all other terms have the same meanings as above.

The density of the a given non-dominated space is then:

\[ D_{ps}(i) = \frac{Pct(i)}{V_{ps}(i)} \]

where \( Pct(i) \) is the number of points on the non-dominated frontier at generation \( i \).

The percentage increase in density of the frontier is then calculated as

\[ Cd = \frac{abs(D_{ps}(i) - D_{ps}(i-1))}{D_{ps}(i-1)} \]

where \( Cd \) is the change in density metric.

The final metric is one that monitors the "goodness" of the non-dominated frontier. This metric is computed by considering each design in the previous population and determining if it is dominated by any designs in the current population. All that are determined to be dominated are counted. The metric is the ratio of the number that are dominated to the total number that exist in the previous population.

As mentioned above, each of these metrics is a percentage. The tracker records the largest of these three at each generation. Once the recorded percentage is below the supplied percent change for the supplied number of generations consecutively, the algorithm is converged.

7.2.33.4.2 percent_change

- Keywords Area
- method
- moga
- convergence_type
- percent_change

Define the convergence criterion for JEGA methods

Specification

Alias: none

Argument(s): REAL

Default: 0.1

Description

The percent_change is the threshold beneath which convergence is attained whereby it is compared to the metric value computed.

7.2.33.4.3 num_generations

- Keywords Area
- method
Define the convergence criterion for JEGA methods

**Specification**

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** 10

**Description**

The `num_generations` is the number of generations over which the metric value should be tracked. Convergence will be attained if the recorded metric is below `percent_change` for `num_generations` consecutive generations.

**postprocessor_type**

- **Keywords Area**
- **method**
- **moga**
- **postprocessor_type**

Post process the final solution from moga

**Specification**

</thead>
<tbody>
<tr>
<td>orthogonal_distance</td>
<td></td>
<td></td>
<td>Get subset of Pareto front based on distance</td>
</tr>
</tbody>
</table>

**Description**

The purpose of this operation is to perform any needed data manipulations on the final solution deemed necessary. Currently the `orthogonal_distance` is the only one. It reduces the final solution set size such that a minimum distance in each direction exists between any two designs.
7.2.33.5.1 orthogonal_distance

- Keywords Area
- method
- moga
- postprocessor_type
- orthogonal_distance

Get subset of Pareto front based on distance

**Specification**

**Alias:** none

**Argument(s):** REALIST

**Default:** 0.01 for all objectives

**Description**

Note that MOGA and SOGA create additional output files during execution. "finaldata.dat" is a file that holds the final set of Pareto optimal solutions after any post-processing is complete. "discards.dat" holds solutions that were discarded from the population during the course of evolution. It can often be useful to plot objective function values from these files to visually see the Pareto front and ensure that finaldata.dat solutions dominate discards.dat solutions. The solutions are written to these output files in the format "Input1...InputN..Output1...OutputM". If MOGA is used in a hybrid optimization meta-iteration (which requires one optimal solution from each individual optimization method to be passed to the subsequent optimization method as its starting point), the solution in the Pareto set closest to the "utopia" point is given as the best solution. This solution is also reported in the Dakota output. This "best" solution in the Pareto set has minimum distance from the utopia point. The utopia point is defined as the point of extreme (best) values for each objective function. For example, if the Pareto front is bounded by (1,100) and (90,2), then (1,2) is the utopia point. There will be a point in the Pareto set that has minimum L2-norm distance to this point, for example (10,10) may be such a point. In SOGA, the solution that minimizes the single objective function is returned as the best solution. If moga is used in meta-iteration which may require passing multiple solutions to the next level (such as the surrogate_based_global or hybrid methods), the orthogonal_distance postprocessor type may be used to specify the distances between each solution value to winnow down the solutions in the full Pareto front to a subset which will be passed to the next iteration.

7.2.33.6 max_iterations

- Keywords Area
- method
- moga
- max_iterations

Number of iterations allowed for optimizers and adaptive UQ methods

**Topics**

This keyword is related to the topics:

- method_independent_controls
7.2 method

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: fsu_cvt, local_reliability: 25; global_(reliability, interval_est, evidence) / efficient_global: 25+n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed \( \text{max_iterations} \) iterations. In cases where there are multiple nested iterations to be controlled, \( \text{max_iterations} \) generally controls the outer-most context.

Default Behavior

Default value is 100.

See Also

These keywords may also be of interest:

- \( \text{max_function_evaluations} \)

7.2.33.7 \( \text{max_function_evaluations} \)

- Keywords Area
- method
- moga
- \( \text{max_function_evaluations} \)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- \( \text{method_independent_controls} \)

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed \( \text{max_function_evaluations} \) evaluations. See also \( \text{max_iterations} \).
Some optimizers (e.g. ncsu_direct) may run past this limit in the course of an iteration step that began before max_function_evaluations was exceeded.

Default Behavior
Default value is 1000.

7.2.33.8 scaling

• Keywords Area
• method
• moga
• scaling

Turn on scaling for variables, responses, and constraints

Topics
This keyword is related to the topics:

• method_independent_controls

Specification
Alias: none
Argument(s): none
Default: no scaling

Description
Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the scaling keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords scale_types and/or *scales in the variables and responses blocks. When the scaling keyword is omitted from method, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

• a *scales keyword, which gives characteristic values (divisors)
• a *scale_types keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in responses for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types
There are three scale types:
1. **value** - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.

2. **auto** - automatic scaling
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   - two-sided bounds scaled into the interval \([0,1]\);
   - one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
   - no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into \([0,1]\).

3. **log** - logarithmic scaling
   First, any characteristic values from the optional \(*_scales\) specification are applied. Then logarithm base 10 scaling is applied.
   Logarithmic scaling is not available for linear constraints.
   When continuous design variables are log scaled, linear constraints are not allowed.

**Scales**

The \(*_scales\) keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding \(*_scale_types\), as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- **auto, log** - optional
- **value** - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than \(1.0e10*DBL_MIN\). User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

**Examples**

The two examples below are equivalent:

```plaintext
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100

responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

**7.2.33.9 population_size**

- Keywords Area
- method
Set the initial population size in JEGA methods

Specification

Alias: none
Argument(s): INTEGER
Default: 50

Description

The number of designs in the initial population is specified by the `population_size`. Note that the `population_size` only sets the size of the initial population. The population size may vary in the JEGA methods according to the type of operators chosen for a particular optimization run.

Also note that some initializers may not strictly respect the initial population size. See the SOGA flat_file or MOGA flat_file initializer for an example.

7.2.33.10 log_file

Specify the name of a log file

Specification

Alias: none
Argument(s): STRING
Default: JEGAGlobal.log

Description

New as of JEGA v2.0 is the introduction of the `log_file` specification. JEGA now uses a logging library to output messages and status to the user. JEGA can be configured at build time to log to both the console window and a text file, one or the other, or neither. The `log_file` input is a string name of a file into which to log. If the build was configured without file logging in JEGA, this input is ignored. If file logging is enabled and no `log_file` is specified, the default file name of JEGAGlobal.log is used.

7.2.33.11 print_each_pop

Specify the name of a log file

Specification

Alias: none
Argument(s): STRING
Default: JEGAGlobal.log

Description

New as of JEGA v2.0 is the introduction of the `log_file` specification. JEGA now uses a logging library to output messages and status to the user. JEGA can be configured at build time to log to both the console window and a text file, one or the other, or neither. The `log_file` input is a string name of a file into which to log. If the build was configured without file logging in JEGA, this input is ignored. If file logging is enabled and no `log_file` is specified, the default file name of JEGAGlobal.log is used.
7.2 method

- moga
- print_each_pop

Print every population to a population file

Specification

Alias: none
Argument(s): none
Default: No printing

Description

New to JEGA v2.0 is the introduction of the print_each_pop specification. It serves as a flag and if supplied, the population at each generation will be printed to a file named "population<GEN#>.dat" where <GEN#> is the number of the current generation.

7.2.33.12 initialization_type

- Keywords Area
- method
- moga
- initialization_type

Specify how to initialize the population

Specification

Alias: none
Argument(s): none
Default: unique_random

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required (Choose One)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Description of Group</th>
<th>Initiative Type (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>simple_random</td>
<td>unique_random</td>
<td>Create random initial solutions, but enforce uniqueness (default)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>flat_file</td>
<td>Read initial solutions from file</td>
</tr>
</tbody>
</table>

Description

The initialization_type defines how the initial population is created for the GA. There are three types:

1. simple_random
2. unique_random (default)

3. flat_file

Setting the size for the flat_file initializer has the effect of requiring a minimum number of designs to create. If this minimum number has not been created once the files are all read, the rest are created using the unique_random initializer and then the simple_random initializer if necessary.

7.2.33.12.1 simple_random

- Keywords Area
- method
- moga
- initialization_type
- simple_random

Create random initial solutions

Specification

Alias: none

Argument(s): none

Description

simple_random creates initial solutions with random variable values according to a uniform random number distribution. It gives no consideration to any previously generated designs.

7.2.33.12.2 unique_random

- Keywords Area
- method
- moga
- initialization_type
- unique_random

Create random initial solutions, but enforce uniqueness (default)

Specification

Alias: none

Argument(s): none

Description

unique_random is the same as simple_random, except that when a new solution is generated, it is checked against the rest of the solutions. If it duplicates any of them, it is rejected.
7.2 method

7.2.33.12.3 flat_file

• Keywords Area
• method
• moga
• initialization_type
• flat_file

Read initial solutions from file

Specification

Alias: none
Argument(s): STRING

Description

flat_file allows the initial population to be read from a flat file. If flat_file is specified, a file name must be given.

Variables can be delimited in the flat file in any way you see fit with a few exceptions. The delimiter must be the same on any given line of input with the exception of leading and trailing whitespace. So a line could look like: 1.1, 2.2, 3.3 for example but could not look like: 1.1, 2.2 3.3. The delimiter can vary from line to line within the file which can be useful if data from multiple sources is pasted into the same input file. The delimiter can be any string that does not contain any of the characters .+-dDeE or any of the digits 0-9. The input will be read until the end of the file. The algorithm will discard any configurations for which it was unable to retrieve at least the number of design variables. The objective and constraint entries are not required but if ALL are present, they will be recorded and the design will be tagged as evaluated so that evaluators may choose not to re-evaluate them.

Setting the size for this initializer has the effect of requiring a minimum number of designs to create. If this minimum number has not been created once the files are all read, the rest are created using the unique_random initializer and then the simple_random initializer if necessary. If more designs are found in the initialization files than specified by the initial size, then the initial size is ignored and all designs read out of the files are kept in the initial population.

**Description**

There are many crossover types available. `multi_point_binary` crossover requires an integer number, \(N\), of crossover points. This crossover type performs a bit switching crossover at \(N\) crossover points in the binary encoded genome of two designs. Thus, crossover may occur at any point along a solution chromosome (in the middle of a gene representing a design variable, for example). `multi_point_parameterized_binary` crossover is similar in that it performs a bit switching crossover routine at \(N\) crossover points. However, this crossover type performs crossover on each design variable individually. So the individual chromosomes are crossed at \(N\) locations. `multi_point_real` crossover performs a variable switching crossover routing at \(N\) crossover points in the real real valued genome of two designs. In this scheme, crossover only occurs between design variables (chromosomes). Note that the standard solution chromosome representation in the JEGA algorithm is real encoded and can handle integer or real design variables. For any crossover types that use a binary representation, real variables are converted to long integers by multiplying the real number by \(10^6\) and then truncating. Note that this assumes a precision of only six decimal places. Discrete variables are represented as integers (indices within a list of possible values) within the algorithm and thus require no special treatment by the binary operators.

The final crossover type is `shuffle_random`. This crossover type performs crossover by choosing design variables at random from a specified number of parents enough times that the requested number of children are produced. For example, consider the case of 3 parents producing 2 children. This operator would go through and for each design variable, select one of the parents as the donor for the child. So it creates a random shuffle of the parent design variable values. The relative numbers of children and parents are controllable to allow for as much mixing as desired. The more parents involved, the less likely that the children will wind up exact duplicates of the parents.

All crossover types take a `crossover_rate`. The crossover rate is used to calculate the number of crossover operations that take place. The number of crossovers is equal to the rate \(\times\) population size.

7.2.33.13.5  crossover_rate

- Keywords Area
- method
- moga
- crossover_type
- crossover_rate

Specify the probability of a crossover event

Specification

Alias: none
Argument(s): REAL
Default: 0.8

Description

The crossover_type controls what approach is employed for combining parent genetic information to create offspring, and the crossover_rate specifies the probability of a crossover operation being performed to generate a new offspring. The SCOLIB EA method supports three forms of crossover, two_point, blend, and uniform, which generate a new individual through combinations of two parent individuals. Two-point crossover divides each parent into three regions, where offspring are created from the combination of the middle region from one parent and the end regions from the other parent. Since the SCOLIB EA does not utilize bit representations of variable values, the crossover points only occur on coordinate boundaries, never within the bits of a particular coordinate. Uniform crossover creates offspring through random combination of coordinates from the two parents. Blend crossover generates a new individual randomly along the multidimensional vector connecting the two parents.

7.2.33.14  mutation_type

</tbody>
</table>

Description

Five mutation types are available for selection by keyword: replace_uniform, bit_random, offset_cauchy, offset_normal, and offset_uniform. They are described in greater detail on their respective keyword pages.

The offset_* mutators all act by adding a random "offset" to a variable value. The random amount has a mean of zero in all cases. The size of the offset is controlled using the mutation_scale keyword, which is interpreted differently for each offset_* type.

The rate of mutations for all types is controlled using the mutation_rate. The rate is applied differently in each mutation_type.

7.2.33.14.1 bit_random

- Keywords Area
- method
- moga
- mutation_type
- bit_random

Mutate by flipping a random bit

Specification

Alias: none
Argument(s): none
Description

The bit_random mutator introduces random variation by first converting a randomly chosen variable of a randomly chosen design into a binary string. It then flips a randomly chosen bit in the string from a 1 to a 0 or visa versa. In this mutation scheme, the resulting value has more probability of being similar to the original value.

7.2.33.14.2 replace_uniform

- Keywords Area
- method
- moga
- mutation_type
- replace_uniform

Use uniformly distributed value over range of parameter

Specification

Alias: none
Argument(s): none

Description

replace_uniform introduces random variation by first randomly choosing a design variable of a randomly selected design and reassigning it to a random valid value for that variable. No consideration of the current value is given when determining the new value.

7.2.33.14.3 offset_normal

- Keywords Area
- method
- moga
- mutation_type
- offset_normal

Set mutation offset to use a normal distribution

Specification

Alias: none
Argument(s): none

### 7.2 method

<table>
<thead>
<tr>
<th>Optional</th>
<th>mutation_scale</th>
<th>Scales mutation across range of parameter</th>
</tr>
</thead>
</table>

### Description

The **offset_normal** mutator introduces random variation by adding a Gaussian random amount to a variable value. The random amount has a standard deviation dependent on the **mutation_scale**.

#### 7.2.33.14.3.1 mutation_scale

- **Keywords Area**
- **method**
- **moga**
- **mutation_type**
- **offset_normal**
- **mutation_scale**

Scales mutation across range of parameter

### Specification

- **Alias**: none
- **Argument(s)**: REAL
- **Default**: 0.15

### Description

The **mutation_scale** is a fraction in the range [0, 1] and is meant to help control the amount of variation that takes place when a variable is mutated. Its behavior depends on the selected **mutation_type**. For **offset_normal** and **offset_cauchy**, **mutation_scale** is multiplied by the range of the variable being mutated to obtain the standard deviation of the offset. For **offset_uniform**, the range of possible deviation amounts is \(+/- 1/2 \times (mutation_scale \times variable\) range).

#### 7.2.33.14.4 offset_cauchy

- **Keywords Area**
- **method**
- **moga**
- **mutation_type**
- **offset_cauchy**

Use a Cauchy distribution for the mutation offset

### Specification

- **Alias**: none
- **Argument(s)**: none
- **Child Keywords**: 

**Dakota Version 6.16 Reference Manual generated on May 12, 2022**
Description

The `offset_cauchy` mutator introduces random variation by adding a Cauchy random amount to a variable value. The random amount has a standard deviation dependent on the `mutation_scale`.

7.2.33.14.4.1 `mutation_scale`

- **Keywords Area**
- **method**
- **moga**
- **mutation_type**
- **offset_cauchy**
- **mutation_scale**

Scales mutation across range of parameter

**Specification**

*Alias*: none

*Argument(s)*: REAL

*Default*: 0.15

**Description**

The `mutation_scale` is a fraction in the range [0, 1] and is meant to help control the amount of variation that takes place when a variable is mutated. Its behavior depends on the selected `mutation_type`. For `offset_normal` and `offset_cauchy`, `mutation_scale` is multiplied by the range of the variable being mutated to obtain the standard deviation of the offset. For `offset_uniform`, the range of possible deviation amounts is $+\frac{1}{2} \times (mutation_{scale} \times variable\ range)$.

7.2.33.14.5 `offset_uniform`

- **Keywords Area**
- **method**
- **moga**
- **mutation_type**
- **offset_uniform**

Set mutation offset to use a uniform distribution
Specification

Alias: none
Argument(s): none
Child Keywords:
Description

The `offset_uniform` mutator introduces random variation by adding a uniform random amount to a variable value. The random amount depends on the `mutation_scale`.

7.2.33.14.5.1 mutation_scale

- Keywords Area
- method
- moga
- mutation_type
- offset_uniform
- mutation_scale

Scales mutation across range of parameter

Specification

Alias: none
Argument(s): REAL
Default: 0.15

Description

The mutation_scale is a fraction in the range [0, 1] and is meant to help control the amount of variation that takes place when a variable is mutated. Its behavior depends on the selected mutation_type. For `offset_normal` and `offset_cauchy`, mutation_scale is multiplied by the range of the variable being mutated to obtain the standard deviation of the offset. For `offset_uniform`, the range of possible deviation amounts is +/- 1/2 * (mutation_scale * variable range).

7.2.33.14.6 mutation_rate

- Keywords Area
- method
- moga
- mutation_type
- mutation_rate

Set probability of a mutation
7.2 method

Specification

Alias: none
Argument(s): REAL
Default: 0.08

Description

All mutation types have a mutation_rate, which controls the number of mutations performed. For replace-uniform and all the offset_* types, the number of mutations performed is the product of mutation_rate and population_size. For bit_random, it’s the product of the mutation_rate, number of design variables, and population size.

7.2.33.15 seed

- Keywords Area
- method
- moga
- seed

Seed of the random number generator

Specification

Alias: none
Argument(s): INTEGER
Default: system-generated (non-repeatable)

Description

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```
7.2.33.16 convergence_tolerance

- Keywords Area
- method
- moga
- convergence_tolerance

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The convergence_tolerance specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by convergence_tolerance, then this convergence criterion is satisfied on the current iteration. Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See nl2sol
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance
- **moga**
- **model_pointer**

Identifier for model block to be used by a method

**Topics**

This keyword is related to the topics:

- **block_pointer**

**Specification**

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)

**Description**

The `model_pointer` is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

**Usage Tips**

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

**Examples**

```plaintext
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
                     0.1 0.2 0.6
                     0.1 0.2 0.6
  sample_type lhs
distribution cumulative

model
  id_model = 'SURR'
  surrogate global,
  dace_method_pointer = 'DACE'
  polynomial quadratic

method
  id_method = 'DACE'
```

Dakota Version 6.16 Reference Manual generated on May 12, 2022

### Description

**soga** stands for Single-objective Genetic Algorithm, which is a global optimization method that supports general constraints and a mixture of real and discrete variables. **soga** is part of the JEGA library.

### Constraints

**soga** can utilize linear constraints.

### Configuration

The genetic algorithm configurations are:
The pool of potential members is the current population and the current set of offspring. Choice of fitness assessors is strongly related to the type of replacement algorithm being used and can have a profound effect on the solutions selected for the next generation.

**Stopping Criteria**

The soga method respects the `max_iterations` and `max_function_evaluations` method independent controls to provide integer limits for the maximum number of generations and function evaluations, respectively.

The algorithm also stops when convergence is reached. This involves repeated assessment of the algorithm's progress in solving the problem, until some criterion is met.

**Expected Outputs**

The soga method respects the `output` method independent control to vary the amount of information presented to the user during execution.

The final results are written to the Dakota tabular output. Additional information is also available - see the `log_file` and `print_each_pop` keywords.

**Expected HDF5 Output**

If Dakota was built with HDF5 support and run with the `hdf5` keyword, this method writes the following results to HDF5:

- **Best Parameters**
- **Best Objective Functions** (when `objective_functions`) are specified
- **Best Nonlinear Constraints**
- **Calibration** (when `calibration_terms` are specified)

**Theory**

The basic steps of the soga algorithm are as follows:

1. Initialize the population
2. Evaluate the population (calculate the values of the objective function and constraints for each population member)
3. Loop until converged, or stopping criteria reached
   
   (a) Perform crossover
   
   (b) Perform mutation
   
   (c) Evaluate the new population
   
   (d) Assess the fitness of each member in the population
   
   (e) Replace the population with members selected to continue in the next generation
   
   (f) Test for convergence

Description

The two JEGA methods use different fitness types, which are described on their respective pages.

7.2.34.1.1 merit_function

- Keywords Area
- method
- soga
- fitness_type
- merit_function

Balance goals of reducing objective function and satisfying constraints

Specification

Alias: none

Argument(s): none
A merit function is a function in constrained optimization that attempts to provide joint progress toward reducing the objective function and satisfying the constraints.

7.2.34.1.2 constraint_penalty

- Keywords Area
- method
- soga
- fitness_type
- constraint_penalty

Multiplier for the penalty function

Specification

Alias: none
Argument(s): REAL
Default: 1.0

Description

The merit function fitness assessor uses an exterior penalty function formulation to penalize infeasible designs. The specification allows the input of a constraint_penalty which is the multiplier to use on the constraint violations.

7.2.34.2 replacement_type

- Keywords Area
- method
- soga
- replacement_type

Select a replacement type for JEGA methods

Specification

Alias: none
Argument(s): none
Default: elitist

Child Keywords:
Replace the population with members selected to continue in the next generation. The pool of potential members is the current population and the current set of offspring. The replacement_type of roulette_wheel or unique_roulette_wheel may be used either with MOGA or SOGA problems however they are not recommended for use with MOGA. Given that the only two fitness assessors for MOGA are the layer_rank and domination_count, the recommended selector is the below_limit selector. The below_limit replacement will only keep designs that are dominated by fewer than a limiting number of other designs.

In roulette_wheel replacement, each design is conceptually allotted a portion of a wheel proportional to its fitness relative to the fitnesses of the other Designs. Then, portions of the wheel are chosen at random and the design occupying those portions are duplicated into the next population. Those Designs allotted larger portions of the wheel are more likely to be selected (potentially many times). unique_roulette_wheel replacement is the same as roulette_wheel replacement, with the exception that a design may only be selected once. The below_limit selector attempts to keep all designs for which the negated fitness is below a certain limit. The values are negated to keep with the convention that higher fitness is better. The inputs to the below_limit selector are the limit as a real value, and a shrinkage_percentage as a real value. The shrinkage_percentage defines the minimum amount of selections that will take place if enough designs are available. It is interpreted as a percentage of the population size that must go on to the subsequent generation. To enforce this, below_limit makes all the selections it would make anyway and if that is not enough, it takes the remaining that it needs from the best of what is left (effectively raising its limit as far as it must to get the minimum number of selections). It continues until it has made enough selections. The shrinkage_percentage is designed to prevent extreme decreases in the population size at any given generation, and thus prevent a big loss of genetic diversity in a very short time. Without a shrinkage limit, a small group of “super” designs may appear and quickly cull the population down to a size on the order of the limiting value. In this case, all the diversity of the population is lost and it is expensive to re-diversify and spread the population.

The replacement_type for a SOGA may be roulette_wheel, unique_roulette_wheel, elitist, or favor_feasible. The elitist selector simply chooses the required number of designs taking the most fit. For example, if 100 selections are requested, then the top 100 designs as ranked by fitness will be selected and the remaining will be discarded. The favor_feasible replacement type first considers feasibility as a selection criteria. If that does not produce a “winner” then it moves on to considering fitness value. Because of this, any fitness assessor used with the favor_feasible selector must only account objectives in the creation of fitness. Therefore, there is such a fitness assessor and it’s use is enforced when the favor_feasible selector is chosen. In that case, and if the output level is set high enough, a message will be presented indicating that the weighted_sum_only fitness assessor will be used.

### 7.2.34.2.1 elitist

- Keywords Area
- method
- soga
- replacement_type
- elitist

Use the best designs to form a new population
Specification

Alias: none
Argument(s): none

Description

The elitist (default) setting creates a new population using (a) the replacement_size best individuals from the current population, (b) and population_size - replacement_size individuals randomly selected from the newly generated individuals. It is possible in this case to lose a good solution from the newly generated individuals if it is not randomly selected for replacement; however, the default new_solutions_generated value is set such that the entire set of newly generated individuals will be selected for replacement.

7.2.34.2.2 favor_feasible

- Keywords Area
- method
- soga
- replacement_type
- favor_feasible

Prioritize feasible designs

Specification

Alias: none
Argument(s): none

Description

This replacement operator will always prefer a more feasible design to a less feasible one. Beyond that, it favors solutions based on an assigned fitness value which must have been installed by the weighted sum only fitness assessor.

The favor_feasible replacement type first considers feasibility as a selection criteria. If that does not produce a "winner" then it moves on to considering fitness value. Because of this, any fitness assessor used with the favor_feasible selector must only account objectives in the creation of fitness. Therefore, there is such a fitness assessor and it's use is enforced when the favor_feasible selector is chosen. In that case, and if the output level is set high enough, a message will be presented indicating that the weighted_sum_only fitness assessor will be used.

7.2.34.2.3 roulette_wheel

- Keywords Area
- method
- soga
- replacement_type
- roulette_wheel

Replace population
7.2 method

Specification

Alias: none
Argument(s): none

Description

Replace the population with members selected to continue in the next generation. The pool of potential members is the current population and the current set of offspring. The replacement_type of roulette_wheel or unique_roulette_wheel may be used either with MOGA or SOGA problems however they are not recommended for use with MOGA. Given that the only two fitness assessors for MOGA are the layer_rank and domination_count, the recommended selector is the below_limit selector. The below_limit replacement will only keep designs that are dominated by fewer than a limiting number of other designs. The replacement_type of favor_feasible is specific to a SOGA. This replacement operator will always prefer a more feasible design to a less feasible one. Beyond that, it favors solutions based on an assigned fitness value which must have been installed by the weighted sum only fitness assessor (see the discussion below).

7.2.34.2.4 unique_roulette_wheel

- Keywords Area
- method
- soga
- replacement_type
- unique_roulette_wheel

Replace population

Specification

Alias: none
Argument(s): none

Description

Replace the population with members selected to continue in the next generation. The pool of potential members is the current population and the current set of offspring. The replacement_type of roulette_wheel or unique_roulette_wheel may be used either with MOGA or SOGA problems however they are not recommended for use with MOGA. Given that the only two fitness assessors for MOGA are the layer_rank and domination_count, the recommended selector is the below_limit selector. The below_limit replacement will only keep designs that are dominated by fewer than a limiting number of other designs. The replacement_type of favor_feasible is specific to a SOGA. This replacement operator will always prefer a more feasible design to a less feasible one. Beyond that, it favors solutions based on an assigned fitness value which must have been installed by the weighted sum only fitness assessor (see the discussion below).

7.2.34.3 convergence_type

- Keywords Area
- method
- soga
• **convergence_type**

Select the convergence type for JEGA methods

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** average_fitness_tracker  

**Child Keywords:**

<tr>
<td><strong>Optional</strong></td>
<td></td>
<td><strong>percent_change</strong></td>
<td>Define the convergence criterion for JEGA methods</td>
</tr>
</tbody>
</table>
Optional  num_generations  Define the convergence criterion for JEGA methods

Description

The `best_fitness_tracker` tracks the best fitness in the population. Convergence occurs after `num_generations` has passed and there has been less than `percent_change` in the best fitness value. The percent change can be as low as 0% in which case there must be no change at all over the number of generations.

See Also

These keywords may also be of interest:

- `average_fitness_tracker`

7.2.34.3.1.1 percent_change

- Keywords Area
- method
- soga
- convergence_type
- best_fitness_tracker
- percent_change

Define the convergence criterion for JEGA methods

Specification

**Alias:** none

**Argument(s):** REAL

**Default:** 0.1

Description

The `percent_change` is the threshold beneath which convergence is attained whereby it is compared to the metric value computed.

7.2.34.3.1.2 num_generations

- Keywords Area
- method
- soga
- convergence_type
- best_fitness_tracker
- num_generations

Define the convergence criterion for JEGA methods
Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** 10

Description

The `num_generations` is the number of generations over which the metric value should be tracked. Convergence will be attained if the recorded metric is below `percent_change` for `num_generations` consecutive generations.

7.2.34.3.2 average_fitness_tracker

- Keywords Area
- method
- soga
- convergence_type
- average_fitness_tracker

Tracks the average fitness of the population

Description

The convergence_type called average_fitness_tracker keeps track of the average fitness in a population. If this average fitness does not change more than `percent_change` over some number of generations, `num_generations`, then the solution is reported as converged and the algorithm terminates.

See Also

These keywords may also be of interest:

- best_fitness_tracker

- percent_change

Define the convergence criterion for JEGA methods

Specification

**Alias:** none

**Argument(s):** REAL

**Default:** 0.1

**Description**

The *percent_change* is the threshold beneath which convergence is attained whereby it is compared to the metric value computed.

7.2.34.3.2.2 num_generations

- Keywords Area
- method
- soga
- convergence_type
- average_fitness_tracker
- num_generations

Define the convergence criterion for JEGA methods

Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** 10

**Description**

The *num_generations* is the number of generations over which the metric value should be tracked. Convergence will be attained if the recorded metric is below *percent_change* for *num_generations* consecutive generations.
7.2.34.4 max_iterations

- Keywords Area
- method
- soga
- max_iterations

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: fsu_cvt, local_reliability: 25; global_(reliability, interval_est, evidence) / efficient_global: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed max_iterations iterations. In cases where there are multiple nested iterations to be controlled, max_iterations generally controls the outer-most context.

Default Behavior

Default value is 100.

See Also

These keywords may also be of interest:

- max_function_evaluations

7.2.34.5 max_function_evaluations

- Keywords Area
- method
- soga
- max_function_evaluations

Number of function evaluations allowed for optimizers
Topics

This keyword is related to the topics:

- method_independent_controls

Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed \texttt{max\_function\_evaluations} evaluations. See also \texttt{max\_iterations}.

Some optimizers (e.g. \texttt{ncsu\_direct}) may run past this limit in the course of an iteration step that began before \texttt{max\_function\_evaluations} was exceeded.

**Default Behavior**

Default value is 1000.

7.2.34.6 scaling

- Keywords Area
- method
- soga
- scaling

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

**Alias:** none

**Argument(s):** none

**Default:** no scaling

Description

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the \texttt{scaling} keyword. Discrete variable scaling is not supported.
When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords `scale_types` and/or `*scales` in the `variables` and `responses` blocks. When the `scaling` keyword is omitted from `method`, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

- a `*scales` keyword, which gives characteristic values (divisors)
- a `*scale_types` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in `responses` for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

**Scale Types**

There are three scale types:

1. **value** - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.

2. **auto** - automatic scaling
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   - two-sided bounds scaled into the interval [0,1];
   - one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
   - no bounds or targets: no automatic scaling possible, therefore no scaling for this component

   Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

3. **log** - logarithmic scaling
   First, any characteristic values from the optional `*_scales` specification are applied. Then logarithm base 10 scaling is applied.
   Logarithmic scaling is not available for linear constraints.
   When continuous design variables are log scaled, linear constraints are not allowed.

**Scales**

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*scale_types`, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- `auto, log` - optional
- `value` - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than `1.0e10*DBL_MIN`. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.
Examples

The two examples below are equivalent:

```
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100

responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

7.2.34.7 population_size

- **Keywords Area**
- **method**
- **soga**
- **population_size**

Set the initial population size in JEGA methods

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 50

**Description**

The number of designs in the initial population is specified by the `population_size`. Note that the `population_size` only sets the size of the initial population. The population size may vary in the JEGA methods according to the type of operators chosen for a particular optimization run.

Also note that some initializers may not strictly respect the initial population size. See the SOGA `flat_file` or MOGA `flat_file` initializer for an example.

7.2.34.8 log_file

- **Keywords Area**
- **method**
- **soga**
- **log_file**

Specify the name of a log file
Specification

**Alias:** none

**Argument(s):** STRING

**Default:** JEGAGlobal.log

Description

New as of JEGA v2.0 is the introduction of the `log_file` specification. JEGA now uses a logging library to output messages and status to the user. JEGA can be configured at build time to log to both the console window and a text file, one or the other, or neither. The `log_file` input is a string name of a file into which to log. If the build was configured without file logging in JEGA, this input is ignored. If file logging is enabled and no `log_file` is specified, the default file name of JEGAGlobal.log is used.

7.2.34.9 print_each_pop

- **Keywords Area**
- **method**
- **soga**
- **print_each_pop**

Print every population to a population file

Specification

**Alias:** none

**Argument(s):** none

**Default:** No printing

Description

New to JEGA v2.0 is the introduction of the `print_each_pop` specification. It serves as a flag and if supplied, the population at each generation will be printed to a file named "population<GEN#>.dat" where `<GEN#>` is the number of the current generation.

7.2.34.10 initialization_type

- **Keywords Area**
- **method**
- **soga**
- **initialization_type**

Specify how to initialize the population
7.2 method

Specification

Alias: none

Argument(s): none

Default: unique_random

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Method</td>
<td>(Choose One)</td>
<td>simple_random</td>
<td>Create random initial solutions</td>

<tr>
<td>Initialization Type (Group 1)</td>
<td>unique_random</td>
<td>Create random initial solutions, but enforce uniqueness (default)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>flat_file</td>
<td>Read initial solutions from file</td>
<td></td>
</tr>
</tbody>
</table>

Description

The initialization_type defines how the initial population is created for the GA. There are three types:

1. simple_random
2. unique_random (default)
3. flat_file

Setting the size for the flat_file initializer has the effect of requiring a minimum number of designs to create. If this minimum number has not been created once the files are all read, the rest are created using the unique_random initializer and then the simple_random initializer if necessary.

7.2.34.10.1 simple_random

- Keywords Area
- method
- soga
- initialization_type
- simple_random

Create random initial solutions

Specification

Alias: none

Argument(s): none

Description

simple_random creates initial solutions with random variable values according to a uniform random number distribution. It gives no consideration to any previously generated designs.
7.2.34.10.2 unique_random

- Keywords Area
- method
- soga
- initialization_type
- unique_random

Create random initial solutions, but enforce uniqueness (default)

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

`unique_random` is the same as `simple_random`, except that when a new solution is generated, it is checked against the rest of the solutions. If it duplicates any of them, it is rejected.

7.2.34.10.3 flat_file

- Keywords Area
- method
- soga
- initialization_type
- flat_file

Read initial solutions from file

**Specification**

**Alias:** none

**Argument(s):** STRING

**Description**

`flat_file` allows the initial population to be read from a flat file. If `flat_file` is specified, a file name must be given.

Variables can be delimited in the flat file in any way you see fit with a few exceptions. The delimiter must be the same on any given line of input with the exception of leading and trailing whitespace. So a line could look like: 1.1, 2.2, 3.3 for example but could not look like: 1.1, 2.2 3.3. The delimiter can vary from line to line within the file which can be useful if data from multiple sources is pasted into the same input file. The delimiter can be any string that does not contain any of the characters .+dDeE or any of the digits 0-9. The input will be read until the end of the file. The algorithm will discard any configurations for which it was unable to retrieve at least the number of design variables. The objective and constraint entries are not required but if ALL are present, they will be recorded and the design will be tagged as evaluated so that evaluators may choose not to re-evaluate them.
Setting the size for this initializer has the effect of requiring a minimum number of designs to create. If this minimum number has not been created once the files are all read, the rest are created using the unique_random initializer and then the simple_random initializer if necessary. If more designs are found in the initialization files than specified by the initial size, then the initial size is ignored and all designs read out of the files are kept in the initial population.

7.2.34.11 crossover_type

- Keywords Area
  - method
  - soga
  - crossover_type

Select a crossover type for JEGA methods

Specification

Alias: none
Argument(s): none
Default: shuffle_random

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required (Choose One)</td>
<td>Crossover Type (Group 1)</td>

</tr>
<tr>
<td></td>
<td></td>
<td>shuffle_random</td>
<td>Perform crossover by choosing design variable(s)</td>
</tr>
</tbody>
</table>

Optional | crossover_rate | Specify the probability of a crossover event |

Description

There are many crossover types available. multi_point_binary crossover requires an integer number, N, of crossover points. This crossover type performs a bit switching crossover at N crossover points in the binary encoded genome of two designs. Thus, crossover may occur at any point along a solution chromosome (in the middle of a gene representing a design variable, for example). multi_point_parameterized_binary crossover is similar in that it performs a bit switching crossover routine at N crossover points. However, this crossover type performs crossover on each design variable individually. So the individual chromosomes are crossed at N locations. multi_point_real crossover performs a variable switching crossover routing at N crossover points in the real real valued genome of two designs. In this scheme, crossover only occurs between design variables (chromosomes). Note that the standard solution chromosome representation in the JEGA algorithm is real encoded and can handle integer or real design variables. For any crossover types that use a binary representation, real variables are converted to long integers by multiplying the real number by 10^6 and then truncating. Note that this
assumes a precision of only six decimal places. Discrete variables are represented as integers (indices within a list of possible values) within the algorithm and thus require no special treatment by the binary operators.

The final crossover type is shuffle_random. This crossover type performs crossover by choosing design variables at random from a specified number of parents enough times that the requested number of children are produced. For example, consider the case of 3 parents producing 2 children. This operator would go through and for each design variable, select one of the parents as the donor for the child. So it creates a random shuffle of the parent design variable values. The relative numbers of children and parents are controllable to allow for as much mixing as desired. The more parents involved, the less likely that the children will wind up exact duplicates of the parents.

All crossover types take a crossover_rate. The crossover rate is used to calculate the number of crossover operations that take place. The number of crossovers is equal to the rate * population_size.

7.2.34.11.1 multi_point_binary

- Keywords Area
- method
- soga
- crossover_type
- multi_point_binary

Use bit switching for crossover events

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Description**

There are many crossover types available. multi_point_binary crossover requires an integer number, N, of crossover points. This crossover type performs a bit switching crossover at N crossover points in the binary encoded genome of two designs. Thus, crossover may occur at any point along a solution chromosome (in the middle of a gene representing a design variable, for example). multi_point_parameterized_binary crossover is similar in that it performs a bit switching crossover routine at N crossover points. However, this crossover type performs crossover on each design variable individually. So the individual chromosomes are crossed at N locations. multi_point_real crossover performs a variable switching crossover routing at N crossover points in the real real valued genome of two designs. In this scheme, crossover only occurs between design variables (chromosomes). Note that the standard solution chromosome representation in the JEGA algorithm is real encoded and can handle integer or real design variables. For any crossover types that use a binary representation, real variables are converted to long integers by multiplying the real number by 10^-6 and then truncating. Note that this assumes a precision of only six decimal places. Discrete variables are represented as integers (indices within a list of possible values) within the algorithm and thus require no special treatment by the binary operators.

7.2.34.11.2 multi_point_parameterized_binary

- Keywords Area
- method
- soga
- crossover_type
- multi_point_parameterized_binary

Use bit switching to crossover each design variable
7.2 method

Specification

Alias: none
Argument(s): INTEGER

Description

There are many crossover types available. multi_point_binary crossover requires an integer number, N, of crossover points. This crossover type performs a bit switching crossover at N crossover points in the binary encoded genome of two designs. Thus, crossover may occur at any point along a solution chromosome (in the middle of a gene representing a design variable, for example). multi_point_parameterized_binary crossover is similar in that it performs a bit switching crossover routine at N crossover points. However, this crossover type performs crossover on each design variable individually. So the individual chromosomes are crossed at N locations. multi_point_real crossover performs a variable switching crossover routing at N crossover points in the real valued genome of two designs. In this scheme, crossover only occurs between design variables (chromosomes). Note that the standard solution chromosome representation in the JEGA algorithm is real encoded and can handle integer or real design variables. For any crossover types that use a binary representation, real variables are converted to long integers by multiplying the real number by $10^6$ and then truncating. Note that this assumes a precision of only six decimal places. Discrete variables are represented as integers (indices within a list of possible values) within the algorithm and thus require no special treatment by the binary operators.

7.2.34.11.3 multi_point_real

- Keywords Area
- method
- soga
- crossover_type
- multi_point_real

Perform crossover in real valued genome

Specification

Alias: none
Argument(s): INTEGER

Description

There are many crossover types available. multi_point_binary crossover requires an integer number, N, of crossover points. This crossover type performs a bit switching crossover at N crossover points in the binary encoded genome of two designs. Thus, crossover may occur at any point along a solution chromosome (in the middle of a gene representing a design variable, for example). multi_point_parameterized_binary crossover is similar in that it performs a bit switching crossover routine at N crossover points. However, this crossover type performs crossover on each design variable individually. So the individual chromosomes are crossed at N locations. multi_point_real crossover performs a variable switching crossover routing at N crossover points in the real real valued genome of two designs. In this scheme, crossover only occurs between design variables (chromosomes). Note that the standard solution chromosome representation in the JEGA algorithm is real encoded and can handle integer or real design variables. For any crossover types that use a binary representation, real variables are converted to long integers by multiplying the real number by $10^6$ and then truncating. 7.2.34.11.5 crossover_rate

- Keywords Area
- method
- soga
- crossover_type
- crossover_rate

Specify the probability of a crossover event

Specification

Alias: none

Argument(s): REAL

Default: 0.8
Description

The `crossover_type` controls what approach is employed for combining parent genetic information to create offspring, and the `crossover_rate` specifies the probability of a crossover operation being performed to generate a new offspring. The SCOLIB EA method supports three forms of crossover, `two_point`, `blend`, and `uniform`, which generate a new individual through combinations of two parent individuals. Two-point crossover divides each parent into three regions, where offspring are created from the combination of the middle region from one parent and the end regions from the other parent. Since the SCOLIB EA does not utilize bit representations of variable values, the crossover points only occur on coordinate boundaries, never within the bits of a particular coordinate. Uniform crossover creates offspring through random combination of coordinates from the two parents. Blend crossover generates a new individual randomly along the multidimensional vector connecting the two parents.

7.2.34.12 `mutation_type`

- `Keywords Area`
- `method`
- `soga`

Description

Five mutation types are available for selection by `keyword`: `replace_uniform`, `bit_random`, `offset_cauchy`, `offset_normal`, and `offset_uniform`. They are described in greater detail on their respective keyword pages.
The offset_* mutators all act by adding a random "offset" to a variable value. The random amount has a mean of zero in all cases. The size of the offset is controlled using the mutation_scale keyword, which is interpreted differently for each offset_* type.

The rate of mutations for all types is controlled using the mutation_rate. The rate is applied differently in each mutation_type.

7.2.34.12.1 bit_random

Mutate by flipping a random bit

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The bit_random mutator introduces random variation by first converting a randomly chosen variable of a randomly chosen design into a binary string. It then flips a randomly chosen bit in the string from a 1 to a 0 or visa versa. In this mutation scheme, the resulting value has more probability of being similar to the original value.

7.2.34.12.2 replace_uniform

Use uniformly distributed value over range of parameter

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

replace_uniform introduces random variation by first randomly choosing a design variable of a randomly selected design and reassigning it to a random valid value for that variable. No consideration of the current value is given when determining the new value.
7.2.34.12.3  offset_normal

- Keywords Area
- method
- soga
- mutation_type
- offset_normal

Set mutation offset to use a normal distribution

**Specification**

**Alias:** none

**Argument(s):** none

**Child Keywords:**

<td></td>
<td>mutation_scale</td>
<td>Scales mutation across range of parameter</td>
</tr>
</tbody>
</table>

**Description**

The *offset_normal* mutator introduces random variation by adding a Gaussian random amount to a variable value. The random amount has a standard deviation dependent on the *mutation_scale*.

7.2.34.12.3.1  mutation_scale

- Keywords Area
- method
- soga
- mutation_type
- offset_normal
- mutation_scale

Scales mutation across range of parameter

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 0.15
Description

The mutation_scale is a fraction in the range [0, 1] and is meant to help control the amount of variation that takes place when a variable is mutated. Its behavior depends on the selected mutation_type. For offset_normal and offset_cauchy, mutation_scale is multiplied by the range of the variable being mutated to obtain the standard deviation of the offset. For offset_uniform, the range of possible deviation amounts is \( +/- \frac{1}{2} \times \) (mutation_scale \( \times \) variable range).

7.2.34.12.4 offset_cauchy

- Keywords Area
- method
- soga
- mutation_type
- offset_cauchy

Use a Cauchy distribution for the mutation offset

Specification

Alias: none

Argument(s): none

**Description**

The offset\_uniform mutator introduces random variation by adding a uniform random amount to a variable value. The random amount depends on the mutation\_scale.

7.2.34.12.5.1 mutation\_scale

- Keywords Area
- method
- soga
- mutation\_type
- offset\_uniform
- mutation\_scale

Scales mutation across range of parameter

**Specification**

Alias: none

Argument(s): REAL

Default: 0.15
Description

The mutation_scale is a fraction in the range \([0, 1]\) and is meant to help control the amount of variation that takes place when a variable is mutated. Its behavior depends on the selected mutation_type. For offset_-normal and offset_cauchy, mutation_scale is multiplied by the range of the variable being mutated to obtain the standard deviation of the offset. For offset_uniform, the range of possible deviation amounts is \(\pm \frac{1}{2} \times (\text{mutation_scale} \times \text{variable range})\).

7.2.3.4.12.6 mutation_rate

- Keywords Area
- method
- soga
- mutation_type
- mutation_rate

Set probability of a mutation

Specification

Alias: none

Argument(s): REAL

Default: 0.08

Description

All mutation types have a mutation_rate, which controls the number of mutations performed. For replace_uniform and all the offset_* types, the number of mutations performed is the product of mutation_rate and population_size. For bit_random, it’s the product of the mutation_rate, number of design variables, and population size.

7.2.3.4.13 seed

- Keywords Area
- method
- soga
- seed

Seed of the random number generator

Specification

Alias: none

Argument(s): INTEGER

Default: system-generated (non-repeatable)
Description

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

7.2.34.14 convergence_tolerance

- Keywords Area
- method
- soga
- convergence_tolerance

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none
Argument(s): REAL
Default: 1.e-4

Description

The convergence_tolerance specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by convergence_tolerance, then this convergence criterion is satisfied on the current iteration.
Therefore, permissible values are between 0 and 1, non-inclusive.

**Behavior Varies by Package/Library**

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See nl2sol
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

### 7.2.34.15 model_pointer

- **Keywords Area**
  - method
  - soga
  - model_pointer

Identifier for model block to be used by a method

**Topics**

This keyword is related to the topics:

- block_pointer

**Specification**

**Alias:** none  

**Argument(s):** STRING  

**Default:** method use of last model parsed (or use of default model if none parsed)

**Description**

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

**Usage Tips**

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_-pointer` for each method is imperative.  

See `block_pointer` for details about pointers.
Examples

environment
  tabular_data
  method_pointer = 'UQ'

method

Pattern search techniques are nongradient-based optimization methods which use a set of offsets from the current iterate to locate improved points in the design space.

**See the page package_scolib for important information regarding all SCOLIB methods**

**coliny_pattern_search** supports concurrency up to the size of the search pattern.

Traditional pattern search methods search with a fixed pattern of search directions to try to find improvements to the current iterate. The SCOLIB pattern search methods generalize this simple algorithmic strategy to enable control of how the search pattern is adapted, as well as how each search pattern is evaluated. The stochastic and synchronization specifications denote how the the trial points are evaluated. The stochastic specification indicates that the trial points are considered in a random order. For parallel pattern search, synchronization dictates whether the evaluations are scheduled using a blocking scheduler or a nonblocking scheduler. In the blocking case, all points in the pattern are evaluated (in parallel), and if the best of these trial points is an improving point, then it becomes the next iterate. These runs are reproducible, assuming use of the same seed in the stochastic case. In the nonblocking case, all points in the pattern may not be evaluated, since the first improving point found becomes the next iterate. Since the algorithm steps will be subject to parallel timing variabili-
ties, these runs will not generally be repeatable. The synchronization specification has similar connotations for sequential pattern search. If blocking is specified, then each sequential iteration terminates after all trial points have been considered, and if nonblocking is specified, then each sequential iteration terminates after the first improving trial point is evaluated. In this release, both blocking and nonblocking specifications result in blocking behavior (except in the case where exploratory_moves below is set to adaptive_pattern). Nonblocking behavior will be re-enabled after some underlying technical issues have been resolved.

The particular form of the search pattern is controlled by the pattern_basis specification. If pattern_basis is coordinate basis, then the pattern search uses a plus and minus offset in each coordinate direction, for a total of $2n$ function evaluations in the pattern. This case is depicted in Figure 5.3 for three coordinate dimensions.

![Figure 7.1: Depiction of coordinate pattern search algorithm](image)

If pattern_basis is simplex, then pattern search uses a minimal positive basis simplex for the parameter space, for a total of $n+1$ function evaluations in the pattern. Note that the simplex pattern basis can be used for unbounded problems only. The total_pattern_size specification can be used to augment the basic coordinate and simplex patterns with additional function evaluations, and is particularly useful for parallel load balancing. For example, if some function evaluations in the pattern are dropped due to duplication or bound constraint interaction, then the total_pattern_size specification instructs the algorithm to generate new offsets to bring the total number of evaluations up to this consistent total.

The exploratory_moves specification controls how the search pattern is adapted. (The search pattern can be adapted after an improving trial point is found, or after all trial points in a search pattern have been found to be unimproving points.) The following exploratory_moves selections are supported by SCOLIB:

- The basic_pattern case is the simple pattern search approach, which uses the same pattern in each iteration.
- The multi_step case examines each trial step in the pattern in turn. If a successful step is found, the pattern search continues examining trial steps about this new point. In this manner, the effects of multiple successful steps are cumulative within a single iteration. This option does not support any parallelism and will result in a serial pattern search.
The adaptive_pattern case invokes a pattern search technique that adaptively rescales the different search directions to maximize the number of redundant function evaluations. See [46] for details of this method. In preliminary experiments, this method had more robust performance than the standard basic_pattern case in serial tests. This option supports a limited degree of parallelism. After successful iterations (where the step length is not contracted), a parallel search will be performed. After unsuccessful iterations (where the step length is contracted), only a single evaluation is performed.

The initial_delta and variable_tolerance specifications provide the initial offset size and the threshold size at which to terminate the algorithm. For any dimension that has both upper and lower bounds, this step length will be internally rescaled to provide search steps of length $\text{initial_delta} \times \text{range} \times 0.1$. This rescaling does not occur for other dimensions, so search steps in those directions have length $\text{initial_delta}$. Note that the factor of 0.1 in the rescaling could result in an undesirably small initial step. This can be offset by providing a large initial_delta.

In general, pattern search methods can expand and contract their step lengths. SCOLIB pattern search methods contract the step length by the value contraction_factor, and they expand the step length by the value $(1/\text{contraction_factor})$. The expand_after_success control specifies how many successful objective function improvements must occur with a specific step length prior to expansion of the step length, whereas the no_expansion flag instructs the algorithm to forgo pattern expansion altogether.

Finally, constraint infeasibility can be managed in a somewhat more sophisticated manner than the simple weighted penalty function. If the constant_penalty specification is used, then the simple weighted penalty scheme described above is used. Otherwise, the constraint penalty is adapted to the value $\text{constraint_penalty}/L$, where $L$ is the the smallest step length used so far.

**Expected HDF5 Output**

If Dakota was built with HDF5 support and run with the hdf5 keyword, this method writes the following results to HDF5:

- Best Parameters
- Best Objective Functions (when objective_functions are specified)
- Best Nonlinear Constraints
- Calibration (when calibration_terms are specified)

**7.2.35.1 constant_penalty**

- Keywords Area
- method
- coliny_pattern_search
- constant_penalty

Use a simple weighted penalty to manage feasibility
7.2 method

Specification

**Alias:** none

**Argument(s):** none

**Default:** algorithm dynamically adapts the constraint penalty

Description

Finally, constraint infeasibility can be managed in a somewhat more sophisticated manner than the simple weighted penalty function. If the `constant_penalty` specification is used, then the simple weighted penalty scheme described above is used. Otherwise, the constraint penalty is adapted to the value `constraint_penalty/L`, where $L$ is the smallest step length used so far.

7.2.35.2 no_expansion

- **Keywords Area**
- **method**
- **coliny_pattern_search**
- **no_expansion**

Don’t allow expansion of the search pattern

Specification

**Alias:** none

**Argument(s):** none

**Default:** algorithm may expand pattern size

Description

In general, pattern search methods can expand and contract their step lengths. SCOLIB pattern search methods contract the step length by the value `contraction_factor`, and they expand the step length by the value $(1/\text{contraction}\_\text{factor})$. The `expand\_after\_success` control specifies how many successful objective function improvements must occur with a specific step length prior to expansion of the step length, whereas the `no\_\text{expansion}` flag instructs the algorithm to forgo pattern expansion altogether.

7.2.35.3 expand_after_success

- **Keywords Area**
- **method**
- **coliny_pattern_search**
- **expand_after_success**

Set the factor by which a search pattern can be expanded
Specification

Alias: none
Argument(s): INTEGER
Default: 5

Description

In general, pattern search methods can expand and contract their step lengths. SCOLIB pattern search methods contract the step length by the value contraction_factor, and they expand the step length by the value (1/contraction_factor). The expand_after_success control specifies how many successful objective function improvements must occur with a specific step length prior to expansion of the step length, whereas the no_expansion flag instructs the algorithm to forgo pattern expansion altogether.

7.2.35.4 pattern_basis

- Keywords Area
- method

Description

The exploratory_moves specification controls how the search pattern is adapted. (The search pattern can be adapted after an improving trial point is found, or after all trial points in a search pattern have been found to be unimproving points.) The following exploratory moves selections are supported by SCOLIB:

7.2.35.7.1 multi_step

* Keywords Area
  * method
    * coliny_pattern_search
    * exploratory_moves
    * multi_step

Examine trial step around successful new point

Specification

Alias: none
Argument(s): none

Description

The multi_step case examines each trial step in the pattern in turn. If a successful step is found, the pattern search continues examining trial steps about this new point. In this manner, the effects of multiple successful steps are cumulative within a single iteration. This option does not support any parallelism and will result in a serial pattern

7.2.35.7.2 adaptive_pattern

* Keywords Area
  * method
    * coliny_pattern_search
Adaptively rescale search directions

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The `adaptive_pattern` case invokes a pattern search technique that adaptively rescales the different search directions to maximize the number of redundant function evaluations. See [46] for details of this method. In preliminary experiments, this method had more robust performance than the standard `basic_pattern` case in serial tests. This option supports a limited degree of parallelism. After successful iterations (where the step length is not contracted), a parallel search will be performed. After unsuccessful iterations (where the step length is contracted), only a single evaluation is performed.

7.2.35.7.3 `basic_pattern`

- Keywords Area
- method
- `coliny_pattern_search`
- `exploratory_moves`
- `basic_pattern`

Use the same search pattern every iteration

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The `basic_pattern` case is the simple pattern search approach, which uses the same pattern in each iteration.

7.2.35.8 `synchronization`

- Keywords Area
- method
- `coliny_pattern_search`
- `synchronization`

Select how Dakota schedules a batch of concurrent function evaluations in a parallel algorithm
7.2 method

Specification

**Alias:** none  
**Argument(s):** none  
**Default:** method specific

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional Required (Choose One)</th>
<th>Description of Group Synchronization (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>blocking</td>
<td>Complete concurrent evaluation of all evaluations within a batch</td>
</tr>
<tr>
<td></td>
<td></td>
<td>nonblocking</td>
<td>A batch of concurrent evaluations are queried for completions and a partial set is returned to the algorithm</td>
</tr>
</tbody>
</table>

**Description**

The synchronization specification can be used to specify the use of either blocking or nonblocking schedulers, where the former must block until all evaluations are completed and the latter does not block, returning only the partial set that has been completed for a particular call to the scheduler.

7.2.35.8.1 blocking

- **Keywords Area**
- **method**
- **coliny_pattern_search**
- **synchronization**
- **blocking**

Complete concurrent evaluation of all evaluations within a batch

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

In the blocking case, all of the concurrent evaluations in the batch must be completed and all results are returned together to the algorithm.

These runs are reproducible, assuming use of the same seed in cases with random number generation.
7.2.35.8.2  nonblocking

- Keywords Area
- method
- coliny_pattern_search
- synchronization
- nonblocking

A batch of concurrent evaluations are queried for completions and a partial set is returned to the algorithm

Specification

Alias: none

Argument(s): none

Description

In the nonblocking case, the set of running evaluations is queried for completion and a partial set of results is returned to an asynchronous algorithm, which can then generate new evaluations based on these partial results.

In all cases, the algorithm steps will be subject to parallel timing variabilities / race conditions such that these runs will not generally be repeatable regardless of seed specification.

7.2.35.9  contraction_factor

- Keywords Area
- method
- coliny_pattern_search
- contraction_factor

Amount by which step length is rescaled

Specification

Alias: none

Argument(s): REAL

Default: 0.5

Description

For pattern search methods, contraction_factor specifies the amount by which step length is rescaled after unsuccessful iterates, must be strictly between 0 and 1.

For methods that can expand the step length, the expansion is \(1/\text{contraction\_factor}\)
7.2.35.10  constraint_penalty

• Keywords Area
• method
• coliny_pattern_search
• constraint_penalty

Multiplier for the penalty function

Specification

Alias: none
Argument(s): REAL
Default: 1.0

Description

Most SCOLIB optimizers treat constraints with a simple penalty scheme that adds \( \text{constraint\_penalty} \times \) the sum of squares of the constraint violations to the objective function. The default value of \( \text{constraint\_penalty} \) is 1000.0, except for methods that dynamically adapt their constraint penalty, for which the default value is 1.0.

7.2.35.11  initial_delta

• Keywords Area
• method
• coliny_pattern_search
• initial_delta

Initial step size for derivative-free optimizers

Specification

Alias: none
Argument(s): REAL
Default: 1.0 (COBYLA), 0.1*range (PS, SW)

Description

The \( \text{initial\_delta} \) keyword defines the size of the first search step in derivative-free optimization methods, specifically async_pattern_search, coliny_cobyla, coliny_pattern_search, coliny_solis_wets, and mesh_adaptive_search. It is applied in an absolute sense to all search directions.

Default Behavior
The default value is 1.0.

Usage Tips
It is recommended that `initial_delta` be the approximate distance from the initial point to the solution. If this distance is unknown, it is advisable to err on the side of choosing an `initial_delta` that is too large or to not specify it. Relative application of `initial_delta` is not available unless the user scales the problem accordingly.

**Examples**

Three example method input blocks appear below.

For `asynch_pattern_search`:

```plaintext
method
  asynch_pattern_search
    initial_delta = .5
    contraction_factor = 0.25
    merit_function merit1_smooth
    smoothing_factor = 1.0
    constraint_tolerance = 1.e-6
```

For `coliny_pattern_search`:

```plaintext
method
  coliny_pattern_search
    initial_delta = .2
    variable_tolerance = 1.e-4
    max_iterations 100
    solution_accuracy = 1.e-6
    seed = 1234
    max_function_evaluations = 1000
```

For `mesh_adaptive_search`

```plaintext
method
  mesh_adaptive_search
    initial_delta = 2.0
    seed = 1234
```

### 7.2.35.12 variable_tolerance

- **Keywords Area**
- **method**
- **coliny_pattern_search**
- **variable_tolerance**

Step length-based stopping criteria for derivative-free optimizers

**Specification**

- **Alias:** none
- **Argument(s):** REAL
- **Default:** 1.0e-4 (COBYLA), 1.0e-5 (PS), 1.0e-6 (SW)

**Description**

The `variable_tolerance` keyword defines the minimum step length allowed by the optimizer and is used to determine convergence. It is applicable to `asynch_pattern_search`, `coliny_cobyla`, `coliny_pattern_search`, `coliny_solis_wets`, and `mesh_adaptive_search`. 
Default Behavior

The default value varies according to method as follows:

- `asynch_pattern_search`: 1.0e-2
- `coliny_cobyla`: 1.0e-4
- `coliny_pattern_search`: 1.0e-5
- `coliny_solis_wets`: 1.0e-6
- `mesh_adaptive_search`: 1.0e-6

Usage Tips

It is recommended that `variable_tolerance` be set to a value for which changes of that scale in parameter values cause negligible changes in the objective function.

Examples

Three example method input blocks appear below.

For `asynch_pattern_search`:

```
method asynch_pattern_search
  contraction_factor = 0.25
  variable_tolerance = 1.e-4
  solution_target = 1.e-6
  max_function_evaluations = 500
  constraint_tolerance = 1.e-6
```

For `coliny_pattern_search`:

```
method coliny_pattern_search
  initial_delta = .2
  variable_tolerance = 1.e-4
  max_iterations = 100
  solution_accuracy = 1.e-6
  seed = 1234
  max_function_evaluations = 1000
```

For `mesh_adaptive_search`:

```
method mesh_adaptive_search
  variable_tolerance = 0.01
  seed = 1234
```

7.2.35.13 solution_target

- Keywords Area
- method
- `coliny_pattern_search`
- `solution_target`

Stopping criteria based on objective function value
Specification

**Alias:** solution_accuracy

**Argument(s):** REAL

**Default:** -DBL_MAX

Description

solution_target is a termination criterion. The algorithm will terminate when the function value falls below solution_target.

7.2.35.14 seed

- Keywords Area
- method
- coliny_pattern_search
- seed

Seed of the random number generator

Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** system-generated (non-repeatable)

Description

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```
7.2.35.15  show_misc_options

- Keywords Area
- method
- coliny_pattern_search
- show_misc_options

Show algorithm parameters not exposed in Dakota input

Specification

Alias: none
Argument(s): none
Default: no dump of specification options

Description

All SCOLIB methods support the show_misc_options optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The misc_options optional specification provides a means for inputing additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification: they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

7.2.35.16  misc_options

- Keywords Area
- method
- coliny_pattern_search
- misc_options

Set method options not available through Dakota spec

Specification

Alias: none
Argument(s): STRINGLIST
Default: no misc options

Description

All SCOLIB methods support the show_misc_options optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The misc_options optional specification provides a means for inputing additional settings supported by the SCOLIB...
methods but which are not currently mapped through the Dakota input specification. Care must be taken in using
this specification; they should only be employed by users familiar with the full range of parameter specifications
available directly from SCOLIB and understand any differences that exist between those specifications and the
ones available through Dakota.

7.2.35.17 max_iterations

- Keywords Area
- method
- coliny_pattern_search
- max_iterations

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none
Argument(s): INTEGER
Default: 100 (exceptions: fsu_cvt, local_reliability: 25; global_(reliability , interval_est , evidence) / efficient_global: 25+n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If
it has not reached any other stopping criteria first, the method will stop after it has performed max_iterations
iterations. In cases where there are multiple nested iterations to be controlled, max_iterations generally
controls the outer-most context.

Default Behavior

Default value is 100.

See Also

These keywords may also be of interest:

- max_function_evaluations

7.2.35.18 convergence_tolerance

- Keywords Area
- method
- coliny_pattern_search
• convergence_tolerance

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

• method_independent_controls

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The convergence_tolerance specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by convergence_tolerance, then this convergence criterion is satisfied on the current iteration. Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

• DOT: relative tolerance that must be satisfied for two consecutive iterations

• NL2SOL: See nl2sol

• NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance

• NPSOL: used as a line search tolerance, not as a relative convergence tolerance

7.2.35.19 max_function_evaluations

• Keywords Area

• method

• coliny_pattern_search

• max_function_evaluations

Number of function evaluations allowed for optimizers
Topics

This keyword is related to the topics:

- method_independent_controls

Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g., `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

**Default Behavior**

Default value is 1000.

7.2.35.20 scaling

- Keywords Area
- method
- coliny_pattern_search
- scaling

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

**Alias:** none

**Argument(s):** none

**Default:** no scaling

Description

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the `scaling` keyword. Discrete variable scaling is not supported.
When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords `scale_types` and/or `*scales` in the `variables` and `responses` blocks. When the `scaling` keyword is omitted from `method`, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

- a `*scales` keyword, which gives characteristic values (divisors)
- a `*scale_types` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in `responses` for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

**Scale Types**

There are three scale types:

1. **value** - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.

2. **auto** - automatic scaling
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   - two-sided bounds scaled into the interval [0,1];
   - one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
   - no bounds or targets: no automatic scaling possible, therefore no scaling for this component

   Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

3. **log** - logarithmic scaling
   First, any characteristic values from the optional `*_scales` specification are applied. Then logarithm base 10 scaling is applied.

   Logarithmic scaling is not available for linear constraints.

   When continuous design variables are log scaled, linear constraints are not allowed.

**Scales**

The `*scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `*scale_types`, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- `auto, log` - optional
- `value` - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than `1.0e10*DBL_MIN`. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.
Examples

The two examples below are equivalent:

```
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100

responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

7.2.35.21 model_pointer

- Keywords Area
- method
- coliny_pattern_search
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

**Usage Tips**

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative. See `block_pointer` for details about pointers.
Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
      0.1 0.2 0.6
    sample_type lhs
  distribution cumulative

model
  id_model = 'SURR'
    surrogate global,
    dace_method_pointer = 'DACE'
    polynomial quadratic

method
  id_method = 'DACE'
  model_pointer = 'DACE_M'
  sampling sample_type lhs
    samples = 121 seed = 5034 rng rnum2

model
  id_model = 'DACE_M'
    single
    interface_pointer = 'I1'

variables
  uniform_uncertain = 2
    lower_bounds = 0. 0.
    upper_bounds = 1. 1.
  descriptors = 'x1' 'x2'

interface
  id_interface = 'I1'
  system asynch evaluation_concurrency = 5
    analysis_driver = 'text_book'

responses
  response_functions = 3
  no_gradients
  no_hessians
```

7.2.36 coliny_solis_wets

- Keywords Area
- method
- coliny_solis_wets

Simple greedy local search method

Topics

This keyword is related to the topics:

- package_scolib
- package_coliny
### Specification

Description

The Solis-Wets method is a simple greedy local search heuristic for continuous parameter spaces. Solis-Wets generates trial points using a multivariate normal distribution, and unsuccessful trial points are reflected about the current point to find a descent direction.

See the page package_scolib for important information regarding all SCOLIB methods

coliny_solis_wets is inherently serial, no concurrency is used.

These specifications have the same meaning as corresponding specifications for coliny_pattern_search. Please see that page for specification details.

In particular, coliny_solis_wets supports dynamic rescaling of the step length, and dynamic rescaling of the constraint penalty. The only new specification is contract_after_failure, which specifies the number of unsuccessful cycles which must occur with a specific delta prior to contraction of the delta.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the hdf5 keyword, this method writes the following results to HDF5:

- Best Parameters
- Best Objective Functions (when objective_functions) are specified
- Best Nonlinear Constraints
- Calibration (when calibration_terms are specified)

See Also

These keywords may also be of interest:

- coliny_beta
• coliny_direct
• coliny_pattern_search
• coliny_cobyla
• coliny_ea

7.2.36.1 contract_after_failure

• Keywords Area
• method
• coliny_solis_wets
• contract_after_failure

The number of unsuccessful cycles prior to contraction.

**Specification**

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** 4+number of variables

**Description**

In particular, coliny_solis_wets supports dynamic rescaling of the step length, and dynamic rescaling of the constraint penalty. The only new specification is contract_after_failure, which specifies the number of unsuccessful cycles which must occur with a specific delta prior to contraction of the delta.

7.2.36.2 no_expansion

• Keywords Area
• method
• coliny_solis_wets
• no_expansion

Don’t allow expansion of the search pattern

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** algorithm may expand pattern size
Description

In general, pattern search methods can expand and contract their step lengths. SCOLIB pattern search methods contract the step length by the value $\text{contraction_factor}$, and they expand the step length by the value $(1/\text{contraction_factor})$. The expand$_{\text{after_success}}$ control specifies how many successful objective function improvements must occur with a specific step length prior to expansion of the step length, whereas the no$_{\text{-}}$expansion flag instructs the algorithm to forgo pattern expansion altogether.

7.2.36.3 expand$_{\text{after_success}}$

- Keywords Area
- method
- coliny$_{\text{-}}$solis$_{\text{-}}$wets
- expand$_{\text{after_success}}$

Set the factor by which a search pattern can be expanded

Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** 5

Description

In general, pattern search methods can expand and contract their step lengths. SCOLIB pattern search methods contract the step length by the value $\text{contraction_factor}$, and they expand the step length by the value $(1/\text{contraction_factor})$. The expand$_{\text{after_success}}$ control specifies how many successful objective function improvements must occur with a specific step length prior to expansion of the step length, whereas the no$_{\text{-}}$expansion flag instructs the algorithm to forgo pattern expansion altogether.

7.2.36.4 constant$_{\text{penalty}}$

- Keywords Area
- method
- coliny$_{\text{-}}$solis$_{\text{-}}$wets
- constant$_{\text{penalty}}$

Use a simple weighted penalty to manage feasibility

Specification

**Alias:** none

**Argument(s):** none

**Default:** algorithm dynamically adapts the constraint penalty
Finally, constraint infeasibility can be managed in a somewhat more sophisticated manner than the simple weighted penalty function. If the `constant_penalty` specification is used, then the simple weighted penalty scheme described above is used. Otherwise, the constraint penalty is adapted to the value $\text{constraint\_penalty}/L$, where $L$ is the the smallest step length used so far.

7.2.36.5 contraction_factor

- **Keywords Area**
- **method**
- **coliny_solis_wets**
- **contraction_factor**

Amount by which step length is rescaled

**Specification**

**Alias**: none

**Argument(s)**: REAL

**Default**: 0.5

**Description**

For pattern search methods, `contraction_factor` specifies the amount by which step length is rescaled after unsuccessful iterates, must be strictly between 0 and 1.

For methods that can expand the step length, the expansion is $1/\text{contraction\_factor}$

7.2.36.6 constraint_penalty

- **Keywords Area**
- **method**
- **coliny_solis_wets**
- **constraint_penalty**

Multiplier for the penalty function

**Specification**

**Alias**: none

**Argument(s)**: REAL

**Default**: 1.0
7.2 method

Description

Most SCOLIB optimizers treat constraints with a simple penalty scheme that adds \( \text{constraint\_penalty} \) times the sum of squares of the constraint violations to the objective function. The default value of \( \text{constraint\_penalty} \) is 1000.0, except for methods that dynamically adapt their constraint penalty, for which the default value is 1.0.

7.2.36.7 \ initial_delta

- Keywords Area
- method
- coliny_solis_wets
- \ initial_delta

Initial step size for derivative-free optimizers

Specification

Alias: none
Argument(s): REAL
Default: 1.0 (COBYLA), 0.1*range (PS, SW)

Description

The initial_delta keyword defines the size of the first search step in derivative-free optimization methods, specifically asynch_pattern_search, coliny_cobyla, coliny_pattern_search, coliny.solis_wets, and mesh_adaptive_search. It is applied in an absolute sense to all search directions.

Default Behavior

The default value is 1.0.

Usage Tips

It is recommended that initial_delta be the approximate distance from the initial point to the solution. If this distance is unknown, it is advisable to err on the side of choosing an initial_delta that is too large or to not specify it. Relative application of initial_delta is not available unless the user scales the problem accordingly.

Examples

Three example method input blocks appear below.

For asynch_pattern_search:

```
method
  asynch_pattern_search
  initial_delta = .5
  contraction_factor = 0.25
  merit_function merit1_smooth
  smoothing_factor = 1.0
  constraint_tolerance = 1.e-6
```

For coliny_pattern_search:

```
method
  coliny_pattern_search
```
initial_delta = .2
variable_tolerance = 1.e-4
max_iterations 100
solution_accuracy = 1.e-6
seed = 1234
max_function_evaluations = 1000

For mesh_adaptive_search

method
    mesh_adaptive_search
        initial_delta = 2.0
        seed = 1234

7.2.36.8 variable_tolerance

- Keywords Area
- method
- coliny_solis_wets
- variable_tolerance

Step length-based stopping criteria for derivative-free optimizers

Specification

Alias: none
Argument(s): REAL
Default: 1.0e-4 (COBYLA), 1.0e-5 (PS), 1.0e-6 (SW)

Description

The variable_tolerance keyword defines the minimum step length allowed by the optimizer and is used to determine convergence. It is applicable to asynch_pattern_search, coliny_cobyla, coliny_pattern_search, coliny_solis_wets, and mesh_adaptive_search.

Default Behavior
The default value varies according to method as follows:

- asynch_pattern_search: 1.0e-2
- coliny_cobyla: 1.0e-4
- coliny_pattern_search: 1.0e-5
- coliny_solis_wets: 1.0e-6
- mesh_adaptive_search: 1.0e-6

Usage Tips

It is recommended that variable_tolerance be set to a value for which changes of that scale in parameter values cause negligible changes in the objective function.
Examples

Three example method input blocks appear below.
For `asynch_pattern_search`:

```plaintext
method
    asynch_pattern_search
    contraction_factor = 0.25
    variable_tolerance = 1.e-4
    solution_target = 1.e-6
    max_function_evaluations = 500
    constraint_tolerance = 1.e-6
```

For `coliny_pattern_search`:

```plaintext
method
    coliny_pattern_search
    initial_delta = .2
    variable_tolerance = 1.e-4
    max_iterations = 100
    solution_accuracy = 1.e-6
    seed = 1234
    max_function_evaluations = 1000
```

For `mesh_adaptive_search`:

```plaintext
method
    mesh_adaptive_search
    variable_tolerance = 0.01
    seed = 1234
```

7.2.36.9 solution_target

- Keywords Area
- method
- coliny_solis_wets
- solution_target

Stopping criteria based on objective function value

Specification

**Alias:** solution_accuracy

**Argument(s):** REAL

**Default:** -DBL_MAX

**Description**

`solution_target` is a termination criterion. The algorithm will terminate when the function value falls below `solution_target`.

7.2.36.10 seed

- Keywords Area
- method
Seed of the random number generator

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** system-generated (non-repeatable)

**Description**

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

**Default Behavior**

If not specified, the seed is randomly generated.

**Expected Output**

If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

**Usage Tips**

If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

**Examples**

```dakota
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

**show_misc_options**

Show algorithm parameters not exposed in Dakota input

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** no dump of specification options
Description

All SCOLIB methods support the `show_misc_options` optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The `misc_options` optional specification provides a means for inputting additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

7.2.36.12 misc_options

- Keywords Area
- method
- coliny_solis_wets
- misc_options

Set method options not available through Dakota spec

Specification

**Alias:** none

**Argument(s):** STRINGLIST

**Default:** no misc options

Description

All SCOLIB methods support the `show_misc_options` optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The `misc_options` optional specification provides a means for inputting additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

7.2.36.13 max_iterations

- Keywords Area
- method
- coliny_solis_wets
- max_iterations

Number of iterations allowed for optimizers and adaptive UQ methods
Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: fsu_cv t, local_reliability: 25; global_(reliability, interval_est, evidence) / efficient_global: 25∗n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed max_iterations iterations. In cases where there are multiple nested iterations to be controlled, max_iterations generally controls the outer-most context.

Default Behavior

Default value is 100.

See Also

These keywords may also be of interest:

- max_function_evaluations

7.2.36.14 convergence_tolerance

- Keywords Area
- method
- coliny_solis_wets
- convergence_tolerance

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4
Description

The *convergence_tolerance* specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a *relative convergence tolerance* for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by *convergence_tolerance*, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See nl2sol
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

### 7.2.36.15 max_function_evaluations

- **Keywords Area**
- **method**
- **coliny_solis_wets**
- **max_function_evaluations**

Number of function evaluations allowed for optimizers

**Topics**

This keyword is related to the topics:

- **method_independent_controls**

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 1000

**Description**

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed *max_function_evaluations* evaluations. See also *max_iterations*. 

Dakota Version 6.16 Reference Manual generated on May 12, 2022
Some optimizers (e.g., ncsu_direct) may run past this limit in the course of an iteration step that began before max_function_evaluations was exceeded.

**Default Behavior**

Default value is 1000.

### 7.2.36.16 scaling

- **Keywords Area**
- **method**
- **coliny_solis_wets**
- **scaling**

Turn on scaling for variables, responses, and constraints

**Topics**

This keyword is related to the topics:

- **method_independent_controls**

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** no scaling

**Description**

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords `scale_types` and/or `*scales` in the `variables` and `responses` blocks. When the `scaling` keyword is omitted from `method`, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

- a `*scales` keyword, which gives characteristic values (divisors)
- a `*scale_types` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in `responses` for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

**Scale Types**

There are three scale types:
1. **value** - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.

2. **auto** - automatic scaling
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   - two-sided bounds scaled into the interval \([0,1]\);
   - one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
   - no bounds or targets: no automatic scaling possible, therefore no scaling for this component

   Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into \([0,1]\).

3. **log** - logarithmic scaling
   First, any characteristic values from the optional \(*_scales\) specification are applied. Then logarithm base 10 scaling is applied.

   Logarithmic scaling is not available for linear constraints.

   When continuous design variables are log scaled, linear constraints are not allowed.

**Scales**

The \(*_scales\) keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding \(*_scale_types\), as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- **auto, log** - optional
- **value** - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than \(1.0e10 \times \text{DBL_MIN}\). User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

**Examples**

The two examples below are equivalent:

```plaintext
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100

responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

**7.2.36.17 model_pointer**

- **Keywords Area**
- **method**
**model_pointer**

Identifier for model block to be used by a method

**Topics**

This keyword is related to the topics:

- **block_pointer**

**Specification**

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)

**Description**

The **model_pointer** is used to specify which **model** block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a **model** block in the Dakota input file that has a corresponding **id_model** with the same name.

**Usage Tips**

When doing advanced analyses that involve using multiple methods and multiple models, defining a **model_pointer** for each method is imperative.

See **block_pointer** for details about pointers.

**Examples**

```plaintext
environment
tabular_data
method_pointer = 'UQ'

method
id_method = 'UQ'
model_pointer = 'SURR'
sampling,
samples = 10
seed = 98765 rng rnum2
response_levels = 0.1 0.2 0.6
   0.1 0.2 0.6
   0.1 0.2 0.6
sample_type lhs
distribution cumulative

model
id_model = 'SURR'
surrogate global,
dace_method_pointer = 'DACE'
polynomial quadratic

method
id_method = 'DACE'
```
7.2 method

    model_pointer = 'DACE_M'
sampling sample_type lhs
    samples = 121 seed = 5034 rng rnum2

model
    id_model = 'DACE_M'

The Constrained Optimization BY Linear Approximations (COBYLA) algorithm is an extension to the Nelder-Mead simplex algorithm for handling general linear/nonlinear constraints and is invoked using the `coliny_cobyla` group specification. The COBYLA algorithm employs linear approximations to the objective and constraint functions, the approximations being formed by linear interpolation at N+1 points in the space of the variables. We regard these interpolation points as vertices of a simplex. The step length parameter controls the size of the simplex and it is reduced automatically from `initial_delta` to `variable_tolerance`. One advantage that COBYLA has over many of its competitors is that it treats each constraint individually when calculating a change to the variables, instead of lumping the constraints together into a single penalty function.

See the page `package_scolib` for important information regarding all SCOLIB methods.

`coliny_cobyla` is inherently serial.

### Stopping Criteria

COBYLA currently only supports termination based on

- `max_function_evaluations`
- `solution_target`

Other method-independent stopping criteria (`max_iterations` and `convergence_tolerance`) will be ignored if set.

### Known Bugs

The implementation of the `coliny_cobyla` optimization method is such that the best function value is not always returned to Dakota for reporting. The user is advised to look through the Dakota screen output or the tabular output file (if generated) to confirm what the best function value and corresponding parameter values are.

The `coliny_cobyla` optimization method does not always respect bound constraints when scaling is turned on.

Neither bug will be fixed, as maintaining third-party source code (such as COBYLA) is outside of the Dakota project scope.

### Expected HDF5 Output

If Dakota was built with HDF5 support and run with the `hdf5` keyword, this method writes the following results to HDF5:

- Best Parameters
- Best Objective Functions (when `objective_functions` are specified)
- Best Nonlinear Constraints
- Calibration (when `calibration_terms` are specified)

### See Also

These keywords may also be of interest:

- `coliny_beta`
- `coliny_direct`
- `coliny_pattern_search`
### initial_delta

**Keywords Area**

- method
- coliny_cobyla

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 1.0 (COBYLA), 0.1 × range (PS, SW)

**Description**

*initial_delta* for COBYLA should be set to be a value that is reasonable for initial changes to the optimization variables. It represents a distance from the initial simplex within which linear approximation subproblems can be trusted to be sufficiently representative of the true problem. It is analogous to the initial trust-region size used in trust-region methods.

**Default Behavior**

The default value is 1.0.

### variable_tolerance

**Keywords Area**

- method
- coliny_cobyla

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 1.0 × 10^{-4} (COBYLA), 1.0 × 10^{-5} (PS), 1.0 × 10^{-6} (SW)
7.2 method

Description

Unlike its use as a stopping criteria in other methods, `variable_tolerance` is used to communicate the accuracy of the optimization variables to COBYLA. It represents the minimum distance from the simplex within which linear approximation subproblems can be trusted to be sufficiently representative of the true problem. It is analogous to the minimum trust-region size used in trust-region methods. Note that, per COBYLA documentation, the level of accuracy is not guaranteed.

Default Behavior

The default value is 0.0001.

Additional Discussion

While `variable_tolerance` is not a stopping criteria for COBYLA, we note that it may have a side effect regarding convergence. In particular, if lower accuracy is required of the optimization variables, it may stop sooner than if higher accuracy is required.

7.2.37.3 solution_target

- Keywords Area
- method
- coliny_cobyla
- solution_target

Stopping criteria based on objective function value

Specification

Alias: solution_accuracy

Argument(s): REAL

Default: -DBL_MAX

Description

`solution_target` is a termination criterion. The algorithm will terminate when the function value falls below `solution_target`.

7.2.37.4 seed

- Keywords Area
- method
- coliny_cobyla
- seed

Seed of the random number generator
Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** system-generated (non-repeatable)

**Description**

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

**Default Behavior**

If not specified, the seed is randomly generated.

**Expected Output**

If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

**Usage Tips**

If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

**Examples**

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

Show algorithm parameters not exposed in Dakota input

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** no dump of specification options

**Description**

All SCOLIB methods support the `show_misc_options` optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface.
**misc_options** optional specification provides a means for inputing additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

### 7.2.37 misc_options

- Keywords Area
- method
- coliny_cobyla
- misc_options

Set method options not available through Dakota spec

**Specification**

**Alias:** none

**Argument(s):** STRINGLIST

**Default:** no misc options

**Description**

All SCOLIB methods support the **show_misc_options** optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The **misc_options** optional specification provides a means for inputing additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

### 7.2.37.7 max_iterations

- Keywords Area
- method
- coliny_cobyla
- max_iterations

Number of iterations allowed for optimizers and adaptive UQ methods

**Topics**

This keyword is related to the topics:

- method_independent_controls
Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** 100 (exceptions: fsu_cvt, local_reliability: 25; global_(reliability, interval_est, evidence) / efficient_global: 25*n)

**Description**

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed \( \text{max_iterations} \) iterations. In cases where there are multiple nested iterations to be controlled, \( \text{max_iterations} \) generally controls the outer-most context.

**Default Behavior**

Default value is 100.

**See Also**

These keywords may also be of interest:

- max_function_evaluations

7.2.37.8 convergence_tolerance

- Keywords Area
- method
- coliny_cobyla
- convergence_tolerance

Stopping criterion based on objective function or statistics convergence

**Topics**

This keyword is related to the topics:

- method_independent_controls

Specification

**Alias:** none

**Argument(s):** REAL

**Default:** 1.e-4

**Description**

The convergence_tolerance specification provides a real value for controlling the termination of iteration.
For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by convergence_tolerance, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See nl2sol
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

7.2.37.9 max_function_evaluations

- Keywords Area
- method
- coliny_cobyla
- max_function_evaluations

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed max_function_evaluations evaluations. See also max_iterations.

Some optimizers (e.g. ncsu_direct) may run past this limit in the course of an iteration step that began before max_function_evaluations was exceeded.

Default Behavior

Default value is 1000.
7.2.37.10 scaling

- Keywords Area
- method
- coliny_cobyla
- scaling

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none
Argument(s): none
Default: no scaling

Description

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the scaling keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords \texttt{scale\_types} and/or \texttt{*scales} in the variables and responses blocks. When the \texttt{scaling} keyword is omitted from \texttt{method}, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

- a \texttt{*scales} keyword, which gives characteristic values (divisors)
- a \texttt{*scale\_types} keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in responses for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are three scale types:

1. value - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.
2. **auto** - automatic scaling
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   - two-sided bounds scaled into the interval \([0,1]\);
   - one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
   - no bounds or targets: no automatic scaling possible, therefore no scaling for this component

   Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into \([0,1]\).

3. **log** - logarithmic scaling
   First, any characteristic values from the optional \(*_{scales}\) specification are applied. Then logarithm base 10 scaling is applied.

   Logarithmic scaling is not available for linear constraints.

   When continuous design variables are log scaled, linear constraints are not allowed.

### Scales

The \(*_{scales}\) keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding \(*_{scale\_types}\), as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- **auto**, **log** - optional
- **value** - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than \(1.0e10*DBL\_MIN\). User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

### Examples

The two examples below are equivalent:

```plaintext
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100

responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

7.2.37.11 **model_pointer**

- Keywords Area
- method
- coliny_cobyla
- model_pointer

Identifier for model block to be used by a method
Topics

This keyword is related to the topics:

• block_pointer

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.

See block_pointer for details about pointers.

Examples

environment

**Description**

The Dividing RECTangles (DIRECT) optimization algorithm is a derivative free global optimization method that balances local search in promising regions of the design space with global search in unexplored regions. As shown in Figure 5.1, DIRECT adaptively subdivides the space of feasible design points so as to guarantee that iterates are generated in the neighborhood of a global minimum in finitely many iterations.

DIRECT" image latex direct1.eps "Design space partitioning with DIRECT" width=10cm
In practice, DIRECT has proven an effective heuristic for engineering design applications, for which it is able to quickly identify candidate solutions that can be further refined with fast local optimizers.

See the page package_scolib for important information regarding all SCOLIB methods

The DIRECT algorithm supports concurrency up to twice the number of variables being optimized.

DIRECT uses the solution_target, constraint_penalty and show_misc_options specifications that are described in package_scolib. Note, however, that DIRECT uses a fixed penalty value for constraint violations (i.e. it is not dynamically adapted as is done in coliny_pattern_search).

Search Parameters

The global_balance_parameter controls how much global search is performed by only allowing a subregion to be subdivided if the size of the subregion divided by the size of the largest subregion is at least global_balance_parameter. Intuitively, this forces large subregions to be subdivided before the smallest subregions are refined. The local_balance_parameter provides a tolerance for estimating whether the smallest subregion can provide a sufficient decrease to be worth subdividing; the default value is a small value that is suitable for most applications.

Stopping Criteria

DIRECT can be terminated with:

- max_function_evaluations
- max_iterations
- convergence_tolerance
- solution_target
- max_boxsize_limit
- min_boxsize_limit - most effective in practice

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the hdf5 keyword, this method writes the following results to HDF5:

- Best Parameters
- Best Objective Functions (when objective_functions) are specified
- Best Nonlinear Constraints
- Calibration (when calibration_terms are specified)

<th>Dakota Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>major_dimension</td>
</tr>
</tbody>
</table>

- major_dimension

(default) Longest edge of subregion is subdivided

Description

The division specification determines how DIRECT subdivides each subregion of the search space.

If division is set to major_dimension, then the dimension representing the longest edge of the subregion is subdivided (this is the default). If division is set to all_dimensions, then all dimensions are simultaneously subdivided.

7.2.38.1.1 major_dimension

- Keywords Area
- method
- coliny_direct
- division

- major_dimension

(default) Longest edge of subregion is subdivided

Specification

Alias: none

Argument(s): none
Description

Longest edge of subregion is subdivided

7.2.38.1.2 all_dimensions

- Keywords Area
- method
- coliny_direct
- division
- all_dimensions

All dimensions are simultaneously subdivided

Specification

Alias: none

Argument(s): none

Description

All dimensions are simultaneously subdivided

7.2.38.2 global_balance_parameter

- Keywords Area
- method
- coliny_direct
- global_balance_parameter

Tolerance for whether a subregion is worth dividing

Specification

Alias: none

Argument(s): REAL

Default: 0.0

Description

The global_balance_parameter controls how much global search is performed by only allowing a subregion to be subdivided if the size of the subregion divided by the size of the largest subregion is at least global_balance_parameter. Intuitively, this forces large subregions to be subdivided before the smallest subregions are refined.
7.2.38.3  local_balance_parameter

- Keywords Area
- method
- coliny_direct
- local_balance_parameter

Tolerance for whether a subregion is worth dividing

Specification

Alias: none

Argument(s): REAL

Default: 1.e-8

Description

See parent page. The local_balance_parameter provides a tolerance for estimating whether the smallest subregion can provide a sufficient decrease to be worth subdividing; the default value is a small value that is suitable for most applications.

7.2.38.4  max_boxsize_limit

- Keywords Area
- method
- coliny_direct
- max_boxsize_limit

Stopping Criterion based on longest edge of hyperrectangle

Specification

Alias: none

Argument(s): REAL

Default: 0.0

Description

Each subregion considered by DIRECT has a size, which corresponds to the longest diagonal of the subregion. max_boxsize_limit specification terminates DIRECT if the size of the largest subregion falls below this threshold.
Stopping Criterion based on shortest edge of hyperrectangle

### Specification

**Alias:** none  
**Argument(s):** REAL  
**Default:** 1.0e-4

**Description**

`min_boxsize_limit` is a setting that terminates the optimization when the measure of a hyperrectangle $S$ with $f(c(S)) = f_{\text{min}}$ is less than `min_boxsize_limit`. Each subregion considered by DIRECT has a size, which corresponds to the longest diagonal of the subregion. `min_boxsize_limit` specification terminates DIRECT if the size of the smallest subregion falls below this threshold. In practice, this specification is likely to be more effective at limiting DIRECT's search.

### Multiplier for the penalty function

**Description**

Most SCOLIB optimizers treat constraints with a simple penalty scheme that adds `constraint_penalty` times the sum of squares of the constraint violations to the objective function. The default value of `constraint_penalty` is 1000.0, except for methods that dynamically adapt their constraint penalty, for which the default value is 1.0.
7.2.38.7  solution_target

- Keywords Area
- method
- coliny_direct
- solution_target

Stopping criteria based on objective function value

Specification

Alias: solution_accuracy
Argument(s): REAL
Default: -DBL_MAX

Description

solution_target is a termination criterion. The algorithm will terminate when the function value falls below solution_target.

7.2.38.8  seed

- Keywords Area
- method
- coliny_direct
- seed

Seed of the random number generator

Specification

Alias: none
Argument(s): INTEGER
Default: system-generated (non-repeatable)

Description

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips
If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

**Examples**

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

### 7.2.38.9 show_misc_options

- **Keywords Area**
- **method**
- **coliny_direct**
- **show_misc_options**

Show algorithm parameters not exposed in Dakota input

#### Specification

**Alias:** none

**Argument(s):** none

**Default:** no dump of specification options

#### Description

All SCOLIB methods support the `show_misc_options` optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The `misc_options` optional specification provides a means for inputing additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

### 7.2.38.10 misc_options

- **Keywords Area**
- **method**
- **coliny_direct**
- **misc_options**

Set method options not available through Dakota spec
Specification

**Alias:** none

**Argument(s):** STRINGLIST

**Default:** no misc options

**Description**

All SCOLIB methods support the `show_misc_options` optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The `misc_options` optional specification provides a means for inputting additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

### 7.2.38.11 max_iterations

- **Keywords Area**
- **method**
- **coliny_direct**
- **max_iterations**

Number of iterations allowed for optimizers and adaptive UQ methods

**Topics**

This keyword is related to the topics:

- **method_independent_controls**

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 100 (exceptions: fsu_cvt, local_reliability: 25; global_(reliability, interval_est, evidence) / efficient_global: 25*n)

**Description**

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed `max_iterations` iterations. In cases where there are multiple nested iterations to be controlled, `max_iterations` generally controls the outer-most context.

**Default Behavior**

Default value is 100.
7.2 method

See Also

These keywords may also be of interest:

- max_function_evaluations

7.2.38.12 convergence_tolerance

- Keywords Area
- method
- coliny_direct
- convergence_tolerance

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none
Argument(s): REAL
Default: 1.e-4

Description

The convergence_tolerance specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by convergence_tolerance, then this convergence criterion is satisfied on the current iteration. Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See nl2sol
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance
7.2.38.13 max_function_evaluations

- Keywords Area
- method
- coliny_direct
- max_function_evaluations

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed max_function_evaluations evaluations. See also max_iterations.

Some optimizers (e.g. ncsu_direct) may run past this limit in the course of an iteration step that began before max_function_evaluations was exceeded.

Default Behavior

Default value is 1000.

7.2.38.14 scaling

- Keywords Area
- method
- coliny_direct
- scaling

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- method_independent_controls
7.2 method

Specification

**Alias:** none

**Argument(s):** none

**Default:** no scaling

**Description**

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords `scale_types` and/or `*_scales` in the `variables` and `responses` blocks. When the `scaling` keyword is omitted from `method`, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled:

- A `*_scales` keyword, which gives characteristic values (divisors)
- A `*_scale_types` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in responses for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

**Scale Types**

There are three scale types:

1. `value` - characteristic value scaling

   The target quantity will be scaled (divided) by the specified characteristic value.

2. `auto` - automatic scaling

   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:

   - two-sided bounds scaled into the interval \([0, 1]\);
   - one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
   - no bounds or targets: no automatic scaling possible, therefore no scaling for this component

   Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into \([0, 1]\).

3. `log` - logarithmic scaling

   First, any characteristic values from the optional `*_scales` specification are applied. Then logarithm base 10 scaling is applied.

   Logarithmic scaling is not available for linear constraints.

   When continuous design variables are log scaled, linear constraints are not allowed.
Scales

The *scales* keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding *scale_types*, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- auto, log - optional
- value - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10 \times \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```plaintext
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100

responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

7.2.38.15 model_pointer

- Keywords Area
- method
- coliny_direct
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)
7.2 method

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
    0.1 0.2 0.6
    0.1 0.2 0.6
  sample_type lhs
  distribution cumulative

model
  id_model = 'SURR'
  surrogate global,
  dace_method_pointer = 'DACE'
  polynomial quadratic

method
  id_method = 'DACE'
  model_pointer = 'DACE_M'
  sampling sample_type lhs
  samples = 121 seed = 5034 rng rnum2

model
  id_model = 'DACE_M'
  single
  interface_pointer = 'I1'

variables
  uniform_uncertain = 2
  lower_bounds = 0. 0.
  upper_bounds = 1. 1.
  descriptors = 'x1' 'x2'

interface
  id_interface = 'I1'
  system asynch evaluation_concurrency = 5
  analysis_driver = 'text_book'

responses
  response_functions = 3
  no_gradients
  no_hessians
```

## Description

**Evolutionary Algorithm**

*See the page* package_scolib *for important information regarding all SCOLIB methods*

coliny_pattern_search supports concurrency up to the size of the population

The random seed control provides a mechanism for making a stochastic optimization repeatable. That is, the use of the same random seed in identical studies will generate identical results. The population_size control specifies how many individuals will comprise the EA's population.

The initialization_type defines the type of initialization for the population of the EA. There are three types: simple_random, unique_random, and flat_file. simple_random creates initial solutions with random variable values according to a uniform random number distribution. It gives no consideration to any previously generated designs. The number of designs is specified by the population_size. unique_random is the same as simple_random, except that when a new solution is generated, it is checked against the rest of the solutions. If it duplicates any of them, it is rejected. flat_file allows the initial population to be read from a flat file. If flat_file is specified, a file name must be given.
The \texttt{fitness\_type} controls how strongly differences in "fitness" (i.e., the objective function) are weighted in the process of selecting "parents" for crossover:

- the \texttt{linear\_rank} setting uses a linear scaling of probability of selection based on the rank order of each individual's objective function within the population

- the \texttt{merit\_function} setting uses a proportional scaling of probability of selection based on the relative value of each individual's objective function within the population

The \texttt{replacement\_type} controls how current populations and newly generated individuals are combined to create a new population. Each of the \texttt{replacement\_type} selections accepts an integer value, which is referred to below as the \texttt{replacement\_size}.

- The \texttt{random} setting creates a new population using (a) \texttt{replacement\_size} randomly selected individuals from the current population, and (b) \texttt{population\_size} \texttt{replacement\_size} individuals randomly selected from among the newly generated individuals (the number of which is optionally specified using \texttt{new\_solutions\_generated}) that are created for each generation (using the selection, crossover, and mutation procedures).

- The \texttt{chc} setting creates a new population using (a) the \texttt{replacement\_size} best individuals from the combination of the current population and the newly generated individuals, and (b) \texttt{population\_size} \texttt{replacement\_size} individuals randomly selected from among the remaining individuals in this combined pool. The \texttt{chc} setting is the preferred selection for many engineering problems.

- The \texttt{elitist} (default) setting creates a new population using (a) the \texttt{replacement\_size} best individuals from the current population, (b) and \texttt{population\_size} \texttt{replacement\_size} individuals randomly selected from the newly generated individuals. It is possible in this case to lose a good solution from the newly generated individuals if it is not randomly selected for replacement; however, the default \texttt{new\_solutions\_generated} value is set such that the entire set of newly generated individuals will be selected for replacement.

Note that \texttt{new\_solutions\_generated} is not recognized by Dakota as a valid keyword unless \texttt{replacement\_type} has been specified.

\textbf{Expected HDF5 Output}

If Dakota was built with HDF5 support and run with the \texttt{hdf5} keyword, this method writes the following results to HDF5:

- Best Parameters

- Best Objective Functions (when \texttt{objective\_functions} are specified)

- Best Nonlinear Constraints

- Calibration (when \texttt{calibration\_terms} are specified)

\textbf{Theory}

The basic steps of an evolutionary algorithm are depicted in Figure 5.2.
They can be enumerated as follows:

1. Select an initial population randomly and perform function evaluations on these individuals
2. Perform selection for parents based on relative fitness
3. Apply crossover and mutation to generate new solutions generated new individuals from the selected parents
   - Apply crossover with a fixed probability from two selected parents
   - If crossover is applied, apply mutation to the newly generated individual with a fixed probability
   - If crossover is not applied, apply mutation with a fixed probability to a single selected parent
4. Perform function evaluations on the new individuals
5. Perform replacement to determine the new population
6. Return to step 2 and continue the algorithm until convergence criteria are satisfied or iteration limits are exceeded

7.2.39.1 population_size

- Keywords Area
- method
Set the population size

**Specification**

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** 50

**Description**

The number of designs in the population is specified by the `population_size`.

### 7.2.39.2 initialization_type

- **Keywords Area**  
- **method**  
- **coliny_ea**  
- **initialization_type**

Specify how to initialize the population

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** unique_random

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>

<tr>
<td>unique_random</td>
<td>Create random initial solutions, but enforce uniqueness (default)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>flat_file</td>
<td>Read initial solutions from file</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Description**

The `initialization_type` defines how the initial population is created for the GA. There are three types:

1. `simple_random`
2. `unique_random` (default)
3. flat_file

Setting the size for the flat_file initializer has the effect of requiring a minimum number of designs to create. If this minimum number has not been created once the files are all read, the rest are created using the unique_random initializer and then the simple_random initializer if necessary.

7.2.39.2.1 simple_random

- Keywords Area
- method
- coliny_ea
- initialization_type
- simple_random

Create random initial solutions

Specification

Alias: none
Argument(s): none

Description

simple_random creates initial solutions with random variable values according to a uniform random number distribution. It gives no consideration to any previously generated designs.

7.2.39.2.2 unique_random

- Keywords Area
- method
- coliny_ea
- initialization_type
- unique_random

Create random initial solutions, but enforce uniqueness (default)

Specification

Alias: none
Argument(s): none

Description

unique_random is the same as simple_random, except that when a new solution is generated, it is checked against the rest of the solutions. If it duplicates any of them, it is rejected.
### flat_file

Read initial solutions from file

**Specification**

*Alias*: none

*Argument(s)*: STRING

**Description**

`flat_file` allows the initial population to be read from a flat file. If `flat_file` is specified, a file name must be given.

### fitness_type

Select fitness type

**Specification**

*Alias*: none

*Argument(s)*: none

*Default*: linear_rank

Dakota Version 6.16 Reference Manual generated on May 12, 2022
Description

The *fitness_type* controls how strongly differences in "fitness" (i.e., the objective function) are weighted in the process of selecting "parents" for crossover. It has two options, *linear_rank* and *merit_function*.

### 7.2.39.3.1 linear_rank

- **Keywords Area**
- **method**
- **coliny_ea**
- **fitness_type**
- **linear_rank**

Set selection scaling

#### Specification

**Alias**: none

**Argument(s)**: none

**Description**

The *linear_rank* setting uses a linear scaling of probability of selection based on the rank order of each individual’s objective function within the population.

### 7.2.39.3.2 merit_function

- **Keywords Area**
- **method**
- **coliny_ea**
- **fitness_type**
- **merit_function**

Balance goals of reducing objective function and satisfying constraints

#### Specification

**Alias**: none

**Argument(s)**: none

**Description**

A *merit_function* is a function in constrained optimization that attempts to provide joint progress toward reducing the objective function and satisfying the constraints.
7.2.39.4  replacement_type

- Keywords Area
- method
- coliny_ea
- replacement_type

Select a replacement type for SCOLIB evolutionary algorithm (coliny_ea)

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** elitist=1

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Required (Choose One)</strong></td>
<td>Replacement Type (Group 1)</td>
<td>random</td>
<td>Create new population randomly</td>
</tr>
<tr>
<td>chc</td>
<td>Create new population using replacement</td>
<td></td>
<td></td>
</tr>
<tr>
<td>elitist</td>
<td>Use the best designs to form a new population</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Optional</strong></td>
<td>new_solutions_generated</td>
<td>Replace population with individuals chosen from population</td>
<td></td>
</tr>
</tbody>
</table>

**Description**

The replacement_type controls how current populations and newly generated individuals are combined to create a new population. Each of the replacement_type selections accepts an associated integer value, which is specified by the replacement_size:

The random setting creates a new population using (a) replacement_size randomly selected individuals from the current population, and (b) population_size - replacement_size individuals randomly selected from among the newly generated individuals (the number of which is optionally specified using new_solutions_generated) that are created for each generation (using the selection, crossover, and mutation procedures).

The chc setting creates a new population using (a) the replacement_size best individuals from the combination of the current population and the newly generated individuals, and (b) population_size - replacement_size individuals randomly selected from among the remaining individuals in this combined pool. The chc setting is the preferred selection for many engineering problems.

The elitist (default) setting creates a new population using (a) the replacement_size best individuals from the current population, (b) and population_size - replacement_size individuals randomly selected from the newly generated individuals. It is possible in this case to lose a good solution from the newly generated individuals if it is not randomly selected for replacement; however, the default new_solutions_generated value is set such that the entire set of newly generated individuals will be selected for replacement.

Note that new_solutions_generated is not recognized by Dakota as a valid keyword unless replacement_type has been specified.
7.2 method

7.2.39.4.1 random

- Keywords Area
- method
- coliny_ea
- replacement_type
- random

Create new population randomly

Specification

Alias: none
Argument(s): INTEGER

Description

The replacement_type controls how current populations and newly generated individuals are combined to create a new population. Each of the replacement_type selections accepts an integer value, which is referred as the replacement_size:

The random setting creates a new population using:

- replacement_size randomly selected individuals from the current population, and
- population_size - replacement_size individuals randomly selected from among the newly generated individuals (the number of which is optionally specified using new_solutions_generated) that are created for each generation (using the selection, crossover, and mutation procedures).

7.2.39.4.2 chc

- Keywords Area
- method
- coliny_ea
- replacement_type
- chc

Create new population using replacement

Specification

Alias: none
Argument(s): INTEGER
Description

The replacement_type controls how current populations and newly generated individuals are combined to create a new population. Each of the replacement_type selections accepts an integer value, which is referred as the replacement_size:

The chc setting creates a new population using (a) the replacement_size best individuals from the combination of the current population and the newly generated individuals, and (b) population_size - replacement_size individuals randomly selected from among the remaining individuals in this combined pool. The chc setting is the preferred selection for many engineering problems.

7.2.39.4.3 elitist

- Keywords Area
- method
- coliny_ea
- replacement_type
- elitist

Use the best designs to form a new population

Specification

Alias: none

Argument(s): INTEGER

Description

The elitist (default) setting creates a new population using (a) the replacement_size best individuals from the current population, (b) and population_size - replacement_size individuals randomly selected from the newly generated individuals. It is possible in this case to lose a good solution from the newly generated individuals if it is not randomly selected for replacement; however, the default new_solutions_generated value is set such that the entire set of newly generated individuals will be selected for replacement.

7.2.39.4.4 new_solutions_generated

- Keywords Area
- method
- coliny_ea
- replacement_type
- new_solutions_generated

Replace population with individuals chosen from population

Specification

Alias: none

Argument(s): INTEGER

Default: population_size - replacement_size
7.2 method

Description

- The random setting creates a new population using (a) \( \text{replacement\_size} \) randomly selected individuals from the current population, and (b) \( \text{population\_size} \cdot \text{replacement\_size} \) individuals randomly selected from among the newly generated individuals (the number of which is optionally specified using \( \text{new\_solutions\_generated} \)) that are created for each generation (using the selection, crossover, and mutation procedures).

7.2.39.5 crossover_rate

- Keywords Area

- method

- coliny_ea

- crossover_rate

Specify the probability of a crossover event

Specification

Alias: none

Argument(s): REAL

Default: 0.8

Description

The crossover_type controls what approach is employed for combining parent genetic information to create offspring, and the crossover_rate specifies the probability of a crossover operation being performed to generate a new offspring. The SCOLIB EA method supports three forms of crossover, two_point, blend, and uniform, which generate a new individual through combinations of two parent individuals. Two-point crossover divides each parent into three regions, where offspring are created from the combination of the middle region from one parent and the end regions from the other parent. Since the SCOLIB EA does not utilize bit representations of variable values, the crossover points only occur on coordinate boundaries, never within the bits of a particular coordinate. Uniform crossover creates offspring through random combination of coordinates from the two parents. Blend crossover generates a new individual randomly along the multidimensional vector connecting the two parents.

7.2.39.6 crossover_type

- Keywords Area

- method

- coliny_ea

- crossover_type

Select a crossover type
Specification

Alias: none
Argument(s): none
Default: two_point
Child Keywords:
<table>
<thead>

<tr>
<td></td>
<td></td>
<td>uniform</td>
<td>Randomly combine coordinates from parents</td>
</tr>
</tbody>
</table>

**Description**

The `crossover_type` controls what approach is employed for combining parent genetic information to create offspring. The SCOLIB EA method supports three forms of crossover, `two_point`, `blend`, and `uniform`, which generate a new individual through combinations of two parent individuals.

### 7.2.39.6.1 two_point

- **Keywords Area**
- **method**
- **coliny_ea**
- **crossover_type**
- **two_point**

Combine middle of one parent with end of another

**Specification**

**Alias**: none

**Argument(s)**: none

**Description**

Two-point crossover divides each parent into three regions, where offspring are created from the combination of the middle region from one parent and the end regions from the other parent. Since the SCOLIB EA does not utilize bit representations of variable values, the crossover points only occur on coordinate boundaries, never within the bits of a particular coordinate.

### 7.2.39.6.2 blend

- **Keywords Area**
- **method**
- **coliny_ea**
- **crossover_type**
- **blend**

Random blend of parents
Specification

**Alias:** none  
**Argument(s):** none

Description

`blend` crossover generates a new individual randomly along the multidimensional vector connecting the two parents.

7.2.39.6.3 uniform

- **Keywords Area**
- **method**
- **coliny_ea**
- **crossover_type**
- **uniform**

Randomly combine coordinates from parents

Specification

**Alias:** none  
**Argument(s):** none

Description

Uniform crossover creates offspring through random combination of coordinates from the two parents.

7.2.39.7 mutation_rate

- **Keywords Area**
- **method**
- **coliny_ea**
- **mutation_rate**

Set probability of a mutation

Specification

**Alias:** none  
**Argument(s):** REAL  
**Default:** 1.0
Description

The *mutation_rate* controls the probability of mutation being performed on an individual, both for new individuals generated by crossover (if crossover occurs) and for individuals from the existing population. It is the fraction of trial points that are mutated in a given iteration and therefore must be specified to be between 0 and 1.

### 7.2.39.8 mutation_type

- **Keywords Area**
  - method
  - coliny_ea
  - mutation_type

Select a mutation type

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** offset_normal

#### Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>

<td></td>
<td></td>
<td>offset_uniform</td>
<td>Set mutation offset to use a uniform distribution</td>
</tr>
<tr>
<td>Optional</td>
<td>non_adaptive</td>
<td>non_adaptive</td>
<td>Disable self-adaptive mutation</td>
</tr>
</tbody>
</table>

**Description**

The *mutation_type* controls what approach is employed in randomly modifying continuous design variables within the EA population. Each of the mutation methods generates coordinate-wise changes to individuals, usually by adding a random variable to a given coordinate value (an *offset_* mutation), but also by replacing a given coordinate value with a random variable (a *replace_* mutation).

Discrete design variables are always mutated using the *offset_uniform* method.

### 7.2.39.8.1 replace_uniform

- **Keywords Area**
  - method
Replace coordinate with randomly generated value

Specification

Alias: none
Argument(s): none

Description

The replace_uniform mutation type generates a replacement value for a coordinate using a uniformly distributed value over the total range for that coordinate.

7.2.39.8.2 offset_normal

Set mutation offset to use a normal distribution

Specification

Alias: none
Argument(s): none

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>mutation_scale</td>
<td>Scales mutation across range of parameter</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>mutation_range</td>
<td>Set uniform offset control for discrete parameters</td>
</tr>
</tbody>
</table>

Description

The offset_normal type is an "offset" mutation that adds a 0-mean random variable with a normal uniform distribution to the existing coordinate value. The offset is limited in magnitude by mutation_scale.
7.2 method

7.2.39.8.2.1  mutation_scale

• Keywords Area
• method
• coliny_ea
• mutation_type
• offset_normal
• mutation_scale

Scales mutation across range of parameter

Specification

Alias: none
Argument(s): REAL
Default: 0.1

Description

The mutation_scale specifies a scale factor which scales continuous mutation offsets; this is a fraction of the total range of each dimension, so mutation_scale is a relative value between 0 and 1.

7.2.39.8.2.2  mutation_range

• Keywords Area
• method
• coliny_ea
• mutation_type
• offset_normal
• mutation_range

Set uniform offset control for discrete parameters

Specification

Alias: none
Argument(s): INTEGER
Default: 1

Description

The mutation_range is used to control offset_uniform mutation used for discrete parameters. The replacement discrete value is the original value plus or minus an integer value up to mutation_range.
Use a Cauchy distribution for the mutation offset

**Specification**

**Alias:** none  
**Argument(s):** none

<table>

Description

The `mutation_range` is used to control `offset_uniform` mutation used for discrete parameters. The replacement discrete value is the original value plus or minus an integer value up to `mutation_range`.

7.2.39.8.4 `offset_uniform`

- Keywords Area
- `method`
- `coliny_ea`
- `mutation_type`
- `offset_uniform`

Set mutation offset to use a uniform distribution

Specification

Alias: none

Argument(s): none

Child Keywords:
### Description

The **offset_uniform** type is an "offset" mutation that adds a 0-mean random variable with a uniform distribution to the existing coordinate value. The offset is limited in magnitude by **mutation_scale**.

For discrete design variables, **offset_uniform** is always used, and **mutation_range** controls the magnitude of the mutation.

#### 7.2.39.8.4.1 mutation_scale
- **Keywords Area**
- **method**
- **coliny_ea**
- **mutation_type**
- **offset_uniform**
- **mutation_scale**

Scales mutation across range of parameter

#### Specification

**Alias**: none

**Argument(s)**: REAL

**Default**: 0.1

#### Description

The **mutation_scale** specifies a scale factor which scales continuous mutation offsets; this is a fraction of the total range of each dimension, so **mutation_scale** is a relative value between 0 and 1.

#### 7.2.39.8.4.2 mutation_range
- **Keywords Area**
- **method**
- **coliny_ea**
- **mutation_type**
- **offset_uniform**
- **mutation_range**

Set uniform offset control for discrete parameters
7.2 method

Specification

Alias: none
Argument(s): INTEGER
Default: 1

Description

The mutation_range is used to control offset_uniform mutation used for discrete parameters. The replacement discrete value is the original value plus or minus an integer value up to mutation_range.

7.2.39.8.5 non_adaptive

- Keywords Area
- method
- coliny_ea
- mutation_type
- non_adaptive

Disable self-adaptive mutation

Specification

Alias: none
Argument(s): none
Default: Adaptive mutation

Description

The SCOLIB EA method uses self-adaptive mutation, which modifies the mutation scale dynamically. This mechanism is borrowed from EAs like evolution strategies. The non_adaptive flag can be used to deactivate the self-adaptation, which may facilitate a more global search.

Note that non_adaptive is not recognized by Dakota as a valid keyword unless mutation_type has been specified.

7.2.39.9 constraint_penalty

- Keywords Area
- method
- coliny_ea
- constraint_penalty

Multiplier for the penalty function

Specification

Alias: none
Argument(s): REAL

Dakota Version 6.16 Reference Manual generated on May 12, 2022
Most SCOLIB optimizers treat constraints with a simple penalty scheme that adds $\text{constraint\_penalty}$ times the sum of squares of the constraint violations to the objective function. The default value of $\text{constraint\_penalty}$ is 1000.0, except for methods that dynamically adapt their constraint penalty, for which the default value is 1.0.

7.2.39.10 solution_target

- Keywords Area
- method
- coliny_ea
- solution_target

Stopping criteria based on objective function value

Specification

Alias: solution_accuracy
Argument(s): REAL
Default: -DBL_MAX

Description

solution_target is a termination criterion. The algorithm will terminate when the function value falls below solution_target.

7.2.39.11 seed

- Keywords Area
- method
- coliny_ea
- seed

Seed of the random number generator

Specification

Alias: none
Argument(s): INTEGER
Default: system-generated (non-repeatable)
Description

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

```plaintext
method
    sampling
        sample_type lhs
        samples = 10
        seed = 15347
```

7.2.39.12 show_misc_options

- Keywords Area
- method
- coliny_ea
- show_misc_options

Show algorithm parameters not exposed in Dakota input

Specification

**Alias:** none

**Argument(s):** none

**Default:** no dump of specification options

Description

All SCOLIB methods support the show_misc_options optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The misc_options optional specification provides a means for inputting additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.
7.2.39.13 misc_options

- Keywords Area
- method
- coliny_ea
- misc_options

Set method options not available through Dakota spec

**Specification**

**Alias:** none

**Argument(s):** STRINGLIST

**Default:** no misc options

**Description**

All SCOLIB methods support the `show_misc_options` optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The `misc_options` optional specification provides a means for inputting additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

7.2.39.14 max_iterations

- Keywords Area
- method
- coliny_ea
- max_iterations

Number of iterations allowed for optimizers and adaptive UQ methods

**Topics**

This keyword is related to the topics:

- method_independent_controls

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 100 (exceptions: fsu_cvt, local_reliability: 25; global_{reliability, interval_est, evidence} / efficient_global: 25×n)
Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed $\text{max\_iterations}$ iterations. In cases where there are multiple nested iterations to be controlled, $\text{max\_iterations}$ generally controls the outer-most context.

Default Behavior
Default value is 100.

See Also

These keywords may also be of interest:

- $\text{max\_function\_evaluations}$

7.2.39.15 convergence_tolerance

- Keywords Area
- method
- coliny_ea
- convergence_tolerance

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- $\text{method\_independent\_controls}$

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The convergence_tolerance specification provides a real value for controlling the termination of iteration.

For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by convergence_tolerance, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Libary

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.
Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See nl2sol
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

7.2.39.16 max_function_evaluations

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none
Argument(s): INTEGER
Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed max_function_evaluations evaluations. See also max_iterations.

Some optimizers (e.g. ncsu_direct) may run past this limit in the course of an iteration step that began before max_function_evaluations was exceeded.

Default Behavior

Default value is 1000.

7.2.39.17 scaling

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none
Argument(s): DOUBLE
Default: 1.0

Description

The scaling keyword is used to scale the initial guess for the optimization problem. This can be useful for problems with vastly different scales. The scaling factor is applied to the initial guess for each variable in the optimization problem.

Some optimizers (e.g. ncsu_direct) may run past this limit in the course of an iteration step that began before max_function_evaluations was exceeded.

Default Behavior

Default value is 1.0.
• **scaling**

Turn on scaling for variables, responses, and constraints

**Topics**

This keyword is related to the topics:

• method_independent_controls

**Specification**

**Alias**: none  
**Argument(s)**: none  
**Default**: no scaling

**Description**

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords `scale_types` and/or `*scales` in the `variables` and `responses` blocks. When the `scaling` keyword is omitted from `method`, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

- a `*scales` keyword, which gives characteristic values (divisors)
- a `*scale_types` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in `responses` for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

**Scale Types**

There are three scale types:

1. **value** - characteristic value scaling  
   - The target quantity will be scaled (divided) by the specified characteristic value.

2. **auto** - automatic scaling  
   - First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
     - two-sided bounds scaled into the interval [0,1];
     - one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into \([0,1]\).

3. \(\log\) - logarithmic scaling

First, any characteristic values from the optional \(\ast\_\text{scales}\) specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints. When continuous design variables are log scaled, linear constraints are not allowed.

**Scales**

The \(\ast\_\text{scales}\) keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding \(\ast\_\text{scale\_types}\), as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- **auto, log** - optional
- **value** - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than \(1.0\ast\text{DBL\_MIN}\). User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

**Examples**

The two examples below are equivalent:

```dakota
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100

responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

7.2.39.18 \texttt{model\_pointer}

- **Keywords Area**
- **method**
- **coliny\_ea**
- **model\_pointer**

Identifier for model block to be used by a method

**Topics**

This keyword is related to the topics:

- **block\_pointer**
7.2 method

Specification

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)

**Description**

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

**Default Behavior**

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

**Usage Tips**

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

**Examples**

```plaintext
environment
   tabular_data
   method_pointer = 'UQ'

method
   id_method = 'UQ'
   model_pointer = 'SURR'
   sampling,
      samples = 10

| Optional          | misc_options     | Set method options not available through Dakota spec |
### Description

This method keyword allows testing of experimental (beta) Coliny (Scolib) optimization solvers during software development. It is intended primarily for developer use. Additional information on Coliny solvers is available at package_scolib.

### See Also

These keywords may also be of interest:

- `coliny_direct`
- `coliny_pattern_search`
- `coliny_cobyla`
- `coliny_ea`
- `coliny_solis_wets`

#### 7.2.40.1 beta_solver_name

- Keywords Area
- method
- `coliny_beta`
- `beta_solver_name`

Use an in-development SCOLIB solver
Specifications

Alias: none
Argument(s): STRING

Description

This is a means of accessing new methods in SCOLIB before they are exposed through the Dakota interface. Seek help from a Dakota or SCOLIB developer or a Dakota developer.

7.2.40.2 solution_target

- Keywords Area
- method
- coliny_beta
- solution_target

Stopping criteria based on objective function value

Specifications

Alias: solution_accuracy
Argument(s): REAL
Default: -DBL_MAX

Description

solution_target is a termination criterion. The algorithm will terminate when the function value falls below solution_target.

7.2.40.3 seed

- Keywords Area
- method
- coliny_beta
- seed

Seed of the random number generator

Specifications

Alias: none
Argument(s): INTEGER
Default: system-generated (non-repeatable)
Description

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347

7.2.40.4 show_misc_options

- Keywords Area
- method
- coliny_beta
- show_misc_options

Show algorithm parameters not exposed in Dakota input

Specification

Alias: none

Argument(s): none

Default: no dump of specification options

Description

All SCOLIB methods support the show_misc_options optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The misc_options optional specification provides a means for inputting additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.
7.2.40.5 misc_options

- Keywords Area
- method
- coliny_beta
- misc_options

Set method options not available through Dakota spec

**Specification**

**Alias:** none  
**Argument(s):** STRINGLIST  
**Default:** no misc options

**Description**

All SCOLIB methods support the `show_misc_options` optional specification which results in a dump of all the allowable method inputs. Note that the information provided by this command refers to optimizer parameters that are internal to SCOLIB, and which may differ from corresponding parameters used by the Dakota interface. The `misc_options` optional specification provides a means for inputing additional settings supported by the SCOLIB methods but which are not currently mapped through the Dakota input specification. Care must be taken in using this specification; they should only be employed by users familiar with the full range of parameter specifications available directly from SCOLIB and understand any differences that exist between those specifications and the ones available through Dakota.

7.2.40.6 max_iterations

- Keywords Area
- method
- coliny_beta
- max_iterations

Number of iterations allowed for optimizers and adaptive UQ methods

**Topics**

This keyword is related to the topics:

- method_independent_controls

**Specification**

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** 100 (exceptions: fsu_cvt , local_reliability: 25; global_{reliability , interval_est , evidence} / efficient_global: 25+n)
Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed \( \text{max\_iterations} \) iterations. In cases where there are multiple nested iterations to be controlled, \( \text{max\_iterations} \) generally controls the outer-most context.

Default Behavior

Default value is 100.

See Also

These keywords may also be of interest:

- \( \text{max\_function\_evaluations} \)

7.2.40.7 convergence_tolerance

- Keywords Area
- method
- coliny_beta
- convergence_tolerance

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- method\_independent\_controls

Specification

\textbf{Alias}: none

\textbf{Argument(s)}: REAL

\textbf{Default}: 1.e-4

Description

The \texttt{convergence\_tolerance} specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a \textit{relative convergence tolerance} for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by \texttt{convergence\_tolerance}, then this convergence criterion is satisfied on the current iteration. Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.
Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

• DOT: relative tolerance that must be satisfied for two consecutive iterations
• NL2SOL: See nl2sol
• NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
• NPSOL: used as a line search tolerance, not as a relative convergence tolerance

7.2.40.8 max_function_evaluations

• Keywords Area
• method
• coliny_beta
• max_function_evaluations

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

• method_independent_controls

Specification

Alias: none
Argument(s): INTEGER
Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed max_function_evaluations evaluations. See also max_iterations.

Some optimizers (e.g. ncsu_direct) may run past this limit in the course of an iteration step that began before max_function_evaluations was exceeded.

Default Behavior

Default value is 1000.

7.2.40.9 scaling

• Keywords Area
• method
• coliny_beta
7.2 method

- scaling

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the scaling keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords scale_types and/or ∗scales in the variables and responses blocks. When the scaling keyword is omitted from method, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

• a ∗scales keyword, which gives characteristic values (divisors)

• a ∗scale_types keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in responses for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are three scale types:

1. value - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.

2. auto - automatic scaling
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   • two-sided bounds scaled into the interval [0,1];
   • one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into \([0,1]\).

3. **log** - logarithmic scaling

   First, any characteristic values from the optional *scales* specification are applied. Then logarithm base 10 scaling is applied.

   Logarithmic scaling is not available for linear constraints.

   When continuous design variables are log scaled, linear constraints are not allowed.

### Scales

The *scales* keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding *scale_types*, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- **auto, log** - optional
- **value** - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than \(1.0\times 10^{10}\). User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

### Examples

The two examples below are equivalent:

```
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100

responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

### 7.2.40.10 model_pointer

- **Keywords Area**
- **method**
- **coliny_beta**
- **model_pointer**

Identifier for model block to be used by a method

### Topics

This keyword is related to the topics:

- **block_pointer**
7.2 method

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

Examples

```
environment
tabular_data
method_pointer = 'UQ'

method
id_method = 'UQ'
model_pointer = 'SURR'
sampling,
samples = 10
seed = 98765 rng rnum2
response_levels = 0.1 0.2 0.6
                   0.1 0.2 0.6
                   0.1 0.2 0.6
sample_type lhs
distribution cumulative

model
id_model = 'SURR'
surrogate global,
dace_method_pointer = 'DACE'
   polynomial quadratic

method
id_method = 'DACE'
model_pointer = 'DACE_M'
sampling sample_type lhs
samples = 121 seed = 5034 rng rnum2

model
id_model = 'DACE_M'
single
interface_pointer = 'I1'

variables
uniform_uncertain = 2
   lower_bounds = 0. 0.
   upper_bounds = 1. 1.
descriptors = 'x1' 'x2'

interface
id_interface = 'I1'
system asynch evaluation_concurrency = 5
```
analysis_driver = 'text_book'

responses
response_functions = 3
no_gradients
no_hessians

7.2.41 nl2sol

- Keywords Area
- method
- nl2sol

Trust-region method for nonlinear least squares

Topics

This keyword is related to the topics:

- nonlinear_least_squares

Description

NL2SOL is available as nl2sol and addresses unconstrained and bound-constrained least squares problems. It uses a trust-region method (and thus can be viewed as a generalization of the Levenberg-Marquardt algorithm) and adaptively chooses between two Hessian approximations, the Gauss-Newton approximation alone and the Gauss-Newton approximation plus a quasi-Newton approximation to the rest of the Hessian. Even on small-residual problems, the latter Hessian approximation can be useful when the starting guess is far from the solution. On problems that are not over-parameterized (i.e., that do not involve more optimization variables than the data support), NL2SOL usually exhibits fast convergence.

Several internal NL2SOL convergence tolerances are adjusted in response to function_precision, which gives the relative precision to which responses are computed. These tolerances may also be specified explicitly using:

- `convergence_tolerance` (NL2SOL's `rfctol`)
- `x_conv_tol` (NL2SOL's `xctol`)
- `absolute_conv_tol` (NL2SOL's `afctol`)
- `singular_conv_tol` (NL2SOL's `sctol`)
- `false_conv_tol` (NL2SOL's `xftol`)
- `initial_trust_radius` (NL2SOL's `lmax0`)

The internal NL2SOL defaults can be obtained for many of these controls by specifying the value -1. The internal defaults are often functions of machine epsilon (as limited by function_precision).
Expected HDF5 Output

If Dakota was built with HDF5 support and run with the hdf5 keyword, this method writes the following results to HDF5:

- Best Parameters
- Best Nonlinear Constraints
- Calibration (when calibration_terms are specified)
- Parameter Confidence Intervals (when num_experiments equals 1)

Examples

An example of nl2sol is given below, and is discussed in the User’s Manual.

Note that in this usage of calibration_terms, the driver script rosenbrock, is returning "residuals", which the nl2sol method is attempting to minimize. Another use case is to provide a data file, which Dakota will attempt to match the model responses to. See calibration_data_file. Finally, as of Dakota 6.2, the field data capability may be used with nl2sol. That is, the user can specify field simulation data and field experiment data, and Dakota will interpolate and provide the proper residuals for the calibration.

```
# Dakota Input File: rosen_opt_nls.in
environment
  tabular_data
    tabular_data_file = 'rosen_opt_nls.dat'

method
  max_iterations = 100
  convergence_tolerance = 1e-4
  nl2sol

    descriptors 'x1' "x2"

interface
  analysis_driver = 'rosenbrock'
  direct

responses
  calibration_terms = 2
  analytic_gradients
  no_hessians
```

Theory

NL2SOL has a variety of internal controls as described in AT&T Bell Labs CS TR 153 (http://cm.bell-labs.com/cm/cs/cstr/153.ps.gz). A number of existing Dakota controls (method independent controls and responses controls) are mapped into these NL2SOL internal controls. In particular, Dakota’s convergence_tolerance, max_iterations, max_function_evaluations, and fd_gradient_step_size are mapped directly into NL2SOL’s rfctol, mxiter, mxfcal, and dltdfdj controls, respectively. In addition, Dakota’s fd_hessian_step_size is mapped into both delta0 and dltdfdc, and Dakota’s output verbosity is mapped into NL2SOL’s auxpr and outlev (for normal/verbose/debug output, NL2SOL prints initial guess, final solution, solution statistics, non-default values, and changes to the active bound constraint set on every iteration; for quiet output, NL2SOL prints only the initial guess and final solution; and for silent output, NL2SOL output is suppressed).

7.2.41.1 function_precision

Specify the maximum precision of the analysis code responses

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 1.0e-10

**Description**

The `function_precision` control provides the algorithm with an estimate of the accuracy to which the problem functions can be computed. This is used to prevent the algorithm from trying to distinguish between function values that differ by less than the inherent error in the calculation.

7.2.41.2 absolute_conv_tol

Absolute convergence tolerance

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** -1. (use NL2SOL internal default)
**Description**

*absolute_conv_tol* (NL2SOL’s *afctol*) is the absolute function convergence tolerance (stop when half the sum of squares is less than *absolute_conv_tol*, which is mainly of interest on zero-residual test problems).

The internal default is a function of machine epsilon (as limited by *function_precision*). The default is selected with a value of -1.

---

### 7.2.41.3  x_conv_tol

- **Keywords Area**
- **method**
- **nl2sol**
- **x_conv_tol**

X-convergence tolerance

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** -1. (use NL2SOL internal default)

**Description**

*x_conv_tol* maps to the internal NL2SOL control *xctol*. It is the X-convergence tolerance (scaled relative accuracy of the solution variables).

The internal default is a function of machine epsilon (as limited by *function_precision*). The default is selected with a value of -1.

---

### 7.2.41.4  singular_conv_tol

- **Keywords Area**
- **method**
- **nl2sol**
- **singular_conv_tol**

Singular convergence tolerance

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** -1. (use NL2SOL internal default)
Description

`singular_conv_tol` (NL2SOL's `sctol`) is the singular convergence tolerance, which works in conjunction with `singular_radius` to test for underdetermined least-squares problems (stop when the relative reduction yet possible in the sum of squares appears less than `singular_conv_tol` for steps of scaled length at most `singular_radius`).

The internal default is a function of machine epsilon (as limited by `function_precision`). The default is selected with a value of -1.

7.2.41.5 `singular_radius`

- Keywords Area
- method
- nl2sol
- `singular_radius`

Singular radius

Specification

Alias: none

Argument(s): REAL

Default: -1. (use NL2SOL internal default of 1)

Description

`singular_radius` works in conjunction with `singular_conv_tol` to test for underdetermined least-squares problems (stop when the relative reduction yet possible in the sum of squares appears less than `singular_conv_tol` for steps of scaled length at most `singular_radius`).

The internal default results in the internal use of steps of length 1. The default is selected with a value of -1.

7.2.41.6 `false_conv_tol`

- Keywords Area
- method
- nl2sol
- `false_conv_tol`

False convergence tolerance

Specification

Alias: none

Argument(s): REAL

Default: -1. (use NL2SOL internal default)
false_conv_tol (NL2 SOL's xftol) is the false-convergence tolerance (stop with a suspicion of discontinuity when a more favorable stopping test is not satisfied and a step of scaled length at most false_conv_tol is not accepted).

The internal default is a function of machine epsilon (as limited by function_precision). The default is selected with a value of -1.

### 7.2.41.7 initial_trust_radius

- **Keywords Area**
- **method**
- **nl2sol**
- **initial_trust_radius**

Initial trust region radius

**Specification**

**Alias:** none  
**Argument(s):** REAL  
**Default:** -1. (use NL2SOL internal default of 1)

**Description**

initial_trust_radius specification (NL2SOL's lmax0) specifies the initial trust region radius for the algorithm.

The internal default results in the internal use of steps of length 1. The default is selected with a value of -1.

### 7.2.41.8 covariance

- **Keywords Area**
- **method**
- **nl2sol**
- **covariance**

Determine how the final covariance matrix is computed

**Specification**

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** 0 (no covariance)
7.2 method

Description

covariance (NL2SOL's covreq) specifies whether and how NL2SOL computes a final covariance matrix.

The desired covariance approximation:

- 0 = default = none
- 1 or -1 ==> $\sigma^2 H^{-1} J^T J H^{-1}$
- 2 or -2 ==> $\sigma^2 H^{-1}$
- 3 or -3 ==> $\sigma^2 (J^T J)^{-1}$
- Negative values ==> estimate the final Hessian H by finite differences of function values only (using fd_hessian_step_size)
- Positive values ==> differences of gradients (using fd_hessian_step_size)

7.2.41.9 regression_diagnostics

- Keywords Area
- method
- nl2sol
- regression_diagnostics

Turn on regression diagnostics

Specification

Alias: none
Argument(s): none
Default: no regression diagnostics

Description

When regression_diagnostics (NL2SOL's rdreq) is specified and a positive-definite final Hessian approximation H is computed, NL2SOL computes and prints a regression diagnostic vector RD such that if omitting the i-th observation would cause alpha times the change in the solution that omitting the j-th observation would cause, then RD[i] = |alpha| RD[j]. The finite-difference step-size tolerance affecting H is fd_step_size (NL2SOL's delta0 and dltfdc).

7.2.41.10 convergence_tolerance

- Keywords Area
- method
- nl2sol
- convergence_tolerance

Stopping criterion based on objective function or statistics convergence
Topics

This keyword is related to the topics:

• method_independent_controls

Specification

Alias: none
Argument(s): REAL
Default: 1.e-4

Description

The convergence_tolerance specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by convergence_tolerance, then this convergence criterion is satisfied on the current iteration. Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

• DOT: relative tolerance that must be satisfied for two consecutive iterations
• NL2SOL: See nl2sol
• NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
• NPSOL: used as a line search tolerance, not as a relative convergence tolerance

7.2.41.11 max_iterations

• Keywords Area
• method
• nl2sol
• max_iterations

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

• method_independent_controls
7.2 method

Specification

Alias: none
Argument(s): INTEGER
Default: 100 (exceptions: fsu_cvt, local_reliability: 25; global_(reliability, interval_est, evidence) / efficient_global: 25×n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed \( \text{max\_iterations} \) iterations. In cases where there are multiple nested iterations to be controlled, \( \text{max\_iterations} \) generally controls the outer-most context.

Default Behavior

Default value is 100.

See Also

These keywords may also be of interest:

- \( \text{max\_function\_evaluations} \)

7.2.41.12 speculative

- Keywords Area
- method
- nl2sol
- speculative

Compute speculative gradients

Topics

This keyword is related to the topics:

- \( \text{method\_independent\_controls} \)

Specification

Alias: none
Argument(s): none
Default: no speculation

Description

When performing gradient-based optimization in parallel, speculative gradients can be selected to address the load imbalance that can occur between gradient evaluation and line search phases. In a typical gradient-based
optimization, the line search phase consists primarily of evaluating the objective function and any constraints at a trial point, and then testing the trial point for a sufficient decrease in the objective function value and/or constraint violation. If a sufficient decrease is not observed, then one or more additional trial points may be attempted successively. However, if the trial point is accepted then the line search phase is complete and the gradient evaluation phase begins. By speculating that the gradient information associated with a given line search trial point will be used later, additional coarse grained parallelism can be introduced by computing the gradient information (either by finite difference or analytically) in parallel, at the same time as the line search phase trial-point function values. This balances the total amount of computation to be performed at each design point and allows for efficient utilization of multiple processors. While the total amount of work performed will generally increase (since some speculative gradients will not be used when a trial point is rejected in the line search phase), the run time will usually decrease (since gradient evaluations needed at the start of each new optimization cycle were already performed in parallel during the line search phase). Refer to [13] for additional details. The speculative specification is implemented for the gradient-based optimizers in the DOT, CONMIN, and OPT++ libraries, and it can be used with dakota numerical or analytic gradient selections in the responses specification (refer to responses gradient section for information on these specifications). It should not be selected with vendor numerical gradients since vendor internal finite difference algorithms have not been modified for this purpose. In full-Newton approaches, the Hessian is also computed speculatively. NPSOL and NLSSOL do not support speculative gradients, as their gradient-based line search in user-supplied gradient mode (dakota numerical or analytic gradients) is a superior approach for load-balanced parallel execution.

The speculative specification enables speculative computation of gradient and/or Hessian information, where applicable, for parallel optimization studies. By speculating that the derivative information at the current point will be used later, the complete data set (all available gradient/Hessian information) can be computed on every function evaluation. While some of these computations will be wasted, the positive effects are a consistent parallel load balance and usually shorter wall clock time. The speculative specification is applicable only when parallelism in the gradient calculations can be exploited by Dakota (it will be ignored for vendor numerical gradients).

7.2.41.13 max_function_evaluations

- Keywords Area
- method
- nl2sol
- max_function_evaluations

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed max_function_evaluations evaluations. See also max_iterations.
Some optimizers (e.g., ncsu_direct) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

**Default Behavior**
Default value is 1000.

### 7.2.41.14 scaling

- **Keywords Area**
- **method**
- **nl2sol**
- **scaling**

Turn on scaling for variables, responses, and constraints

**Topics**

This keyword is related to the topics:

- **method_independent_controls**

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** no scaling

**Description**

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords `scale_types` and/or `scales` in the `variables` and `responses` blocks. When the `scaling` keyword is omitted from `method`, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

- a `scales` keyword, which gives characteristic values (divisors)
- a `scale_types` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in `responses` for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

**Scale Types**

There are three scale types:
1. **value** - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.

2. **auto** - automatic scaling
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   - two-sided bounds scaled into the interval [0,1];
   - one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
   - no bounds or targets: no automatic scaling possible, therefore no scaling for this component

   Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

3. **log** - logarithmic scaling
   First, any characteristic values from the optional *_scales specification are applied. Then logarithm base 10 scaling is applied.
   Logarithmic scaling is not available for linear constraints.
   When continuous design variables are log scaled, linear constraints are not allowed.

**Scales**
The *scales keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding *scale_types, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- **auto, log** - optional
- **value** - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than 1.0e10*DBL_MIN. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

**Examples**
The two examples below are equivalent:

```plaintext
responses
objective_functions 3
sense "maximize"
primary_scale_types = "value"
primary_scales = 1 1 100

responses
objective_functions 3
sense "maximize"
primary_scale_types = "value" "value" "value"
primary_scales = 1 1 100
```

7.2.41.15 model_pointer

- Keywords Area
- method
7.2 method

- nl2sol
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.

See block_pointer for details about pointers.

Examples

```
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
    0.1 0.2 0.6
    0.1 0.2 0.6
  sample_type lhs
  distribution cumulative

model
  id_model = 'SURR'
  surrogate global,
  dace_method_pointer = 'DACE'
  polynomial quadratic

method
  id_method = 'DACE'
```
model_pointer = 'DACE_M'
sampling sample_type lhs
samples = 121 seed = 5034 rng rnum2

model
  id_model = 'DACE_M'
single
  interface_pointer = 'I1'

variables
  uniform_uncertain = 2
  lower_bounds = 0. 0.
  upper_bounds = 1. 1.
  descriptors = 'x1' 'x2'

interface
  id_interface = 'I1'
  system asynch evaluation_concurrency = 5
  analysis_driver = 'text_book'

responses
  response_functions = 3
  no_gradients
  no_hessians

7.2.42 nonlinear_cg

- Keywords Area

- method

- nonlinear_cg

(Experimental) nonlinear conjugate gradient optimization

Topics

This keyword is related to the topics:

- local_optimization_methods

Specification

Alias: none

Argument(s): none

### Description

This method is an incomplete experimental implementation of nonlinear conjugate gradient optimization, a local, gradient-based solver.

#### 7.2.42.1 misc_options

- **Keywords Area**
  - method
  - nonlinear_cg
  - misc_options

Options for nonlinear CG optimizer

### Specification

**Alias:** none

**Argument(s):** STRINGLIST

**Default:** no misc options

### Description

List of miscellaneous string options to pass to the experimental nonlinear CG solver (see NonlinearCGOptimizer.cpp in the Dakota source code for available controls). Includes controls for step sizes, linesearch control, convergence, etc.
7.2.42.2 convergence_tolerance

- Keywords Area
- method
- nonlinear_cg
- convergence_tolerance

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): REAL

Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by convergence_tolerance, then this convergence criterion is satisfied on the current iteration. Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do. Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See nl2sol
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

7.2.42.3 max_iterations

- Keywords Area
- method
7.2 method

- nonlinear_cg
- max_iterations

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** 100 (exceptions: fsu_cvt, local_reliability: 25; global (reliability , interval_est , evidence) / efficient_global: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed \( \text{max_iterations} \) iterations. In cases where there are multiple nested iterations to be controlled, \( \text{max_iterations} \) generally controls the outer-most context.

**Default Behavior**

Default value is 100.

See Also

These keywords may also be of interest:

- max_function_evaluations

7.2.42.4 scaling

- Keywords Area
- method
- nonlinear_cg
- scaling

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- method_independent_controls
Specification

Alias: none
Argument(s): none
Default: no scaling

Description

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the `scaling` keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords `scale_types` and/or `*_scales` in the `variables` and `responses` blocks. When the `scaling` keyword is omitted from `method`, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

- a `*_scales` keyword, which gives characteristic values (divisors)
- a `*_scale_types` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in `responses` for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are three scale types:

1. **value** - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.

2. **auto** - automatic scaling
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   - two-sided bounds scaled into the interval [0,1];
   - one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
   - no bounds or targets: no automatic scaling possible, therefore no scaling for this component

   Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

3. **log** - logarithmic scaling
   First, any characteristic values from the optional `*_scales` specification are applied. Then logarithm base 10 scaling is applied.
   Logarithmic scaling is not available for linear constraints.

   When continuous design variables are log scaled, linear constraints are not allowed.
Scales

The `scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `scale_types`, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- `auto, log` - optional
- `value` - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than `1.0e10*DBL_MIN`. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```plaintext
responses objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100

responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

7.2.42.5 model_pointer

- Keywords Area
- method
- nonlinear_cg
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)
Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

Examples

```plaintext
environment
   tabular_data
   method_pointer = 'UQ'

method
   id_method = 'UQ'
   model_pointer = 'SURR'
   sampling,
      samples = 10
      seed = 98765 rng rnum2
      response_levels = 0.1 0.2 0.6
      0.1 0.2 0.6
      0.1 0.2 0.6
      sample_type lhs
      distribution cumulative

model
   id_model = 'SURR'
   surrogate global,
   dace_method_pointer = 'DACE'

North Carolina State University (NCSU) has an implementation of the DIRECT algorithm (Dividing RECTangles algorithm that is outlined in the SCOLIB method section above). This version is documented in [28] We have found that the NCSU DIRECT implementation works better and is more robust for some problems than coliny-direct. Currently, we maintain both versions of DIRECT in Dakota; in the future, we may deprecate one.

The NCSU DIRECT method is selected with ncsu_direct. We have tried to maintain consistency between the keywords in SCOLIB and NCSU implementation of DIRECT, but the algorithms have different parameters, so the keywords sometimes have slightly different meaning.

**Stopping Criteria**

The algorithm stops based on:

1. max_iterations - number of iterations
2. max_function_evaluations - number of function evaluations
3. solution_target and convergence_tolerance
4. min_boxsize_limit
5. volume_boxsize_limit

This method will always strictly respect the number of iterations, but may slightly exceed the number of function evaluations, as it will always explore all sub-rectangles at the current level.

**Expected HDF5 Output**

If Dakota was built with HDF5 support and run with the hdf5 keyword, this method writes the following results to HDF5:

- Best Parameters
- Best Objective Functions (when objective_functions) are specified
- Best Nonlinear Constraints
- Calibration (when calibration_terms are specified)

**See Also**

These keywords may also be of interest:

- coliny_direct
7.2 method

7.2.43.1 solution_target

- Keywords Area
- method
- ncsu_direct
- solution_target

Specifies a globally optimal value toward which the optimizer should track

Specification

Alias: solution_accuracy
Argument(s): REAL
Default: 0

Description

The solution target specifies a goal toward which the optimizer should track.

This is used for test problems, when the true global minimum is known (call it \( \text{solution_target} := f_{\text{global}} \)). Then, the optimization terminates when \( 100(f_{\text{min}} - f_{\text{global}}) / \max(1, \text{abs}(f_{\text{global}})) < \text{convergence_tolerance} \). The default for \( f_{\text{global}} \) is \(-1.0e100\) and the default for convergence tolerance is described at \text{convergence_tolerance}.

7.2.43.2 min_boxsize_limit

- Keywords Area
- method
- ncsu_direct
- min_boxsize_limit

Stopping Criterion based on shortest edge of hyperrectangle

Specification

Alias: none
Argument(s): REAL
Default: 1.0e-4

Description

\( \text{min_boxsize_limit} \) is a setting that terminates the optimization when the measure of a hyperrectangle \( S \) with \( f(c(S)) = f_{\text{min}} \) is less than \( \text{min_boxsize_limit} \).

Each subregion considered by DIRECT has a size, which corresponds to the longest diagonal of the subregion. \( \text{min_boxsize_limit} \) specification terminates DIRECT if the size of the smallest subregion falls below this threshold.

In practice, this specification is likely to be more effective at limiting DIRECT’s search.
7.2.43.3 volume_boxsize_limit

• Keywords Area
• method
• ncsu_direct
• volume_boxsize_limit

Stopping criterion based on volume of search space

Specification

Alias: none
Argument(s): REAL
Default: 1.0e-6

Description

volume_boxsize_limit is a setting that terminates the optimization when the volume of a hyperrectangle S with f(c(S)) = \( f_{\text{min}} \) is less than volume_boxsize_limit percent of the original hyperrectangle. Basically, volume_boxsize_limit stops the optimization when the volume of the particular rectangle which has \( f_{\text{min}} \) is less than a certain percentage of the whole volume.

7.2.43.4 convergence_tolerance

• Keywords Area
• method
• ncsu_direct
• convergence_tolerance

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

• method_independent_controls

Specification

Alias: none
Argument(s): REAL
Default: 1.e-4
Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a **relative convergence tolerance** for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration. Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See `nl2sol`
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

7.2.43.5  max_iterations

- **Keywords Area**
- **method**
- **ncsu_direct**
- **max_iterations**

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- **method_independent_controls**

Specification

**Alias**: none

**Argument(s)**: INTEGER

**Default**: 100 (exceptions: fsu_cvt, local_reliability: 25; global_(reliability, interval_est, evidence) / efficient_global: 25*n)
Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed \( \text{max\_iterations} \) iterations. In cases where there are multiple nested iterations to be controlled, \( \text{max\_iterations} \) generally controls the outer-most context.

**Default Behavior**

Default value is 100.

7.2.43.6 \( \text{max\_function\_evaluations} \)

- Keywords Area
- method
- \( \text{ncsu\_direct} \)
- \( \text{max\_function\_evaluations} \)

Number of function evaluations allowed for optimizers

Topics

This keyword is related to the topics:

- \( \text{method\_independent\_controls} \)

Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed \( \text{max\_function\_evaluations} \) evaluations. See also \( \text{max\_iterations} \).

Some optimizers (e.g. \( \text{ncsu\_direct} \)) may run past this limit in the course of an iteration step that began before \( \text{max\_function\_evaluations} \) was exceeded.

**Default Behavior**

Default value is 1000.
7.2.43.7  scaling

- Keywords Area
- method
- ncsu_direct
- scaling

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the scaling keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords scale_types and/or *scales in the variables and responses blocks. When the scaling keyword is omitted from method, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

- a *scales keyword, which gives characteristic values (divisors)
- a *scale_types keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in responses for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are three scale types:

1. value - characteristic value scaling
   - The target quantity will be scaled (divided) by the specified characteristic value.
2. auto - automatic scaling

First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:

- two-sided bounds scaled into the interval [0,1];
- one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
- no bounds or targets: no automatic scaling possible, therefore no scaling for this component

Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

3. log - logarithmic scaling

First, any characteristic values from the optional *_scales specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The *scales keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding *scale_types, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- auto, log - optional
- value - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than 1.0e10*DBL_MIN. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100
```

```
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

7.2.43.8 model_pointer

- Keywords Area
- method
- ncsu_direct
- model_pointer

Identifier for model block to be used by a method
Topics

This keyword is related to the topics:

• block_pointer

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.

See block_pointer for details about pointers.

Description

OPT-Darts method is a fast alternative to DIRECT for global Lipschitzian optimization purposes. Instead of hyperrectangular, OPT-Darts decomposes a high-dimensional domain into Voronoi cells, and places samples via stochastic blue noise instead of deterministic cell division.

To refine a cell, OPT-Darts first adds a new sample within it via spoke-dart sampling, then set the conflict radius to the cell’s inscribed hypersphere radius, to avoid adding a sample point that is too close to a prior sample, then divide
that cell (and update its neighboring cells) via the approximate Delaunay graph, and use the computed witnesses to
decide the next refinement candidate. These two steps replace the corresponding deterministic center-sample and
rectangular cell division in DIRECT, respectively.

OPT-Darts is the first exact stochastic Lipschitzian optimization technique that combines the benefits of guaranteed
convergence in [Jones et al. 1993] and high dimensional efficiency in [Spall 2005]. Computing blue noise and
Voronoi regions has been intractable in high dimensions, and are being done within OPT-Darts using Spoke-Darts.

**Expected HDF5 Output**

If Dakota was built with HDF5 support and run with the hdf5 keyword, this method writes the following results to
HDF5:

- Best Parameters
- Best Objective Functions (when objective_functions are specified)
- Calibration (when calibration_terms are specified)

### 7.2.44.1 seed

- **Keywords Area**
- method
- genie_opt_darts
- **seed**

Seed of the random number generator

**Specification**

*Alias:* none

*Argument(s):* INTEGER

*Default:* system-generated (non-repeatable)

**Description**

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of
the same random seed in identical studies will generate identical results.

**Default Behavior**

If not specified, the seed is randomly generated.

**Expected Output**

If seed is specified, a stochastic study will generate identical results when repeated using the same seed value.
Otherwise, results are not guaranteed to be the same.

**Usage Tips**

If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same
seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That
value can then be added to the Dakota input file.
Examples

```
method
sampling
  sample_type lhs
  samples = 10
  seed = 15347
```

### 7.2.44.2 max_function_evaluations

- **Keywords Area**
- **method**
- **genie_opt_darts**
- **max_function_evaluations**

Number of function evaluations allowed for optimizers

**Topics**

This keyword is related to the topics:

- **method_independent_controls**

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 1000

**Description**

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed `max_function_evaluations` evaluations. See also `max_iterations`.

Some optimizers (e.g. `ncsu_direct`) may run past this limit in the course of an iteration step that began before `max_function_evaluations` was exceeded.

**Default Behavior**

Default value is 1000.

### 7.2.44.3 scaling

- **Keywords Area**
- **method**
- **genie_opt_darts**
- **scaling**

Turn on scaling for variables, responses, and constraints
7.2 method

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the scaling keyword. Discrete variable scaling is not supported.

When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords scale_types and/or ∗scales in the variables and responses blocks. When the scaling keyword is omitted from method, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

- a ∗scales keyword, which gives characteristic values (divisors)
- a ∗scale_types keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in responses for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

Scale Types

There are three scale types:

1. value - characteristic value scaling
   The target quantity will be scaled (divided) by the specified characteristic value.

2. auto - automatic scaling
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   • two-sided bounds scaled into the interval [0,1];
   • one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
   • no bounds or targets: no automatic scaling possible, therefore no scaling for this component

   Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].
3. log - logarithmic scaling

First, any characteristic values from the optional *_scales specification are applied. Then logarithm base 10 scaling is applied.

Logarithmic scaling is not available for linear constraints.

When continuous design variables are log scaled, linear constraints are not allowed.

Scales

The *scales keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding *scale_types, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- auto, log - optional
- value - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than $1.0e10\cdot \text{DBL_MIN}$. User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.

Examples

The two examples below are equivalent:

```plaintext
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100

responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value" "value" "value"
  primary_scales = 1 1 100
```

7.2.44.4 model_pointer

- Keywords Area
- method
- genie_opt_darts
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer
7.2 method

Specification

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

Examples

```plaintext
environment
tabular_data
method_pointer = 'UQ'

Description

DIRECT (DIviding RECTangles) partitions the domain into hyperrectangles and uses an iterative Lipschitzian optimization approach to search for a global optimal point.

DIRECT begins by scaling the domain into the unit hypercube by adopting a center-sampling strategy. The objective function is evaluated at the midpoint of the domain, where a lower bound is constructed. In one-dimension, the domain is tri-sected and two new center points are sampled. At each iteration (dividing and sampling), DIRECT identifies intervals that contain the best minimal value of the objective function found up to that point. This strategy of selecting and dividing gives DIRECT its performance and convergence properties compared to other deterministic methods.

The classical DIRECT method [Shubert 1972] has two limitations: poor scaling to high dimensions; and relying on a global $K$ whose exact value is often unknown. The enhanced DIRECT algorithm [Jones et al. 1993] generalizes [Shubert 1972] to higher dimensions and does not require knowledge of the Lipschitz constant.
7.2.45.1 seed

- Keywords Area
- method
- genie_direct
- seed

Seed of the random number generator

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** system-generated (non-repeatable)

**Description**

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

**Default Behavior**

If not specified, the seed is randomly generated.

**Expected Output**

If `seed` is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

**Usage Tips**

If a stochastic study was run without `seed` specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

**Examples**

```dakota
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

7.2.45.2 max_function_evaluations

- method
- genie_direct
- max_function_evaluations

Number of function evaluations allowed for optimizers
Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): INTEGER

Default: 1000

Description

The maximum number of function evaluations is used as a stopping criterion for optimizers. If it has not reached any other stopping criteria first, the optimizer will stop after it has performed max_function_evaluations evaluations. See also max_iterations.

Some optimizers (e.g. ncsu_direct) may run past this limit in the course of an iteration step that began before max_function_evaluations was exceeded.

Default Behavior

Default value is 1000.

7.2.45.3 scaling

- Keywords Area
- method
- genie_direct
- scaling

Turn on scaling for variables, responses, and constraints

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): none

Default: no scaling

Description

Some optimization and calibration methods support scaling of continuous design variables, objective functions, calibration terms, and constraints. This is activated with the scaling keyword. Discrete variable scaling is not supported.
When scaling is enabled, variables, functions, gradients, Hessians, etc., are transformed such that the method iterates in scaled variable space, whereas evaluations of the computational model as specified in the interface are performed on the original problem scale. Therefore using scaling does not require rewriting the interface to the simulation code.

Scaling also requires the specification of additional keywords `scale_types` and/or `scales` in the `variables` and `responses` blocks. When the `scaling` keyword is omitted from `method`, these scaling type and value specifications are ignored in the variables and responses sections.

This page describes the usage of all scaling related keywords. The additional keywords come in pairs, one pair for each set of quantities (variables, primary responses, or constraints) to be scaled.

- a `scales` keyword, which gives characteristic values (divisors)
- a `scale_types` keyword, which determines how to use the characteristic values

The pair of keywords both take argument(s), and the length of the arguments can be either be one or equal to the number of quantities to be scaled (see details in `responses` for lengths when field responses are active). If one argument is given, it will apply to all quantities in the set. See the examples below.

**Scale Types**

There are three scale types:

1. `value` - characteristic value scaling
   
   The target quantity will be scaled (divided) by the specified characteristic value.

2. `auto` - automatic scaling
   
   First the quantity is scaled by any characteristic value, then automatic scaling will be attempted according to the following scheme:
   - two-sided bounds scaled into the interval [0,1];
   - one-sided bound or targets are scaled by the characteristic value, moving the bound or target to 1 and changing the sense of inequalities where necessary;
   - no bounds or targets: no automatic scaling possible, therefore no scaling for this component

   Automatic scaling is not available for objective functions nor calibration terms since they lack bound constraints. Further, when automatically scaled, linear constraints are scaled by characteristic values only, not affinely scaled into [0,1].

3. `log` - logarithmic scaling
   
   First, any characteristic values from the optional `scales` specification are applied. Then logarithm base 10 scaling is applied.

   Logarithmic scaling is not available for linear constraints.

   When continuous design variables are log scaled, linear constraints are not allowed.

**Scales**

The `scales` keywords are used to specify the characteristic values. These must be non-zero real numbers. The numbers are used according to the corresponding `scale_types`, as described above. A value of 1.0 can be used to selectively omit some quantities in a vector from being scaled.

Depending on the scale type, the characteristic values may be required or optional.

- `auto, log` - optional
- `value` - required.

A warning is issued if scaling would result in division by a value smaller in magnitude than \( 1.0 \times 10^{-16} \). User-provided values violating this lower bound are accepted unaltered, whereas for automatically calculated scaling, the lower bound is enforced.
Examples

The two examples below are equivalent:

```
responses
  objective_functions 3
  sense "maximize"
  primary_scale_types = "value"
  primary_scales = 1 1 100
```

```
responses
  objective_functions 3

The Efficient Global Optimization (EGO) method was first developed by Jones, Schonlau, and Welch [55]. In EGO, a stochastic response surface approximation for the objective function is developed based on some sample points from the "true" simulation.

Note that several major differences exist between our implementation and that of [55]. First, rather than using a branch and bound method to find the point which maximizes the EIF, we use the DIRECT global optimization method.

Second, we support both global optimization and global nonlinear least squares as well as general nonlinear constraints through abstraction and subproblem recasting.

The efficient global method is in prototype form. Currently, we do not expose any specification controls for the underlying Gaussian process model used or for the optimization of the expected improvement function (which is currently performed by the NCSU DIRECT algorithm using its internal defaults).

By default, EGO uses the Surfpack GP (Kriging) model, but the Dakota implementation may be selected instead. If use_derivatives is specified the GP model will be built using available derivative data (Surfpack GP only).

**Expected HDF5 Output**

If Dakota was built with HDF5 support and run with the hdf5 keyword, this method writes the following results to HDF5:

- Best Parameters
- Best Objective Functions (when objective_functions are specified)
- Best Nonlinear Constraints
- Calibration (when calibration_terms are specified)

**Theory**

The particular response surface used is a Gaussian process (GP). The GP allows one to calculate the prediction at a new input location as well as the uncertainty associated with that prediction. The key idea in EGO is to maximize the Expected Improvement Function (EIF). The EIF is used to select the location at which a new training point should be added to the Gaussian process model by maximizing the amount of improvement in the objective function that can be expected by adding that point. A point could be expected to produce an improvement in the objective function if its predicted value is better than the current best solution, or if the uncertainty in its prediction is such that the probability of it producing a better solution is high. Because the uncertainty is higher in regions of the design space with few observations, this provides a balance between exploiting areas of the design space that predict good solutions, and exploring areas where more information is needed. EGO trades off this "exploitation vs. exploration."

The general procedure for these EGO-type methods is:

- Build an initial Gaussian process model of the objective function
- Find the point that maximizes the EIF. If the EIF value at this point is sufficiently small, stop.
- Evaluate the objective function at the point where the EIF is maximized. Update the Gaussian process model using this new point.
- Return to the previous step.
See Also

These keywords may also be of interest:

- surrogate_based_local
- surrogate_based_global

7.2.46.1 initial_samples

- Keywords Area
- method
- efficient_global
- initial_samples

Initial number of samples for sampling-based methods

Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** \((d+1)(d+2)/2\)

Description

The *initial_samples* keyword is used to define the number of initial samples (i.e., randomly chosen sets of variable values) at which to execute a model. The initial samples may later be augmented in an iterative process.

**Default Behavior**

By default, Dakota will use the minimum number of samples required by the chosen method.

**Usage Tips**

To obtain linear sensitivities or to construct a linear response surface, at least \(d+1\) samples should be used, where \(d\) is the number of variables. For sensitivities to quadratic terms or quadratic response surfaces, at least \((d+1)(d+2)/2\) samples are needed. For uncertainty quantification, we recommend at least \(10+d\) samples. For variance_based_decomp, we recommend hundreds to thousands of samples. Note that for variance_based_decomp, the number of simulations performed will be \(N\times(d+2)\).

**Examples**

```plaintext
method
sampling
  sample_type random
  initial_samples = 20
  refinement_samples = 5
```

7.2.46.2 seed

- Keywords Area
- method
- efficient_global
7.2 method

- **seed**

Seed of the random number generator

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** system-generated (non-repeatable)

**Description**

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

**Default Behavior**

If not specified, the seed is randomly generated.

**Expected Output**

If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

**Usage Tips**

If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

**Examples**

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347
```

7.2.46.3 batch_size

- Keywords Area
- method
- efficient_global
- batch_size

Total batch size in parallel EGO

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Child Keywords:**
### Description

Refinement candidates are generated by an acquisition function such as maximum expected improvement, which balances exploration and exploitation. Refinement candidates can also be generated by purely explorative metrics such as maximum prediction variance. For a specified `batch_size`, `exploration` specifies the subset of this total that will be dedicated to pure exploration of the parameter space.

**Default Behavior** All of the batch size is devoted to the standard acquisition approach, balancing exploration and exploitation.

### Examples

```dakota
method, efficient_global
  seed = 1237
  batch_size = 8  # total
  exploration = 2  # 2 out of 8
```

7.2.46.3.1 exploration

- Keywords Area
- method
- efficient_global
- batch_size
- exploration

Portion of batch size dedicated to exploration in parallel EGO

### Specification

**Alias:** none

**Argument(s):** INTEGER

### Description

Refinement candidates are generated by an acquisition function such as maximum expected improvement, which balances exploration and exploitation. Refinement candidates can also be generated by purely explorative metrics...
such as maximum prediction variance. For a specified batch_size, exploration specifies the subset of this total that will be dedicated to pure exploration of the parameter space.

**Default Behavior**  All of the batch size is devoted to the standard acquisition approach, balancing exploration and exploitation.

**Examples**

```plaintext
method,  
    efficient_global  
seed = 1237  
batch_size = 8   # total  
exploration = 2  # 2 out of 8
```

7.2.46.3.2  synchronization

- Keywords Area
- method
- efficient_global
- batch_size
- synchronization

Select how Dakota schedules a batch of concurrent function evaluations in a parallel algorithm

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** method specific

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional Required (Choose One)</th>
<th>Description of Group Synchronization (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>

<td>Complete concurrent evaluation of all evaluations within a batch</td>
</tr>
<tr>
<td></td>
<td></td>
<td>nonblocking</td>
<td>A batch of concurrent evaluations are queried for completions and a partial set is returned to the algorithm</td>
</tr>
</tbody>
</table>

**Description**

The synchronization specification can be used to specify the use of either blocking or nonblocking schedulers, where the former must block until all evaluations are completed and the latter does not block, returning only the partial set that has been completed for a particular call to the scheduler.
7.2.46.3.2.1 blocking

- Keywords Area
- method
- efficient_global
- batch_size
- synchronization
- blocking

Complete concurrent evaluation of all evaluations within a batch

Specification

**Alias:** none

**Argument(s):** none

Description

In the **blocking** case, all of the concurrent evaluations in the batch must be completed and all results are returned together to the algorithm.

These runs are reproducible, assuming use of the same seed in cases with random number generation.

7.2.46.3.2.2 nonblocking

- Keywords Area
- method
- efficient_global
- batch_size
- synchronization
- nonblocking

A batch of concurrent evaluations are queried for completions and a partial set is returned to the algorithm

Specification

**Alias:** none

**Argument(s):** none

Description

In the **nonblocking** case, the set of running evaluations is queried for completion and a partial set of results is returned to an asynchronous algorithm, which can then generate new evaluations based on these partial results.

In all cases, the algorithm steps will be subject to parallel timing variabilities / race conditions such that these runs will not generally be repeatable regardless of seed specification.
7.2.46.4 max_iterations

- Keywords Area
- method
- efficient_global
- max_iterations

Number of iterations allowed for optimizers and adaptive UQ methods

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: fsu_cvt, local_reliability: 25; global_(reliability, interval_est, evidence) / efficient_global: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed max_iterations iterations. In cases where there are multiple nested iterations to be controlled, max_iterations generally controls the outer-most context.

Default Behavior

Default value is 100.

Gaussian Process surrogate model

Specification

**Alias:** kriging  
**Argument(s):** none  
**Default:** Surfpack Gaussian process

**Child Keywords:**
Use the Gaussian process (GP) surrogate from Surfpack, which is specified using the `surfpack` keyword.

An alternate version of GP surrogates was available in prior versions of Dakota. For now, both versions are supported but the `dakota` version is deprecated and intended to be removed in a future release.

Known Issue: When using discrete variables, there have been sometimes significant differences in surrogate behavior observed across computing platforms in some cases. The cause has not yet been fully diagnosed and is currently under investigation. In addition, guidance on appropriate construction and use of surrogates with discrete variables is under development. In the meantime, users should therefore be aware that there is a risk of inaccurate results when using surrogates with discrete variables.

<td>Exports surrogate model in user-specified format(s)</td>
</tr>
</tbody>
</table>
Description

This keyword specifies the use of the Gaussian process that is incorporated in our surface fitting library called Surfpack.

Several user options are available:

1. Optimization methods:
   Maximum Likelihood Estimation (MLE) is used to find the optimal values of the hyper-parameters governing the trend and correlation functions. By default the global optimization method DIRECT is used for MLE, but other options for the optimization method are available. See optimization_method.
   The total number of evaluations of the likelihood function can be controlled using the max_trials keyword followed by a positive integer. Note that the likelihood function does not require running the "truth" model, and is relatively inexpensive to compute.

2. Trend Function:
The GP models incorporate a parametric trend function whose purpose is to capture large-scale variations. See trend.

3. Correlation Lengths:
Correlation lengths are usually optimized by Surfpack, however, the user can specify the lengths manually. See correlation_lengths.

4. Ill-conditioning
   One of the major problems in determining the governing values for a Gaussian process or Kriging model is the fact that the correlation matrix can easily become ill-conditioned when there are too many input points close together. Since the predictions from the Gaussian process model involve inverting the correlation matrix, ill-conditioning can lead to poor predictive capability and should be avoided.
   Note that a sufficiently bad sample design could require correlation lengths to be so short that any interpolatory GP model would become inept at extrapolation and interpolation.
   The surfpack model handles ill-conditioning internally by default, but behavior can be modified using

5. Gradient Enhanced Kriging (GEK).
   The use_derivatives keyword will cause the Surfpack GP to be constructed from a combination of function value and gradient information (if available).
   See notes in the Theory section.

Theory

Gradient Enhanced Kriging

Incorporating gradient information will only be beneficial if accurate and inexpensive derivative information is available, and the derivatives are not infinite or nearly so. Here “inexpensive” means that the cost of evaluating a function value plus gradient is comparable to the cost of evaluating only the function value, for example gradients computed by analytical, automatic differentiation, or continuous adjoint techniques. It is not cost effective to use derivatives computed by finite differences. In tests, GEK models built from finite difference derivatives were also significantly less accurate than those built from analytical derivatives. Note that GEK’s correlation matrix tends to have a significantly worse condition number than Kriging for the same sample design.

This issue was addressed by using a pivoted Cholesky factorization of Kriging’s correlation matrix (which is a small sub-matrix within GEK’s correlation matrix) to rank points by how much unique information they contain. This reordering is then applied to whole points (the function value at a point immediately followed by gradient information at the same point) in GEK’s correlation matrix. A standard non-pivoted Cholesky is then applied to the reordered GEK correlation matrix and a bisection search is used to find the last equation that meets the constraint on the (estimate of) condition number. The cost of performing pivoted Cholesky on Kriging’s correlation matrix is usually negligible compared to the cost of the non-pivoted Cholesky factorization of GEK’s correlation matrix. In tests, it also resulted in more accurate GEK models than when pivoted Cholesky or whole-point-block pivoted Cholesky was performed on GEK’s correlation matrix.

</tbody>
</table>

Description

Export the surrogate for later re-import to Dakota or evaluation using the surfpack executable (bin/surfpack) or a user-developed tool. Export format is controlled using the formats specification. Four formats are available in Dakota; however, not all have been enabled for all surrogates.

The four formats are:

- text_archive - Plain-text, machine-readable archive for re-import or use with the surfpack executable
- binary_archive - Binary, machine-readable archive for re-import or use with the surfpack executable
- algebraic_file - Plain-text, human-readable file intended for use with user-created tools; not compatible with Dakota or the surfpack executable
- algebraic_console - Print the model in algebraic format to the screen; not compatible with Dakota or the surfpack executable
These global surrogates can be exported in all four formats:

- Gaussian process (keyword `gaussian_process` surfpack)
- Artificial neural network (keyword `neural_network`)
- Radial basis Funtions (keyword `radial_basis`)
- Polynomial (keyword `polynomial`)

However, for experimental Gaussian Process and polynomial models as well as Multivariate Adaptive Regression Spline (keyword `mars`) and moving least squares (keyword `moving_least_squares`) models, only text_ARCHIVE and binary_ARCHIVE formats may be used.
Currently, no other surrogate models can be exported.

**Default Behavior**

No export.

**Expected Output**

Output depends on selected format; see the formats specification.

**Additional Discussion**

The Dakota examples include a demonstration of using the surfpack executable with an exported model file.

7.2.46.7.1.2 filename_prefix

- Keywords Area
- method
- efficient_global
- gaussian_process
- surfpack
- export_model
- filename_prefix

User-customizable portion of exported/imported surrogate model filenames

**Topics**

This keyword is related to the topics:

- surrogate_models

**Specification**

**Alias:** none

**Argument(s):** STRING

**Default:** exported_surrogate
7.2 method

Description

Dakota surrogate model files are exported and imported using one file per response, per requested format. The files are named using the pattern \{prefix\}.{response_descriptor}.{extension}. This filename_prefix keyword is used to supply the prefix portion of the pattern.

The response_descriptor portion of the pattern is filled in using the response descriptors provided by the user (or, if none are specified, descriptors automatically generated by Dakota). Extension is a three or four letter string that depends on the format.

Examples

This input snippet directs Dakota to write one algebraic format file and one binary archive file for each response. The names of the files will follow the patterns my_surrogate.{response_descriptor}.alg (for the algebraic files) and my_surrogate.{response_descriptor}.bsps (for the binary files).

```plaintext
surrogate global gaussian_process surfpack
export_model
   filename_prefix = 'my_surrogate'
   formats
      algebraic_file
      binary_archive
```

Surrogate model binary archive file format

Topics

This keyword is related to the topics:

- surrogate_models

Specification

Alias: none
Argument(s): none

Description

When specified, the surrogate model will be exported (or imported) using a binary archive format. Experimental surrogates will export to (import from) binary archives named \{prefix\}\{response_descriptor\}.bin. Other (Surfpack) surrogates will export/import using files named \{prefix\}\{response_descriptor\}.bsps, in which ‘bsps’ stands for binary Surfpack surrogate. See filename_prefix for further information about surrogate file naming.

Examples

The Dakota examples include a demonstration of using the surfpack executable with an exported model file.

7.2.46.7.2  dakota

- Keywords Area
- method
- efficient_global
- gaussian_process
Select the built in Gaussian Process surrogate

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

A second version of GP surrogates was available in prior versions of Dakota. **For now, both versions are supported but the dakota version is deprecated and intended to be removed in a future release.** Historically these models were drastically different, but in Dakota 5.1, they became quite similar. They now differ in that the Surfpack GP has a richer set of features/options and tends to be more accurate than the Dakota version. Due to how the Surfpack GP handles ill-conditioned correlation matrices (which significantly contributes to its greater accuracy), the Surfpack GP can be a factor of two or three slower than Dakota’s. As of Dakota 5.2, the Surfpack implementation is the default in all contexts except Bayesian calibration. More details on the `gaussian_process` dakota model can be found in [60].

Dakota’s GP deals with ill-conditioning in two ways. First, when it encounters a non-invertible correlation matrix it iteratively increases the size of a “nugget,” but in such cases the resulting approximation smooths rather than interpolates the data. Second, it has a `point_selection` option (default off) that uses a greedy algorithm to select a well-spaced subset of points prior to the construction of the GP. In this case, the GP will only interpolate the selected subset. Typically, one should not need point selection in trust-region methods because a small number of points are used to develop a surrogate within each trust region. Point selection is most beneficial when constructing with a large number of points, typically more than order one hundred, though this depends on the number of variables and spacing of the sample points.

This differs from the `point_selection` option of the Dakota GP which initially chooses a well-spaced subset of points and finds the correlation parameters that are most likely for that one subset.

### Specification

**Alias**: none

**Argument(s)**: none

**Child Keywords**:
Description

Export the surrogate for later re-import to Dakota or evaluation using the surfpack executable (bin/surfpack) or a user-developed tool. Export format is controlled using the \texttt{formats} specification. Four formats are available in Dakota; however, not all have been enabled for all surrogates.

The four formats are:

- \texttt{text_archive} - Plain-text, machine-readable archive for re-import or use with the surfpack executable
- \texttt{binary_archive} - Binary, machine-readable archive for re-import or use with the surfpack executable
- \texttt{algebraic_file} - Plain-text, human-readable file intended for use with user-created tools; not compatible with Dakota or the surfpack executable
- \texttt{algebraic_console} - Print the model in algebraic format to the screen; not compatible with Dakota or the surfpack executable

These global surrogates can be exported in all four formats:

- Gaussian process (keyword \texttt{gaussian_process} surfpack)
- Artificial neural network (keyword \texttt{neural_network})
- Radial basis Funtions (keyword \texttt{radial_basis})
- Polynomial (keyword \texttt{polynomial})

However, for experimental Gaussian Process and polynomial models as well as Multivariate Adaptive Regression Spline (keyword \texttt{mars}) and moving least squares (keyword \texttt{moving_least_squares}) models, only \texttt{text_archive} and \texttt{binary_archive} formats may be used.

Currently, no other surrogate models can be exported.

Default Behavior

No export.

Expected Output

Output depends on selected format; see the \texttt{formats} specification.

Additional Discussion

The Dakota examples include a demonstration of using the surfpack executable with an exported model file.

lower bound: 1.0e-2
upper bound: 1.0e2
verbosity: 1

7.2.46.8 use_derivatives

- Keywords Area
- method
- efficient_global
- use_derivatives

Use derivative data to construct surrogate models

Specification

Alias: none
Argument(s): none
Default: use function values only

Description

The use_derivatives flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).
However, it's use with Surfpack Gaussian process is not recommended.

7.2.46.9 import_build_points_file

- Keywords Area
- method
- efficient_global
- import_build_points_file

File containing points you wish to use to build a surrogate

Specification

Alias: import_points_file
Argument(s): STRING
Default: no point import from a file
Child Keywords:
### Description

The `import_build_points_file` allows the user to specify a file that contains a list of points and truth model responses used to construct a surrogate model. These can be used by all methods that (explicitly, e.g. surrogate-based optimization, or implicitly, e.g. efficient global optimization) operate on a surrogate. In particular, these points and responses are used in place of truth model evaluations to construct the initial surrogate. When used to construct surrogate models or emulators these are often called build points or training data.

### Default Behavior

By default, methods do not import points from a file.

### Usage Tips

Dakota parses input files without regard to whitespace, but the `import_build_points_file` must be in one of three formats:

- `annotated` *(default)*
- `custom_annotated`
- `freeform`

### Examples

```dakota
method
    polynomial_chaos
        expansion_order = 4
        import_build_points_file = 'dakota_uq_rosenbrock_pce_import.annot.pts.dat'
```

7.2.46.9.1 `custom_annotated`

- **Keywords Area**
- **method**
- **efficient_global**
- **import_build_points_file**
- **custom_annotated**

Selects custom-annotated tabular file format
Topics

This keyword is related to the topics:

• file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional Group</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>header</td>
<td>header</td>
<td>Enable header row in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td>eval_id</td>
<td>eval_id</td>
<td>Enable evaluation ID column in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td>interface_id</td>
<td>interface_id</td>
<td>Enable interface ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom.annotated, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
custom_annotated header eval_id

Resulting tabular file:

%eval_id x1  x2  obj_fn nln_ineq_con_1 nln_ineq_con_2
1   0.9  1.1  0.0002 0.26 0.76
2  0.90009 1.1 0.0001996404857 0.2601620081 0.759955

Description

See description of parent custom_annotated

7.2.46.9.2 annotated

- Keywords Area
- method
- efficient_global
- import_build_points_file
- annotated

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none
Default: annotated format
Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
  tabular_data_file = 'dakota_summary.dat'
annotated
```

Resulting tabular file:

```
%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 NO_ID 0.9 1.1 0.0002 0.26 0.76
2 NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 NO_ID 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...```

7.2.46.9.3 freeform

- Keywords Area
- method
- efficient_global
- import_build_points_file
- freeform

Selects freeform file format

Topics

This keyword is related to the topics:

- file_formats
Specification

**Alias**: none  
**Argument(s)**: none  
**Default**: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The **annotated** format is the default for tabular export/import. To change this behavior, specify **freeform** in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to **annotated** format, though **freeform** remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In **freeform**, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the **freeform** option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```dakota
environment
  tabular_data
  tabular_data_file = 'dakota_summary.dat'
  freeform

Resulting tabular file:

<p>| | | | | |</p>
<table>

```

Dakota Version 6.16 Reference Manual generated on May 12, 2022
Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword active_only indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

7.2.46.10 export_approx_points_file

- Keywords Area
- method
- efficient_global
- export_approx_points_file

Output file for surrogate model value evaluations

Specification

Alias: export_points_file
Argument(s): STRING
Default: no point export to a file

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional (Choose One)</td>
<td>Tabular Format (Group 1)</td>
<td>custom_annotated</td>
<td>Selects custom-annotated tabular file format</td>
</tr>
<tr>
<td></td>
<td></td>
<td>annotated</td>
<td>Selects annotated tabular file format</td>
</tr>
</tbody>
</table>
Description

Specifies a file in which the points (input variable values) at which the surrogate model is evaluated and corresponding response values computed by the surrogate model will be written. The response values are the surrogate’s predicted approximation to the truth model responses at those points.

Usage Tips

Dakota exports tabular data in one of three formats:

- annotated (default)
- custom_annotated
- freeform

7.2.46.10.1 custom_annotated

- Keywords Area
- method
- efficient_global
- export_approx_points_file

<td>Enable header row in custom-annotated tabular file</td>
</tr>
</tbody>
</table>
A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

Usage Tips

• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

evironment
tabular_data
tabular_data_file = ’dakota_summary.dat’
custom_annotated header eval_id

Resulting tabular file:

<table>
<thead>
<tr>
<th>eval_id</th>
<th>x1</th>
<th>x2</th>
<th>obj_fn</th>
<th>nln_ineq_con_1</th>
<th>nln_ineq_con_2</th>

  - **method**
  - **efficient_global**
  - **export_approx_points_file**
  - **annotated**

Selects annotated tabular file format

**Topics**

This keyword is related to the topics:

- **file_formats**

**Specification**

- **Alias:** none
- **Argument(s):** none
- **Default:** annotated format

**Description**

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

**Default Behavior**

By default, Dakota imports and exports tabular files in annotated format. The `annotated` keyword can be used to explicitly specify this.

**Usage Tips**

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify `custom_annotated header eval_id`

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.
• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```plaintext
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
annotated
```

Resulting tabular file:

```plaintext
%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 NO_ID 0.9 1.1 0.0002 0.26 0.76
2 NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 NO_ID 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...
```

7.2.46.10.3 freeform

• Keywords Area

• method

• efficient_global

• export_approx_points_file

• freeform

Selects freeform file format

Topics

This keyword is related to the topics:

• file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

Dakota Version 6.16 Reference Manual generated on May 12, 2022
The **annotated** format is the default for tabular export/import. To change this behavior, specify **freeform** in the relevant export/import context.

### Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to **annotated** format, though **freeform** remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In **freeform**, the `num_rows x num_cols` total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the **freeform** option.

### Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
  tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

```
0.9 1.1 0.0002 0.26 0.76
0.90009 1.1 0.0001996404857 0.2601620081 0.759955
0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...```

### Identifier for model block to be used by a method

#### Topics

This keyword is related to the topics:

- **block_pointer**

#### Specification

**Alias**: none

**Argument(s)**: STRING

**Default**: method use of last model parsed (or use of default model if none parsed)
Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

Examples

```
environment
tabular_data
method_pointer = 'UQ'

method
id_method = 'UQ'
model_pointer = 'SURR'
sampling,
samples = 10
seed = 98765 rng rnum2
response_levels = 0.1 0.2 0.6
                    0.1 0.2 0.6
                    0.1 0.2 0.6
sample_type lhs
distribution cumulative

</tbody>
</table>

**Description**

As surrogate models by stochastic expansion migrate into the model specification, this method provides a general-purpose UQ method to interrogate the surrogate for generating statistics.

This method must identify the surrogate of interest through its `model_pointer`, distinguishing it from fully-
integrated method specifications such as polynomial_chaos, stoch_collocation, and function_train that couple directly with a simulation model (and form the PCE, SC, FT surrogate approximations implicitly prior to using them for generating statistics).

See Also

These keywords may also be of interest:

- polynomial_chaos
- stoch_collocation
- function_train

7.2.47.1 samples_on_emulator

- Keywords Area
- method
- surrogate_based_uq
- samples_on_emulator

Number of samples at which to evaluate an emulator (surrogate)

Specification

**Alias:** samples

**Argument(s):** INTEGER

Description

How many approximate function evaluations to perform on the emulator model, e.g., to compute statistics

**Default Behavior**

The default number of samples is method-dependent.

**Examples**

Perform 10000 samples on the PCE approximation of the true model:

```plaintext
method
  polynomial_chaos
    quadrature_order = 2
    samples_on_emulator = 10000
```

7.2.47.2 sample_type

- Keywords Area
- method
- surrogate_based_uq
- sample_type

Selection of sampling strategy
7.2 method

Specification

**Alias:** none

**Argument(s):** none

**Default:** random

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group Sample Type (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td><strong>lhs</strong></td>
<td>Uses Latin Hypercube Sampling (LHS) to sample variables</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>random</strong></td>
<td>Uses purely random Monte Carlo sampling to sample variables</td>
</tr>
</tbody>
</table>

**Description**

The `sample_type` keyword allows the user to select between two types of sampling: Monte Carlo (pure random) and Latin hypercube (stratified) sampling.

The incremental keywords are deprecated; instead use `samples` together with `refinement_samples`.

**Default Behavior**

If the `sample_type` keyword is present, it must be accompanied by `lhs` or `random`. In most contexts, `lhs` is the default (exception: `multilevel_sampling` uses Monte Carlo by default).

**Examples**

```
method
  sampling
    sample_type lhs
    samples = 20
    seed = 83921
```

7.2.47.2.1 `lhs`

- Keywords Area
- method
- surrogate_based_uq
- sample_type
- lhs

Uses Latin Hypercube Sampling (LHS) to sample variables

**Specification**

**Alias:** none

**Argument(s):** none
Description

The `lhs` keyword invokes Latin Hypercube Sampling as the means of drawing samples of uncertain variables according to their probability distributions. This is a stratified, space-filling approach that selects variable values from a set of equi-probable bins.

Default Behavior

Latin Hypercube Sampling is the default sampling mode in most contexts (exception: multilevel_sampling). To explicitly specify LHS in the Dakota input file, the `lhs` keyword must appear in conjunction with the `sample_type` keyword.

Usage Tips

Latin Hypercube Sampling is very robust and can be applied to any problem. It is fairly effective at estimating the mean of model responses and linear correlations with a reasonably small number of samples relative to the number of variables.

Examples

```
method sampling
   sample_type lhs
   samples = 20
```

7.2.47.2.2 random

- Keywords Area
- method
- surrogate_based_uq
- sample_type
- random

Uses purely random Monte Carlo sampling to sample variables

Specification

**Alias:** none

**Argument(s):** none

Description

The `random` keyword invokes Monte Carlo sampling as the means of drawing samples of uncertain variables according to their probability distributions.

Default Behavior

In most contexts, Monte Carlo sampling is not the default sampling mode (exception: multilevel_sampling). To change this behavior, the `random` keyword must be specified in conjunction with the `sample_type` keyword.

Usage Tips

Monte Carlo sampling is more computationally expensive than Latin Hypercube Sampling as it requires a larger number of samples to accurately estimate statistics.
7.2 method

Examples

```
method
  sampling
    sample_type random
    samples = 200
```

7.2.47.3 rng

- Keywords
  - Area
  - method
  - surrogate_based_uq
  - rng

Selection of a random number generator

Specification

Alias: none

Argument(s): none

Default: Mersenne twister (mt19937)

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional Required (Choose One)</th>
<th>Description of Group RNG Algorithm (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>mt19937</td>
<td>Generates random numbers using the Mersenne twister</td>
</tr>
<tr>
<td></td>
<td></td>
<td>rnum2</td>
<td>Generates pseudo-random numbers using the Pecos package</td>
</tr>
</tbody>
</table>

Description

The `rng` keyword is used to indicate a choice of random number generator.

Default Behavior

If specified, the `rng` keyword must be accompanied by either `rnum2` (pseudo-random numbers) or `mt19937` (random numbers generated by the Mersenne twister). Otherwise, `mt19937`, the Mersenne twister is used by default.

Usage Tips

The default is recommended, as the Mersenne twister is a higher quality random number generator.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2
```
Generates random numbers using the Mersenne twister

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The `mt19937` keyword directs Dakota to use the Mersenne twister to generate random numbers. Additional information can be found on wikipedia: [http://en.wikipedia.org/wiki/Mersenne_twister](http://en.wikipedia.org/wiki/Mersenne_twister).

**Default Behavior**

`mt19937` is the default random number generator. To specify it explicitly in the Dakota input file, however, it must be specified in conjunction with the `rng` keyword.

**Usage Tips**

Use of the Mersenne twister random number generator (`mt19937`) is recommended.

**Examples**

```dakota
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng mt19937
```

Generates pseudo-random numbers using the Pecos package

**Specification**

**Alias:** none

**Argument(s):** none
Description

The `rnum2` keyword directs Dakota to use pseudo-random numbers generated by the Pecos package.

Default Behavior

`rnum2` is not used by default. To change this behavior, it must be specified in conjunction with the `rng` keyword.

Usage Tips

Use of the Mersenne twister random number generator (`mt19937`) is recommended over `rnum2`.

Examples

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2
```

7.2.47.4 probability_refinement

- Keywords Area
- method
- surrogate_based_uq
- probability_refinement

Allow refinement of probability and generalized reliability results using importance sampling.

Topics

This keyword is related to the topics:

- reliability_methods

Specification

Alias: sample_refinement

Argument(s): none

Default: no refinement

Child Keywords:

<table>
<thead>

<th>Importance sampling option for probability refinement</th>
</tr>
</thead>
</table>

### mm_adapt_import

<table>
<thead>
<tr>
<th>Importance sampling option for probability refinement</th>
</tr>
</thead>
</table>

#### Optional

<table>
<thead>
<tr>
<th>refinement_samples</th>
<th>Number of samples used to refine a probability estimate or sampling design.</th>
</tr>
</thead>
</table>

### Description

The `probability_refinement` allows refinement of probability and generalized reliability results using importance sampling. If one specifies `probability_refinement`, there are some additional options. One can specify which type of importance sampling to use (`import`, `adapt_import`, or `mm_adapt_import`). Additionally, one can specify the number of refinement samples to use with `refinement_samples` and the seed to use with `seed`.

The `probability_refinement density reweighting accounts originally was developed based on Gaussian distributions. It now accounts for additional non-Gaussian cases.

#### 7.2.47.4.1 import

- Keywords Area
- method
- surrogate_based_uq
- probability_refinement
- import

Importance sampling option for probability refinement

#### Specification

**Alias:** none

**Argument(s):** none

#### Description

import centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level).

#### 7.2.47.4.2 adapt_import

- Keywords Area
- method
- surrogate_based_uq
- probability_refinement
7.2 method

- **adapt_import**

  Importance sampling option for probability refinement

  **Specification**

  **Alias:** none
  **Argument(s):** none

  **Description**

  `adapt_import` centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level). This continues iteratively until the failure probability estimate converges.

7.2.47.4.3 **mm_adapt_import**

- **Keywords** Area
  - method
  - surrogate_based_uq
  - probability_refinement
  - mm_adapt_import

  Importance sampling option for probability refinement

  **Specification**

  **Alias:** none
  **Argument(s):** none

  **Description**

  `mm_adapt_import` starts with all of the samples located in the failure region to build a multimodal sampling density. First, it uses a small number of samples around each of the initial samples in the failure region. Note that these samples are allocated to the different points based on their relative probabilities of occurrence: more probable points get more samples. This early part of the approach is done to search for “representative” points. Once these are located, the multimodal sampling density is set and then `mm_adapt_import` proceeds similarly to `adapt_import` (sample until convergence).

7.2.47.4.4 **refinement_samples**

- **Keywords** Area
  - method
  - surrogate_based_uq
  - probability_refinement
  - refinement_samples

  Number of samples used to refine a probability estimate or sampling design.
Specification

**Alias:** none

**Argument(s):** INTEGERLIST

### Description

Probability estimate: Specify the (scalar) number of samples used to improve a probability estimate. If using unimodal sampling all samples are assigned to the sampling center. If using multi-modal sampling the samples are split between multiple samples according to some internally computed weights.

Sampling design: Specify one or a sequence of refinement samples to augment the initial samples in a sampling design.

7.2.47.5 final_moments

- **Keywords Area**
- method
- surrogate_based_uq
- final_moments

Output moments of the specified type and include them within the set of final statistics.

### Specification

**Alias:** none

**Argument(s):** none

**Default:** standard

**Child Keywords:**

<table>

<tr>
<td>Required (Choose One)</td>
<td>Final moment type (Group 1)</td>
<td>none</td>
<td>Omit moments from the set of final statistics.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>standard</td>
<td>Output standardized moments and include them within the set of final statistics.</td>
</tr>
</tbody>
</table>
**Description**

When performing a nested study that may employ moment statistics on the inner loop, it can be desirable to control the type of these moments. The `final_moments` specification supports options of `none`, `standard` (default), or `central`, corresponding to omission of moments, standardized moments (mean, standard deviation, skewness, and excess kurtosis), or central moments (mean, variance, 3rd central, and 4th central).

The presence or omission of moment results in the final statistics influences the outer level mappings in the case of a nested study. For example, `final_moments none` can allow for a more compact specification of primary and/or secondary response mappings.

**Examples**

The following method specification overrides the default to print central moments and include them in the set of final statistics.

```
method,
sampling
  samples = 50 seed = 1234
  response_levels = 3.6e+11 1.2e+05 3.5e+05
  final_moments central
```

Overriding the default to `none` as follows:

```
method,
sampling
  samples = 50 seed = 1234
  response_levels = 3.6e+11 1.2e+05 3.5e+05
  final_moments none
```

allows associated nested model mappings to be simplified from:

```
model
  nested
    sub_method_pointer = 'UQ'
    primary_response_mapping = 0. 0. 1. 0. 0. 1. 0. 0. 0.
    secondary_response_mapping = 0. 0. 0. 0. 0. 0. 0. 0. 1.
```

to a more compact version focused only on the response level mappings (two leading zeros per response function for moment mappings have been removed):

```
model
  nested
    sub_method_pointer = 'UQ'
    primary_response_mapping = 1. 1. 0.
    secondary_response_mapping = 0. 0. 1.
```

**7.2.47.5.1 none**

- Keywords Area
- method
- surrogate_based_uq
- final_moments
Omit moments from the set of final statistics.

Specification

Alias: none

Argument(s): none

Description

The omission of moment results from the final statistics can allow for a more compact definition of primary and/or secondary response mappings within a nested model specification.

Examples

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
  final_moments none
```

7.2.47.5.2 standard

- Keywords Area
- method
- surrogate_based_uq
- final_moments
- standard

Output standardized moments and include them within the set of final statistics.

Specification

Alias: none

Argument(s): none

Description

Output standardized moments (mean, standard deviation, skewness, and excess kurtosis) and include the first two within the set of final statistics to be used at a higher level (e.g., optimization under uncertainty, mixed aleatory-epistemic UQ). This inclusion of moment results affects the primary and/or secondary response mappings in a nested model specification.

Examples

The following method specification overrides the default to print central moments and include them in the set of final statistics.
7.2 method

method,
sampling
  samples = 50 seed = 1234
  response_levels = 3.6e+11 1.2e+05 3.5e+05
  final_moments standard

7.2.47.5.3 central

• Keywords Area
• method
• surrogate_based_uq
• final_moments
• central

Output central moments and include them within the set of final statistics.

Specification

Argument(s): none

Description

Output central moments (mean, variance, 3rd central, and 4th central) and include the first two within the set of final statistics to be used at a higher level (e.g., optimization under uncertainty, mixed aleatory-epistemic UQ). This inclusion of moment results affects the primary and/or secondary response mappings in a nested model specification.

Examples

The following method specification overrides the default to print central moments and include them in the set of final statistics.

method,
sampling
  samples = 50 seed = 1234
  response_levels = 3.6e+11 1.2e+05 3.5e+05
  final_moments central

7.2.47.6 response_levels

• Keywords Area
• method
• surrogate_based_uq
• response_levels

Values at which to estimate desired statistics for each response
Specification

**Alias:** none

**Argument(s):** REALLIST

**Default:** No CDF/CCDF probabilities/reliabilities to compute

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>num_response_levels</td>
<td>Number of values at which to estimate desired statistics for each response</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>compute</td>
<td>Selection of statistics to compute at each response level</td>
</tr>
</tbody>
</table>

**Description**

The `response_levels` specification provides the target response values for which to compute probabilities, reliabilities, or generalized reliabilities (forward mapping).

**Default Behavior**

If `response_levels` are not specified, no statistics will be computed. If they are, probabilities will be computed by default.

**Expected Outputs**

If `response_levels` are specified, Dakota will create two tables in the standard output: a Probability Density function (PDF) histogram and a Cumulative Distribution Function (CDF) table. The PDF histogram has the lower and upper endpoints of each bin and the corresponding density of that bin. Note that the PDF histogram has bins defined by the `probability_levels` and/or `response_levels` in the Dakota input file. If there are not very many levels, the histogram will be coarse. Dakota does not do anything to optimize the bin size or spacing. The CDF table has the list of response levels and the corresponding probability that the response value is less than or equal to each response level threshold.

**Usage Tips**

The `num_response_levels` is used to specify which arguments of the `response_levels` correspond to which response.

**Examples**

For example, specifying a `response_levels` of 52.3 followed with `compute probabilities` will result in the calculation of the probability that the response value is less than or equal to 52.3, given the uncertain distributions on the inputs.

For an example with multiple responses, the following specification

```
response_levels = 1. 2. .1 .2 .3 .4 10. 20. 30.
num_response_levels = 2 4 3
```

would assign the first two response levels (1., 2.) to response function 1, the next four response levels (.1, .2, .3, .4) to response function 2, and the final three response levels (10., 20., 30.) to response function 3. If the `num-`
The response levels key were omitted from this example, then the response levels would be evenly distributed among the response functions (three levels each in this case).

The Dakota input file below specifies a sampling method with response levels of interest.

```
method,
    sampling,
        samples = 100 seed = 1
        complementary distribution
        response_levels = 3.6e+11 4.0e+11 4.4e+11

### Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

A forward mapping involves computing the belief and plausibility probability level for a specified response level.

7.2.47.6.1 num_response_levels

- Keywords Area
- method
- surrogate_based_uq
- response_levels
- num_response_levels

Number of values at which to estimate desired statistics for each response

### Specification

**Alias:** none

**Argument(s):** INTEGERLIST

**Default:** response_levels evenly distributed among response functions

### Description

The num_response_levels keyword allows the user to specify the number of response values, for each response, at which estimated statistics are of interest. Statistics that can be computed are probabilities and reliabilities, both according to either a cumulative distribution function or a complementary cumulative distribution function.

**Default Behavior**

If num_response_levels is not specified, the response_levels will be evenly distributed among the responses.
Expected Outputs

The specific output will be determined by the type of statistics that are specified. In a general sense, the output will be a list of response level-statistic pairs that show the estimated value of the desired statistic for each response level specified.

Examples

```
method sampling
  samples = 100
  seed = 34785
  num_response_levels = 1 1 1
  response_levels = 0.5 0.5 0.5
```

7.2.47.6.2 compute

- Keywords Area
- method
- surrogate_based_uq
- response_levels
- compute

Selection of statistics to compute at each response level

Specification

**Alias:** none

**Argument(s):** none

**Default:** probabilities

**Child Keywords:**

</table>
Keywords Area

<table>
<thead>
<tr>
<th>Optional</th>
<th>system</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Compute system reliability (series or parallel)</td>
</tr>
</tbody>
</table>

Description

The compute keyword is used to select which forward statistical mapping is calculated at each response level.

Default Behavior

If response_levels is not specified, no statistics are computed. If response_levels is specified but compute is not, probabilities will be computed by default. If both response_levels and compute are specified, then one of the following must be specified: probabilities, reliabilities, or gen_reliabilities.

Expected Output

The type of statistics specified by compute will be reported for each response level.

Usage Tips

CDF/CCDF probabilities are calculated for specified response levels using a simple binning approach.

CDF/CCDF reliabilities are calculated for specified response levels by computing the number of sample standard deviations separating the sample mean from the response level.

Examples

```
method sampling
  sample_type random
  samples = 100 seed = 1
complementary distribution
  response_levels = 3.6e+11 4.0e+11 4.4e+11
                  6.0e+04 6.5e+04 7.0e+04
                  3.5e+05 4.0e+05 4.5e+05
  compute reliabilities
```

7.2.47.6.2.1 probabilities

- Keywords Area
- method
- surrogate_based_uq
- response_levels
- compute
- probabilities

Computes probabilities associated with response levels

Specification

Alias: none
Argument(s): none
Description

The `probabilities` keyword directs Dakota to compute the probability that the model response will be below (cumulative) or above (complementary cumulative) a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the probabilities are computed by default. To explicitly specify it in the Dakota input file, though, the `probabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-probability pairs that give the probability that the model response will be below or above the corresponding response level, depending on the distribution defined.

Examples

```plaintext
method sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                      6.0e+04 6.5e+04 7.0e+04
                      3.5e+05 4.0e+05 4.5e+05
    compute probabilities
```

7.2.47.6.2.2 reliability

- Keywords Area
- method
- surrogate_based_uq
- response_levels
- compute
- reliabilities

Computes reliabilities associated with response levels

Specification

Alias: none
Argument(s): none

Description

The `reliabilities` keyword directs Dakota to compute reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the reliabilities are not computed by default. To change this behavior, the `reliabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-reliability pairs according to the distribution defined.
Examples

method
sampling
  sample_type random
  samples = 100 seed = 1
complementary distribution
  response_levels = 3.6e+11 4.0e+11 4.4e+11
                             6.0e+04 6.5e+04 7.0e+04
                             3.5e+05 4.0e+05 4.5e+05
  compute gen_reliabilities

7.2.47.6.2.3 gen_reliabilities

• Keywords Area

• method

• surrogate_based_uq

• response_levels

• compute

• gen_reliabilities

Computes generalized reliabilities associated with response levels

Specification

Alias: none

Argument(s): none

Description

The gen_reliabilities keyword directs Dakota to compute generalized reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

Default Behavior

If response_levels is specified, the generalized reliabilities are not computed by default. To change this behavior, the gen_reliabilities keyword should be specified in conjunction with the compute keyword.

Expected Outputs

The Dakota output is a set of response level-generalized reliability pairs according to the distribution defined.

Examples

method
sampling
  sample_type random
  samples = 100 seed = 1
complementary distribution
  response_levels = 3.6e+11 4.0e+11 4.4e+11
                             6.0e+04 6.5e+04 7.0e+04
                             3.5e+05 4.0e+05 4.5e+05

<tr>
<td>Required (Choose One)</td>
<td>series</td>
<td>Aggregate response statistics assuming a series system</td>
</tr>
<tr>
<td></td>
<td>parallel</td>
<td>Aggregate response statistics assuming a parallel system</td>
</tr>
</tbody>
</table>

Description

With the system probability/reliability option, statistics for specified response_levels are calculated and reported assuming the response functions combine either in series or parallel to produce a total system response.

For a series system, the system fails when any one component (response) fails. The probability of failure is the complement of the product of the individual response success probabilities.

For a parallel system, the system fails only when all components (responses) fail. The probability of failure is the product of the individual response failure probabilities.

Specify probability levels at which to estimate the corresponding response value

Specification

**Alias:** none
**Argument(s):** REALLIST
**Default:** No CDF/CCDF response levels to compute

Child Keywords:
7.2 method

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>num_probability_levels</td>
<td></td>
<td>Specify which probability_levels correspond to which response</td>
</tr>
</tbody>
</table>

Description

Response levels are calculated for specified CDF/CCDF probabilities by indexing into a sorted samples array (the response levels computed are not interpolated and will correspond to one of the sampled values).

Expected Output

If `probability_levels` are specified, Dakota will create two tables in the standard output: a Probability Density function (PDF) histogram and a Cumulative Distribution Function (CDF) table. The PDF histogram has the lower and upper endpoints of each bin and the corresponding density of that bin. Note that the PDF histogram has bins defined by the `probability_levels` and/or `response_levels` in the Dakota input file. If there are not very many levels, the histogram will be coarse. Dakota does not do anything to optimize the bin size or spacing. The CDF table has the list of response levels and the corresponding probability that the response value is less than or equal to each response level threshold.

Examples

The Dakota input file below specifies a sampling method with probability levels of interest.

```dakota
method,
    sampling,
    samples = 100 seed = 1
    complementary distribution
    probability_levels = 1. .66 .33 .0 .
                       1. .8 .5 .0 .
                       1. .3 .2 .0 .
variables,
    normal_uncertain = 2
        means = 248.89, 593.33
        std_deviations = 12.4, 29.7
        descriptors = 'TF1n', 'TF2n'
    uniform_uncertain = 2
        lower_bounds = 199.3, 474.63
        upper_bounds = 298.5, 712.
        descriptors = 'TF1u', 'TF2u'
    weibull_uncertain = 2
        alphas = 12., 30.
        betas = 250., 590.
        descriptors = 'TF1w', 'TF2w'
histogram_bin_uncertain = 2
    num_pairs = 3 4
    abscissas = 5 8 10 .1 .2 .3 .4
    counts = 17 21 0 12 24 12 0
    descriptors = 'TF1h', 'TF2h'
interface,
    system asynch evaluation_concurrency = 5
    analysis_driver = 'text_book'
responses,
    response_functions = 3
```

Dakota Version 6.16 Reference Manual generated on May 12, 2022
Given the above Dakota input file, the following excerpt from the output shows the PDF and CCDF generated. Note that the bounds on the bins of the PDF are the response values that correspond the probability levels specified in the input file. Those response values are also shown in the CCDF.

Probability Density Function (PDF) histograms for each response function:

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).

7.2.47.10 distribution

- Keywords Area
- method
Selection of cumulative or complementary cumulative functions

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** cumulative (CDF)

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group Distribution Type (CDF/CCDF) (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required(Choose One)</td>
<td></td>
<td>cumulative</td>
<td>Computes statistics according to cumulative functions</td>
</tr>
<tr>
<td></td>
<td></td>
<td>complementary</td>
<td>Computes statistics according to complementary cumulative functions</td>
</tr>
</tbody>
</table>

**Description**

The `distribution` keyword allows the user to select between a cumulative distribution/belief/plausibility function and a complementary cumulative distribution/belief/plausibility function. This choice affects how probabilities and reliability indices are reported.

**Default Behavior**

If the `distribution` keyword is present, it must be accompanied by either `cumulative` or `complementary`. Otherwise, a cumulative distribution will be used by default.

**Expected Outputs**

Output will be a set of model response-probability pairs determined according to the choice of distribution. The choice of distribution also defines the sign of the reliability or generalized reliability indices.

**Examples**

```
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

7.2.47.10.1  cumulative

- Keywords Area
- method
- surrogate_based_uq
7.2 method

- distribution
- cumulative

Computes statistics according to cumulative functions

**Specification**

**Alias**: none

**Argument(s)**: none

**Description**

Statistics on model responses will be computed according to a cumulative distribution/belief/plausibility function.

**Default Behavior**

By default, a cumulative distribution/belief/plausibility function will be used. To explicitly specify it in the Dakota input file, however, the `cumulative` keyword must appear in conjunction with the `distribution` keyword.

**Expected Outputs**

Output will be a set of model response-probability pairs determined according to a cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls below given response thresholds.

**Examples**

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

7.2.47.10.2 complementary

- Keywords Area
- method
- surrogate_based_uq
- distribution
- complementary

Computes statistics according to complementary cumulative functions

**Specification**

**Alias**: none

**Argument(s)**: none
Statistics on model responses will be computed according to a complementary cumulative distribution/belief/plausibility function.

**Default Behavior**

By default, a complementary cumulative distribution/belief/plausibility function will not be used. To change that behavior, the `complementary` keyword must be appear in conjunction with the `distribution` keyword.

**Expected Outputs**

Output will be a set of model response-probability pairs determined according to a complementary cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls above given response thresholds.

**Examples**

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    distribution complementary
```

7.2.47.11 variance_based_decomp

- **Keywords Area**
- method
- surrogate_based_uq
- variance_based_decomp

Activates global sensitivity analysis based on decomposition of response variance into main, interaction, and total effects.

**Specification**

- **Alias**: none
- **Argument(s)**: none
- **Default**: no variance-based decomposition

**Child Keywords**:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>interaction_order</td>
<td>interaction_order</td>
<td>Specify the maximum number of variables allowed in an interaction when reporting interaction metrics.</td>
</tr>
</tbody>
</table>
Description

Dakota can calculate sensitivity indices through variance-based decomposition using the keyword `variance_based_decomp`. This approach decomposes main, interaction, and total effects in order to identify the most important variables and combinations of variables in contributing to the variance of output quantities of interest.

Default Behavior

Because of processing overhead and output volume, `variance_based_decomp` is inactive by default, unless required for dimension-adaptive refinement using Sobol’ indices.

Expected Outputs

When `variance_based_decomp` is specified, sensitivity indices for main effects, total effects, and any interaction effects will be reported. Each of these effects represents the percent contribution to the variance in the model response, where main effects include the aggregated set of univariate terms for each individual variable, interaction effects represent the set of mixed terms (the complement of the univariate set), and total effects represent the complete set of terms (univariate and mixed) that contain each individual variable. The aggregated set of main and interaction sensitivity indices will sum to one, whereas the sum of total effects sensitivity indices will be greater than one due to redundant counting of mixed terms.

Usage Tips

An important consideration is that the number of possible interaction terms grows exponentially with dimension and expansion order. To mitigate this, both in terms of compute time and output volume, possible interaction effects are suppressed whenever no contributions are present due to the particular form of an expansion. In addition, the `interaction_order` and `drop_tolerance` controls can further limit the computational and output requirements.

Examples

```plaintext
method,
    polynomial_chaos # or stoch_collocation
    sparse_grid_level = 3
    variance_based_decomp interaction_order = 2
```

Theory

In this context, we take sensitivity analysis to be global, not local as when calculating derivatives of output variables with respect to input variables. Our definition is similar to that of [76] : "The study of how uncertainty in the output of a model can be apportioned to different sources of uncertainty in the model input.”

Variance based decomposition is a way of using sets of samples to understand how the variance of the output behaves, with respect to each input variable. A larger value of the sensitivity index, $S_i$, means that the uncertainty in the input variable $i$ has a larger effect on the variance of the output. More details on the calculations and interpretation of the sensitivity indices can be found in [90].
Specify the maximum number of variables allowed in an interaction when reporting interaction metrics.

**Specification**

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** Unrestricted (VBD includes all interaction orders present in the expansion)

**Description**

The interaction_order option has been added to allow suppression of higher-order interactions, since the output volume (and memory and compute consumption) of these results could be extensive for high dimensional problems (note: the previous univariate_effects specification is equivalent to interaction_order = 1 in the current specification). Similar to suppression of interactions is the covariance control, which can be selected to be diagonal_covariance or full_covariance, with the former supporting suppression of the off-diagonal covariance terms (to again save compute and memory resources and reduce output volume).

**7.2.47.11.2 drop_tolerance**

- Keywords Area
- method
- surrogate_based_uq
- variance_based_decomp
- drop_tolerance

Suppresses output of sensitivity indices with values lower than this tolerance

**Specification**

**Alias:** none  
**Argument(s):** REAL  
**Default:** All VBD indices displayed

**Description**

The drop_tolerance keyword allows the user to specify a value below which sensitivity indices generated by variance_based_decomp are not displayed.

**Default Behavior**

By default, all sensitivity indices generated by variance_based_decomp are displayed.

**Usage Tips**

For polynomial_chaos, which outputs main, interaction, and total effects by default, the univariate_effects may be a more appropriate option. It allows suppression of the interaction effects since the output volume of these results can be prohibitive for high dimensional problems. Similar to suppression of these interactions is the covariance control, which can be selected to be diagonal_covariance or full_covariance, with the former supporting suppression of the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).
7.2 method

Examples

method,
sampling
  sample_type lhs
  samples = 100
  variance_based_decomp
drop_tolerance = 0.001

7.2.47.12 diagonal_covariance

• Keywords Area
• method
• surrogate_based_uq
• diagonal_covariance

Display only the diagonal terms of the covariance matrix

Specification

Alias: none

Argument(s): none

Default: diagonal_covariance for response vector > 10; else full_covariance

Description

With a large number of responses, the covariance matrix can be very large. diagonal_covariance is used to suppress the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

7.2.47.13 full_covariance

• Keywords Area
• method
• surrogate_based_uq
• full_covariance

Display the full covariance matrix

Specification

Alias: none

Argument(s): none

Description

With a large number of responses, the covariance matrix can be very large. full_covariance is used to force Dakota to output the full covariance matrix.
### 7.2.47.14 import_approx_points_file

- **Keywords Area**
- **method**
- **surrogate_based_uq**
- **import_approx_points_file**

Filename for points at which to evaluate the PCE/SC surrogate

#### Specification

**Alias:** none  
**Argument(s):** STRING  
**Default:** no point import from a file  

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>custom_annotated</td>
<td>Selects custom-annotated tabular file format</td>
</tr>
<tr>
<td>Optional (Choose One)</td>
<td>Tabular Format (Group 1)</td>
<td>annotated</td>
<td>Selects annotated tabular file format</td>
</tr>
<tr>
<td></td>
<td></td>
<td>freeform</td>
<td>Selects freeform file format</td>
</tr>
<tr>
<td>Optional</td>
<td>active_only</td>
<td>Import only active variables from tabular data file</td>
<td></td>
</tr>
</tbody>
</table>

#### Description

**Default Behavior**  No import of points at which to evaluate the surrogate.  

**Expected Output**  The PCE/SC surrogate model will be evaluated at the list of points (input variable values) provided in the file and results tabulated and/or statistics computed at them, depending on the method context.

#### Examples

```dakota
method
polynomial_chaos
  expansion_order = 4
  import_approx_points_file = 'import.mcmc_annot.dat'
  annotated
```

### 7.2.47.14.1 custom_annotated

- **Keywords Area**
- **method**
- **surrogate_based_uq**
• import_approx_points_file
• custom.annotated

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

• file_formats

Specification

Alias: none
Argument(s): none
Default: annotated format
Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>header</td>
<td></td>
<td>Enable header row in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td>eval_id</td>
<td></td>
<td>Enable evaluation ID column in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td>interface_id</td>
<td></td>
<td>Enable interface ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom.annotated, followed by options, in the relevant export/import context.

Usage Tips

• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id

Resulting tabular file:

%eval_id x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 0.9  1.1  0.0002  0.26  0.76
2 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...
```

7.2.47.14.1.1 header

• Keywords Area
• method
• surrogate_based_uq
• import_approx_points_file
• custom_annotated
• header

Enable header row in custom-annotated tabular file

Specification

Alias: none

Argument(s): none

Default: no header

Description

See description of parent custom_annotated

7.2.47.14.1.2 eval_id

• Keywords Area
• method
• surrogate_based_uq
• import_approx_points_file
• custom_annotated
• eval_id

Enable evaluation ID column in custom-annotated tabular file
7.2 method

Specification

Alias: none
Argument(s): none
Default: no eval_id column

Description

See description of parent custom_annotated

7.2.47.14.1.3 interface_id

- Keywords Area
- method
- surrogate_based_uq
- import_approx_points_file
- custom_annotated
- interface_id

Enable interface ID column in custom-annotated tabular file

Specification

Alias: none
Argument(s): none
Default: no interface_id column

Description

See description of parent custom_annotated

7.2.47.14.2 annotated

- Keywords Area
- method
- surrogate_based_uq
- import_approx_points_file
- annotated

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- file_formats
Specification

Alias: none
Argument(s): none
Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

• To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id

• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```dakota
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
annotated
```

Resulting tabular file:

```text
%eval_id interface  x1  x2  obj_fn  nln_ineq_con_1  nln_ineq_con_2
1   NO_ID  0.9   1.1  0.0002  0.26   0.76
2   NO_ID  0.9009999999999999  1.1  0.0001996404857  0.2601620081  0.759955
3   NO_ID  0.89991  1.1  0.0002003604863  0.2598380081  0.760045
...
```

7.2.47.14.3 freeform

• Keywords Area

• method

• surrogate_based_uq

• import_approx_points_file

• freeform

Selects freeform file format
Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none
Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    freeform
```

Resulting tabular file:

```
  0.9  1.1  0.0002  0.26  0.76
  0.90009  1.1  0.0001996404857  0.2601620081  0.759955
  0.89991  1.1  0.0002003604863  0.2598380081  0.760045
...
```

7.2.47.14.4 active_only

- Keywords Area
• method
• surrogate_based_uq
• import_approx_points_file
• active_only

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

• file_formats

Specification

Alias: none
Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword active_only indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

7.2.47.15 export_approx_points_file

• Keywords Area
• method
• surrogate_based_uq
• export_approx_points_file

Output file for surrogate model value evaluations

Specification

Alias: export_points_file
Argument(s): STRING
Default: no point export to a file
Child Keywords:

</table>

Description

Specifies a file in which the points (input variable values) at which the surrogate model is evaluated and corresponding response values computed by the surrogate model will be written. The response values are the surrogate’s predicted approximation to the truth model responses at those points.

Usage Tips

Dakota exports tabular data in one of three formats:

- annotated (default)
- custom_annotated
- freeform

7.2.47.15.1 custom_annotated

- Keywords Area
- method
- surrogate_based_uq
- export_approx_points_file
- custom_annotated

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format

Child Keywords:
<table>

</tr>
</tbody>
</table>

**Description**

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

**Default Behavior**

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

**Usage Tips**

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

**Examples**

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
tabular_data_file = 'dakota_summary.dat'
custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id  x1  x2  obj_fn  nln_ineq_con_1  nln_ineq_con_2
1  0.9  1.1  0.0002  0.26  0.76
2  0.90009  1.1  0.0001996404857  0.2601620081  0.759955
3  0.89991  1.1  0.0002003604863  0.2598380081  0.760045
...```
7.2.47.15.1.1 header

7.2.47.15.2  annotated

- **Keywords Area**
- **method**
- **surrogate_based_uq**
- **export_approx_points_file**
- **annotated**

Selects annotated tabular file format

**Topics**

This keyword is related to the topics:

- **file_formats**

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** annotated format
Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
  tabular_data_file = 'dakota_summary.dat'
  annotated
```

Resulting tabular file:

```
%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 NO_ID 0.9 1.1 0.0002 0.26 0.76
2 NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 NO_ID 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
```

7.2.47.15.3 freeform

- Keywords Area
- method
- surrogate_based_uq
- export_approx_points_file
- freeform

Selects freeform file format

Topics

This keyword is related to the topics:

- file_formats
Specification

Alias: none
Argument(s): none
Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

• Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    freeform
```

Resulting tabular file:

```
0.9  1.1   0.0002  0.26   0.76
0.90009 1.1 0.0001996404857 0.2601620081 0.759955
0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...
```

7.2.47.16 seed

• Keywords Area
• method
• surrogate_based_uq
• seed

Seed of the random number generator
7.2 method

Specification

Alias: none
Argument(s): INTEGER
Default: system-generated (non-repeatable)

Description

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

Default Behavior

If not specified, the seed is randomly generated.

Expected Output

If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

Usage Tips

If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.

Examples

method
  sampling
    sample_type lhs
    samples = 10
    seed = 15347

7.2.47.17 fixed_seed

- Keywords Area
- method
- surrogate_based_uq
- fixed_seed

Reuses the same seed value for multiple random sampling sets

Specification

Alias: none
Argument(s): none
Default: not fixed; pattern varies run-to-run

Description

The fixed_seed flag is relevant if multiple sampling sets will be generated over the coarse of a Dakota analysis. This occurs when using advance methods (e.g., surrogate-based optimization, optimization under uncertainty).
same seed value is reused for each of these multiple sampling sets, which can be important for reducing variability in the sampling results.

Default Behavior

The default behavior is to not use a fixed seed, as the repetition of the same sampling pattern can result in a modeling weakness that an optimizer could potentially exploit (resulting in actual reliabilities that are lower than the estimated reliabilities). For repeatable studies, the seed must also be specified.

Examples

```plaintext
method
  sampling
    sample_type lhs
  samples = 10
  fixed_seed
```

7.2.47.18 model_pointer

- Keywords Area
- method
- surrogate_based_uq
- model_pointer

Identifier for model block to be used by a method

Topics

This keyword is related to the topics:

- block_pointer

Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.

See block_pointer for details about pointers.
Examples

environment
tabular_data
method_pointer = 'UQ'

method
id_method = 'UQ'
model_pointer = 'SURR'
sampling,

**Description**

Tensor train decompositions are approximations that exploit low rank structure in an input-output mapping. Refer to the `function_train` surrogate model for additional details.

**Usage Tips**

This method is a self-contained method alternative to the `function_train` surrogate model specification, similar to current method specifications for polynomial chaos and stochastic collocation. In particular, this `function_train` method specification directly couples with a simulation model (optionally identified with a `model_pointer`) and an additional `function_train` surrogate model specification is not required as these options have been embedded within the method specification.

**Examples**

```dakota
method, function_train
  start_order = 2
  start_rank = 2 kick_rank = 2 max_rank = 10
  adapt_rank
  solver_tolerance = 1e-12
  rounding_tolerance = 1e-12
  convergence_tol = 1e-6
  collocation_points = 100
  samples_on_emulator = 100000
  seed = 531
  response_levels = .1 1. 50. 100. 500. 1000.
  variance_based_decomp
```

<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required</td>
<td></td>
<td>uniform</td>
<td>Refine an expansion uniformly in all dimensions.</td>
</tr>
</tbody>
</table>

**Description**

The `p_refinement` keyword specifies the usage of automated polynomial order refinement, which can be either **uniform** or **dimension_adaptive**.

The **dimension_adaptive** option is supported for the tensor-product quadrature and Smolyak sparse grid options and **uniform** is supported for tensor and sparse grids as well as regression approaches (**collocation_points** or **collocation_ratio**).

Each of these refinement cases makes use of the `max_iterations` and `convergence_tolerance` method independent controls. The former control limits the number of refinement iterations, and the latter control terminates refinement when the two-norm of the change in the response covariance matrix (or, in goal-oriented approaches, the two-norm of change in the statistical quantities of interest (QOI)) falls below the tolerance.

The **dimension_adaptive** case can be further specified to utilize **sobol**, **decay**, or **generalized** refinement controls. The former two cases employ anisotropic tensor/sparse grids in which the anisotropic dimension preference (leading to anisotropic integrations/expansions with differing refinement levels for different random dimensions) is determined using either total Sobol’ indices from variance-based decomposition (**sobol case**: high indices result in high dimension preference) or using spectral coefficient decay rates from a rate estimation technique similar to Richardson extrapolation (**decay case**: low decay rates result in high dimension preference). In these two cases as well as the **uniform** refinement case, the **quadrature_order** or **sparse_grid_level** are ramped by one on each refinement iteration until either of the two convergence controls is satisfied. For the **uniform** refinement case with regression approaches, the **expansion_order** is ramped by one on each iteration while the oversampling ratio (either defined by **collocation_ratio** or inferred from **collocation_points** based on the initial expansion) is held fixed. Finally, the **generalized dimension_adaptive** case is the default adaptive approach; it refers to the generalized sparse grid algorithm, a greedy approach in which
candidate index sets are evaluated for their impact on the statistical QOI, the most influential sets are selected and used to generate additional candidates, and the index set frontier of a sparse grid is evolved in an unstructured and goal-oriented manner (refer to User's Manual PCE descriptions for additional specifics).

For the case of p_refinement or the case of an explicit nested override, Gauss-Hermite rules are replaced with Genz-Keister nested rules and Gauss-Legendre rules are replaced with Gauss-Patterson nested rules, both of which exchange lower integrand precision for greater point reuse.

7.2.48.1.1 uniform

- Keywords Area
- method
- function_train
- p_refinement
- uniform

Refine an expansion uniformly in all dimensions.

Specification

Alias: none

</tbody>
</table>
Description

The quadrature_order or sparse_grid_level are ramped by one on each refinement iteration until either of the two convergence controls is satisfied. For the uniform refinement case with regression approaches, the expansion_order is ramped by one on each iteration while the oversampling ratio (either defined by collocation_ratio or inferred from collocation_points based on the initial expansion) is held fixed.

7.2.48.1.1.1 increment_start_rank

- Keywords Area
- method
- function_train
- p_refinement
- uniform
- increment_start_rank

candidate generation by advancement of starting rank

Specification

Alias: none

Argument(s): none

Description

Within adaptive refinement processes, this specification selects the advancement of start_rank to create new refinement candidates. It is typically used in the absence of adapt_rank to more rigidly define a refinement sequence.

7.2.48.1.1.2 increment_start_order

- Keywords Area
- method
- function_train
- p_refinement
- uniform
- increment_start_order

candidate generation by advancement of starting basis order
Specification

**Alias:** none

**Argument(s):** none

**Description**

Within adaptive refinement processes, this specification selects the advancement of `start_order` to create new refinement candidates. It is typically used in the absence of `adapt_order` to more rigidly define a refinement sequence.

7.2.48.1.1.3 increment_max_rank

- **Keywords Area**
- **method**
- **function_train**
- **p_refinement**
- **uniform**
- **increment_max_rank**

candidate generation by advancement of maximum rank

Specification

**Alias:** none

**Argument(s):** none

**Description**

Within adaptive refinement processes, this specification selects the advancement of `max_rank` to create new refinement candidates. This option requires the use of `adapt_rank`, for which this advancement creates an expanded range for the cross validation (CV) process. Once the CV process saturates (the best rank is less than the max), then no further advancement can occur and the refinement process (for a particular model level/fidelity) halts.

7.2.48.1.1.4 increment_max_order

- **Keywords Area**
- **method**
- **function_train**
- **p_refinement**
- **uniform**
- **increment_max_order**

candidate generation by advancement of maximum basis order
7.2 method

Specification

Alias: none
Argument(s): none

Description

Within adaptive refinement processes, this specification selects the advancement of $\text{max\_order}$ to create new refinement candidates. This option requires the use of $\text{adapt\_order}$, for which this advancement creates an expanded range for the cross validation (CV) process. Once the CV process saturates (the best order is less than the max), then no further advancement can occur and the refinement process (for a particular model level/fidelity) halts.

7.2.48.1.1.5 increment_max_rank_order

- Keywords Area
- method
- function_train
- $p\text{\_refinement}$
- uniform
- increment_max_rank_order

candidate generation by advancement of maximum rank and maximum basis order

Specification

Alias: none
Argument(s): none

Description

Within adaptive refinement processes, this specification selects the advancement of both $\text{max\_rank}$ and $\text{max\_order}$ to create new refinement candidates. This option requires the use of $\text{adapt\_rank}$ and $\text{adapt\_order}$, for which this advancement creates expanded ranges for the cross validation (CV) process. Once the CV process saturates for one or more of these two dimensions (the best rank is less than the max rank and/or the best order is less than the max order), then no further advancement can occur in that dimension for a particular model level/fidelity.

7.2.48.2 max_refinement_iterations

- Keywords Area
- method
- function_train
- max_refinement_iterations

Maximum number of expansion refinement iterations
Specification

Alias: none
Argument(s): INTEGER
Default: 100

Description

Limits the number of times the expansion can be refined under various refinement strategies.

Examples

```
method,
polynomial_chaos
dimension_adaptive generalized
p_refinement
  max_refinement_iterations = 20
  convergence_tol = 1.e-4
  sparse_grid_level = 1
```

7.2.48.3 convergence_tolerance

- Keywords Area
- method
- function_train
- convergence_tolerance

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none
Argument(s): REAL
Default: 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by convergence_tolerance, then this convergence criterion is satisfied on the current iteration.

Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library
This control is used with most optimization and least squares iterators (DOT, CONMIN, NLQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See nl2sol
- NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

7.2.48.4 metric_scale

- Keywords Area
- method
- function_train
- metric_scale

define scaling of statistical metrics when adapting UQ surrogates

Specification

Alias: none
Argument(s): none
Default: relative

<td>absolute</td>
<td>use of absolute statistical metrics when adapting UQ surrogates</td>
</tr>
</tbody>
</table>

Description

When adapting a UQ surrogate model, e.g., by change in response covariance matrix or level mappings, this option controls the use of scaling. The absolute option indicates that there is no scaling such that the statistical change is compared directly to the convergence tolerance. The relative option indicates that the change is measured relative to the current reference value (which evolves during the refinement), such that the convergence tolerance controls the relative change.
Default Behavior
The default is relative.

<td>rls2</td>
<td>Use regularized regression solver for forming function train approximations</td>
</tr>
</tbody>
</table>

Description

Function train approximations are formed based on regression for the set of coefficients described at function_train. Solver options include least squares and regularized regression, where the latter penalizes high-order terms to mitigate overfitting.

Default Behavior

The default regression solver is least squares.

7.2.48.5.1 ls

- Keywords Area
Use least squares solver for forming function train approximations by regression

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

Least squares is the standard solver for forming function train approximations based on regression. This option does not include regularization.

7.2.48.5.2  rls2

**Description**

RLS2 is a regularized least squares solver that applies an $L2$ penalty to mitigate overfitting. It includes the option to specify a penalty parameter.
Penalty value applied in regularized regression solver for function train approximations

Specification

Alias: none
Argument(s): REAL

Description

Regularized regression applies a penalty to aspects of the recovered solution (e.g., cardinality, higher-order oscillatory terms, et al.) to mitigate overfitting. This specification provides the scalar penalty parameter (its value is not currently adapted or cross-validated).

Default Behavior

If this penalty parameter is not specified, then we adopt the internal C3 default.

See Also

These keywords may also be of interest:

• rls2
**Specification**

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** 100

**Description**

When using an iterative polynomial coefficient estimation approach, e.g., cross-validation-based solvers, limits the maximum iterations in the coefficient solver.

7.2.48.7 max_cross_iterations

- Keywords Area
- method
- function_train
- max_cross_iterations

Maximum number of iterations for cross-approximation during a rank adaptation.

**Specification**

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** 1

**Description**

The number of iterations for the cross-approximation algorithm is limited within the adapt_rank procedure.

**See Also**

These keywords may also be of interest:

- adapt_rank

7.2.48.8 solver_tolerance

- Keywords Area
- method
- function_train
- solver_tolerance

Convergence tolerance for the optimizer used during the regression solve.
7.2 method

Specification

**Alias:** none  
**Argument(s):** REAL  
**Default:** 1.0e-10

Description

Defines the function value and function gradient tolerance for optimizer used solving the regression problem for the functional tensor train coefficients.

7.2.48.9 response_scaling

- **Keywords Area**
- **method**
- **function_train**
- **response_scaling**

Perform bounds-scaling on response values prior to surrogate emulation

Specification

**Alias:** none  
**Argument(s):** none  
**Default:** use original data

Description

Particularly in multifidelity methods based on regression solutions at each level of a model hierarchy, scaling can be an issue since the magnitude of discrepancy data may decay rapidly and regression solvers may employ absolute tolerances in places.

By activating `response_scaling`, the set of response data used for each recovery is scaled to [0,1] based on the minimum value and range of the data set. This prevents loss of accuracy due to imbalances in scale across model levels.

These keywords may also be of interest:

- **multifidelity_polynomial_chaos**
- **multifidelity_function_train**

7.2.48.10 tensor_grid

- **Keywords Area**
- **method**
Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** regression with random sample set

**Description**

The collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

7.2.48.11 *collocation_points*

- **Keywords Area**
- **method**
- **function_train**
- **collocation_points**

Number of collocation points used to estimate expansion coefficients

**Specification**

**Alias:** none  
**Argument(s):** INTEGER

**Description**

Specify the number of collocation points used to estimate expansion coefficients using regression approaches. A corresponding sequence specification is documented at, e.g., *collocation_points_sequence* and *collocation_points_sequence_*

**See Also**

These keywords may also be of interest:

- `collocation_points_sequence` method-multilevel_polynomial_chaos-expansion_order_sequence-collocation_ratio-collocation_points_sequence
7.2 method

7.2.48.12 collocation_ratio

- Keywords Area
- method
- function_train
- collocation_ratio

Set the number of points used to build a PCE via regression to be proportional to the number of terms in the expansion.

Specification

**Alias:** none

**Argument(s):** REAL

**Description**

Set the number of points used to build a PCE via regression to be proportional to the number of terms in the expansion. To avoid requiring the user to calculate N from n and p, the collocation_ratio allows for specification of a constant factor applied to N (e.g., collocation_ratio = 2. produces samples = 2N). In addition, the default linear relationship with N can be overridden using a real-valued exponent specified using ratio_order. In this case, the number of samples becomes \( cn^\alpha \) where \( c \) is the collocation_ratio and \( \alpha \) is the ratio_order. The use_derivatives flag informs the regression approach to include derivative matching equations (limited to gradients at present) in the least squares solutions, enabling the use of fewer collocation points for a given expansion order and dimension (number of points required becomes \( cn^\alpha + 1 \)).

7.2.48.13 rounding_tolerance

- Keywords Area
- method
- function_train
- rounding_tolerance

An accuracy tolerance that is used to guide rounding during rank adaptation.

Specification

**Alias:** none

**Argument(s):** REAL

**Default:** 1.e-10

**Description**

The rounding tolerance is used to measure how closely one can approximate a functional tensor train representation at a step of the optimization procedure using one of lower ranks. If this tolerance is small, then less compression is achieved but greater accuracy is obtained. If this tolerance is big, greater compression is achieved at the expense of accuracy.

**Default Behavior**

If this tolerance is not specified, then we adopt the internal C3 default.
See Also

These keywords may also be of interest:

- adapt_rank
- arithmetic_tolerance

7.2.48.14 arithmetic_tolerance

- Keywords Area
- method
- function_train
- arithmetic_tolerance

A secondary rounding tolerance used for post-processing

Specification

Alias: none
Argument(s): REAL
Default: 1.e-10

Description

After forming one or more function train approximations, this tolerance is used for rolling up final results, in particular, combining multilevel/multifidelity expansions and forming products for higher-order moment estimation. It is generally intended as a looser tolerance than rounding_tolerance.

Default Behavior

If this tolerance is not specified, then we adopt the internal C3 default.

See Also

These keywords may also be of interest:

- rounding_tolerance

7.2.48.15 start_order

- Keywords Area
- method
- function_train
- start_order

(Initial) polynomial order of each univariate function within the functional tensor train.
7.2 method

**Specification**

**Alias:** order

**Argument(s):** INTEGER

**Default:** 2

**Child Keywords:**

<table>
<thead>

<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Description**

This specifies the initial polynomial order of each univariate function that makes up the functional tensor train decomposition. In the case of `adapt_order`, polynomial order starts from this value and is then advanced; its maximum value is limited by `max_order` and increments are controlled by `kick_order`.

**Default Behavior**

Default is 2.

**See Also**

These keywords may also be of interest:

- `adapt_order`
- `kick_order`
- `max_order`

7.2.48.15.1 dimension_preference

- Keywords Area
- method
- function_train
- start_order
- dimension_preference

A set of weights specifying the relative importance of each uncertain variable (dimension)

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Default:** isotropic grids

Dakota Version 6.16 Reference Manual generated on May 12, 2022
Description

A set of weights specifying the relative importance of each uncertain variable (dimension). Using this specification leads to anisotropic integrations with differing refinement levels for different random dimensions.

See Also

These keywords may also be of interest:

- sobol
- decay

7.2.48.16 adapt_order

- Keywords Area
- method
- function_train
- adapt_order

Activate adaptive procedure for determining the best basis order

Specification

Alias: none
Argument(s): none
Default: false

Description

This option activates a cross validation procedure to select the best basis order for representing the current set of data. It searches from \( \text{start\_order} \) to \( \text{max\_order} \) in increments of \( \text{kick\_order} \).

Default Behavior
No cross validation for basis order.

Examples

This example shows specification of an order adaptation starting at order 2, incrementing by 2, and limited at order 6.

```plaintext
model,
    id_model = 'FT'
surrogate global function_train
    start_rank = 4
adapt_order start_order = 2 kick_order = 2 max_order = 6
solver_tolerance = 1e-12
    rounding_tolerance = 1e-12
daace_method_pointer = 'SAMPLING'
```

Note that adapt_rank and adapt_order can either be combined or used separately.
See Also

These keywords may also be of interest:

- `start_order`
- `kick_order`
- `max_order`

### 7.2.48.17 kick_order

- Keywords Area
- method
- function_train
- kick_order

increment used when adapting the basis order in function train methods

#### Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** 1

#### Description

Used in combination with `adapt_order, kick_order` defines the size of the increment that is used during the cross validation process, within the range of `start_order` and `max_order`.

#### Default Behavior

Default is 1.

#### See Also

These keywords may also be of interest:

- `adapt_order`

### 7.2.48.18 max_order

- Keywords Area
- method
- function_train
- max_order

Maximum polynomial order of each univariate function within the functional tensor train.
**Specification**

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** unsigned short max

**Description**

This specification is inactive for current adaptation options.  
In future adaptation options (i.e., cross-approximation adaptation), this will specify the maximum order that can be obtained during adaptation, where polynomial order will start from `start_order` and be limited by `max_order`.

**Default Behavior**

Max order is unbounded (adaptive sweep will stop when CV error increases).

**See Also**

These keywords may also be of interest:

- `start_order`

7.2.48.19 `max_cv_order_candidates`

- `Keywords Area`
- `method`
- `function_train`
- `max_cv_order_candidates`

Limit the number of cross-validation candidates for basis order

**Specification**

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** ushort max

**Description**

When generating refinement candidates by advancing the upper bound used for a cross-validation range, the number of cross-validation can eventually become excessive and hamper algorithm progress. This control limits the maximum number of candidates, which when active, will increase the lower bound for this range as the upper bound is advanced.

**See Also**

These keywords may also be of interest:

7.2.48.20 start_rank

• Keywords Area
• method
• function_train
• start_rank

The initial rank used for the starting point during a rank adaptation.

Specification

**Alias:** rank

**Argument(s):** INTEGER

**Default:** 2

Description

The *adapt_rank* procedure increments the rank on each iteration, starting from the rank defined by *start_rank*.

**Default Behavior**

Default is 2.

See Also

These keywords may also be of interest:

• *adapt_rank*

7.2.48.21 adapt_rank

• Keywords Area
• method
• function_train
• adapt_rank

Activate adaptive procedure for determining best rank representation
Specification

_alias: none

_Argument(s): none

_Default: false

Description

The adaptive algorithm proceeds as follows:

1. Start from rank \( \text{start\_rank} \) and form an approximation.
2. Adapt the current approximation by searching for a solution with lower rank that achieves L2 accuracy within epsilon tolerance of the reference.
3. If a lower rank solution is found with comparable accuracy, then stop. If not, increase the rank by an amount specified by \( \text{kick\_rank} \).
4. Return to step 2 and continue until either \( \text{max\_rank} \) is reached or a converged rank (rank less than current reference with comparable accuracy) is found.

Default Behavior

No cross validation for rank.

Examples

This example shows specification of a rank adaptation starting at rank 2, incrementing by 2, and limited at rank 10.

```python
model,
    id_model = 'FT'
    surrogate global function_train
    start_order = 5
    adapt_rank start_rank = 2 kick_rank = 2 max_rank = 10
    solver_tolerance = 1e-12
    rounding_tolerance = 1e-12
    dace_method_pointer = 'SAMPLING'
```

Note that \( \text{adapt\_rank} \) and \( \text{adapt\_order} \) can either be combined or used separately.

- _method_
- _function_train_
- _kick_rank_

The increment in rank employed during each iteration of the rank adaptation.
7.2 method

Specification

Alias: none
Argument(s): INTEGER
Default: 1

Description

The adapt_rank procedure increments the rank on each iteration, using an increment defined by kick_rank

Default Behavior

Default is 1.

See Also

These keywords may also be of interest:

- adapt_rank

7.2.48.23 max_rank

- Keywords Area
- method
- function_train
- max_rank

Limits the maximum rank that is explored during a rank adaptation.

Specification

Alias: none
Argument(s): INTEGER
Default: size_t max

Description

The adapt_rank procedure increments the rank on each iteration, and the maximum value is limited by max_rank

Default Behavior

Max rank is unbounded (adaptive sweep will stop when CV error increases).

See Also

These keywords may also be of interest:

- adapt_rank
7.2.48.24  max_cv_rank_candidates

- Keywords Area
- method
- function_train
- max_cv_rank_candidates

Limit the number of cross-validation candidates for rank

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** size_t max

**Description**

When generating refinement candidates by advancing the upper bound used for a cross-validation range, the number of cross-validation can eventually become excessive and hamper algorithm progress. This control limits the maximum number of candidates, which when active, will increase the lower bound for this range as the upper bound is advanced.

- function_train
- multifidelity_function_train

7.2.48.25  samples_on_emulator

- Keywords Area
- method
- function_train
- samples_on_emulator

Number of samples at which to evaluate an emulator (surrogate)

**Specification**

**Alias:** samples

**Argument(s):** INTEGER
Description

How many approximate function evaluations to perform on the emulator model, e.g., to compute statistics.

Default Behavior

The default number of samples is method-dependent.

Examples

Perform 10000 samples on the PCE approximation of the true model:

```plaintext
method
   polynomial_chaos
       quadrature_order = 2
       samples_on_emulator = 10000
```

7.2.48.26 sample_type

- Keywords Area
- method
- function_train
- sample_type

Selection of sampling strategy

Specification

Alias: none

Argument(s): none

Default: random

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional Required (Choose One)</th>
<th>Description of Group Sample Type (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>lhs</td>
<td>Uses Latin Hypercube Sampling (LHS) to sample variables</td>
</tr>
<tr>
<td></td>
<td></td>
<td>random</td>
<td>Uses purely random Monte Carlo sampling to sample variables</td>
</tr>
</tbody>
</table>

Description

The `sample_type` keyword allows the user to select between two types of sampling: Monte Carlo (pure random) and Latin hypercube (stratified) sampling.

The incremental keywords are deprecated; instead use `samples` together with `refinement_samples`.

Default Behavior
If the `sample_type` keyword is present, it must be accompanied by `lhs` or `random`. In most contexts, `lhs` is the default (exception: multilevel_sampling uses Monte Carlo by default).

**Examples**

```
method
  sampling
    sample_type lhs
    samples = 20
    seed = 83921
```

7.2.48.26.1  lhs

- Keywords Area
- method
- function_train
- sample_type
- lhs

Uses Latin Hypercube Sampling (LHS) to sample variables

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The `lhs` keyword invokes Latin Hypercube Sampling as the means of drawing samples of uncertain variables according to their probability distributions. This is a stratified, space-filling approach that selects variable values from a set of equi-probable bins.

**Default Behavior**

Latin Hypercube Sampling is the default sampling mode in most contexts (exception: multilevel_sampling). To explicitly specify LHS in the Dakota input file, the `lhs` keyword must appear in conjunction with the `sample_type` keyword.

**Usage Tips**

Latin Hypercube Sampling is very robust and can be applied to any problem. It is fairly effective at estimating the mean of model responses and linear correlations with a reasonably small number of samples relative to the number of variables.

**Examples**

```
method
  sampling
    sample_type lhs
    samples = 20
```

7.2.48.26.2  random

- Keywords Area
- method
Uses purely random Monte Carlo sampling to sample variables

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The `random` keyword invokes Monte Carlo sampling as the means of drawing samples of uncertain variables according to their probability distributions.

**Default Behavior**

In most contexts, Monte Carlo sampling is not the default sampling mode (exception: `multilevel_sampling`). To change this behavior, the `random` keyword must be specified in conjunction with the `sample_type` keyword.

**Usage Tips**

Monte Carlo sampling is more computationally expensive than Latin Hypercube Sampling as it requires a larger number of samples to accurately estimate statistics.

**Examples**

```plaintext
method
    sampling
        sample_type random
        samples = 200
```

**rng**

- **Keywords Area**
- **method**
- **function_train**
- **rng**

Selection of a random number generator

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** Mersenne twister ( mt19937 )

**Child Keywords:**
### Description

The `rng` keyword is used to indicate a choice of random number generator.

#### Default Behavior

If specified, the `rng` keyword must be accompanied by either `rnum2` (pseudo-random numbers) or `mt19937` (random numbers generated by the Mersenne twister). Otherwise, `mt19937`, the Mersenne twister is used by default.

#### Usage Tips

The default is recommended, as the Mersenne twister is a higher quality random number generator.

#### Examples

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2

7.2.48.27.1  mt19937
```

- Keywords Area
- method
- function_train
- rng
- mt19937

Generates random numbers using the Mersenne twister

### Specification

- **Alias:** none
- **Argument(s):** none

### Description

The `mt19937` keyword directs Dakota to use the Mersenne twister to generate random numbers. Additional information can be found on wikipedia: [http://en.wikipedia.org/wiki/Mersenne_twister](http://en.wikipedia.org/wiki/Mersenne_twister).
Default Behavior

mt19937 is the default random number generator. To specify it explicitly in the Dakota input file, however, it must be specified in conjunction with the rng keyword.

Usage Tips

Use of the Mersenne twister random number generator (mt19937) is recommended.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng mt19937
```

7.2.48.27.2  rnum2

- Keywords Area
- method
- function_train
- rng
- rnum2

Generates pseudo-random numbers using the Pecos package

Specification

Alias: none
Argument(s): none

Description

The rnum2 keyword directs Dakota to use pseudo-random numbers generated by the Pecos package.

Default Behavior

rnum2 is not used by default. To change this behavior, it must be specified in conjunction with the rng keyword.

Usage Tips

Use of the Mersenne twister random number generator (mt19937) is recommended over rnum2.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2
```
7.2.48.28 probability_refinement

- Keywords Area
- method
- function_train
- probability_refinement

Allow refinement of probability and generalized reliability results using importance sampling.

Topics

This keyword is related to the topics:

- reliability_methods

Specification

Alias: sample_refinement

Argument(s): none

Default: no refinement

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group Importance Sampling Approach (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required (Choose One)</td>
<td>Importance sampling option for probability refinement</td>
<td>import</td>
<td></td>

<td>Importance sampling option for probability refinement</td>
<td>mm_adapt_import</td>
<td></td>
</tr>
<tr>
<td>Optional</td>
<td>Number of samples used to refine a probability estimate or sampling design</td>
<td>refinement_samples</td>
<td></td>
</tr>
</tbody>
</table>

Description

The `probability_refinement` allows refinement of probability and generalized reliability results using importance sampling. If one specifies `probability_refinement`, there are some additional options. One can specify which type of importance sampling to use (`import`, `adapt_import`, or `mm_adapt_import`). Additionally, one can specify the number of refinement samples to use with `refinement_samples` and the seed to use with `seed`.

The `probability_refinement` density reweighting accounts originally was developed based on Gaussian distributions. It now accounts for additional non-Gaussian cases.
Importance sampling option for probability refinement

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

`import` centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level).

Importance sampling option for probability refinement

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

`adapt_import` centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level). This continues iteratively until the failure probability estimate converges.
7.2.48.28.3 mm_adapt_import

- Keywords Area
- method
- function_train
- probability_refinement
- mm_adapt_import

Importance sampling option for probability refinement

Specification

Alias: none
Argument(s): none

Description

mm_adapt_import starts with all of the samples located in the failure region to build a multimodal sampling density. First, it uses a small number of samples around each of the initial samples in the failure region. Note that these samples are allocated to the different points based on their relative probabilities of occurrence: more probable points get more samples. This early part of the approach is done to search for “representative” points. Once these are located, the multimodal sampling density is set and then mm_adapt_import proceeds similarly to adapt_import (sample until convergence).

7.2.48.28.4 refinement_samples

- Keywords Area
- method
- function_train
- probability_refinement
- refinement_samples

Number of samples used to refine a probability estimate or sampling design.

Specification

Alias: none
Argument(s): INTEGERLIST

Description

Probability estimate: Specify the (scalar) number of samples used to improve a probability estimate. If using unimodal sampling all samples are assigned to the sampling center. If using multi-modal sampling the samples are split between multiple samples according to some internally computed weights.

Sampling design: Specify one or a sequence of refinement samples to augment the initial_samples in a sampling design.
Output moments of the specified type and include them within the set of final statistics.

**Specification**

**Alias:** none  
**Argument(s):** none

</table>

**Description**

When performing a nested study that may employ moment statistics on the inner loop, it can be desirable to control the type of these moments. The `final_moments` specification supports options of `none`, `standard` (default), or `central`, corresponding to omission of moments, standardized moments (mean, standard deviation, skewness, and excess kurtosis), or central moments (mean, variance, 3rd central, and 4th central).

The presence or omission of moment results in the final statistics influences the outer level mappings in the case of a nested study. For example, `final_moments none` can allow for a more compact specification of primary and/or secondary response mappings.

**Examples**

The following method specification overrides the default to print `central` moments and include them in the set of final statistics.

```
method,  
sampling
```
samples = 50 seed = 1234  
response_levels = 3.6e+11 1.2e+05 3.5e+05  
final_moments central

Overriding the default to `none` as follows:

```
method,  
sampling  
samples = 50 seed = 1234  
response_levels = 3.6e+11 1.2e+05 3.5e+05  
final_moments none
```

allows associated nested model mappings to be simplified from:

```
model  
nested  
  sub_method_pointer = 'UQ'  
  primary_response_mapping = 0. 0. 1. 0. 0. 1. 0. 0. 0.  
  secondary_response_mapping = 0. 0. 0. 0. 0. 0. 0. 0. 1.
```

to a more compact version focused only on the response level mappings (two leading zeros per response function for moment mappings have been removed):

```
model  
nested  
  sub_method_pointer = 'UQ'  
  primary_response_mapping = 1. 1. 0.  
  secondary_response_mapping = 0. 0. 1.
```

- Keywords Area
- method
- function_train
- final_moments
- none

Omit moments from the set of final statistics.

**Specification**

*Alias:* none

*Argument(s):* none

**Description**

The omission of moment results from the final statistics can allow for a more compact definition of primary and/or secondary response mappings within a nested model specification.

**Examples**

```
method,  
sampling  
samples = 50 seed = 1234  
response_levels = 3.6e+11 1.2e+05 3.5e+05  
final_moments none
```
Output standardized moments and include them within the set of final statistics.

**Specification**

**Alias**: none

**Argument(s)**: none

**Description**

Output standardized moments (mean, standard deviation, skewness, and excess kurtosis) and include the first two within the set of final statistics to be used at a higher level (e.g., optimization under uncertainty, mixed aleatory-
epistemic UQ). This inclusion of moment results affects the primary and/or secondary response mappings in a nested model specification.

**Examples**

The following method specification overrides the default to print central moments and include them in the set of final statistics.

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments standard
```

Output central moments and include them within the set of final statistics.

**Specification**

**Alias**: none

**Argument(s)**: none
Output central moments (mean, variance, 3rd central, and 4th central) and include the first two within the set of final statistics to be used at a higher level (e.g., optimization under uncertainty, mixed aleatory-epistemic U-Q). This inclusion of moment results affects the primary and/or secondary response mappings in a nested model specification.

Examples

The following method specification overrides the default to print central moments and include them in the set of final statistics.

```
method,
sampling
   samples = 50 seed = 1234
   response_levels = 3.6e+11 1.2e+05 3.5e+05
   final_moments central
```

- Keywords Area
- method
- function_train
- response_levels

Values at which to estimate desired statistics for each response

Specification

Alias: none

Argument(s): REALLIST

Default: No CDF/CCDF probabilities/reliabilities to compute

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_response_levels</td>
<td>Number of values at which to estimate desired statistics for each response</td>
<td></td>
<td></td>
</tr>
<tr>
<td>compute</td>
<td>Selection of statistics to compute at each response level</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Description

The response_levels specification provides the target response values for which to compute probabilities, reliabilities, or generalized reliabilities (forward mapping).

Default Behavior
If `response_levels` are not specified, no statistics will be computed. If they are, probabilities will be computed by default.

**Expected Outputs**

If `response_levels` are specified, Dakota will create two tables in the standard output: a Probability Density function (PDF) histogram and a Cumulative Distribution Function (CDF) table. The PDF histogram has the lower and upper endpoints of each bin and the corresponding density of that bin. Note that the PDF histogram has bins defined by the `probability_levels` and/or `response_levels` in the Dakota input file. If there are not very many levels, the histogram will be coarse. Dakota does not do anything to optimize the bin size or spacing. The CDF table has the list of response levels and the corresponding probability that the response value is less than or equal to each response level threshold.

**Usage Tips**

The `num_response_levels` is used to specify which arguments of the `response_level` correspond to which response.

**Examples**

For example, specifying a `response_level` of 52.3 followed with `compute probabilities` will result in the calculation of the probability that the response value is less than or equal to 52.3, given the uncertain distributions on the inputs.

For an example with multiple responses, the following specification

```plaintext
response_levels = 1, 2, 3, 4, 52, 30, 10
num_response_levels = 2, 4, 3
```

would assign the first two response levels (1, 2) to response function 1, the next four response levels (3, 4, 52, 30) to response function 2, and the final three response levels (10, 20, 30) to response function 3. If the `num_response_levels` key were omitted from this example, then the response levels would be evenly distributed among the response functions (three levels each in this case).

The Dakota input file below specifies a sampling method with response levels of interest.

```plaintext
method,    
sampling,  
samples = 100, seed = 1  
complementary distribution  
response_levels = 3.6e+11 4.0e+11 4.4e+11 5.0e+11 6.0e+11 6.5e+11 7.0e+11 3.5e+14 4.0e+14 4.5e+14
variables,  
normal_uncertain = 2  
means = 248.89, 593.33  
std deviations = 12.4, 29.7  
descriptors = 'TF1n', 'TF2n'  
uniform_uncertain = 2  
lower_bounds = 199.3, 474.63  
upper_bounds = 298.5, 712  
descriptors = 'TF1u', 'TF2u'  
weibull_uncertain = 2  
alphas = 12., 30.  
betas = 250., 590.  
descriptors = 'TF1w', 'TF2w'  
histogram_bin_uncertain = 2  
num_pairs = 3, 4  
abscissas = 5 8 10 .1 .2 .3 .4  
counts = 17 21 0 12 24 12 0  
descriptors = 'TF1h', 'TF2h'  
histogram_point_uncertain = 1  
real = 1  
num_pairs = 2  
abscissas = 3 4  
counts = 1 1  
descriptors = 'TF3h'
```
Given the above Dakota input file, the following excerpt from the output shows the PDF and CCDF generated. Note that the bounds on the bins of the PDF are the response values specified in the input file. The probability levels corresponding to those response values are shown in the CCDF.

**Theory**

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

A forward mapping involves computing the belief and plausibility probability level for a specified response level.
7.2.48.30.1  num_response_levels

- Keywords Area
- method
- function_train
- response_levels
- num_response_levels

Number of values at which to estimate desired statistics for each response

Specification

**Alias:** none  

**Argument(s):** INTEGERLIST  

**Default:** response_levels evenly distributed among response functions

Description

The `num_response_levels` keyword allows the user to specify the number of response values, for each response, at which estimated statistics are of interest. Statistics that can be computed are probabilities and reliabilities, both according to either a cumulative distribution function or a complementary cumulative distribution function.

**Default Behavior**

If `num_response_levels` is not specified, the response_levels will be evenly distributed among the responses.

**Expected Outputs**

The specific output will be determined by the type of statistics that are specified. In a general sense, the output will be a list of response level-statistic pairs that show the estimated value of the desired statistic for each response level specified.

**Examples**

```
method
  sampling
    samples = 100
    seed = 34785
    num_response_levels = 1 1 1
    response_levels = 0.5 0.5 0.5
```

7.2.48.30.2  compute

- Keywords Area
- method
- function_train
- response_levels
- compute

Selection of statistics to compute at each response level
Specification

**Alias:** none

**Argument(s):** none

**Default:** probabilities

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group Statistics to Compute (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required (Choose One)</td>
<td>probabilities</td>
<td>probabilities</td>
<td>Computes probabilities associated with response levels</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reliabilities</td>
<td>Computes reliabilities associated with response levels</td>
</tr>
<tr>
<td></td>
<td></td>
<td>gen_reliabilities</td>
<td>Computes generalized reliabilities associated with response levels</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>system</td>
<td>Compute system reliability (series or parallel)</td>
</tr>
</tbody>
</table>

**Description**

The **compute** keyword is used to select which forward statistical mapping is calculated at each response level.

**Default Behavior**

If **response_levels** is not specified, no statistics are computed. If **response_levels** is specified but **compute** is not, probabilities will be computed by default. If both **response_levels** and **compute** are specified, then one of the following must be specified: **probabilities**, **reliabilities**, or **gen_reliabilities**.

**Expected Output**

The type of statistics specified by **compute** will be reported for each response level.

**Usage Tips**

CDF/CCDF probabilities are calculated for specified response levels using a simple binning approach.

CDF/CCDF reliabilities are calculated for specified response levels by computing the number of sample standard deviations separating the sample mean from the response level.

**Examples**

```plaintext
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11 6.0e+04 6.5e+04 7.0e+04
```
7.2.48.30.2.1 probabilities

- Keywords Area
- method
- function_train
- response_levels
- compute
- probabilities

Computes probabilities associated with response levels

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

The **probabilities** keyword directs Dakota to compute the probability that the model response will be below (cumulative) or above (complementary cumulative) a specified response value. This is done for every response level designated for each response.

**Default Behavior**

If **response_levels** is specified, the probabilities are computed by default. To explicitly specify it in the Dakota input file, though, the **probabilities** keyword should be specified in conjunction with the **compute** keyword.

**Expected Outputs**

The Dakota output is a set of response level-probability pairs that give the probability that the model response will be below or above the corresponding response level, depending on the distribution defined.

**Examples**

```
method  
sampling  
sample_type random  
samples = 100 seed = 1  
complementary_distribution  
response_levels = 3.6e+11 4.0e+11 4.4e+11  
6.0e+04 6.5e+04 7.0e+04  
3.5e+05 4.0e+05 4.5e+05  
compute probabilities
```

7.2.48.30.2.2 reliabilities

- Keywords Area
- method
- function_train
- response_levels
Computes reliabilities associated with response levels

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

The *reliabilities* keyword directs Dakota to compute reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

**Default Behavior**

If *response_levels* is specified, the reliabilities are not computed by default. To change this behavior, the *reliabilities* keyword should be specified in conjunction with the *compute* keyword.

**Expected Outputs**

The Dakota output is a set of response level-reliability pairs according to the distribution defined.

**Examples**

```
method sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11 6.0e+04 6.5e+04 7.0e+04 3.5e+05 4.0e+05 4.5e+05
    compute reliabilities
```

Computes generalized reliabilities associated with response levels

**Specification**

**Alias:** none  
**Argument(s):** none
Description

The `gen_reliabilities` keyword directs Dakota to compute generalized reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the generalized reliabilities are not computed by default. To change this behavior, the `gen_reliabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-generalized reliability pairs according to the distribution defined.

Examples

```plaintext
method sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                     6.0e+04 6.5e+04 7.0e+04
                     3.5e+05 4.0e+05 4.5e+05
    compute gen_reliabilities
```

<td><strong>series</strong></td>
<td>Aggregate response statistics assuming a series system</td>
</tr>
</tbody>
</table>
Description

With the system probability/reliability option, statistics for specified response_levels are calculated and reported assuming the response functions combine either in series or parallel to produce a total system response.

For a series system, the system fails when any one component (response) fails. The probability of failure is the complement of the product of the individual response success probabilities.

For a parallel system, the system fails only when all components (responses) fail. The probability of failure is the product of the individual response failure probabilities.

- `function_train`
- `probability_levels`

Specify probability levels at which to estimate the corresponding response value

Specification

**Alias:** none

**Argument(s):** REALLIST

**Default:** No CDF/CCDF response levels to compute

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_probability_levels</td>
<td>Specify which probability_levels correspond to which response</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Description

Response levels are calculated for specified CDF/CCDF probabilities by indexing into a sorted samples array (the response levels computed are not interpolated and will correspond to one of the sampled values).

Expected Output

If `probability_levels` are specified, Dakota will create two tables in the standard output: a Probability Density function (PDF) histogram and a Cumulative Distribution Function (CDF) table. The PDF histogram has the lower and upper endpoints of each bin and the corresponding density of that bin. Note that the PDF histogram has bins defined by the `probability_levels` and/or `response_levels` in the Dakota input file. If there are not very many levels, the histogram will be coarse. Dakota does not do anything to optimize the bin size or spacing. The CDF table has the list of response levels and the corresponding probability that the response value is less than or equal to each response level threshold.

Examples

The Dakota input file below specifies a sampling method with probability levels of interest.
Given the above Dakota input file, the following excerpt from the output shows the PDF and CCDF generated. Note that the bounds on the bins of the PDF are the response values that correspond to the probability levels specified in the input file. Those response values are also shown in the CCDF.

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).

7.2.48.31.1 num_probability_levels

- Keywords Area
- method
- function_train
- probability_levels
- num_probability_levels

Specify which probability_levels correspond to which response

Specification

Alias: none

Argument(s): INTEGERLIST

Default: probability_levels evenly distributed among response functions

Description

See parent page

7.2.48.32 reliability_levels

- Keywords Area
- method
Specify reliability levels at which the response values will be estimated

**Specify which reliability_levels correspond to which response**

**Specification**

**Alias:** none

**Argument(s):** REALLIST

**Default:** No CDF/CCDF response levels to compute

**Child Keywords:**

<table>

7.2.48.34  distribution

- Keywords Area
- method
- function_train
- distribution

Selection of cumulative or complementary cumulative functions

Specification

Alias: none
Argument(s): none
Default: cumulative (CDF)

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional Required (Choose One)</th>
<th>Description of Group Distribution Type (CDF/CCDF) (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>cumulative</td>
<td></td>
<td>Computes statistics according to cumulative functions</td>
</tr>
</tbody>
</table>
Description

The `distribution` keyword allows the user to select between a cumulative distribution/belief/plausibility function and a complementary cumulative distribution/belief/plausibility function. This choice affects how probabilities and reliability indices are reported.

Default Behavior

If the `distribution` keyword is present, it must be accompanied by either `cumulative` or `complementary`. Otherwise, a cumulative distribution will be used by default.

Expected Outputs

Output will be a set of model response-probability pairs determined according to the choice of distribution. The choice of distribution also defines the sign of the reliability or generalized reliability indices.

Examples

```dakota
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

### 7.2.48.34.1 cumulative

- **Keywords Area**
- **method**
- **function_train**
- **distribution**
- **cumulative**

Computes statistics according to cumulative functions

Specification

**Alias:** none

**Argument(s):** none

Description

Statistics on model responses will be computed according to a cumulative distribution/belief/plausibility function.

Default Behavior

By default, a cumulative distribution/belief/plausibility function will be used. To explicitly specify it in the Dakota input file, however, the `cumulative` keyword must be appear in conjunction with the `distribution` keyword.

Expected Outputs
Output will be a set of model response-probability pairs determined according to a cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls below given response thresholds.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

7.2.48.34.2 complementary

- Keywords Area
- method
- function_train
- distribution
- complementary

Computes statistics according to complementary cumulative functions

Specification

**Alias:** none

**Argument(s):** none

Description

Statistics on model responses will be computed according to a complementary cumulative distribution/belief/plausibility function.

**Default Behavior**

By default, a complementary cumulative distribution/belief/plausibility function will not be used. To change that behavior, the `complementary` keyword must appear in conjunction with the `distribution` keyword.

**Expected Outputs**

Output will be a set of model response-probability pairs determined according to a complementary cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls above given response thresholds.

Examples

```
method
  sampling
    sample_type lhs
    samples = 10
    distribution complementary
```

7.2.48.35 variance_based_decomp

- Keywords Area
Activates global sensitivity analysis based on decomposition of response variance into main, interaction, and total effects.

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** no variance-based decomposition

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>interaction_order</td>
<td>Specify the maximum number of variables allowed in an interaction when reporting interaction metrics.</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>drop_tolerance</td>
<td>Suppresses output of sensitivity indices with values lower than this tolerance</td>
</tr>
</tbody>
</table>

**Description**

Dakota can calculate sensitivity indices through variance-based decomposition using the keyword `variance_based_decomp`. This approach decomposes main, interaction, and total effects in order to identify the most important variables and combinations of variables in contributing to the variance of output quantities of interest.

**Default Behavior**

Because of processing overhead and output volume, `variance_based_decomp` is inactive by default, unless required for dimension-adaptive refinement using Sobol’ indices.

**Expected Outputs**

When `variance_based_decomp` is specified, sensitivity indices for main effects, total effects, and any interaction effects will be reported. Each of these effects represents the percent contribution to the variance in the model response, where main effects include the aggregated set of univariate terms for each individual variable, interaction effects represent the set of mixed terms (the complement of the univariate set), and total effects represent the complete set of terms (univariate and mixed) that contain each individual variable. The aggregated set of main and interaction sensitivity indices will sum to one, whereas the sum of total effects sensitivity indices will be greater than one due to redundant counting of mixed terms.

**Usage Tips**

An important consideration is that the number of possible interaction terms grows exponentially with dimension and expansion order. To mitigate this, both in terms of compute time and output volume, possible interaction effects are suppressed whenever no contributions are present due to the particular form of an expansion. In addition, the `interaction_order` and `drop_tolerance` controls can further limit the computational and output requirements.
Examples

method, polynomial_chaos # or stoch_collocation
    sparse_grid_level = 3
    variance_based_decomp interaction_order = 2

Theory

In this context, we take sensitivity analysis to be global, not local as when calculating derivatives of output variables with respect to input variables. Our definition is similar to that of [76] : "The study of how uncertainty in the output of a model can be apportioned to different sources of uncertainty in the model input."

Variance based decomposition is a way of using sets of samples to understand how the variance of the output behaves, with respect to each input variable. A larger value of the sensitivity index, $S_i$, means that the uncertainty in the input variable $i$ has a larger effect on the variance of the output. More details on the calculations and interpretation of the sensitivity indices can be found in [90].

7.2.48.35.1 interaction_order

- Keywords Area
- method
- function_train
- variance_based_decomp
- interaction_order

Specify the maximum number of variables allowed in an interaction when reporting interaction metrics.

Specification

Alias: none

Argument(s): INTEGER

Default: Unrestricted (VBD includes all interaction orders present in the expansion)

Description

The interaction_order option has been added to allow suppression of higher-order interactions, since the output volume (and memory and compute consumption) of these results could be extensive for high dimensional problems (note: the previous univariate_effects specification is equivalent to interaction_order = 1 in the current specification). Similar to suppression of interactions is the covariance control, which can be selected to be diagonal_covariance or full_covariance, with the former supporting suppression of the off-diagonal covariance terms (to again save compute and memory resources and reduce output volume).

7.2.48.35.2 drop_tolerance

- Keywords Area
- method
- function_train
- variance_based_decomp
- drop_tolerance

Suppresses output of sensitivity indices with values lower than this tolerance
**7.2 method**

**Specification**

**Alias:** none  
**Argument(s):** REAL  
**Default:** All VBD indices displayed

**Description**

The `drop_tolerance` keyword allows the user to specify a value below which sensitivity indices generated by `variance_based_decomp` are not displayed.

**Default Behavior**

By default, all sensitivity indices generated by `variance_based_decomp` are displayed.

**Usage Tips**

For `polynomial_chaos`, which outputs main, interaction, and total effects by default, the `univariate_effects` may be a more appropriate option. It allows suppression of the interaction effects since the output volume of these results can be prohibitive for high dimensional problems. Similar to suppression of these interactions is the covariance control, which can be selected to be `diagonal_covariance` or `full_covariance`, with the former supporting suppression of the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

**Examples**

```plaintext
method,  
sampling  
    sample_type lhs  
    samples = 100  
    variance_based_decomp  
    drop_tolerance = 0.001
```

**7.2.48.36 diagonal_covariance**

- **Keywords Area**
- **method**
- **function_train**
- **diagonal_covariance**

Display only the diagonal terms of the covariance matrix

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** diagonal_covariance for response vector > 10; else full_covariance

**Description**

With a large number of responses, the covariance matrix can be very large. `diagonal_covariance` is used to suppress the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).
7.2.48.37 full_covariance

- Keywords Area
- method
- function_train
- full_covariance

Display the full covariance matrix

Specification

**Alias:** none  
**Argument(s):** none

Description

With a large number of responses, the covariance matrix can be very large. `full_covariance` is used to force Dakota to output the full covariance matrix.

7.2.48.38 import_approx_points_file

- Keywords Area
- method
- function_train
- import_approx_points_file

Filename for points at which to evaluate the PCE/SC surrogate

Specification

**Alias:** none  
**Argument(s):** STRING  
**Default:** no point import from a file

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional (Choose One)</td>
<td>Tabular Format (Group 1)</td>
<td>custom_annotated</td>
<td>Selects custom-annotated tabular file format</td>
</tr>
<tr>
<td></td>
<td></td>
<td>annotated</td>
<td>Selects annotated tabular file format</td>
</tr>
</tbody>
</table>
Description

**Default Behavior**  No import of points at which to evaluate the surrogate.

**Expected Output**  The PCE/SC surrogate model will be evaluated at the list of points (input variable values) provided in the file and results tabulated and/or statistics computed at them, depending on the method context.

Examples

```plaintext
method polynomial_chaos
    expansion_order = 4
    import_approx_points_file = 'import.mcmc_annot.dat'
```

**7.2.48.38.1 custom_annotated**

- **Keywords Area**
- **method**
- **function_train**
- **import_approx_points_file**
- **custom_annotated**

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

- **file_formats**

Specification

**Alias:** none

**Argument(s):** none

**Default:** annotated format

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>freeform</td>
<td>Selects freeform file format</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>active_only</td>
<td>Import only active variables from tabular data file</td>
</tr>
</tbody>
</table>
A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
tabular_data_file = 'dakota_summary.dat'
custom_annotated header eval_id
```

Resulting tabular file:

```plaintext
%eval_id x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 0.9 1.1 0.0002 0.26 0.76
2 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...```

7.2.48.38.2 annotated

• Keywords Area
• method
• function_train
• import_approx_points_file
• annotated

Selects annotated tabular file format

Topics

This keyword is related to the topics:

• file_formats

Specification

Alias: none
Argument(s): none
Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

• To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id
7.2 method

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated

Resulting tabular file:

%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 NO_ID  0.9  1.1  0.0002  0.26  0.76
2 NO_ID  0.90009 1.1 0.0001996404857  0.2601620081  0.759955
3 NO_ID  0.89991 1.1 0.0002003604863  0.2598380081  0.760045
...
```

7.2.48.38.3 freeform

- Keywords Area
  - method
  - function_train
  - import_approx_points_file
  - freeform

Selects freeform file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format
Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```plaintext
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
freeform

Resulting tabular file:

<p>| | | | | |</p>
<table>
<thead>
<tr>

<td>0.38</td>
</tr>
</tbody>
</table>

7.2.48.38.4 active_only

- Keywords Area
- method
- function_train
- import_approx_points_file
- active_only

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- file_formats
7.2 method

Specification

Alias: none
Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

7.2.48.39 export_approx_points_file

- Keywords Area
- method
- function_train
- export_approx_points_file

Output file for surrogate model value evaluations

Specification

Alias: export_points_file
Argument(s): STRING
Default: no point export to a file

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>

7.2.48.39.3 freeform

- Keywords Area
- method
- function_train
- export_approx_points_file
- freeform

Selects freeform file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
• In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
freeform
```

Resulting tabular file:

```
  0.9  1.1  0.0002  0.26  0.76
0.90009 1.1  0.0001996404857  0.2601620081  0.759955
0.89991 1.1  0.0002003604863  0.2598380081  0.760045
...
```

7.2.48.40 seed

• Keywords Area
  • method
  • function_train
  • seed

Seed of the random number generator

Specification

**Alias:** none

**Argument(s):** INTEGER

**Default:** system-generated (non-repeatable)

Description

The random seed control provides a mechanism for making a stochastic method repeatable. That is, the use of the same random seed in identical studies will generate identical results.

**Default Behavior**

If not specified, the seed is randomly generated.

**Expected Output**

If seed is specified, a stochastic study will generate identical results when repeated using the same seed value. Otherwise, results are not guaranteed to be the same.

**Usage Tips**

If a stochastic study was run without seed specified, and the user later wishes to repeat the study using the same seed, the value of the seed used in the original study can be found in the output Dakota prints to the screen. That value can then be added to the Dakota input file.
Examples

```plaintext
method
    sampling
        sample_type lhs
        samples = 10
        seed = 15347
```

7.2.48.41 fixed_seed

- Keywords Area
- method
- function_train
- fixed_seed

Reuses the same seed value for multiple random sampling sets

Specification

**Alias:** none

**Argument(s):** none

**Default:** not fixed; pattern varies run-to-run

Description

The `fixed_seed` flag is relevant if multiple sampling sets will be generated over the course of a Dakota analysis. This occurs when using advanced methods (e.g., surrogate-based optimization, optimization under uncertainty). The same seed value is reused for each of these multiple sampling sets, which can be important for reducing variability in the sampling results.

Default Behavior

The default behavior is to not use a fixed seed, as the repetition of the same sampling pattern can result in a modeling weakness that an optimizer could potentially exploit (resulting in actual reliabilities that are lower than the estimated reliabilities). For repeatable studies, the `seed` must also be specified.

Examples

```plaintext
method
    sampling
        sample_type lhs
        samples = 10
        fixed_seed
```

7.2.48.42 model_pointer

- Keywords Area
- method
- function_train
- model_pointer

Identifier for model block to be used by a method
Topics

This keyword is related to the topics:

- block_pointer

Specification

**Alias:** none

**Argument(s):** STRING

**Default:** method use of last model parsed (or use of default model if none parsed)

Description

The *model_pointer* is used to specify which *model* block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a *model* block in the Dakota input file that has a corresponding *id_model* with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a *model_pointer* for each method is imperative.

See *block_pointer* for details about pointers.

Examples

```plaintext
environment
  tabular_data
  method_pointer = 'UQ'

method
  id_method = 'UQ'
  model_pointer = 'SURR'
  sampling,
    samples = 10
    seed = 98765 rng rnum2
    response_levels = 0.1 0.2 0.6
    0.1 0.2 0.6
    0.1 0.2 0.6
  sample_type lhs
distribution cumulative

model
  id_model = 'SURR'
  surrogate global,
  dace_method_pointer = 'DACE'
  polynomial quadratic

method
  id_method = 'DACE'
  model_pointer = 'DACE_M'
  sampling sample_type lhs
  samples = 121 seed = 5034 rng rnum2

model
  id_model = 'DACE_M'
  single
  interface_pointer = 'I1'
```
variables
uniform_uncertain = 2
  lower_bounds = 0. 0.
  upper_bounds = 1. 1.
  descriptors = ’x1’ ’x2’

interface
  id_interface = ’I1’
  system asynch evaluation_concurrency = 5
  analysis_driver = ’text_book’

responses
  response_functions = 3
  no_gradients
  no_hessians

### Description

As described in the `function_train` method and the `function_train` model, the function train (FT) approximation is a polynomial expansion that exploits low rank structure within the mapping from input random variables to output quantities of interest (QoI). For multilevel and multifidelity function train approximations, we decompose this expansion into several constituent expansions, one per model form or solution control level, where independent function train approximations are constructed for the low-fidelity/coarse resolution model and one or more levels of model discrepancy.

In a three-model case with low-fidelity (L), medium-fidelity (M), and high-fidelity (H) models and an additive discrepancy approach, we can denote this as:

\[
Q^H \approx \hat{Q}_L^H + \hat{\Delta}_{ML}^H + \hat{\Delta}_{HM}^H
\]

where \(\Delta_{ij}^H\) represents a discrepancy expansion computed from \(Q_i - Q_j\) and reduced rank representations of these discrepancies may be targeted (\(r_{HM} < r_{ML} < r_L\)).

In multifidelity approaches, sample allocation for the constituent expansions can be performed with either no, individual, or integrated adaptive refinement as described in `allocation_control`.

### Expected HDF5 Output

If Dakota was built with HDF5 support and run with the `hdf5` keyword, this method writes the following results to HDF5:

- Integration and Expansion Moments (expansion moments only)
- Probability Density
- Level Mappings

In addition, the execution group has the attribute `equiv_hf_evals`, which records the equivalent number of high-fidelity evaluations.

### See Also

<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required</td>
<td>uniform</td>
<td>uniform</td>
<td>Refine an expansion uniformly in all dimensions.</td>
</tr>
</tbody>
</table>

Description

The `p_re refinement` keyword specifies the usage of automated polynomial order refinement, which can be either `uniform` or `dimension_adaptive`.

The `dimension_adaptive` option is supported for the tensor-product quadrature and Smolyak sparse grid options and `uniform` is supported for tensor and sparse grids as well as regression approaches (`collocation_points` or `collocation_ratio`).

Each of these refinement cases makes use of the `max_iterations` and `convergence_tolerance` method independent controls. The former control limits the number of refinement iterations, and the latter control terminates refinement when the two-norm of the change in the response covariance matrix (or, in goal-oriented approaches, the two-norm of change in the statistical quantities of interest (QOI)) falls below the tolerance.

The `dimension_adaptive` case can be further specified to utilize `sobol`, `decay`, or `generalized` refinement controls. The former two cases employ anisotropic tensor/sparse grids in which the anisotropic dimension preference (leading to anisotropic integrations/expansions with differing refinement levels for different random dimensions) is determined using either total Sobol' indices from variance-based decomposition (sobol case: high indices result in high dimension preference) or using spectral coefficient decay rates from a rate estimation technique similar to Richardson extrapolation (decay case: low decay rates result in high dimension preference). In these two cases as well as the `uniform` refinement case, the `quadrature_order` or `sparse_grid_level` are ramped by one on each refinement iteration until either of the two convergence controls is satisfied. For the `uniform` refinement case with regression approaches, the `expansion_order` is ramped by one on each iteration while the oversampling ratio (either defined by `collocation_ratio` or inferred from `collocation_points` based on the initial expansion) is held fixed. Finally, the `generalized dimension_adaptive` case is the default adaptive approach; it refers to the generalized sparse grid algorithm, a greedy approach in which candidate index sets are evaluated for their impact on the statistical QOI, the most influential sets are selected and used to generate additional candidates, and the index set frontier of a sparse grid is evolved in an unstructured and goal-oriented manner (refer to User's Manual PCE descriptions for additional specifics).

For the case of `p_re refinement` or the case of an explicit nested override, Gauss-Hermite rules are replaced with Genz-Keister nested rules and Gauss-Legendre rules are replaced with Gauss-Patterson nested rules, both of which exchange lower integrand precision for greater point reuse.
7.2 method  

7.2.49.1.1 uniform  

- Keywords Area  
- method  
- multifidelity_function_train  
- p_refinement  
- uniform  

Refine an expansion uniformly in all dimensions.

**Specification**

**Description**

Within adaptive refinement processes, this specification selects the advancement of `start_order` to create new refinement candidates. It is typically used in the absence of `adapt_order` to more rigidly define a refinement sequence.
7.2.49.1.3 increment_max_rank

- Keywords Area
- method
- multifidelity_function_train
- p_refinement
- uniform
- increment_max_rank

candidate generation by advancement of maximum rank

Specification

Alias: none
Argument(s): none

Description

Within adaptive refinement processes, this specification selects the advancement of max_rank to create new refinement candidates. This option requires the use of adapt_rank, for which this advancement creates an expanded range for the cross validation (CV) process. Once the CV process saturates (the best rank is less than the max), then no further advancement can occur and the refinement process (for a particular model level/fidelity) halts.

7.2.49.1.4 increment_max_order

- Keywords Area
- method

- method
- multifidelity_function_train
- p_refinement
- uniform
- increment_max_rank_order

candidate generation by advancement of maximum rank and maximum basis order

Specification

Alias: none
Argument(s): none

Description

Within adaptive refinement processes, this specification selects the advancement of both max_rank and max_order to create new refinement candidates. This option requires the use of adapt_rank and adapt_order, for which this advancement creates expanded ranges for the cross validation (CV) process. Once the CV process saturates for one or more of these two dimensions (the best rank is less than the max rank and/or the best order is less than the max order), then no further advancement can occur in that dimension for a particular model level/fidelity.

7.2.49.2 max_refinement_iterations

- Keywords Area
- method
- multifidelity_function_train
- max_refinement_iterations

Maximum number of expansion refinement iterations

Specification

Alias: none
Argument(s): INTEGER
Default: 100

Description

Limits the number of times the expansion can be refined under various refinement strategies.
Examples

```
method,
polynomial_chaos
  dimension_adaptive generalized
  p_refinement
    max_refinement_iterations = 20
    convergence_tol = 1.e-4
  sparse_grid_level = 1
```

7.2.49.3 convergence_tolerance

- **Keywords Area**
- **method**
- **multifidelity_function_train**
- **convergence_tolerance**

Stopping criterion based on objective function or statistics convergence

**Topics**

This keyword is related to the topics:

- **method_independent_controls**

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 1.e-4

**Description**

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by convergence_tolerance, then this convergence criterion is satisfied on the current iteration. Therefore, permissible values are between 0 and 1, non-inclusive.

**Behavior Varies by Package/Library**

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

**Notes on each library:**

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See nl2sol
• NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
• NPSOL: used as a line search tolerance, not as a relative convergence tolerance

7.2.49.4 metric_scale

</tr>
</tbody>
</table>

absolute usage of absolute statistical metrics when adapting UQ surrogates

Description

When adapting a UQ surrogate model, e.g., by change in response covariance matrix or level mappings, this option controls the use of scaling. The absolute option indicates that there is no scaling such that the statistical change is compared directly to the convergence tolerance. The relative option indicates that the change is measured relative to the current reference value (which evolves during the refinement), such that the convergence tolerance controls the relative change.

Default Behavior

The default is relative.

Expected Output

Usage Tips

</table>

Description

Multifidelity surrogate approaches, including polynomial chaos, stochastic collocation, and function train, can optionally employ a integrated greedy competition across the model sequence, where each model index can supply one or more refinement candidates which are competed to determine the candidate with the greatest impact on the QoI statistics per unit cost. This greedy competition implicitly determines the optimal sample allocation across model indices.

Default Behavior

The default, when allocation_control is not specified, is to compute or adapt separately for each model index (individual instead of integrated refinement).

7.2.49.6.1 greedy

• Keywords Area
  • method
  • multifidelity_function_train
  • allocation_control
  • greedy

Sample allocation based on greedy refinement within multifidelity function train

Specification

Alias: none

Argument(s): none
Description

Multifidelity function train supports greedy refinement strategies based on regression approaches for computing expansion coefficients. The key idea is that each level of the model hierarchy being approximated can generate one or more candidates for refinement. These candidates are competed against each other within a unified competition, and the candidate that induces the largest change in the statistical QoI (response covariance by default, or results of any $z/p/\beta/\beta^*$ level mappings when specified), normalized by relative cost of evaluating the candidate, is selected and then used to generate additional candidates for consideration at its model level.

Examples

The following example of greedy multifidelity function train starts from a rank-two order-two reference expansion for each level, with twice as many samples as regression coefficients, and generates candidate refinements for each level that are competed in an integrated greedy competition. The number of new samples for the incremented candidate is determined from the collocation ratio times the regression size (which may either be fixed or adapted in the case of adapt_rank). In this example, the number of candidates for each level is limited to one uniform refinement of the current expansion, and uniform refinement currently involves an advancement in the basis order for all approximation cores in combination with a rank adaptation between two and ten, incrementing in steps of two.

```dakota
method,
  model_pointer = 'HIERARCH'
  multifidelity_function_train
    allocation_control greedy
    p_refinement uniform
    start_rank_sequence = 2 2 2 2
    adapt_rank kick_rank = 2 max_rank = 10
    start_order_sequence = 2 2 2 2 max_order = 10
    collocation_ratio = 2 seed = 160415
    convergence_tolerance = 1.e-2
    max_refinement_iterations = 5
```

7.2.49.7 discrepancy_emulation

- Keywords Area
- method
- multifidelity_function_train
- discrepancy_emulation

Formulation for emulation of model discrepancies.

Specification

Alias: none
Argument(s): none
Default: distinct
Child Keywords:
In many uncertainty quantification approaches, model discrepancies are emulated using, e.g., polynomial chaos, stochastic collocation, or Gaussian process models. Two formulations are available for this emulation:

1. distinct emulation (default), in which we directly approximate the difference or ratio between the evaluations of two models or solution levels.

2. recursive emulation (experimental option), in which we approximate a difference or ratio among the new model evaluation and the emulator approximation of the previous model.

The latter approach is a form of hierarchical emulation in which we emulate the surplus between the previous emulator and the new modeling level. This approach has a few advantages: (i) it reduces bias by correcting for emulation errors that occur at previous levels, and (ii) it does not require paired model evaluations for each discrepancy level, which reduces cost, allows for disparate sample points, and simplifies data imports.

On the other hand, its primary disadvantage is that the aggregate emulation is only as good as its weakest link, in that a poor emulator recovery can create difficulty in accurately resolving discrepancies that are recursively dependent on it. Thus, the distinct approach may tend to be more expensive in exchange for greater robustness.

### Examples

```plaintext
method, multilevel_polynomial_chaos
  expansion_order_sequence = 2
  collocation_ratio = .9
  orthogonal_matching_pursuit
  discrepancy_emulation recursive
```

7.2.49.7.1  distinct

- Keywords Area
- method
- multifidelity_function_train
- discrepancy_emulation
- distinct

Distinct formulation for emulation of model discrepancies.

### Specification

**Alias:** paired  
**Argument(s):** none
Description

The distinct approach to discrepancy emulation directly approximate the difference or ratio between the evaluations of two models or solution levels. Refer to the parent documentation node for additional discussion.

Examples

7.2.49.7.2 recursive

- Keywords Area
- method
- multifidelity_function_train
- discrepancy_emulation
- recursive

Recursive formulation for emulation of model discrepancies.

Specification

Alias: none

Argument(s): none

Description

The recursive approach to discrepancy emulation approximates a difference or ratio among the new model evaluation and the emulator approximation of the previous model. Refer to the parent documentation node for additional discussion.

Examples

7.2.49.8 rounding_tolerance

- Keywords Area
- method
- multifidelity_function_train
- rounding_tolerance

An accuracy tolerance that is used to guide rounding during rank adaptation.

Specification

Alias: none

Argument(s): REAL

Default: 1.e-10
Description

The rounding tolerance is used to measure how closely one can approximate a functional tensor train representation at a step of the optimization procedure using one of lower ranks. If this tolerance is small, then less compression is achieved but greater accuracy is obtained. If this tolerance is big, greater compression is achieved at the expense of accuracy.

**Default Behavior**

If this tolerance is not specified, then we adopt the internal C3 default.

**See Also**

These keywords may also be of interest:

- adapt_rank
- arithmetic_tolerance

**7.2.49.9 arithmetic_tolerance**

- **Keywords Area**
- method
- multifidelity_function_train
- arithmetic_tolerance

A secondary rounding tolerance used for post-processing

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 1.e-10

**Description**

After forming one or more function train approximations, this tolerance is used for rolling up final results, in particular, combining multilevel/multifidelity expansions and forming products for higher-order moment estimation. It is generally intended as a looser tolerance than rounding_tolerance.

**Default Behavior**

If this tolerance is not specified, then we adopt the internal C3 default.

**See Also**

These keywords may also be of interest:

- rounding_tolerance
7.2.49.10 regression_type

- Keywords Area
- method
- multifidelity_function_train
- regression_type

Type of solver for forming function train approximations by regression

Specification

Alias: none
Argument(s): none
Child Keywords:

<table>

<td>Is</td>
<td>Use least squares solver for forming function train approximations by regression</td>
</tr>
<tr>
<td></td>
<td>rls2</td>
<td>Use regularized regression solver for forming function train approximations</td>
<td></td>
</tr>
</tbody>
</table>

Description

Function train approximations are formed based on regression for the set of coefficients described at function_train. Solver options include least squares and regularized regression, where the latter penalizes high-order terms to mitigate overfitting.

Default Behavior

The default regression solver is least squares.

7.2.49.10.1 Is

- Keywords Area
- method
- multifidelity_function_train
- regression_type
- Is

Use least squares solver for forming function train approximations by regression
Specification

Alias: none

Argument(s): none

Description

Least squares is the standard solver for forming function train approximations based on regression. This option does not include regularization.

7.2.49.10.2 rls2

- Keywords Area
- method
- multifidelity_function_train
- regression_type
- rls2

Use regularized regression solver for forming function train approximations

Specification

Alias: none

Argument(s): none

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required</td>
<td></td>
<td>l2_penalty</td>
<td>Penalty value applied in regularized regression solver for function train approximations</td>
</tr>
</tbody>
</table>

Description

RLS2 is a regularized least squares solver that applies an $L_2$ penalty to mitigate overfitting. It includes the option to specify a penalty parameter.

See Also

These keywords may also be of interest:

- l2_penalty
Penalty value applied in regularized regression solver for function train approximations

Specification

**Alias:** none

**Argument(s):** REAL

**Description**

Regularized regression applies a penalty to aspects of the recovered solution (e.g., cardinality, higher-order oscillatory terms, et al.) to mitigate overfitting. This specification provides the scalar penalty parameter (its value is not currently adapted or cross-validated).

**Default Behavior**

If this penalty parameter is not specified, then we adopt the internal C3 default.

**See Also**

These keywords may also be of interest:

- rls2

7.2.49.11 max_solver_iterations

Maximum iterations in determining polynomial coefficients

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 100

**Description**

When using an iterative polynomial coefficient estimation approach, e.g., cross-validation-based solvers, limits the maximum iterations in the coefficient solver.
7.2.49.12  max_cross_iterations

• Keywords Area
• method
• multifidelity_function_train
• max_cross_iterations

Maximum number of iterations for cross-approximation during a rank adaptation.

Specification

Alias: none
Argument(s): INTEGER
Default: 1

Description

The number of iterations for the cross-approximation algorithm is limited within the adapt_rank procedure.

See Also

These keywords may also be of interest:

• adapt_rank

7.2.49.13  solver_tolerance

• Keywords Area
• method
• multifidelity_function_train
• solver_tolerance

Convergence tolerance for the optimizer used during the regression solve.

Specification

Alias: none
Argument(s): REAL
Default: 1.0e-10

Description

Defines the function value and function gradient tolerance for optimizer used solving the regression problem for the functional tensor train coefficients.
7.2.49.14  response_scaling

- Keywords Area
- method
- multifidelity_function_train
- response_scaling

Perform bounds-scaling on response values prior to surrogate emulation

**Specification**

**Alias**: none  
**Argument(s)**: none  
**Default**: use original data

**Description**

Particularly in multifidelity methods based on regression solutions at each level of a model hierarchy, scaling can be an issue since the magnitude of discrepancy data may decay rapidly and regression solvers may employ absolute tolerances in places.

By activating `response_scaling`, the set of response data used for each recovery is scaled to $[0,1]$ based on the minimum value and range of the data set. This prevents loss of accuracy due to imbalances in scale across model levels.

**See Also**

These keywords may also be of interest:

- `multifidelity_polynomial_chaos`
- `multifidelity_function_train`

7.2.49.15  tensor_grid

- Keywords Area
- method
- multifidelity_function_train
- tensor_grid

Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.

**Specification**

**Alias**: none  
**Argument(s)**: none  
**Default**: regression with random sample set
Description

The collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

7.2.49.16 collocation_points_sequence

- Keywords Area
- method
- multifidelity_function_train
- collocation_points_sequence

Sequence of collocation point counts used in a multi-stage expansion

Specification

Alias: pilot_samples

Argument(s): INTEGERLIST

Description

Each level entry of the collocation_points_sequence applies to one expansion within a multi-stage expansion. Current multi-stage expansions that support collocation point sequences include multilevel and multifidelity polynomial chaos and multilevel and multifidelity function train expansions.

If adaptive refinement is active, then this sequence specifies the starting point for each level within either an individual or integrated refinement approach.

A corresponding scalar specification is documented at, e.g., collocation_points

See Also

These keywords may also be of interest:

- collocation_points

7.2.49.17 collocation_ratio

- Keywords Area
- method
- multifidelity_function_train
- collocation_ratio

Set the number of points used to build a PCE via regression to be proportional to the number of terms in the expansion.
7.2 method

Specification

Alias: none

Argument(s): REAL

Default: 0.

Description

Set the number of points used to build a PCE via regression to be proportional to the number of terms in the expansion. To avoid requiring the user to calculate N from n and p, the collocation_ratio allows for specification of a constant factor applied to N (e.g., collocation_ratio = 2. produces samples = 2N). In addition, the default linear relationship with N can be overridden using a real-valued exponent specified using ratio_order. In this case, the number of samples becomes \( cN^\alpha \) where \( c \) is the collocation_ratio and \( \alpha \) is the ratio_order. The use_derivatives flag informs the regression approach to include derivative matching equations (limited to gradients at present) in the least squares solutions, enabling the use of fewer collocation points for a given expansion order and dimension (number of points required becomes \( cN^\alpha n^\alpha \)).

7.2.49.18 start_order_sequence

- Keywords Area
- method
- multifidelity_function_train
- start_order_sequence

Sequence of start orders used in a multi-stage expansion

Specification

Alias: order_sequence

Argument(s): INTEGERLIST

Default: 2

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>dimension_preference</td>
<td>A set of weights specifying the relative importance of each uncertain variable (dimension)</td>
</tr>
</tbody>
</table>

Description

Each level entry of the start_order_sequence applies to one expansion within a multi-stage expansion. Current multi-stage expansions that support start order sequences include multilevel and multifidelity function train expansions.

If adaptive refinement is active, then this sequence specifies the starting point for each level within either an individual or integrated refinement approach.

A corresponding scalar specification is documented at, e.g., start_order
See Also

These keywords may also be of interest:

- start_order

7.2.49.18.1 dimension_preference

- Keywords Area
- method
- multifidelity_function_train
- start_order_sequence
- dimension_preference

A set of weights specifying the relative importance of each uncertain variable (dimension)

Specification

Alias: none

Argument(s): REALLIST

Default: isotropic grids

Description

A set of weights specifying the relative importance of each uncertain variable (dimension). Using this specification leads to anisotropic integrations with differing refinement levels for different random dimensions.

See Also

These keywords may also be of interest:

- sobol
- decay

7.2.49.19 adapt_order

- Keywords Area
- method
- multifidelity_function_train
- adapt_order

Activate adaptive procedure for determining the best basis order

Specification

Alias: none

Argument(s): none

Default: false
Description

This option activates a cross validation procedure to select the best basis order for representing the current set of data. It searches from \texttt{start\_order} to \texttt{max\_order} in increments of \texttt{kick\_order}.

Default Behavior

No cross validation for basis order.

Examples

This example shows specification of an order adaptation starting at order 2, incrementing by 2, and limited at order 6.

```dakota
model,
   id_model = 'FT'
   surrogate_global_function_train
   start_rank = 4
   adapt_order start_order = 2 kick_order = 2 max_order = 6
   solver_tolerance = 1e-12
   rounding_tolerance = 1e-12
   dace_method_pointer = 'SAMPLING'
```

Note that \texttt{adapt\_rank} and \texttt{adapt\_order} can either be combined or used separately.

See Also

These keywords may also be of interest:

- \texttt{start\_order}
- \texttt{kick\_order}
- \texttt{max\_order}

7.2.49.20 kick_order

- \texttt{Keywords Area}
- \texttt{method}
- \texttt{multifidelity\_function\_train}
- \texttt{kick\_order}

increment used when adapting the basis order in function train methods

Specification

\textbf{Alias}: none

\textbf{Argument(s)}: INTEGER

\textbf{Default}: 1
Description

Used in combination with adapt_order, kick_order defines the size of the increment that is used during the cross validation process, within the range of start_order and max_order.

Default Behavior
Default is 1.

See Also

These keywords may also be of interest:
- adapt_order

7.2.49.21 max_order

- Keywords Area
- method
- multifidelity_function_train
- max_order

Maximum polynomial order of each univariate function within the functional tensor train.

Specification

Alias: none

Argument(s): INTEGER

Default: unsigned short max

Description

This specification is inactive for current adaptation options.

In future adaptation options (i.e., cross-approximation adaptation), this will specify the maximum order that can be obtained during adaptation, where polynomial order will start from start_order and be limited by max_order.

Default Behavior
Max order is unbounded (adaptive sweep will stop when CV error increases).

See Also

These keywords may also be of interest:
- start_order

7.2.49.22 max_cv_order_candidates

- Keywords Area
- method
7.2 method

- multifidelity_function_train
- max_cv_order_candidates

Limit the number of cross-validation candidates for basis order

Specification

Alias: none
Argument(s): INTEGER
Default: ushort max

Description

When generating refinement candidates by advancing the upper bound used for a cross-validation range, the number of cross-validation can eventually become excessive and hamper algorithm progress. This control limits the maximum number of candidates, which when active, will increase the lower bound for this range as the upper bound is advanced.

- multifidelity_function_train

7.2.49.23 start_rank_sequence

Sequence of start ranks used in a multi-stage expansion

Specification

Alias: rank_sequence
Argument(s): INTEGERLIST
Default: 2
Description

Each level entry of the `start_rank_sequence` applies to one expansion within a multi-stage expansion. Current multi-stage expansions that support start rank sequences include multilevel and multifidelity function train expansions.

If adaptive refinement is active, then this sequence specifies the starting point for each level within either an individual or integrated refinement approach.

A corresponding scalar specification is documented at, e.g., `start_rank`.

See Also

These keywords may also be of interest:

- `start_rank`

7.2.49.24 `adapt_rank`

- Keywords Area
- `method`
- `multifidelity_function_train`
- `adapt_rank`

Activate adaptive procedure for determining best rank representation

Specification

**Alias:** none

**Argument(s):** none

**Default:** false

Description

The adaptive algorithm proceeds as follows:

1. Start from rank `start_rank` and form an approximation.
2. Adapt the current approximation by searching for a solution with lower rank that achieves L2 accuracy within epsilon tolerance of the reference.
3. If a lower rank solution is found with comparable accuracy, then stop. If not, increase the rank by an amount specified by `kick_rank`.
4. Return to step 2 and continue until either `max_rank` is reached or a converged rank (rank less than current reference with comparable accuracy) is found.

Default Behavior

No cross validation for rank.
Examples

This example shows specification of a rank adaptation starting at rank 2, incrementing by 2, and limited at rank 10.

```plaintext
model,
  id_model = 'FT'
surrogate global function_train
  start_order = 5
  adapt_rank start_rank = 2 kick_rank = 2 max_rank = 10
  solver_tolerance = 1e-12
  rounding_tolerance = 1e-12
dace_method_pointer = 'SAMPLING'
```

Note that `adapt_rank` and `adapt_order` can either be combined or used separately.

See Also

These keywords may also be of interest:

- `start_rank`
- `kick_rank`
- `max_rank`

**7.2.49.25 kick_rank**

- **Keywords Area**
- **method**
- **multifidelity_function_train**
- **kick_rank**

The increment in rank employed during each iteration of the rank adaptation.

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 1

**Description**

The `adapt_rank` procedure increments the rank on each iteration, using an increment defined by `kick_rank`

**Default Behavior**

Default is 1.

**See Also**

These keywords may also be of interest:

- `adapt_rank`
7.2.49.26 max_rank

- Keywords Area
- method
- multifidelity_function_train
- max_rank

Limits the maximum rank that is explored during a rank adaptation.

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** size_t max

**Description**

The `adapt_rank` procedure increments the rank on each iteration, and the maximum value is limited by `max_rank`

**Default Behavior**

Max rank is unbounded (adaptive sweep will stop when CV error increases).

**See Also**

These keywords may also be of interest:

- `adapt_rank`

7.2.49.27 max_cv_rank_candidates

- Keywords Area
- method
- multifidelity_function_train
- max_cv_rank_candidates

Limit the number of cross-validation candidates for rank

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** size_t max
Description

When generating refinement candidates by advancing the upper bound used for a cross-validation range, the number of cross-validation can eventually become excessive and hamper algorithm progress. This control limits the maximum number of candidates, which when active, will increase the lower bound for this range as the upper bound is advanced.

- `increment_max_rank_order`
- `function_train`
- `multifidelity_function_train`

7.2.49.28  samples_on_emulator

Number of samples at which to evaluate an emulator (surrogate)

Specification

**Alias:** samples

**Argument(s):** INTEGER

Description

How many approximate function evaluations to perform on the emulator model, e.g., to compute statistics

Default Behavior

The default number of samples is method-dependent.

Examples

Perform 10000 samples on the PCE approximation of the true model:

```plaintext
method
  polynomial_chaos
  quadrature_order = 2
  samples_on_emulator = 10000
```
7.2.49.29 sample_type

- Keywords Area
- method
- multifidelity_function_train
- sample_type

Selection of sampling strategy

Specification

**Alias:** none

**Argument(s):** none

**Default:** random

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group Type (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required (Choose One)</td>
<td>lhs</td>
<td>random</td>
<td>Uses Latin Hypercube Sampling (LHS) to sample variables</td>
</tr>
<tr>
<td>Sample Type</td>
<td>lhs</td>
<td>random</td>
<td>Uses purely random Monte Carlo sampling to sample variables</td>
</tr>
</tbody>
</table>

**Description**

The `sample_type` keyword allows the user to select between two types of sampling: Monte Carlo (pure random) and Latin hypercube (stratified) sampling.

The incremental keywords are deprecated; instead use `samples` together with `refinement_samples`.

**Default Behavior**

If the `sample_type` keyword is present, it must be accompanied by `lhs` or `random`. In most contexts, `lhs` is the default (exception: multilevel_sampling uses Monte Carlo by default).

**Examples**

```
method
    sampling
    sample_type lhs
    samples = 20
    seed = 83921
```

```
7.2.49.29.1 lhs
```

- Keywords Area
- method
- multifidelity_function_train
7.2.4.10.3  method

- sample_type
- lhs

Uses Latin Hypercube Sampling (LHS) to sample variables

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The `lhs` keyword invokes Latin Hypercube Sampling as the means of drawing samples of uncertain variables according to their probability distributions. This is a stratified, space-filling approach that selects variable values from a set of equi-probable bins.

**Default Behavior**

Latin Hypercube Sampling is the default sampling mode in most contexts (exception: `multilevel_sampling`). To explicitly specify LHS in the Dakota input file, the `lhs` keyword must appear in conjunction with the `sample_type` keyword.

**Usage Tips**

Latin Hypercube Sampling is very robust and can be applied to any problem. It is fairly effective at estimating the mean of model responses and linear correlations with a reasonably small number of samples relative to the number of variables.

**Examples**

```dakota
method
  sampling
    sample_type lhs
    samples = 20
```

7.2.49.29.2  random

- Keywords Area
- method
- multifidelity_function_train
- sample_type
- random

Uses purely random Monte Carlo sampling to sample variables

**Specification**

**Alias:** none

**Argument(s):** none
Description

The random keyword invokes Monte Carlo sampling as the means of drawing samples of uncertain variables according to their probability distributions.

Default Behavior

In most contexts, Monte Carlo sampling is not the default sampling mode (exception: multilevel_sampling). To change this behavior, the random keyword must be specified in conjunction with the sample_type keyword.

Usage Tips

Monte Carlo sampling is more computationally expensive than Latin Hypercube Sampling as it requires a larger number of samples to accurately estimate statistics.

Examples

```
method sampling
    sample_type random
    samples = 200
```

7.2.49.30 rng

- Keywords Area
- method
- multifidelity_function_train
- rng

Selection of a random number generator

Specification

Alias: none

Argument(s): none

Default: Mersenne twister ( mt19937 )

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional Required (Choose One)</th>
<th>Description of Group RNG Algorithm (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>mt19937</td>
<td>Generates random numbers using the Mersenne twister</td>
</tr>
<tr>
<td></td>
<td></td>
<td>rnum2</td>
<td>Generates pseudo-random numbers using the Pecos package</td>
</tr>
</tbody>
</table>

Description

The rng keyword is used to indicate a choice of random number generator.

Default Behavior
If specified, the `rng` keyword must be accompanied by either `rnum2` (pseudo-random numbers) or `mt19937` (random numbers generated by the Mersenne twister). Otherwise, `mt19937`, the Mersenne twister is used by default.

Usage Tips
The default is recommended, as the Mersenne twister is a higher quality random number generator.

Examples

method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2

7.2.49.30.1  mt19937

- Keywords Area
- method
- multifidelity_function_train
- rng
- mt19937

Generates random numbers using the Mersenne twister

Specification

Alias: none
Argument(s): none

Description

The `mt19937` keyword directs Dakota to use the Mersenne twister to generate random numbers. Additional information can be found on wikipedia: [http://en.wikipedia.org/wiki/Mersenne_twister](http://en.wikipedia.org/wiki/Mersenne_twister).

Default Behavior

`mt19937` is the default random number generator. To specify it explicitly in the Dakota input file, however, it must be specified in conjunction with the `rng` keyword.

Usage Tips

Use of the Mersenne twister random number generator (`mt19937`) is recommended.

Examples

method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng mt19937
7.2.49.30.2  rnum2

- Keywords Area
- method
- multifidelity_function_train
- rng
- rnum2

Generates pseudo-random numbers using the Pecos package

Specification

Alias: none
Argument(s): none

Description

The rnum2 keyword directs Dakota to use pseudo-random numbers generated by the Pecos package.

Default Behavior

rnum2 is not used by default. To change this behavior, it must be specified in conjunction with the rng keyword.

Usage Tips

Use of the Mersenne twister random number generator (mt19937) is recommended over rnum2.

Examples

method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2

7.2.49.31  probability_refinement

- Keywords Area
- method
- multifidelity_function_train
- probability_refinement

Allow refinement of probability and generalized reliability results using importance sampling

Topics

This keyword is related to the topics:

- reliability_methods
7.2 method

Specification

Alias: sample_refinement

Argument(s): none

Default: no refinement

Description

The probability_refinement allows refinement of probability and generalized reliability results using importance sampling. If one specifies probability_refinement, there are some additional options. One can specify which type of importance sampling to use (import, adapt_import, or mm_adapt_import). Additionally, one can specify the number of refinement samples to use with refinement_samples and the seed to use with seed. The probability_refinement density reweighting accounts originally was developed based on Gaussian distributions. It now accounts for additional non-Gaussian cases.

7.2.49.31.1 import

- Keywords Area
- method
- multifidelity_function_train
- probability_refinement
- import

Importance sampling option for probability refinement

Specification

Alias: none

Argument(s): none
import centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level).

7.2.49.31.2 adapt_import

- Keywords Area
- method
- multifidelity_function_train
- probability_refinement
- adapt_import

Importance sampling option for probability refinement

Specification

Alias: none
Argument(s): none

Description

adapt_import centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level). This continues iteratively until the failure probability estimate converges.

7.2.49.31.3 mm_adapt_import

- Keywords Area
- method
- multifidelity_function_train
- probability_refinement
- mm_adapt_import

Importance sampling option for probability refinement

Specification

Alias: none
Argument(s): none

Description

mm_adapt_import starts with all of the samples located in the failure region to build a multimodal sampling density. First, it uses a small number of samples around each of the initial samples in the failure region. Note that these samples are allocated to the different points based on their relative probabilities of occurrence.
probable points get more samples. This early part of the approach is done to search for "representative" points. Once these are located, the multimodal sampling density is set and then \texttt{mm\_adapt\_import} proceeds similarly to \texttt{adapt\_import} (sample until convergence).

7.2.49.31.4 refinement_samples

- Keywords Area
- method
- multifidelity_function_train
- probability_refinement
- refinement_samples

Number of samples used to refine a probability estimate or sampling design.

Specification

\textbf{Alias}: none
\textbf{Argument(s)}: INTEGERLIST

Description

Probability estimate: Specify the (scalar) number of samples used to improve a probability estimate. If using unimodal sampling all samples are assigned to the sampling center. If using multi-modal sampling the samples are split between multiple samples according to some internally computed weights.

Sampling design: Specify one or a sequence of refinement samples to augment the initial_samples in a sampling design.

7.2.49.32 final_moments

- Keywords Area
- method
- multifidelity_function_train
- final_moments

Output moments of the specified type and include them within the set of final statistics.

Specification

\textbf{Alias}: none
\textbf{Argument(s)}: none
\textbf{Default}: standard

\textbf{Child Keywords}:

\begin{tabular}{|c|c|c|c|}

\end{tabular}
<table>
<thead>
<tr>
<th>Required (Choose One)</th>
<th>Final moment type (Group 1)</th>
<th>Omit moments from the set of final statistics.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>none</td>
<td></td>
</tr>
<tr>
<td></td>
<td>standard</td>
<td>Output standardized moments and include them within the set of final statistics.</td>
</tr>
<tr>
<td></td>
<td>central</td>
<td>Output central moments and include them within the set of final statistics.</td>
</tr>
</tbody>
</table>

### Description

When performing a nested study that may employ moment statistics on the inner loop, it can be desirable to control the type of these moments. The `final_moments` specification supports options of `none`, `standard` (default), or `central`, corresponding to omission of moments, standardized moments (mean, standard deviation, skewness, and excess kurtosis), or central moments (mean, variance, 3rd central, and 4th central).

The presence or omission of moment results in the final statistics influences the outer level mappings in the case of a nested study. For example, `final_moments none` can allow for a more compact specification of primary and/or secondary response mappings.

### Examples

The following method specification overrides the default to print central moments and include them in the set of final statistics.

```plaintext
method, sampling
  samples = 50 seed = 1234
  response_levels = 3.6e+11 1.2e+05 3.5e+05
final_moments central
```

Overriding the default to `none` as follows:

```plaintext
method, sampling
  samples = 50 seed = 1234
  response_levels = 3.6e+11 1.2e+05 3.5e+05
final_moments none
```

allows associated nested model mappings to be simplified from:

```plaintext
model
  nested
    sub_method_pointer = 'UQ'
    primary_response_mapping = 0. 0. 1. 0. 0. 1. 0. 0. 0.
    secondary_response_mapping = 0. 0. 0. 0. 0. 0. 0. 0. 1.
```

to a more compact version focused only on the response level mappings (two leading zeros per response function for moment mappings have been removed):

```plaintext
model
  nested
    sub_method_pointer = 'UQ'
    primary_response_mapping = 1. 1. 0.
    secondary_response_mapping = 0. 0. 1.
```
Omit moments from the set of final statistics.

**Specification**

- **Alias:** none
- **Argument(s):** none

**Description**

The omission of moment results from the final statistics can allow for a more compact definition of primary and/or secondary response mappings within a nested model specification.

**Examples**

```dakota
method, sampling
  samples = 50 seed = 1234
  response_levels = 3.6e+11 1.2e+05 3.5e+05
  final_moments none
```

Output standardized moments and include them within the set of final statistics.

**Specification**

- **Alias:** none
- **Argument(s):** none

**Description**

Output standardized moments (mean, standard deviation, skewness, and excess kurtosis) and include the first two within the set of final statistics to be used at a higher level (e.g., optimization under uncertainty, mixed aleatory-epistemic UQ). This inclusion of moment results affects the primary and/or secondary response mappings in a nested model specification.
Examples

The following method specification overrides the default to print central moments and include them in the set of final statistics.

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments central
```

7.2.49.32.3 central

- Keywords Area
- method
- multifidelity_function_train
- final_moments
- central

Output central moments and include them within the set of final statistics.

Specification

**Alias:** none

**Argument(s):** none

Description

Output central moments (mean, variance, 3rd central, and 4th central) and include the first two within the set of final statistics to be used at a higher level (e.g., optimization under uncertainty, mixed aleatory-epistemic UQ). This inclusion of moment results affects the primary and/or secondary response mappings in a nested model specification.

Examples

The following method specification overrides the default to print central moments and include them in the set of final statistics.

```
method,
  sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments central
```

7.2.49.33 response_levels

- Keywords Area
- method
- multifidelity_function_train
- response_levels

Values at which to estimate desired statistics for each response
### Speciﬁcation

**Alias:** none  
**Argument(s):** REALLIST  
**Default:** No CDF/CCDF probabilities/reliabilities to compute

### Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>num_response_levels</td>
<td>Number of values at which to estimate desired statistics for each response</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>compute</td>
<td>Selection of statistics to compute at each response level</td>
</tr>
</tbody>
</table>

### Description

The `response_levels` speciﬁcation provides the target response values for which to compute probabilities, reliabilities, or generalized reliabilities (forward mapping).

### Default Behavior

If `response_levels` are not speciﬁed, no statistics will be computed. If they are, probabilities will be computed by default.

### Expected Outputs

If `response_levels` are speciﬁed, Dakota will create two tables in the standard output: a Probability Density function (PDF) histogram and a Cumulative Distribution Function (CDF) table. The PDF histogram has the lower and upper endpoints of each bin and the corresponding density of that bin. Note that the PDF histogram has bins deﬁned by the `probability_levels` and/or `response_levels` in the Dakota input ﬁle. If there are not very many levels, the histogram will be coarse. Dakota does not do anything to optimize the bin size or spacing. The CDF table has the list of response levels and the corresponding probability that the response value is less than or equal to each response level threshold.

### Usage Tips

The `num_response_levels` is used to specify which arguments of the `response_level` correspond to which response.

### Examples

For example, specifying a `response_level` of 52.3 followed with `compute probabilities` will result in the calculation of the probability that the response value is less than or equal to 52.3, given the uncertain distributions on the inputs.

For an example with multiple responses, the following speciﬁcation

```
response_levels = 1. 2. .1 .2 .3 .4 10. 20. 30.
num_response_levels = 2 4 3
```

would assign the ﬁrst two response levels (1., 2.) to response function 1, the next four response levels (.1, .2, .3, .4) to response function 2, and the ﬁnal three response levels (10., 20., 30.) to response function 3.
The Dakota input file below specifies a sampling method with response levels of interest.

```
method,
sampling,
samples = 100 seed = 1
complementary distribution
response_levels = 3.6e+11 4.0e+11 4.4e+11
                6.0e+04 6.5e+04 7.0e+04
                3.5e+05 4.0e+05 4.5e+05
variables,
    normal_uncertain = 2
    means = 248.89, 593.33
    std_deviations = 12.4, 29.7
    descriptors = ‘TF1n’ ‘TF2n’
    uniform_uncertain = 2
    lower_bounds = 199.3, 474.63
    upper_bounds = 298.5, 712.
    descriptors = ‘TF1u’ ‘TF2u’
    weibull_uncertain = 2
    alphas = 12., 30.
    betas = 250., 590.
    descriptors = ‘TF1w’ ‘TF2w’
    histogram_bin_uncertain = 2
    num_pairs = 3 4
    abscissas = 5 8 10 .1 .2 .3 .4
    counts = 17 21 0 12 24 12 0
    descriptors = ‘TF1h’ ‘TF2h’
    histogram_point_uncertain
    real = 1
    num_pairs = 2
    abscissas = 3 4
    counts = 1 1

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

A forward mapping involves computing the belief and plausibility probability level for a specified response level.

7.2.49.33.1  num_response_levels

- Keywords Area
- method
- multifidelity_function_train
- response_levels
- num_response_levels

Number of values at which to estimate desired statistics for each response

Specification

Alias: none

Argument(s): INTEGERLIST

Default: response_levels evenly distributed among response functions

Description

The num_response_levels keyword allows the user to specify the number of response values, for each response, at which estimated statistics are of interest. Statistics that can be computed are probabilities and reliabilities, both according to either a cumulative distribution function or a complementary cumulative distribution function.

Default Behavior

If num_response_levels is not specified, the response_levels will be evenly distributed among the responses.
**Expected Outputs**

The specific output will be determined by the type of statistics that are specified. In a general sense, the output will be a list of response level-statistic pairs that show the estimated value of the desired statistic for each response level specified.

**Examples**

```plaintext
method
  sampling
    samples = 100
    seed = 34785
    num_response_levels = 1 1 1
    response_levels = 0.5 0.5 0.5
```

7.2.49.33.2  compute

- Keywords Area
- method
- multifidelity_function_train
- response_levels
- compute

Selection of statistics to compute at each response level

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** probabilities

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional Required(Choose One)</th>
<th>Description of Group Statistics to Compute (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>probabilities</td>
<td>probabilities</td>
<td>Computes probabilities associated with response levels</td>
</tr>
<tr>
<td></td>
<td>reliabilities</td>
<td>reliabilities</td>
<td>Computes reliabilities associated with response levels</td>
</tr>
<tr>
<td></td>
<td>gen_reliabilities</td>
<td>gen_reliabilities</td>
<td>Computes generalized reliabilities associated with response levels</td>
</tr>
</tbody>
</table>
The `compute` keyword is used to select which forward statistical mapping is calculated at each response level.

**Default Behavior**
If `response_levels` is not specified, no statistics are computed. If `response_levels` is specified but `compute` is not, probabilities will be computed by default. If both `response_levels` and `compute` are specified, then one of the following must be specified: `probabilities`, `reliabilities`, or `gen_reliabilities`.

**Expected Output**
The type of statistics specified by `compute` will be reported for each response level.

**Usage Tips**
CDF/CCDF probabilities are calculated for specified response levels using a simple binning approach.
CDF/CCDF reliabilities are calculated for specified response levels by computing the number of sample standard deviations separating the sample mean from the response level.

**Examples**

```plaintext
method sampling
    sample_type random
    samples = 100 seed = 1
complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                  6.0e+04 6.5e+04 7.0e+04
                  3.5e+05 4.0e+05 4.5e+05
    compute reliabilities
```

**7.2.49.33.2.1 probabilities**

- **Keywords Area**
  - method
  - multifidelity_function_train
  - response_levels
  - compute
  - probabilities

Computes probabilities associated with response levels

**Specification**

- **Alias**: none
- **Argument(s)**: none
Description

The `probabilities` keyword directs Dakota to compute the probability that the model response will be below (cumulative) or above (complementary cumulative) a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the probabilities are computed by default. To explicitly specify it in the Dakota input file, though, the `probabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-probability pairs that give the probability that the model response will be below or above the corresponding response level, depending on the distribution defined.

Examples

```
method sampling
  sample_type random
  samples = 100 seed = 1
  complementary distribution
  response_levels = 3.6e+11 4.0e+11 4.4e+11
                 6.0e+04 6.5e+04 7.0e+04
                 3.5e+05 4.0e+05 4.5e+05
  compute probabilities
```

7.2.49.33.2.2 reliabilities

- Keywords Area
- method
- multifidelity_function_train
- response_levels
- compute
- reliabilities

Computes reliabilities associated with response levels

Specification

Alias: none

Argument(s): none

Description

The `reliabilities` keyword directs Dakota to compute reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the reliabilities are not computed by default. To change this behavior, the `reliabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-reliability pairs according to the distribution defined.
Examples

```method
sampling
  sample_type random
  samples = 100 seed = 1
  complementary distribution
  response_levels = 3.6e+11 4.0e+11 4.4e+11
                   6.0e+04 6.5e+04 7.0e+04
                   3.5e+05 4.0e+05 4.5e+05
  compute reliabilities
```

7.2.49.33.2.3 `gen_reliabilities`

- Keywords
  - Area
- method
- multifidelity_function_train
- response_levels
- compute
- gen_reliabilities

Computes generalized reliabilities associated with response levels

Specification

**Alias:** none

**Argument(s):** none

Description

The `gen_reliabilities` keyword directs Dakota to compute generalized reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the generalized reliabilities are not computed by default. To change this behavior, the `gen_reliabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-generalized reliability pairs according to the distribution defined.

Examples

```method
sampling
  sample_type random
  samples = 100 seed = 1
  complementary distribution
  response_levels = 3.6e+11 4.0e+11 4.4e+11
                   6.0e+04 6.5e+04 7.0e+04
                   3.5e+05 4.0e+05 4.5e+05
  compute gen_reliabilities
```
7.2.49.33.2.4 system

<td>parallel</td>
<td>Aggregate response statistics assuming a parallel system</td>
</tr>
</tbody>
</table>

Description

With the system probability/reliability option, statistics for specified response_levels are calculated and reported assuming the response functions combine either in series or parallel to produce a total system response.

For a series system, the system fails when any one component (response) fails. The probability of failure is the complement of the product of the individual response success probabilities.

For a parallel system, the system fails only when all components (responses) fail. The probability of failure is the product of the individual response failure probabilities.

Specify probability levels at which to estimate the corresponding response value

Specification

Alias: none
Argument(s): REALLIST
Default: No CDF/CCDF response levels to compute
Child Keywords:
Description

Response levels are calculated for specified CDF/CCDF probabilities by indexing into a sorted samples array (the response levels computed are not interpolated and will correspond to one of the sampled values).

Expected Output

If `probability_levels` are specified, Dakota will create two tables in the standard output: a Probability Density function (PDF) histogram and a Cumulative Distribution Function (CDF) table. The PDF histogram has the lower and upper endpoints of each bin and the corresponding density of that bin. Note that the PDF histogram has bins defined by the `probability_levels` and/or `response_levels` in the Dakota input file. If there are not very many levels, the histogram will be coarse. Dakota does not do anything to optimize the bin size or spacing. The CDF table has the list of response levels and the corresponding probability that the response value is less than or equal to each response level threshold.

Examples

The Dakota input file below specifies a sampling method with probability levels of interest.

```
method,  
sampling,  
samples = 100 seed = 1  
complementary distribution  
probability_levels = 1. .66 .33 0.  
1. .8 .5 0.  
1. .3 .2 0.  
variables,  
normal_uncertain = 2  
means = 248.89, 593.33  
std_deviations = 12.4, 29.7  
descriptors = 'TF1n' 'TF2n'  
uniform_uncertain = 2  
lower_bounds = 199.3, 474.63  
upper_bounds = 298.5, 712.  
descriptors = 'TF1u' 'TF2u'  
weibull_uncertain = 2  
alphas = 12., 30.  
betas = 250., 590.  
descriptors = 'TF1w' 'TF2w'  
histogram_bin_uncertain = 2  
num_pairs = 3 4  
abscissas = 5 8 10 .1 .2 .3 .4  
counts = 17 21 0 12 24 12 0  
descriptors = 'TF1h' 'TF2h'  
histogram_point_uncertain  
real = 1  
um_pairs = 2  
abscissas = 3 4  
counts = 1 1  
descriptors = 'TF3h'  
interface,  
system asynch evaluation_concurrency = 5  
analysis_driver = 'text_book'  
responses,  
response_functions = 3
```
Given the above Dakota input file, the following excerpt from the output shows the PDF and CCDF generated. Note that the bounds on the bins of the PDF are the response values that correspond the probability levels specified in the input file. Those response values are also shown in the CCDF.

### Probability Density Function (PDF) histograms for each response function:

### Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).

7.2.49.37 distribution

- Keywords Area
- method
Selection of cumulative or complementary cumulative functions

**Specification**

**Alias:** none  

**Argument(s):** none  

**Default:** cumulative (CDF)  

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group Distribution Type (CDF/CCDF) (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required (Choose One)</td>
<td></td>
<td>cumulative</td>
<td>Computes statistics according to cumulative functions</td>
</tr>
<tr>
<td></td>
<td></td>
<td>complementary</td>
<td>Computes statistics according to complementary cumulative functions</td>
</tr>
</tbody>
</table>

**Description**

The `distribution` keyword allows the user to select between a cumulative distribution/belief/plausibility function and a complementary cumulative distribution/belief/plausibility function. This choice affects how probabilities and reliability indices are reported.

**Default Behavior**

If the `distribution` keyword is present, it must be accompanied by either `cumulative` or `complementary`. Otherwise, a cumulative distribution will be used by default.

**Expected Outputs**

Output will be a set of model response-probability pairs determined according to the choice of distribution. The choice of distribution also defines the sign of the reliability or generalized reliability indices.

**Examples**

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

7.2.49.37.1  cumulative  

- **Keywords Area**  
- **method**  
- **multifidelity_function_train**
Computes statistics according to cumulative functions

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

Statistics on model responses will be computed according to a cumulative distribution/belief/plausibility function.

**Default Behavior**

By default, a cumulative distribution/belief/plausibility function will be used. To explicitly specify it in the Dakota input file, however, the **cumulative** keyword must appear in conjunction with the **distribution** keyword.

**Expected Outputs**

Output will be a set of model response-probability pairs determined according to a cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls below given response thresholds.

**Examples**

```
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

7.2.49.37.2 complementary

- **Keywords Area**
- **method**
- **multifidelity_function_train**
- **distribution**
- **complementary**

Computes statistics according to complementary cumulative functions

**Specification**

**Alias:** none  
**Argument(s):** none
Description

Statistics on model responses will be computed according to a complementary cumulative distribution/belief/plausibility function.

Default Behavior

By default, a complementary cumulative distribution/belief/plausibility function will not be used. To change that behavior, the `complementary` keyword must be appear in conjunction with the `distribution` keyword.

Expected Outputs

Output will be a set of model response-probability pairs determined according to a complementary cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls above given response thresholds.

Examples

```dat
method
  sampling
    sample_type lhs
    samples = 10
    distribution complementary
```

7.2.49.38  variance_based_decomp

- **Keywords Area**
- **method**
- **multifidelity_function_train**
- **variance_based_decomp**

Activates global sensitivity analysis based on decomposition of response variance into main, interaction, and total effects.

Specification

**Alias:** none

**Argument(s):** none

**Default:** no variance-based decomposition

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>interaction_order</td>
<td>Specify the maximum number of variables allowed in an interaction when reporting interaction metrics. Suppresses output of sensitivity indices with values lower than this tolerance</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>drop_tolerance</td>
<td></td>
</tr>
</tbody>
</table>
Description

Dakota can calculate sensitivity indices through variance-based decomposition using the keyword `variance_based_decomp`. This approach decomposes main, interaction, and total effects in order to identify the most important variables and combinations of variables in contributing to the variance of output quantities of interest.

Default Behavior

Because of processing overhead and output volume, `variance_based_decomp` is inactive by default, unless required for dimension-adaptive refinement using Sobol' indices.

Expected Outputs

When `variance_based_decomp` is specified, sensitivity indices for main effects, total effects, and any interaction effects will be reported. Each of these effects represents the percent contribution to the variance in the model response, where main effects include the aggregated set of univariate terms for each individual variable, interaction effects represent the set of mixed terms (the complement of the univariate set), and total effects represent the complete set of terms (univariate and mixed) that contain each individual variable. The aggregated set of main and interaction sensitivity indices will sum to one, whereas the sum of total effects sensitivity indices will be greater than one due to redundant counting of mixed terms.

Usage Tips

An important consideration is that the number of possible interaction terms grows exponentially with dimension and expansion order. To mitigate this, both in terms of compute time and output volume, possible interaction effects are suppressed whenever no contributions are present due to the particular form of an expansion. In addition, the `interaction_order` and `drop_tolerance` controls can further limit the computational and output requirements.

Examples

```dakota
method,
    polynomial_chaos # or stoch_collocation
    sparse_grid_level = 3
    variance_based_decomp interaction_order = 2
```

Theory

In this context, we take sensitivity analysis to be global, not local as when calculating derivatives of output variables with respect to input variables. Our definition is similar to that of [76]: "The study of how uncertainty in the output of a model can be apportioned to different sources of uncertainty in the model input."

Variance based decomposition is a way of using sets of samples to understand how the variance of the output behaves, with respect to each input variable. A larger value of the sensitivity index, $S_i$, means that the uncertainty in the input variable $i$ has a larger effect on the variance of the output. More details on the calculations and interpretation of the sensitivity indices can be found in [90].

7.2.49.38.1 interaction_order

• Keywords Area

• method

• multifidelity_function_train

• variance_based_decomp

• interaction_order

Specify the maximum number of variables allowed in an interaction when reporting interaction metrics.
7.2 method

Specification

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** Unrestricted (VBD includes all interaction orders present in the expansion)

Description

The `interaction_order` option has been added to allow suppression of higher-order interactions, since the output volume (and memory and compute consumption) of these results could be extensive for high dimensional problems (note: the previous `univariate_effects` specification is equivalent to `interaction_order = 1` in the current specification). Similar to suppression of interactions is the covariance control, which can be selected to be `diagonal_covariance` or `full_covariance`, with the former supporting suppression of the off-diagonal covariance terms (to again save compute and memory resources and reduce output volume).

7.2.49.38.2 drop_tolerance

- Keywords Area
  - method
  - multifidelity_function_train
  - variance_based_decomp
  - drop_tolerance

Suppresses output of sensitivity indices with values lower than this tolerance

Specification

**Alias:** none  
**Argument(s):** REAL  
**Default:** All VBD indices displayed

Description

The `drop_tolerance` keyword allows the user to specify a value below which sensitivity indices generated by `variance_based_decomp` are not displayed.

Default Behavior

By default, all sensitivity indices generated by `variance_based_decomp` are displayed.

Usage Tips

For `polynomial_chaos`, which outputs main, interaction, and total effects by default, the `univariate_effects` may be a more appropriate option. It allows suppression of the interaction effects since the output volume of these results can be prohibitive for high dimensional problems. Similar to suppression of these interactions is the covariance control, which can be selected to be `diagonal_covariance` or `full_covariance`, with the former supporting suppression of the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

Examples

```
method,
```
sampling
  sample_type lhs
  samples = 100
  variance_based_decomp
  drop_tolerance = 0.001

7.2.49.39 diagonal_covariance

- Keywords Area
- method
- multifidelity_function_train
- diagonal_covariance

Display only the diagonal terms of the covariance matrix

Specification

Alias: none
Argument(s): none
Default: diagonal_covariance for response vector > 10; else full_covariance

Description

With a large number of responses, the covariance matrix can be very large. **diagonal_covariance** is used to suppress the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

7.2.49.40 full_covariance

- Keywords Area
- method
- multifidelity_function_train
- full_covariance

Display the full covariance matrix

Specification

Alias: none
Argument(s): none

Description

With a large number of responses, the covariance matrix can be very large. **full_covariance** is used to force Dakota to output the full covariance matrix.
import_approx_points_file

- Keywords Area
- method
- multifidelity_function_train
- import_approx_points_file

Filename for points at which to evaluate the PCE/SC surrogate

**Specification**

**Alias:** none

**Argument(s):** STRING

**Default:** no point import from a file

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional (Choose One)</td>
<td>Tabular Format (Group 1)</td>

<td>Selects freeform file format</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Optional</td>
<td>active_only</td>
<td>Import only active variables from tabular data file</td>
<td></td>
</tr>
</tbody>
</table>

**Description**

**Default Behavior** No import of points at which to evaluate the surrogate.

**Expected Output** The PCE/SC surrogate model will be evaluated at the list of points (input variable values) provided in the file and results tabulated and/or statistics computed at them, depending on the method context.

**Examples**

```
method
  polynomial_chaos
    expansion_order = 4
    import_approx_points_file = 'import.mcmc_annot.dat'
  annotated
```

7.2.49.41 custom_annotated

- Keywords Area
- method
- multifidelity_function_train
• `import_approx_points_file`
• `custom_annotated`

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

• `file_formats`

Specification

**Alias:** none

**Argument(s):** none

**Default:** annotated format

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>header</td>
<td></td>
<td>Enable header row in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td>eval_id</td>
<td></td>
<td>Enable evaluation ID column in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td>interface_id</td>
<td></td>
<td>Enable interface ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

Usage Tips

• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
7.2 method

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```plaintext
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id x1   x2   obj_fn nln_ineq_con_1 nln_ineq_con_2
1   0.9   1.1   0.0002   0.26   0.76
2   0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3   0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...```

7.2.49.41.1.1 header

- Keywords Area
- method
- multifidelity_function_train
- import_approx_points_file
- custom_annotated
- header

Enable header row in custom-annotated tabular file

Specification

**Alias:** none

**Argument(s):** none

7.2.49.41.2 annotated

- Keywords Area
- method
- multifidelity_function_train
- import_approx_points_file
- annotated

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- file_formats
7.2 method

Specification

Alias: none
Argument(s): none
Default: annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```
environment
  tabular_data
  tabular_data_file = ‘dakota_summary.dat’
  annotated
```

Resulting tabular file:

```
%eval_id interface   x1   x2   obj_fn nln_ineq_con_1 nln_ineq_con_2
1   NO_ID    0.9   1.1   0.0002   0.26   0.76
2   NO_ID    0.90009 1.1   0.0001996404857 0.2601620081 0.759955
3   NO_ID    0.89991 1.1   0.0002003604863 0.2598380081 0.760045
...```

Specification

**Alias:** none

**Argument(s):** none

**Default:** annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

**Default Behavior**

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

**Usage Tips**

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```plaintext
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
freeform
```

Resulting tabular file:

```
0.9 1.1 0.0002 0.26 0.76
0.90009 1.1 0.0001996404857 0.2601620081 0.759955
0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...
```

7.2.49.41.4 active_only

- Keywords Area
Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword active_only indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

Output file for surrogate model value evaluations

Specification

Alias: export_points_file
Argument(s): STRING
Default: no point export to a file
Child Keywords:
### Description

Specifies a file in which the points (input variable values) at which the surrogate model is evaluated and corresponding response values computed by the surrogate model will be written. The response values are the surrogate’s predicted approximation to the truth model responses at those points.

### Usage Tips

Dakota exports tabular data in one of three formats:

- `annotated` *(default)*
- `custom_annotated`
- `freeform`

#### 7.2.49.42.1 custom_annotated

- **Keywords Area**
- **method**
- **multifidelity_function_train**
- **export_approx_points_file**
- **custom_annotated**

Selects custom-annotated tabular file format

### Topics

This keyword is related to the topics:

- **file_formats**

### Specification

**Alias**: none  
**Argument(s)**: none  
**Default**: annotated format  
**Child Keywords**:
### Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

### Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

### Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

### Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```environment
tabular_data
tabular_data_file = ‘dakota_summary.dat’
custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id    x1    x2    obj_fn  nln_ineq_con_1 nln_ineq_con_2
1  0.9    1.1  0.0002    0.26     0.76
2  0.90009  1.1  0.0001996404857  0.2601620081  0.759955
3  0.89991  1.1  0.0002003604863  0.2598380081  0.760045
...```

- Keywords Area
- method
- multifidelity_function_train
- export_approx_points_file
- annotated

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- **file_formats**

Specification

**Alias:** none

**Argument(s):** none

**Default:** annotated format
Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

• To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id

• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```plaintext
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
annotated

Resulting tabular file:

%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 NO_ID 0.9 1.1 0.0002 0.26 0.76
2 NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 NO_ID 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...
```

7.2.49.43 **seed_sequence**

- **Keywords Area**
- **method**
- **multifidelity_function_train**
- **seed_sequence**

Sequence of seed values for multi-stage random sampling
Specification

**Alias:** none

**Argument(s):** INTEGERLIST

**Default:** system-generated (non-repeatable)

**Description**

This specification allows the stipulation of seed values (passed to a random number generator) for each of a set of stages within a multi-stage random sampling algorithm.

This is particularly useful for reusing sample sets (via restart) that were generated in some other context (e.g., from a single-stage study) within a multi-stage algorithm execution. Normally the random number sequence would continue from a seed specified for the initial sample set, making subsequent sample sets more difficult to recreate outside of their original context. With finer granularity in the seed specification for multi-stage samplers, intermediate portions of a sampling sequence can now be more readily recreated and reused.

**Default Behavior**

As for the scalar case, the default is no seed control, such that a query to a system clock will be used to randomize results.

**Usage Tips**

For $L$ levels in a multilevel method, the seed_sequence can be of any length and seeds will be assigned up to the number of values that are provided or up to the number of levels in the sequence. Thus, a seed_sequence of length 1 recovers the behavior of a scalar seed.

When fixed_seed is unspecified, the seed_sequence specification does not extend to the refinement of the sample set. For example, the value from the seed_sequence defines the initial sample set for a level, but then subsequent sample sets generated as data increments will allow the random number sequence to continue without resetting the seed value. This reflects the need to avoid reusing previous sample values when generating sample augmentations.

**Examples**

Defining a multilevel Monte Carlo in the following way

```plaintext
method,
    model_pointer = 'HIERARCH'
    multilevel_sampling
    pilot_samples = 100 50 40 30 20
    seed_sequence = 1234 2345 3456 4567 5678
```

allows the reuse (via restart) of intermediate sample sets from other sources by matching the seed specifications for the targeted model resolutions.

**See Also**

These keywords may also be of interest:

- `seed`
- `fixed_seed`

7.2.49.44 `fixed_seed`

- **Keywords Area**
Reuses the same seed value for multiple random sampling sets

Specification

**Alias:** none

**Argument(s):** none

**Default:** not fixed; pattern varies run-to-run

**Description**

The `fixed_seed` flag is relevant if multiple sampling sets will be generated over the course of a Dakota analysis. This occurs when using advanced methods (e.g., surrogate-based optimization, optimization under uncertainty). The same seed value is reused for each of these multiple sampling sets, which can be important for reducing variability in the sampling results.

**Default Behavior**

The default behavior is to not use a fixed seed, as the repetition of the same sampling pattern can result in a modeling weakness that an optimizer could potentially exploit (resulting in actual reliabilities that are lower than the estimated reliabilities). For repeatable studies, the `seed` must also be specified.

**Examples**

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    fixed_seed
```

**Topics**

This keyword is related to the topics:

- `block_pointer`
Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The `model_pointer` is used to specify which `model` block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a `model` block in the Dakota input file that has a corresponding `id_model` with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a `model_pointer` for each method is imperative.

See `block_pointer` for details about pointers.

Examples

```plaintext
environment
tabular_data
method_pointer = 'UQ'

Description

As described in the `function_train` method and the `function_train` model, the function train (FT) approximation is a polynomial expansion that exploits low rank structure within the mapping from input random variables to output quantities of interest (QoI). For multilevel and multifidelity function train approximations, we decompose this expansion into several constituent expansions, one per model form or solution control level, where independent function train approximations are constructed for the low-fidelity/coarse resolution model and one or more levels of model discrepancy.

In a three-model case with low-fidelity (L), medium-fidelity (M), and high-fidelity (H) models and an additive discrepancy approach, we can denote this as:

\[ \hat{Q}_H \approx \hat{Q}_L + \hat{\Delta}_{ML} + \hat{\Delta}_{HM} \]

where \( \Delta^{ij} \) represents a discrepancy expansion computed from \( Q^i - Q^j \) and reduced rank representations of these discrepancies may be targeted (\( r_{HM} < r_{ML} < r_L \)).

In multilevel approaches, sample allocation for the constituent expansions is performed as described in `allocation_-control`.

Expected HDF5 Output

If Dakota was built with HDF5 support and run with the `hdf5` keyword, this method writes the following results to HDF5:

- Integration and Expansion Moments (expansion moments only)
- Probability Density
- Level Mappings

In addition, the execution group has the attribute `equiv_hf_evals`, which records the equivalent number of high-fidelity evaluations.

Number of iterations allowed for optimizers and adaptive UQ methods
Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none

Argument(s): INTEGER

Default: 100 (exceptions: fsu_cvt, local_reliability: 25; global_(reliability, interval_est, evidence) / efficient_global: 25*n)

Description

The maximum number of iterations is used as a stopping criterion for optimizers and some adaptive UQ methods. If it has not reached any other stopping criteria first, the method will stop after it has performed \texttt{max_iterations} iterations. In cases where there are multiple nested iterations to be controlled, \texttt{max_iterations} generally controls the outer-most context.

Default Behavior

Default value is 100.

Multilevel expansions, including regression-based polynomial chaos expansion (PCE) and function train (FT) expansions, require a sample allocation strategy. Three options are currently available:

- allocation based on assuming a convergence rate for the estimator variance (for regression PCE)
- restricted isometry property (RIP) sampling (for regression PCE via compressed sensing)
- rank sampling (for FT)

Default Behavior

Current defaults, when allocation_control is not specified, are estimator variance for PCE and rank sampling for FT.

7.2.50.2.1 estimator_variance

<td>Sample allocation based on rank sampling within multilevel function train</td>
</tr>
</tbody>
</table>
Description

Multilevel Monte Carlo performs optimal resource allocation based on a known estimator variance for the mean statistic:

\[ \text{Var}[\hat{Q}] = \frac{\sigma_Q^2}{N} \]

Replacing the simple ensemble average estimator in Monte Carlo with a polynomial chaos estimator results in a different and unknown relationship between the estimator variance and the number of samples. In one approach to multilevel PCE, we can employ a parameterized estimator variance:

\[ \text{Var}[\hat{Q}] = \frac{\sigma_Q^2}{\gamma N^\kappa} \]

for free parameters $\gamma$ and $\kappa$, with default values that may be overridden as part of this specification block.

This approach is supported for regression-based PCE approaches (over-determined least squares, under-determined compressed sensing, or orthogonal least interpolation).

In practice, it can be challenging to estimate a smooth convergence rate for estimator variance in the presence of abrupt transitions in the quality of sparse recoveries. As a result, sample allocation by greedy refinement is generally preferred.

Examples

This example starts with sparse recovery for a second-order candidate expansion at each level. As the number of samples is adapted for each level, as dictated by the convergence of the estimator variance, the candidate expansion order is incremented as needed in order to synchronize with the specified collocation ratio.

```plaintext
method, model_pointer = 'HIERARCH'
multilevel_polynomial_chaos
  orthogonal_matching_pursuit
  expansion_order_sequence = 2
  pilot_samples = 10
  collocation_ratio = .9
  allocation_control
    estimator_variance estimator_rate = 2.5
    seed = 1237
    convergence_tolerance = .01
```

7.2.5.0.2.1.1 estimator_rate

- Keywords Area

- multilevel_function_train
- allocation_control
- estimator_variance
- estimator_rate

Rate of convergence of mean estimator within multilevel polynomial chaos
Specification

**Alias:** none
**Argument(s):** REAL
**Default:** 2

**Description**

Multilevel Monte Carlo performs optimal resource allocation based on a known estimator variance for the mean statistic:

$$Var[\hat{Q}] = \frac{\sigma_Q^2}{N}$$

Replacing the simple ensemble average estimator in Monte Carlo with a polynomial chaos estimator results in a different and unknown relationship between the estimator variance and the number of samples. In one approach to multilevel PCE, we can employ a parameterized estimator variance:

$$Var[\hat{Q}] = \frac{\sigma_Q^2}{\gamma N^\kappa}$$

for free parameters $\gamma$ and $\kappa$.

The default values are $\gamma = 1$ and $\kappa = 2$ (adopts a more aggressive sample profile by assuming a faster convergence rate than Monte Carlo). This advanced specification option allows the user to specify $\kappa$, overriding the default.

7.2.50.2.2 rank_sampling

- Keywords Area
- method
- multilevel_function_train
- allocation_control
- rank_sampling

Sample allocation based on rank sampling within multilevel function train

**Specification**

**Alias:** none
**Argument(s):** none

**Description**

Multilevel function train based on regression may allocate the number of samples per level based on the collocation ratio times the regression size. The regression size is determined by the rank per core and the basis order per dimension as described at function_train, where these ranks and orders may be either user-specified values (for initial sample allocation), incremented values (for external adaptation by Dakota), or recovered values (in the case of internal C3 adaptation using adapt_rank).

The adaptive algorithm starts from a pilot sample, shapes the profile based on the regression size computed from the current orders and recovered ranks, and iterates until convergence.

This capability is experimental and under active development.
Examples

This example starts with rank-two order-two initial expansion for each level, with twice as many samples as regression coefficients. As the recovered rank is updated for each level, as dictated by the internal `adapt_rank` approach, the number of samples is incremented as needed in order to synchronize with the specified collocation ratio. In this case, the basis order is fixed and only the ranks and associated samples are updated for each level.

```plaintext
method,
    model_pointer = 'HIERARCH'
    multifidelity_function_train
    allocation_control rank_sampling
        start_rank_sequence = 2 2 2 2 2
        adapt_rank  kick_rank = 2 max_rank = 10
        start_order_sequence = 2 2 2 2 2
        collocation_ratio = 2. seed = 160415
        convergence_tolerance = 1.e-2
        max_refinement_iterations = 5
```

7.2.50.3 `convergence_tolerance`

- **Keywords Area**
- **method**
- **multilevel_function_train**
- **convergence_tolerance**

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- **method_independent_controls**

Specification

**Alias:** none

**Argument(s):** REAL

**Default:** 1.e-4

Description

The `convergence_tolerance` specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by `convergence_tolerance`, then this convergence criterion is satisfied on the current iteration. Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPSOL, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.
Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See `nl2sol`
- NLPOLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
- NPSOL: used as a line search tolerance, not as a relative convergence tolerance

### 7.2.50.4 metric_scale

- Keywords Area
- method
- multilevel_function_train
- metric_scale

define scaling of statistical metrics when adapting UQ surrogates

#### Specification

**Alias:** none

**Argument(s):** none

**Default:** relative

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional Required (Choose One)</th>
<th>Description of Group scale of refinement metric (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>relative</td>
<td>relative scaling of statistical metrics when adapting UQ surrogates</td>
</tr>
<tr>
<td></td>
<td></td>
<td>absolute</td>
<td>use of absolute statistical metrics when adapting UQ surrogates</td>
</tr>
</tbody>
</table>

#### Description

When adapting a UQ surrogate model, e.g., by change in response covariance matrix or level mappings, this option controls the use of scaling. The `absolute` option indicates that there is no scaling such that the statistical change is compared directly to the convergence tolerance. The `relative` option indicates that the change is measured relative to the current reference value (which evolves during the refinement), such that the convergence tolerance controls the relative change.

**Default Behavior**

The default is `relative`.

**Expected Output**
Usage Tips

Additional Discussion

7.2.50.4.1 relative

- Keywords Area
- method
- multilevel_function_train
- metric_scale
- relative

relative scaling of statistical metrics when adapting UQ surrogates

Specification

Alias: none
Argument(s): none

Description

When adapting a UQ surrogate model, the relative option indicates that the change is measured relative to the current reference value (which evolves during the refinement), such that the convergence tolerance controls the relative change.

Default Behavior

Expected Output

Usage Tips

Additional Discussion

7.2.50.4.2 absolute

- Keywords Area
- method
- multilevel_function_train
- metric_scale
- absolute

use of absolute statistical metrics when adapting UQ surrogates

Specification

Alias: none
Argument(s): none
Description

When adapting a UQ surrogate model, the `absolute` option indicates that there is no scaling such that the statistical change is compared directly to the convergence tolerance.

Default Behavior

Expected Output

Usage Tips

Additional Discussion

7.2.50.5 discrepancy_emulation

- **Keywords Area**
  - method
  - multilevel_function_train
  - discrepancy_emulation

Formulation for emulation of model discrepancies.

Specification

**Alias:** none

**Argument(s):** none

**Default:** distinct

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group Discrepancy Emulation Approach (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required (Choose One)</td>
<td></td>
<td>distinct</td>
<td>Distinct formulation for emulation of model discrepancies.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>recursive</td>
<td>Recursive formulation for emulation of model discrepancies.</td>
</tr>
</tbody>
</table>

Description

In many uncertainty quantification approaches, model discrepancies are emulated using, e.g., polynomial chaos, stochastic collocation, or Gaussian process models. Two formulations are available for this emulation:

1. **distinct** emulation (default), in which we directly approximate the difference or ratio between the evaluations of two models or solution levels.

2. **recursive** emulation (experimental option), in which we approximate a difference or ratio among the new model evaluation and the emulator approximation of the previous model.

The latter approach is a form of hierarchical emulation in which we emulate the surplus between the previous emulator and the new modeling level. This approach has a few advantages: (i) it reduces bias by correcting...
for emulation errors that occur at previous levels, and (ii) it does not require paired model evaluations for each discrepancy level, which reduces cost, allows for disparate sample points, and simplifies data imports.

On the other hand, its primary disadvantage is that the aggregate emulation is only as good as its weakest link, in that a poor emulator recovery can create difficulty in accurately resolving discrepancies that are recursively dependent on it. Thus, the distinct approach may tend to be more expensive in exchange for greater robustness.

Examples

```
method,
    multilevel_polynomial_chaos
    expansion_order_sequence = 2
    collocation_ratio = .9
    orthogonal_matching_pursuit
    discrepancy_emulation recursive
```

7.2.50.5.1 distinct

- Keywords Area
- method
- multilevel_function_train
- discrepancy_emulation
- distinct

Distinct formulation for emulation of model discrepancies.

Specification

**Alias:** paired

**Argument(s):** none

Description

The distinct approach to discrepancy emulation directly approximate the difference or ratio between the evaluations of two models or solution levels. Refer to the parent documentation node for additional discussion.

Examples

7.2.50.5.2 recursive

- Keywords Area
- method
- multilevel_function_train
- discrepancy_emulation
- recursive

Recursive formulation for emulation of model discrepancies.
Specification

**Alias:** none

**Argument(s):** none

Description

The recursive approach to discrepancy emulation approximates a difference or ratio among the new model evaluation and the emulator approximation of the previous model. Refer to the parent documentation node for additional discussion.

Examples

7.2.50.6 rounding_tolerance

- Keywords Area
- method
- multilevel_function_train
- rounding_tolerance

An accuracy tolerance that is used to guide rounding during rank adaptation.

Specification

**Alias:** none

**Argument(s):** REAL

**Default:** 1.e-10

Description

The rounding tolerance is used to measure how closely one can approximate a functional tensor train representation at a step of the optimization procedure using one of lower ranks. If this tolerance is small, then less compression is achieved but greater accuracy is obtained. If this tolerance is big, greater compression is achieved at the expense of accuracy.

**Default Behavior**

If this tolerance is not specified, then we adopt the internal C3 default.

These keywords may also be of interest:

- adapt_rank
- arithmetic_tolerance
7.2.50.7 arithmetic_tolerance

• Keywords Area
  • method
  • multilevel_function_train
  • arithmetic_tolerance

A secondary rounding tolerance used for post-processing

Specification

Alias: none
Argument(s): REAL
Default: 1.e-10

Description

After forming one or more function train approximations, this tolerance is used for rolling up final results, in particular, combining multilevel/multifidelity expansions and forming products for higher-order moment estimation. It is generally intended as a looser tolerance than rounding_tolerance.

Default Behavior

If this tolerance is not specified, then we adopt the internal C3 default.

See Also

These keywords may also be of interest:

• rounding_tolerance

7.2.50.8 regression_type

• Keywords Area
  • method
  • multilevel_function_train
  • regression_type

Type of solver for forming function train approximations by regression

Specification

Alias: none
Argument(s): none

Child Keywords:
Description

Function train approximations are formed based on regression for the set of coefficients described at function_train. Solver options include least squares and regularized regression, where the latter penalizes high-order terms to mitigate overfitting.

Default Behavior

The default regression solver is least squares.

7.2.50.8.1 ls

- Keywords Area
- method
- multilevel_function_train
- regression_type
- ls

Use least squares solver for forming function train approximations by regression

Specification

Alias: none

Argument(s): none

Description

Least squares is the standard solver for forming function train approximations based on regression. This option does not include regularization.

7.2.50.8.2 rls2

- Keywords Area
- method
- multilevel_function_train
- regression_type
- rls2
Use regularized regression solver for forming function train approximations

**Specification**

**Alias:** none  
**Argument(s):** none  
**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional Group</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required</td>
<td></td>
<td>l2_penalty</td>
<td>Penalty value applied in regularized regression solver for function train approximations</td>
</tr>
</tbody>
</table>

**Description**

RLS2 is a regularized least squares solver that applies an \( L2 \) penalty to mitigate overfitting. It includes the option to specify a penalty parameter.

**See Also**

These keywords may also be of interest:

- l2_penalty

**7.2.50.8.2.1 l2_penalty**

- Keywords Area
- method
- multilevel_function_train
- regression_type
- rls2
- l2_penalty

Penalty value applied in regularized regression solver for function train approximations

**Specification**

**Alias:** none  
**Argument(s):** REAL

**Description**

Regularized regression applies a penalty to aspects of the recovered solution (e.g., cardinality, higher-order oscillatory terms, et al.) to mitigate overfitting. This specification provides the scalar penalty parameter (its value is not currently adapted or cross-validated).
Default Behavior
If this penalty parameter is not specified, then we adopt the internal C3 default.

See Also
These keywords may also be of interest:

- rls2

7.2.50.9 max_solver_iterations

- Keywords Area
- method
- multilevel_function_train
- max_solver_iterations

Maximum iterations in determining polynomial coefficients

Specification

Alias: none
Argument(s): INTEGER
Default: 100

Description
When using an iterative polynomial coefficient estimation approach, e.g., cross-validation-based solvers, limits the maximum iterations in the coefficient solver.

7.2.50.10 max_cross_iterations

- Keywords Area
- method
- multilevel_function_train
- max_cross_iterations

Maximum number of iterations for cross-approximation during a rank adaptation.

Specification

Alias: none
Argument(s): INTEGER
Default: 1
Description

The number of iterations for the cross-approximation algorithm is limited within the adapt_rank procedure.

See Also

These keywords may also be of interest:

- adapt_rank

7.2.50.11 solver_tolerance

Convergence tolerance for the optimizer used during the regression solve.

Specification

**Alias**: none

**Argument(s)**: REAL

**Default**: 1.0e-10

Description

Defines the function value and function gradient tolerance for optimizer used solving the regression problem for the functional tensor train coefficients.

7.2.50.12 response_scaling

Perform bounds-scaling on response values prior to surrogate emulation

Specification

**Alias**: none

**Argument(s)**: none

**Default**: use original data
Description

Particularly in multifidelity methods based on regression solutions at each level of a model hierarchy, scaling can be an issue since the magnitude of discrepancy data may decay rapidly and regression solvers may employ absolute tolerances in places.

By activating response_scaling, the set of response data used for each recovery is scaled to \([0, 1]\) based on the minimum value and range of the data set. This prevents loss of accuracy due to imbalances in scale across model levels.

See Also

These keywords may also be of interest:

- multifidelity_polynomial_chaos
- multifidelity_function_train

7.2.50.13 tensor_grid

Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.

Specification

Alias: none
Argument(s): none
Default: regression with random sample set

Description

The collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

7.2.50.14 collocation_points_sequence

Sequence of collocation point counts used in a multi-stage expansion
7.2 method

Specification

**Alias:** pilot_samples

**Argument(s):** INTEGERLIST

**Description**

Each level entry of the `collocation_points_sequence` applies to one expansion within a multi-stage expansion. Current multi-stage expansions that support collocation point sequences include multilevel and multifidelity polynomial chaos and multilevel and multifidelity function train expansions.

If adaptive refinement is active, then this sequence specifies the starting point for each level within either an individual or integrated refinement approach.

A corresponding scalar specification is documented at, e.g., `collocation_points`

**See Also**

These keywords may also be of interest:

- `collocation_points`

7.2.50.15 collocation_ratio

**Keywords Area**

- `method`
- `multilevel_function_train`
- `collocation_ratio`

Set the number of points used to build a PCE via regression to be proportional to the number of terms in the expansion.

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 0.

**Description**

Set the number of points used to build a PCE via regression to be proportional to the number of terms in the expansion. To avoid requiring the user to calculate N from n and p, the collocation_ratio allows for specification of a constant factor applied to N (e.g., collocation_ratio = 2. produces samples = 2N). In addition, the default linear relationship with N can be overridden using a real-valued exponent specified using ratio_order. In this case, the number of samples becomes \( cN^o \) where \( c \) is the collocation_ratio and \( o \) is the ratio_order. The use_derivatives flag informs the regression approach to include derivative matching equations (limited to gradients at present) in the least squares solutions, enabling the use of fewer collocation points for a given expansion order and dimension (number of points required becomes \( cN^o + 1 \)).
7.2.50.16  start_order_sequence

- Keywords Area
- method
- multilevel_function_train
- start_order_sequence

Sequence of start orders used in a multi-stage expansion

**Specification**

**Alias:** order_sequence

**Argument(s):** INTEGERLIST

**Default:** 2

**Child Keywords:**

<table>
<thead>
<tr>
<th>Description of Group</th>
<th>Required/Optional</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dimension_preference</td>
<td>Optional</td>
<td></td>
<td>A set of weights specifying the relative importance of each uncertain variable (dimension)</td>
</tr>
</tbody>
</table>

**Description**

Each level entry of the `start_order_sequence` applies to one expansion within a multi-stage expansion. Current multi-stage expansions that support start order sequences include multilevel and multifidelity function train expansions.

If adaptive refinement is active, then this sequence specifies the starting point for each level within either an individual or integrated refinement approach.

A corresponding scalar specification is documented at, e.g., `start_order`

**See Also**

These keywords may also be of interest:

- `start_order`

7.2.50.16.1  dimension_preference

- Keywords Area
- method
- multilevel_function_train
- start_order_sequence
- dimension_preference

A set of weights specifying the relative importance of each uncertain variable (dimension)
7.2 method

Specification

Alias: none
Argument(s): REALLIST
Default: isotropic grids

Description

A set of weights specifying the relative importance of each uncertain variable (dimension). Using this specification leads to anisotropic integrations with differing refinement levels for different random dimensions.

See Also

These keywords may also be of interest:

- sobol
- decay

7.2.50.17 adapt_order

- Keywords Area
- method
- multilevel_function_train
- adapt_order

Activate adaptive procedure for determining the best basis order

Specification

Alias: none
Argument(s): none
Default: false

Description

This option activates a cross validation procedure to select the best basis order for representing the current set of data. It searches from start_order to max_order in increments of kick_order.

Default Behavior

No cross validation for basis order.

Examples

This example shows specification of an order adaptation starting at order 2, incrementing by 2, and limited at order 6.
model,
  id_model = 'FT'
surrogate global function_train
  start_rank = 4
  adapt_order start_order = 2  kick_order = 2  max_order = 6
  solver_tolerance = 1e-12
  rounding_tolerance = 1e-12
dace_method_pointer = 'SAMPLING'

Note that adapt_rank and adapt_order can either be combined or used separately.

See Also

These keywords may also be of interest:

- start_order
- kick_order
- max_order

7.2.50.18 kick_order

- Keywords Area
- method
- multilevel_function_train
- kick_order

increment used when adapting the basis order in function train methods

Specification

Alias: none
Argument(s): INTEGER
Default: 1

Description

Used in combination with adapt_order, kick_order defines the size of the increment that is used during the cross validation process, within the range of start_order and max_order.

Default Behavior

Default is 1.

See Also

These keywords may also be of interest:

- adapt_order
7.2.50.19  max_order

- Keywords Area
- method
- multilevel_function_train
- max_order

Maximum polynomial order of each univariate function within the functional tensor train.

Specification

Alias: none
Argument(s): INTEGER
Default: unsigned short max

Description

This specification is inactive for current adaptation options.
In future adaptation options (i.e., cross-approximation adaptation), this will specify the maximum order that can be obtained during adaptation, where polynomial order will start from start_order and be limited by max_order.

Default Behavior
Max order is unbounded (adaptive sweep will stop when CV error increases).

See Also

These keywords may also be of interest:

- start_order

7.2.50.20  max_cv_order_candidates

- Keywords Area
- method
- multilevel_function_train
- max_cv_order_candidates

Limit the number of cross-validation candidates for basis order

Specification

Alias: none
Argument(s): INTEGER
Default: ushort max
Description

When generating refinement candidates by advancing the upper bound used for a cross-validation range, the number of cross-validation can eventually become excessive and hamper algorithm progress. This control limits the maximum number of candidates, which when active, will increase the lower bound for this range as the upper bound is advanced.

See Also

These keywords may also be of interest:

7.2.50.21 start_rank_sequence

Sequence of start ranks used in a multi-stage expansion

Specification

Alias: rank_sequence
Argument(s): INTEGERLIST
Default: 2

Description

Each level entry of the start_rank_sequence applies to one expansion within a multi-stage expansion. Current multi-stage expansions that support start rank sequences include multilevel and multifidelity function train expansions.

If adaptive refinement is active, then this sequence specifies the starting point for each level within either an individual or integrated refinement approach.

A corresponding scalar specification is documented at, e.g., start_rank

See Also

These keywords may also be of interest:

- start_rank
7.2 method

7.2.50.22 adapt_rank

- Keywords Area
  - method
  - multilevel_function_train
  - adapt_rank

Activate adaptive procedure for determining best rank representation

Specification

Alias: none
Argument(s): none
Default: false

Description

The adaptive algorithm proceeds as follows:

1. Start from rank \texttt{start\_rank} and form an approximation
2. Adapt the current approximation by searching for a solution with lower rank that achieves L2 accuracy within epsilon tolerance of the reference.
3. If a lower rank solution is found with comparable accuracy, then stop. If not, increase the rank by an amount specified by \texttt{kick\_rank}.
4. Return to step 2 and continue until either \texttt{max\_rank} is reached or a converged rank (rank less than current reference with comparable accuracy) is found.

Default Behavior

No cross validation for rank.

Examples

This example shows specification of a rank adaptation starting at rank 2, incrementing by 2, and limited at rank 10.

\begin{verbatim}
model,
  id_model = 'FT'
surrogate global function_train
  start_order = 5
  adapt_rank start_rank = 2 kick_rank = 2 max_rank = 10
  solver_tolerance = 1e-12
  rounding_tolerance = 1e-12
dace_method_pointer = 'SAMPLING'
\end{verbatim}

Note that \texttt{adapt\_rank} and \texttt{adapt\_order} can either be combined or used separately.

See Also

These keywords may also be of interest:

- \texttt{start\_rank}
- \texttt{kick\_rank}
- \texttt{max\_rank}
7.2.50.23 kick_rank

- Keywords Area
- method
- multilevel_function_train
- kick_rank

The increment in rank employed during each iteration of the rank adaptation.

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 1

**Description**

The `adapt_rank` procedure increments the rank on each iteration, using an increment defined by `kick_rank`

**Default Behavior**

Default is 1.

**See Also**

These keywords may also be of interest:

- `adapt_rank`

7.2.50.24 max_rank

- Keywords Area
- method
- multilevel_function_train
- max_rank

Limits the maximum rank that is explored during a rank adaptation.

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** size_t max
Description

The adapt_rank procedure increments the rank on each iteration, and the maximum value is limited by max_rank.

Default Behavior

Max rank is unbounded (adaptive sweep will stop when CV error increases).

See Also

These keywords may also be of interest:

- adapt_rank

7.2.50.25 max_cv_rank_candidates

Limit the number of cross-validation candidates for rank

Specification

Alias: none

Argument(s): INTEGER

Default: size_t max

Description

When generating refinement candidates by advancing the upper bound used for a cross-validation range, the number of cross-validation can eventually become excessive and hamper algorithm progress. This control limits the maximum number of candidates, which when active, will increase the lower bound for this range as the upper bound is advanced.

See Also

These keywords may also be of interest:

- increment_max_rank
- increment_max_rank_order
- function_train
- multifidelity_function_train
7.2.50.26 samples_on_emulator

- Keywords Area
- method
- multilevel_function_train
- samples_on_emulator

Number of samples at which to evaluate an emulator (surrogate)

Specification

**Alias:** samples

**Argument(s):** INTEGER

Description

How many approximate function evaluations to perform on the emulator model, e.g., to compute statistics

**Default Behavior**

The default number of samples is method-dependent.

**Examples**

Perform 10000 samples on the PCE approximation of the true model:

```python
method
polynomial_chaos
    quadrature_order  = 2
    samples_on_emulator = 10000
```

7.2.50.27 sample_type

- Keywords Area
- method
- multilevel_function_train
- sample_type

Selection of sampling strategy

Specification

**Alias:** none

**Argument(s):** none

**Default:** random

**Child Keywords:**
### Description

The `sample_type` keyword allows the user to select between two types of sampling: Monte Carlo (pure random) and Latin hypercube (stratified) sampling.

The incremental keywords are deprecated; instead use `samples` together with `refinement_samples`.

### Default Behavior

If the `sample_type` keyword is present, it must be accompanied by `lhs` or `random`. In most contexts, `lhs` is the default (exception: multilevel_sampling uses Monte Carlo by default).

### Examples

```plaintext
method
  sampling
    sample_type lhs
    samples = 20
    seed = 83921

7.2.50.27.1  lhs

- Keywords Area
- method
- multilevel_function_train
- sample_type
- lhs

Uses Latin Hypercube Sampling (LHS) to sample variables
```

### Specification

**Alias:** none

**Argument(s):** none

### Description

The `lhs` keyword invokes Latin Hypercube Sampling as the means of drawing samples of uncertain variables according to their probability distributions. This is a stratified, space-filling approach that selects variable values from a set of equi-probable bins.

### Default Behavior
Latin Hypercube Sampling is the default sampling mode in most contexts (exception: multilevel_sampling). To explicitly specify LHS in the Dakota input file, the `lhs` keyword must appear in conjunction with the `sample_type` keyword.

**Usage Tips**

Latin Hypercube Sampling is very robust and can be applied to any problem. It is fairly effective at estimating the mean of model responses and linear correlations with a reasonably small number of samples relative to the number of variables.

**Examples**

```plaintext
method sampling
    sample_type lhs
    samples = 20
```

7.2.50.27.2 random

- Keywords Area
- method
- multilevel_function_train
- sample_type
- random

Uses purely random Monte Carlo sampling to sample variables

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The `random` keyword invokes Monte Carlo sampling as the means of drawing samples of uncertain variables according to their probability distributions.

**Default Behavior**

In most contexts, Monte Carlo sampling is not the default sampling mode (exception: multilevel_sampling). To change this behavior, the `random` keyword must be specified in conjunction with the `sample_type` keyword.

**Usage Tips**

Monte Carlo sampling is more computationally expensive than Latin Hypercube Sampling as it requires a larger number of samples to accurately estimate statistics.

**Examples**

```plaintext
method sampling
    sample_type random
    samples = 200
```
Selection of a random number generator

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** Mersenne twister (mt19937)

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional Required (Choose One)</th>
<th>Description of Group RNG Algorithm (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>mt19937</td>
<td>Generates random numbers using the Mersenne twister</td>
</tr>
</tbody>
</table>

**Description**

The `rng` keyword is used to indicate a choice of random number generator.

**Default Behavior**

If specified, the `rng` keyword must be accompanied by either `rnum2` (pseudo-random numbers) or `mt19937` (random numbers generated by the Mersenne twister). Otherwise, `mt19937`, the Mersenne twister is used by default.

**Usage Tips**

The default is recommended, as the Mersenne twister is a higher quality random number generator.

**Examples**

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2
```

7.2.50.28.1 mt19937

• Keywords Area

• method
Generates random numbers using the Mersenne twister

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

The `mt19937` keyword directs Dakota to use the Mersenne twister to generate random numbers. Additional information can be found on wikipedia: [http://en.wikipedia.org/wiki/Mersenne_twister](http://en.wikipedia.org/wiki/Mersenne_twister).

**Default Behavior**

`mt19937` is the default random number generator. To specify it explicitly in the Dakota input file, however, it must be specified in conjunction with the `rng` keyword.

**Usage Tips**

Use of the Mersenne twister random number generator (`mt19937`) is recommended.

**Examples**

```dakota
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng mt19937
```

Generates pseudo-random numbers using the Pecos package

**Specification**

**Alias:** none  
**Argument(s):** none
Description

The `rnum2` keyword directs Dakota to use pseudo-random numbers generated by the Pecos package.

Default Behavior

`rnum2` is not used by default. To change this behavior, it must be specified in conjunction with the `rng` keyword.

Usage Tips

Use of the Mersenne twister random number generator (`mt19937`) is recommended over `rnum2`.

Examples

```dakota
method
  sampling
    sample_type lhs
    samples = 10
    seed = 98765
    rng rnum2
```

7.2.50.29 probability_refinement

- Keywords Area
- method
- multilevel_function_train
- probability_refinement

Allow refinement of probability and generalized reliability results using importance sampling

Topics

This keyword is related to the topics:

- reliability_methods

Specification

Alias: sample_refinement

Argument(s): none

Default: no refinement

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required (Choose One)</td>
<td>Importance Sampling Approach (Group 1)</td>
<td><code>import</code></td>
<td>Importance sampling option for probability refinement</td>
</tr>
</tbody>
</table>
The probability_refinement allows refinement of probability and generalized reliability results using importance sampling. If one specifies probability_refinement, there are some additional options. One can specify which type of importance sampling to use (import, adapt_import, or mm_adapt_import). Additionally, one can specify the number of refinement samples to use with refinement_samples and the seed to use with seed.

The probability_refinement density reweighting accounts originally was developed based on Gaussian distributions. It now accounts for additional non-Gaussian cases.

### 7.2.50.29.1 import

- Keywords Area
- method
- multilevel_function_train
- probability_refinement
- import

Importance sampling option for probability refinement

#### Specification

**Alias:** none

**Argument(s):** none

#### Description

import centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level).

### 7.2.50.29.2 adapt_import

- Keywords Area
- method
- multilevel_function_train
- probability_refinement
7.2 method

- **adapt_import**

  Importance sampling option for probability refinement

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

*adapt_import* centers a sampling density at one of the initial LHS samples identified in the failure region. It then generates the importance samples, weights them by their probability of occurrence given the original density, and calculates the required probability (CDF or CCDF level). This continues iteratively until the failure probability estimate converges.

7.2.50.29.3 **mm_adapt_import**

- **Keywords Area**
- **method**
- **multilevel_function_train**
- **probability_refinement**
- **mm_adapt_import**

Importance sampling option for probability refinement

**Specification**

**Alias:** none  
**Argument(s):** none

**Description**

*mm_adapt_import* starts with all of the samples located in the failure region to build a multimodal sampling density. First, it uses a small number of samples around each of the initial samples in the failure region. Note that these samples are allocated to the different points based on their relative probabilities of occurrence: more probable points get more samples. This early part of the approach is done to search for "representative" points. Once these are located, the multimodal sampling density is set and then *mm_adapt_import* proceeds similarly to *adapt_import* (sample until convergence).

7.2.50.29.4 **refinement_samples**

- **Keywords Area**
- **method**
- **multilevel_function_train**
- **probability_refinement**
- **refinement_samples**

Number of samples used to refine a probability estimate or sampling design.
Specification

Alias: none
Argument(s): INTEGERLIST

Description

Probability estimate: Specify the (scalar) number of samples used to improve a probability estimate. If using uni-modal sampling all samples are assigned to the sampling center. If using multi-modal sampling the samples are split between multiple samples according to some internally computed weights.

Sampling design: Specify one or a sequence of refinement samples to augment the initial samples in a sampling design.

7.2.50.30 final_moments

- Keywords Area
- method
- multilevel_function_train
- final_moments

Output moments of the specified type and include them within the set of final statistics.

Specification

Alias: none
Argument(s): none
Default: standard

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required(Choose One)</td>
<td>Final moment type (Group 1)</td>
<td>none</td>
<td>Omit moments from the set of final statistics.</td>
</tr>
<tr>
<td>standard</td>
<td>standard</td>
<td>Output standardized moments and include them within the set of final statistics.</td>
<td></td>
</tr>
</tbody>
</table>
### 7.2 method

<table>
<thead>
<tr>
<th>Output central moments and include them within the set of final statistics.</th>
</tr>
</thead>
</table>

### Description

When performing a nested study that may employ moment statistics on the inner loop, it can be desirable to control the type of these moments. The `final_moments` specification supports options of **none**, **standard** (default), or **central**, corresponding to omission of moments, standardized moments (mean, standard deviation, skewness, and excess kurtosis), or central moments (mean, variance, 3rd central, and 4th central).

The presence or omission of moment results in the final statistics influences the outer level mappings in the case of a nested study. For example, `final_moments none` can allow for a more compact specification of primary and/or secondary response mappings.

### Examples

The following method specification overrides the default to print **central** moments and include them in the set of final statistics.

```plaintext
method,
sampling
  samples = 50 seed = 1234
  response_levels = 3.6e+11 1.2e+05 3.5e+05
  final_moments central
```

Overriding the default to **none** as follows:

```plaintext
method,
sampling
  samples = 50 seed = 1234
  response_levels = 3.6e+11 1.2e+05 3.5e+05
  final_moments none
```

allows associated nested model mappings to be simplified from:

```plaintext
model
  nested
    sub_method_pointer = 'UQ'
    primary_response_mapping = 0. 0. 1. 0. 0. 1. 0. 0. 0.
    secondary_response_mapping = 0. 0. 0. 0. 0. 0. 0. 0. 1.
```

to a more compact version focused only on the response level mappings (two leading zeros per response function for moment mappings have been removed):

```plaintext
model
  nested
    sub_method_pointer = 'UQ'
    primary_response_mapping = 1. 1. 0.
    secondary_response_mapping = 0. 0. 1.
```

### 7.2.50.30.1 none

- Keywords Area
- method
- multilevel_function_train
- final_moments

---

Dakota Version 6.16 Reference Manual generated on May 12, 2022
• none

Omit moments from the set of final statistics.

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

The omission of moment results from the final statistics can allow for a more compact definition of primary and/or secondary response mappings within a nested model specification.

**Examples**

```dakota
method,
sampling
  samples = 50 seed = 1234
  response_levels = 3.6e+11 1.2e+05 3.5e+05
  final_moments none
```

7.2.50.30.2 standard

- Keywords Area
- method
- multilevel_function_train
- final_moments
- standard

Output standardized moments and include them within the set of final statistics.

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

Output standardized moments (mean, standard deviation, skewness, and excess kurtosis) and include the first two within the set of final statistics to be used at a higher level (e.g., optimization under uncertainty, mixed aleatory-epistemic UQ). This inclusion of moment results affects the primary and/or secondary response mappings in a nested model specification.

**Examples**

The following method specification overrides the default to print central moments and include them in the set of final statistics.
7.2.50.30.3 central

- Keywords Area
- method
- multilevel_function_train
- final_moments
- central

Output central moments and include them within the set of final statistics.

Specification

Alias: none

Argument(s): none

Description

Output central moments (mean, variance, 3rd central, and 4th central) and include the first two within the set of final statistics to be used at a higher level (e.g., optimization under uncertainty, mixed aleatory-epistemic U-Q). This inclusion of moment results affects the primary and/or secondary response mappings in a nested model specification.

Examples

The following method specification overrides the default to print central moments and include them in the set of final statistics.

```dakota
method,
sampling
    samples = 50 seed = 1234
    response_levels = 3.6e+11 1.2e+05 3.5e+05
    final_moments standard
```

7.2.50.31 response_levels

- Keywords Area
- method
- multilevel_function_train
- response_levels

Values at which to estimate desired statistics for each response
Specification

**Alias:** none

**Argument(s):** REALLIST

**Default:** No CDF/CCDF probabilities/reliabilities to compute

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>num_response_levels</td>
<td></td>
<td>Number of values at which to estimate desired statistics for each response</td>
</tr>
<tr>
<td>Optional</td>
<td>compute</td>
<td></td>
<td>Selection of statistics to compute at each response level</td>
</tr>
</tbody>
</table>

**Description**

The `response_levels` specification provides the target response values for which to compute probabilities, reliabilities, or generalized reliabilities (forward mapping).

**Default Behavior**

If `response_levels` are not specified, no statistics will be computed. If they are, probabilities will be computed by default.

**Expected Outputs**

If `response_levels` are specified, Dakota will create two tables in the standard output: a Probability Density function (PDF) histogram and a Cumulative Distribution Function (CDF) table. The PDF histogram has the lower and upper endpoints of each bin and the corresponding density of that bin. Note that the PDF histogram has bins defined by the `probability_levels` and/or `response_levels` in the Dakota input file. If there are not very many levels, the histogram will be coarse. Dakota does not do anything to optimize the bin size or spacing. The CDF table has the list of response levels and the corresponding probability that the response value is less than or equal to each response level threshold.

**Usage Tips**

The `num_response_levels` is used to specify which arguments of the `response_level` correspond to which response.

**Examples**

For example, specifying a `response_level` of 52.3 followed with `compute` probabilities will result in the calculation of the probability that the response value is less than or equal to 52.3, given the uncertain distributions on the inputs.

For an example with multiple responses, the following specification

```
response_levels = 1. 2. .1 .2 .3 .4 10. 20. 30.
num_response_levels = 2 4 3
```

would assign the first two response levels `(1., 2.)` to response function 1, the next four response levels `(1., .2, .3, .4)` to response function 2, and the final three response levels `(10., 20., 30.)` to response function 3. If the `num-`
The Dakota input file below specifies a sampling method with response levels of interest.

```
method, sampling,
samples = 100 seed = 1
complementary distribution
response_levels = 3.6e+11 4.0e+11 4.4e+11
---------------- 6.0e+04 6.5e+04 7.0e+04
                3.5e+05 4.0e+05 4.5e+05

variables,
normal_uncertain = 2
means = 248.89, 593.33
std_deviations = 12.4, 29.7
descriptors = 'TF1n' 'TF2n'
uniform_uncertain = 2
lower_bounds = 199.3, 474.63
upper_bounds = 298.5, 712.
descriptors = 'TF1u' 'TF2u'
weibull_uncertain = 2
alphas = 12., 30.
betas = 250., 590.
descriptors = 'TF1w' 'TF2w'
histogram_bin_uncertain = 2
num_pairs = 3 4
abscissas = 5 8 10 .1 .2 .3 .4
counts = 17 21 0 12 24 12 0
descriptors = 'TF1h' 'TF2h'
histogram_point_uncertain
real = 1
num_pairs = 2
abscissas = 3 4
counts = 1 1
descriptors = 'TF3h'
```

Given the above Dakota input file, the following excerpt from the output shows the PDF and CCDF generated. Note that the bounds on the bins of the PDF are the response values specified in the input file. The probability levels corresponding to those response values are shown in the CCDF.

```

3.5000000000e+05 4.0000000000e+05 8.6000000000e-06
```
### Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

A forward mapping involves computing the belief and plausibility probability level for a specified response level.

#### 7.2.50.31.1 num_response_levels

- **Keywords Area**
- **method**
- **multilevel_function_train**
- **response_levels**
- **num_response_levels**

Number of values at which to estimate desired statistics for each response

### Specification

**Alias:** none  
**Argument(s):** INTEGERLIST  
**Default:** response_levels evenly distributed among response functions

### Description

The `num_response_levels` keyword allows the user to specify the number of response values, for each response, at which estimated statistics are of interest. Statistics that can be computed are probabilities and reliabilities, both according to either a cumulative distribution function or a complementary cumulative distribution function.

**Default Behavior**

If `num_response_levels` is not specified, the response_levels will be evenly distributed among the responses.
Expected Outputs

The specific output will be determined by the type of statistics that are specified. In a general sense, the output will be a list of response level-statistic pairs that show the estimated value of the desired statistic for each response level specified.

Examples

method
sampling
samples = 100
seed = 34785
num_response_levels = 1 1 1
response_levels = 0.5 0.5 0.5

7.2.50.31.2 compute

• Keywords Area

• method

• multilevel_function_train

• response_levels

• compute

Selection of statistics to compute at each response level

Specification

Alias: none

Argument(s): none

Default: probabilities

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional Required (Choose One)</th>
<th>Description of Group Statistics to Compute (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>probabilities</td>
<td>probabilities</td>
<td>Computes probabilities associated with response levels</td>
</tr>
<tr>
<td></td>
<td>reliabilities</td>
<td></td>
<td>Computes reliabilities associated with response levels</td>
</tr>
<tr>
<td></td>
<td>gen_reliabilities</td>
<td></td>
<td>Computes generalized reliabilities associated with response levels</td>
</tr>
</tbody>
</table>
Keywords Area

| Optional | system | Compute system reliability (series or parallel) |

Description

The `compute` keyword is used to select which forward statistical mapping is calculated at each response level.

Default Behavior

If `response_levels` is not specified, no statistics are computed. If `response_levels` is specified but `compute` is not, probabilities will be computed by default. If both `response_levels` and `compute` are specified, then one of the following must be specified: `probabilities`, `reliabilities`, or `gen_reliabilities`.

Expected Output

The type of statistics specified by `compute` will be reported for each response level.

Usage Tips

CDF/CCDF probabilities are calculated for specified response levels using a simple binning approach.

CDF/CCDF reliabilities are calculated for specified response levels by computing the number of sample standard deviations separating the sample mean from the response level.

Examples

```dakota
method
  sampling
    sample_type random
    samples = 100 seed = 1
    complementary distribution
    response_levels = 3.6e+11 4.0e+11 4.4e+11
                     6.0e+04 6.5e+04 7.0e+04
                     3.5e+05 4.0e+05 4.5e+05
    compute reliabilities

7.2.50.31.2.1 probabilities
```

Computes probabilities associated with response levels

Specification

- **Alias**: none
- **Argument(s)**: none
Description

The `probabilities` keyword directs Dakota to compute the probability that the model response will be below (cumulative) or above (complementary cumulative) a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the probabilities are computed by default. To explicitly specify it in the Dakota input file, though, the `probabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-probability pairs that give the probability that the model response will be below or above the corresponding response level, depending on the distribution defined.

Examples

```
method sampling
  sample_type random
  samples = 100 seed = 1
  complementary distribution
  response_levels = 3.6e+11 4.0e+11 4.4e+11
                   6.0e+04 6.5e+04 7.0e+04
                   3.5e+05 4.0e+05 4.5e+05
  compute probabilities
```

7.2.50.31.2.2 reliabilities

- Keywords Area
- method
- multilevel_function_train
- response_levels
- compute
- reliabilities

Computes reliabilities associated with response levels

Specification

Alias: none
Argument(s): none

Description

The `reliabilities` keyword directs Dakota to compute reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

Default Behavior

If `response_levels` is specified, the reliabilities are not computed by default. To change this behavior, the `reliabilities` keyword should be specified in conjunction with the `compute` keyword.

Expected Outputs

The Dakota output is a set of response level-reliability pairs according to the distribution defined.
Examples

method
sampling
  sample_type random
  samples = 100 seed = 1
complementary distribution
response_levels = 3.6e+11 4.0e+11 4.4e+11
  6.0e+04 6.5e+04 7.0e+04
  3.5e+05 4.0e+05 4.5e+05
compute reliabilities

7.2.50.31.2.3  gen_reliabilities

   • Keywords Area
   • method
   • multilevel_function_train
   • response_levels
   • compute
   • gen_reliabilities

Computes generalized reliabilities associated with response levels

Specification

Alias: none
Argument(s): none

Description

The gen_reliabilities keyword directs Dakota to compute generalized reliabilities according to the specified distribution for a specified response value. This is done for every response level designated for each response.

Default Behavior

If response_levels is specified, the generalized reliabilities are not computed by default. To change this behavior, the gen_reliabilities keyword should be specified in conjunction with the compute keyword.

Expected Outputs

The Dakota output is a set of response level-generalized reliability pairs according to the distribution defined.

Examples

method
sampling
  sample_type random
  samples = 100 seed = 1
complementary distribution
response_levels = 3.6e+11 4.0e+11 4.4e+11
  6.0e+04 6.5e+04 7.0e+04
  3.5e+05 4.0e+05 4.5e+05

<td>System Reliability Mode (Group 1)</td>
<td>series</td>
<td>Aggregate response statistics assuming a series system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>parallel</td>
<td>Aggregate response statistics assuming a parallel system</td>
</tr>
</tbody>
</table>

Description

With the system probability/reliability option, statistics for specified response_levels are calculated and reported assuming the response functions combine either in series or parallel to produce a total system response.

For a series system, the system fails when any one component (response) fails. The probability of failure is the complement of the product of the individual response success probabilities.

For a parallel system, the system fails only when all components (responses) fail. The probability of failure is the product of the individual response failure probabilities.

- probability_levels

Specify probability levels at which to estimate the corresponding response value

**Specification**

**Alias:** none
**Argument(s):** REALLIST

**Default:** No CDF/CCDF response levels to compute

**Child Keywords:**
Description

Response levels are calculated for specified CDF/CCDF probabilities by indexing into a sorted samples array (the response levels computed are not interpolated and will correspond to one of the sampled values).

Expected Output

If `probability_levels` are specified, Dakota will create two tables in the standard output: a Probability Density function (PDF) histogram and a Cumulative Distribution Function (CDF) table. The PDF histogram has the lower and upper endpoints of each bin and the corresponding density of that bin. Note that the PDF histogram has bins defined by the `probability_levels` and/or `response_levels` in the Dakota input file. If there are not very many levels, the histogram will be coarse. Dakota does not do anything to optimize the bin size or spacing. The CDF table has the list of response levels and the corresponding probability that the response value is less than or equal to each response level threshold.

Examples

The Dakota input file below specifies a sampling method with probability levels of interest.

```dakota
method, sampling,
  samples = 100 seed = 1
complementary distribution
  probability_levels = 1.00 .66 .33 0.
  1.00 .50 0.
  1.00 .33 0.

Given the above Dakota input file, the following excerpt from the output shows the PDF and CCDF generated. Note that the bounds on the bins of the PDF are the response values that correspond the probability levels specified in the input file. Those response values are also shown in the CCDF.

Probability Density Function (PDF) histograms for each response function:

Theory

Sets of response-probability pairs computed with the forward/inverse mappings define either a cumulative distribution function (CDF) or a complementary cumulative distribution function (CCDF) for each response function.

In the case of evidence-based epistemic methods, this is generalized to define either cumulative belief and plausibility functions (CBF and CPF) or complementary cumulative belief and plausibility functions (CCBF and CCPF) for each response function.

An inverse mapping involves computing the belief and plausibility response level for either a specified probability level or a specified generalized reliability level (two results for each level mapping in the evidence-based epistemic case, instead of the one result for each level mapping in the aleatory case).
Specify which probability_levels correspond to which response

Specification

Alias: none

Argument(s): INTEGERLIST

Default: probability_levels evenly distributed among response functions

Description

See parent page

7.2.50.33 reliability_levels

Specify reliability levels at which the response values will be estimated

Specification

Alias: none

Argument(s): REALLIST

Default: No CDF/CCDF response levels to compute

Child Keywords:

<td></td>
<td>complementary</td>
<td>Computes statistics according to complementary cumulative functions</td>
</tr>
</tbody>
</table>

**Description**

The `distribution` keyword allows the user to select between a cumulative distribution/belief/plausibility function and a complementary cumulative distribution/belief/plausibility function. This choice affects how probabilities and reliability indices are reported.

**Default Behavior**

If the `distribution` keyword is present, it must be accompanied by either `cumulative` or `complementary`. Otherwise, a cumulative distribution will be used by default.

**Expected Outputs**

Output will be a set of model response-probability pairs determined according to the choice of distribution. The choice of distribution also defines the sign of the reliability or generalized reliability indices.

**Examples**

```plaintext
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

7.250.35.1 cumulative

- Keywords Area
- method
- multilevel_function_train
7.2 method

- distribution
  - cumulative

Computes statistics according to cumulative functions

**Specification**

**Alias:** none

**Argument(s):** none

**Description**

Statistics on model responses will be computed according to a cumulative distribution/belief/plausibility function.

**Default Behavior**

By default, a cumulative distribution/belief/plausibility function will be used. To explicitly specify it in the Dakota input file, however, the `cumulative` keyword must appear in conjunction with the `distribution` keyword.

**Expected Outputs**

Output will be a set of model response-probability pairs determined according to a cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls below given response thresholds.

**Examples**

```dakota
method
  sampling
    sample_type lhs
    samples = 10
    distribution cumulative
```

7.2.50.35.2 complementary

- Keywords Area
  - method
    - multilevel_function_train
      - distribution
        - complementary

Computes statistics according to complementary cumulative functions

**Specification**

**Alias:** none

**Argument(s):** none
Description

Statistics on model responses will be computed according to a complementary cumulative distribution/belief/plausibility function.

Default Behavior

By default, a complementary cumulative distribution/belief/plausibility function will not be used. To change that behavior, the complementary keyword must be appear in conjunction with the distribution keyword.

Expected Outputs

Output will be a set of model response-probability pairs determined according to a complementary cumulative distribution/belief/plausibility function. The probabilities reported are the probabilities that the model response falls above given response thresholds.

Examples

```method
sampling
  sample_type lhs
  samples = 10
  distribution complementary
```

7.2.50.36  variance_based_decomp

- Keywords Area
- method
- multilevel_function_train
- variance_based_decomp

Activates global sensitivity analysis based on decomposition of response variance into main, interaction, and total effects.

Specification

**Alias:** none

**Argument(s):** none

**Default:** no variance-based decomposition

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>interaction_order</td>
<td></td>
<td>Specify the maximum number of variables allowed in an interaction when reporting interaction metrics.</td>
</tr>
</tbody>
</table>
Description

Dakota can calculate sensitivity indices through variance-based decomposition using the keyword `variance_based_decomp`. This approach decomposes main, interaction, and total effects in order to identify the most important variables and combinations of variables in contributing to the variance of output quantities of interest.

Default Behavior

Because of processing overhead and output volume, `variance_based_decomp` is inactive by default, unless required for dimension-adaptive refinement using Sobol' indices.

Expected Outputs

When `variance_based_decomp` is specified, sensitivity indices for main effects, total effects, and any interaction effects will be reported. Each of these effects represents the percent contribution to the variance in the model response, where main effects include the aggregated set of univariate terms for each individual variable, interaction effects represent the set of mixed terms (the complement of the univariate set), and total effects represent the complete set of terms (univariate and mixed) that contain each individual variable. The aggregated set of main and interaction sensitivity indices will sum to one, whereas the sum of total effects sensitivity indices will be greater than one due to redundant counting of mixed terms.

Usage Tips

An important consideration is that the number of possible interaction terms grows exponentially with dimension and expansion order. To mitigate this, both in terms of compute time and output volume, possible interaction effects are suppressed whenever no contributions are present due to the particular form of an expansion. In addition, the `interaction_order` and `drop_tolerance` controls can further limit the computational and output requirements.

Examples

```
method,
    polynomial_chaos # or stoch_collocation
    sparse_grid_level = 3
    variance_based_decomp interaction_order = 2
```

Theory

In this context, we take sensitivity analysis to be global, not local as when calculating derivatives of output variables with respect to input variables. Our definition is similar to that of [76]: "The study of how uncertainty in the output of a model can be apportioned to different sources of uncertainty in the model input."

Variance based decomposition is a way of using sets of samples to understand how the variance of the output behaves, with respect to each input variable. A larger value of the sensitivity index, $S_i$, means that the uncertainty in the input variable $i$ has a larger effect on the variance of the output. More details on the calculations and interpretation of the sensitivity indices can be found in [90].
Specify the maximum number of variables allowed in an interaction when reporting interaction metrics.

**Specification**

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** Unrestricted (VBD includes all interaction orders present in the expansion)

**Description**

The interaction_order option has been added to allow suppression of higher-order interactions, since the output volume (and memory and compute consumption) of these results could be extensive for high dimensional problems (note: the previous univariate_effects specification is equivalent to interaction_order = 1 in the current specification). Similar to suppression of interactions is the covariance control, which can be selected to be diagonal_covariance or full_covariance, with the former supporting suppression of the off-diagonal covariance terms (to again save compute and memory resources and reduce output volume).

### 7.2.50.36.2  drop_tolerance

• Keywords Area  
  • method  
  • multilevel_function_train  
  • variance_based_decomp  
  • drop_tolerance

Suppresses output of sensitivity indices with values lower than this tolerance

**Specification**

**Alias:** none  
**Argument(s):** REAL  
**Default:** All VBD indices displayed

**Description**

The drop_tolerance keyword allows the user to specify a value below which sensitivity indices generated by variance_based_decomp are not displayed.

**Default Behavior**

By default, all sensitivity indices generated by variance_based_decomp are displayed.

**Usage Tips**

For polynomial_chaos, which outputs main, interaction, and total effects by default, the univariate_effects may be a more appropriate option. It allows suppression of the interaction effects since the output volume of these results can be prohibitive for high dimensional problems. Similar to suppression of these interactions is the covariance control, which can be selected to be diagonal_covariance or full_covariance, with the former supporting suppression of the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).
Examples

method,
sampling
  sample_type lhs
  samples = 100
  variance_based_decomp
drop_tolerance = 0.001

7.2.50.37 diagonal_covariance

- Keywords Area
- method
- multilevel_function_train
- diagonal_covariance

Display only the diagonal terms of the covariance matrix

Specification

Alias: none
Argument(s): none
Default: diagonal_covariance for response vector > 10; else full_covariance

Description

With a large number of responses, the covariance matrix can be very large. diagonal_covariance is used to suppress the off-diagonal covariance terms (to save compute and memory resources and reduce output volume).

7.2.50.38 full_covariance

- Keywords Area
- method
- multilevel_function_train
- full_covariance

Display the full covariance matrix

Specification

Alias: none
Argument(s): none

Description

With a large number of responses, the covariance matrix can be very large. full_covariance is used to force Dakota to output the full covariance matrix.
7.2.50.39 import_approx_points_file

- Keywords Area
- method
- multilevel_function_train
- import_approx_points_file

Filename for points at which to evaluate the PCE/SC surrogate

**Specification**

**Alias:** none

**Argument(s):** STRING

**Default:** no point import from a file

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group Tabular Format (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional (Choose One)</td>
<td>annotated</td>
<td>custom_annotated</td>

<td>freeform</td>
<td></td>
<td>Selects freeform file format</td>
</tr>
<tr>
<td>Optional</td>
<td>active_only</td>
<td></td>
<td>Import only active variables from tabular data file</td>
</tr>
</tbody>
</table>

**Description**

**Default Behavior** No import of points at which to evaluate the surrogate.

**Expected Output** The PCE/SC surrogate model will be evaluated at the list of points (input variable values) provided in the file and results tabulated and/or statistics computed at them, depending on the method context.

**Examples**

```dakota
method
    polynomial_chaos
        expansion_order = 4
        import_approx_points_file = 'import.mcmc_annot.dat'
        annotated
```

7.2.50.39.1 custom_annotated

- Keywords Area
- method
- multilevel_function_train
• import_approx_points_file

• custom_annotated

Selects custom-annotated tabular file format

Topics

This keyword is related to the topics:

• file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>header</td>
<td>header</td>
<td>Enable header row in custom-annotated tabular file</td>

<td>Enable evaluation ID column in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td>interface_id</td>
<td>interface_id</td>
<td>Enable interface ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

Usage Tips

• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.
• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```plaintext
evironment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    custom_annotated header eval_id
```

Resulting tabular file:

```plaintext
%eval_id x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 0.9 1.1 0.0002 0.26 0.76
2 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...```

7.2.50.39.1.1 header

• Keywords Area
• method
• multilevel_function_train
• import_approx_points_file
• custom_annotated
• header

Enable header row in custom-annotated tabular file

Specification

Alias: none
Argument(s): none
Default: no header

Description

See description of parent custom_annotated

7.2.50.39.1.2 eval_id

• Keywords Area
• method
• multilevel_function_train
• import_approx_points_file
• custom_annotated
• eval_id

Enable evaluation ID column in custom-annotated tabular file
7.2 method

Specification

Alias: none
Argument(s): none
Default: no eval_id column

Description

See description of parent custom_annotated

7.2.50.39.1.3 interface_id

- Keywords Area
- method
- multilevel_function_train
- import_approx_points_file
- custom_annotated
- interface_id

Enable interface ID column in custom-annotated tabular file

Specification

Alias: none
Argument(s): none
Default: no interface_id column

Description

See description of parent custom_annotated

7.2.50.39.2 annotated

- Keywords Area
- method
- multilevel_function_train
- import_approx_points_file
- annotated

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- file_formats
Specification

**Alias:** none

**Argument(s):** none

**Default:** annotated format

Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    annotated
```

Resulting tabular file:

```plaintext
%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 NO_ID 0.9 1.1 0.0002 0.26 0.76
2 NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 NO_ID 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...
```

7.2.50.39.3 freeform

- Keywords Area

- method

- multilevel_function_train

- import_approx_points_file

- freeform

Selects freeform file format
Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none
Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```
environment
  tabular_data
    tabular_data_file = 'dakota_summary.dat'
    freeform
```

Resulting tabular file:

```
<p>| | | | | |</p>

7.2.50.39.4 active_only

- Keywords Area
• method
• multilevel_function_train
• import_approx_points_file
• active_only

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

• file_formats

Specification

Alias: none
Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword active_only indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

7.2.50.40 export_approx_points_file

• Keywords Area
• method
• multilevel_function_train
• export_approx_points_file

Output file for surrogate model value evaluations

Specification

Alias: export_points_file
Argument(s): STRING
Default: no point export to a file
Child Keywords:
### Description

Specifies a file in which the points (input variable values) at which the surrogate model is evaluated and corresponding response values computed by the surrogate model will be written. The response values are the surrogate’s predicted approximation to the truth model responses at those points.

### Usage Tips

Dakota exports tabular data in one of three formats:

- **annotated** *(default)*
- **custom_annotated*
- **freeform**

#### 7.2.50.40.1 custom_annotated

- **Keywords Area**
  - **method**
  - **multilevel_function_train**
  - **export_approx_points_file**
  - **custom_annotated**

Selects custom-annotated tabular file format

### Topics

This keyword is related to the topics:

- **file_formats**

### Specification

**Alias:** none

**Argument(s):** none

**Default:** annotated format

**Child Keywords:**
Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

Usage Tips

• Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:

```
environment
  tabular_data
  tabular_data_file = ‘dakota_summary.dat’
  custom_annotated header eval_id
```

Resulting tabular file:

```
%eval_id  x1  x2  obj_fn  nln_ineq_con_1  nln_ineq_con_2
1  0.9  1.1  0.0002  0.26  0.76
2  0.90009  1.1  0.0001996404857  0.2601620081  0.759955
3  0.89991  1.1  0.0002003604863  0.2598380081  0.760045

7.2.50.40.2 annotated

- Keywords Area
- method
- multilevel_function_train
- export_approx_points_file
- annotated

Selects annotated tabular file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none
Default: annotated format
Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```plaintext
environment
tabular_data
  tabular_data_file = 'dakota_summary.dat'
  annotated

Resulting tabular file:

%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 NO_ID 0.9 1.1 0.0002 0.26 0.76
2 NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 NO_ID 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...```

7.2.50.40.3 freeform

- Keywords Area
- method
- multilevel_function_train
- export_approx_points_file
- freeform

Selects freeform file format

Topics

This keyword is related to the topics:

- file_formats
Keywords Area

Specification

Alias: none
Argument(s): none
Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```plaintext
environment
  tabular_data
  tabular_data_file = 'dakota_summary.dat'
  freeform
```

Resulting tabular file:

```
0.9  1.1  0.0002  0.26  0.76
0.90009 1.1 0.0001996404857 0.2601620081 0.759955
0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...
```

7.2.50.41 seed_sequence

- Keywords Area
- method
- multilevel_function_train
- seed_sequence

Sequence of seed values for multi-stage random sampling
Specification

**Alias:** none  
**Argument(s):** INTEGERLIST  
**Default:** system-generated (non-repeatable)

**Description**

This specification allows the stipulation of seed values (passed to a random number generator) for each of a set of stages within a multi-stage random sampling algorithm.

This is particularly useful for reusing sample sets (via restart) that were generated in some other context (e.g., from a single-stage study) within a multi-stage algorithm execution. Normally the random number sequence would continue from a seed specified for the initial sample set, making subsequent sample sets more difficult to recreate outside of their original context. With finer granularity in the seed specification for multi-stage samplers, intermediate portions of a sampling sequence can now be more readily recreated and reused.

**Default Behavior**

As for the scalar case, the default is no seed control, such that a query to a system clock will be used to randomize results.

**Usage Tips**

For $L$ levels in a multilevel method, the `seed_sequence` can be of any length and seeds will be assigned up to the number of values that are provided or up to the number of levels in the sequence. Thus, a `seed_sequence` of length 1 recovers the behavior of a scalar seed.

When `fixed_seed` is unspecified, the `seed_sequence` specification does not extend to the refinement of the sample set. For example, the value from the `seed_sequence` defines the initial sample set for a level, but then subsequent sample sets generated as data increments will allow the random number sequence to continue without resetting the seed value. This reflects the need to avoid reusing previous sample values when generating sample augmentations.

**Examples**

Defining a multilevel Monte Carlo in the following way

```plaintext
method,  
  model_pointer = 'HIERARCH'  
  multilevel_sampling  
  pilot_samples = 100  50  40  30  20  
  seed_sequence = 1234 2345 3456 4567 5678
```

allows the reuse (via restart) of intermediate sample sets from other sources by matching the seed specifications for the targeted model resolutions.

**See Also**

These keywords may also be of interest:

- `seed`
- `fixed_seed`

Dakota Version 6.16 Reference Manual generated on May 12, 2022
• method
• multilevel_function_train
• fixed_seed

Reuses the same seed value for multiple random sampling sets

Specification

Alias: none
Argument(s): none
Default: not fixed; pattern varies run-to-run

Description

The fixed_seed flag is relevant if multiple sampling sets will be generated over the coarse of a Dakota analysis. This occurs when using advance methods (e.g., surrogate-based optimization, optimization under uncertainty). The same seed value is reused for each of these multiple sampling sets, which can be important for reducing variability in the sampling results.

Default Behavior

The default behavior is to not use a fixed seed, as the repetition of the same sampling pattern can result in a modeling weakness that an optimizer could potentially exploit (resulting in actual reliabilities that are lower than the estimated reliabilities). For repeatable studies, the seed must also be specified.

Examples

method
  sampling
    sample_type lhs
    samples = 10
    fixed_seed

Topics

This keyword is related to the topics:

• block_pointer
Specification

Alias: none

Argument(s): STRING

Default: method use of last model parsed (or use of default model if none parsed)

Description

The model_pointer is used to specify which model block will be used to perform the function evaluations needed by the Dakota method.

Default Behavior

If not specified, a Dakota method will use the last model block parsed. If specified, there must be a model block in the Dakota input file that has a corresponding id_model with the same name.

Usage Tips

When doing advanced analyses that involve using multiple methods and multiple models, defining a model_pointer for each method is imperative.

See block_pointer for details about pointers.

Examples

environment
   tabular_data
   method_pointer = 'UQ'

method

**Description**

The polynomial chaos expansion (PCE) is a general framework for the approximate representation of random response functions in terms of finite-dimensional series expansions in standardized random variables.
\[ R = \sum_{i=0}^{P} \alpha_i \Psi_i(\xi) \]

where \( \alpha_i \) is a deterministic coefficient, \( \Psi_i \) is a multidimensional orthogonal polynomial and \( \xi \) is a vector of standardized random variables. An important distinguishing feature of the methodology is that the functional relationship between random inputs and outputs is captured, not merely the output statistics as in the case of many nondeterministic methodologies.

**Basis polynomial family (Group 1)**

Group 1 keywords are used to select the type of basis, \( \Psi_i \), of the expansion. Three approaches may be employed:

- **Wiener**: employs standard normal random variables in a transformed probability space, corresponding to Hermite orthogonal basis polynomials (see wiener).

- **Askey**: employs standard normal, standard uniform, standard exponential, standard beta, and standard gamma random variables in a transformed probability space, corresponding to Hermite, Legendre, Laguerre, Jacobi, and generalized Laguerre orthogonal basis polynomials, respectively (see askey).

- **Extended (default if no option is selected)**: The Extended option avoids the use of any nonlinear variable transformations by augmenting the Askey approach with numerically-generated orthogonal polynomials for non-Askey probability density functions. Extended polynomial selections replace each of the sub-optimal Askey basis selections for bounded normal, lognormal, bounded lognormal, loguniform, triangular, gumbel, frechet, weibull, and bin-based histogram.

For supporting correlated random variables, certain fallbacks must be implemented.

- The Extended option is the default and supports only Gaussian correlations.

- If needed to support prescribed correlations (not under user control), the Extended and Askey options will fall back to the Wiener option *on a per variable basis*. If the prescribed correlations are also unsupported by Wiener expansions, then Dakota will exit with an error.

Refer to variable_support for additional information on supported variable types, with and without correlation.

**Coefficient estimation approach (Group 2)**

To obtain the coefficients \( \alpha_i \) of the expansion, seven options are provided:

1. multidimensional integration by a tensor-product of Gaussian quadrature rules (specified with quadrature_order and, optionally, dimension_preference).

2. multidimensional integration by the Smolyak sparse grid method (specified with sparse_grid_level and, optionally, dimension_preference)

3. multidimensional integration by Stroud cubature rules and extensions as specified with cubature_integrand.

4. multidimensional integration by Latin hypercube sampling (specified with expansion_order and expansion_samples).

5. linear regression (specified with expansion_order and either collocation_points or collocation_ratio), using either over-determined (least squares) or under-determined (compressed sensing) approaches.

6. orthogonal least interpolation (specified with orthogonal_least_interpolation and collocation_points)

7. coefficient import from a file (specified with import_expansion_file). The expansion can be comprised of a general set of expansion terms, as indicated by the multi-index annotation within the file.
It is important to note that, for polynomial chaos using a single model fidelity, \texttt{quadrature\_order}, \texttt{sparse\_grid\_level}, and \texttt{expansion\_order} are scalar inputs used for a single expansion estimation. These scalars can be augmented with \texttt{dimension\_preference} to support anisotropy across the random dimension set. This differs from the use of sequence arrays in advanced use cases such as multilevel and multifidelity polynomial chaos, where multiple grid resolutions can be employed across a model hierarchy.

**Active Variables**

The default behavior is to form expansions over aleatory uncertain continuous variables. To form expansions over a broader set of variables, one needs to specify \texttt{active} followed by \texttt{state, epistemic, design, or all} in the variables specification block.

For continuous design, continuous state, and continuous epistemic uncertain variables included in the expansion, Legendre chaos bases are used to model the bounded intervals for these variables. However, these variables are not assumed to have any particular probability distribution, only that they are independent variables. Moreover, when probability integrals are evaluated, only the aleatory random variable domain is integrated, leaving behind a polynomial relationship between the statistics and the remaining design/state/epistemic variables.

**Covariance type (Group 3)**

These two keywords are used to specify how this method computes, stores, and outputs the covariance of the responses. In particular, the diagonal covariance option is provided for reducing post-processing overhead and output volume in high dimensional applications.

**Optional Keywords regarding method outputs**

Each of these sampling specifications refer to sampling on the PCE approximation for the purposes of generating approximate statistics.

- \texttt{sample\_type}
- \texttt{samples}
- \texttt{seed}
- \texttt{fixed\_seed}
- \texttt{rng}
- \texttt{probability\_refinement}
- \texttt{distribution}
- \texttt{reliability\_levels}
- \texttt{response\_levels}
- \texttt{probability\_levels}
- \texttt{gen\_reliability\_levels}

which should be distinguished from simulation sampling for generating the PCE coefficients as described in options 4, 5, and 6 above (although these options will share the \texttt{sample\_type}, \texttt{seed}, and \texttt{rng} settings, if provided).

When using the \texttt{probability\_refinement} control, the number of refinement samples is not under the user’s control (these evaluations are approximation-based, so management of this expense is less critical). This option allows for refinement of probability and generalized reliability results using importance sampling.

**Usage Tips**

If \(n\) is small (e.g., two or three), then tensor-product Gaussian quadrature is quite effective and can be the preferred choice. For moderate to large \(n\) (e.g., five or more), tensor-product quadrature quickly becomes too expensive and the sparse grid and regression approaches are preferred. Random sampling for coefficient estimation is generally not recommended due to its slow convergence rate. For incremental studies, approaches 4 and 5 support reuse of previous samples through the \texttt{incremental\_lhs} and \texttt{reuse\_points} specifications, respectively.

In the quadrature and sparse grid cases, growth rates for nested and non-nested rules can be synchronized for consistency. For a non-nested Gauss rule used within a sparse grid, linear one-dimensional growth rules of \(m = \ldots\)
$2l + 1$ are used to enforce odd quadrature orders, where $l$ is the grid level and $m$ is the number of points in the rule. The precision of this Gauss rule is then $i = 2m - 1 = 4l + 1$. For nested rules, order growth with level is typically exponential; however, the default behavior is to restrict the number of points to be the lowest order rule that is available that meets the one-dimensional precision requirement implied by either a level $l$ for a sparse grid ($i = 4l + 1$) or an order $m$ for a tensor grid ($i = 2m - 1$). This behavior is known as “restricted growth” or “delayed sequences.” To override this default behavior in the case of sparse grids, the unrestricted keyword can be used; it cannot be overridden for tensor grids using nested rules since it also provides a mapping to the available nested rule quadrature orders. An exception to the default usage of restricted growth is the dimension-\_adaptive p_refinement generalized sparse grid case described previously, since the ability to evolve the index sets of a sparse grid in an unstructured manner eliminates the motivation for restricting the exponential growth of nested rules.

**Additional Resources**

**Expected HDF5 Output**

If Dakota was built with HDF5 support and run with the hdf5 keyword, this method writes the following results to HDF5:

- Integration and Expansion Moments
- Probability Density
- Level Mappings
- Variance-Based Decomposition (Sobol’ Indices)

**Examples**

```
method, polynomial_chaos
  sparse_grid_level = 2
  samples = 10000 seed = 12347 rng rnum2
  response_levels = .1 1. 50. 100. 500. 1000.
  variance_based_decomp
```

</thead>
<tbody>
<tr>
<td></td>
<td>uniform</td>
<td>dimension_adaptive</td>
<td>Perform anisotropic expansion refinement by preferentially adapting in dimensions that are detected to have higher ‘importance’.</td>
</tr>
</tbody>
</table>

Description

The `p_refinement` keyword specifies the usage of automated polynomial order refinement, which can be either `uniform` or `dimension_adaptive`.

The `dimension_adaptive` option is supported for the tensor-product quadrature and Smolyak sparse grid options and `uniform` is supported for tensor and sparse grids as well as regression approaches (`collocation_points` or `collocation_ratio`).

Each of these refinement cases makes use of the `max_iterations` and `convergence_tolerance` method independent controls. The former control limits the number of refinement iterations, and the latter control terminates refinement when the two-norm of the change in the response covariance matrix (or, in goal-oriented approaches, the two-norm of change in the statistical quantities of interest (QOI)) falls below the tolerance.

The `dimension_adaptive` case can be further specified to utilize `sobol`, `decay`, or `generalized` refinement controls. The former two cases employ anisotropic tensor/sparse grids in which the anisotropic dimension preference (leading to anisotropic integrations/expansions with differing refinement levels for different random dimensions) is determined using either total Sobol’ indices from variance-based decomposition (sobol case: high indices result in high dimension preference) or using spectral coefficient decay rates from a rate estimation technique similar to Richardson extrapolation (decay case: low decay rates result in high dimension preference). In these two cases as well as the uniform refinement case, the `quadrature_order` or `sparse_grid_level` are ramped by one on each refinement iteration until either of the two convergence controls is satisfied. For the uniform refinement case with regression approaches, the `expansion_order` is ramped by one on each iteration while the oversampling ratio (either defined by `collocation_ratio` or inferred from `collocation_points` based on the initial expansion) is held fixed. Finally, the generalized `dimension_adaptive` case is the default adaptive approach; it refers to the generalized sparse grid algorithm, a greedy approach in which candidate index sets are evaluated for their impact on the statistical QOI, the most influential sets are selected and used to generate additional candidates, and the index set frontier of a sparse grid is evolved in an unstructured and goal-oriented manner (refer to User’s Manual PCE descriptions for additional specifics).

For the case of `p_refinement` or the case of an explicit nested override, Gauss-Hermite rules are replaced with Genz-Keister nested rules and Gauss-Legendre rules are replaced with Gauss-Patterson nested rules, both of which exchange lower integrand precision for greater point reuse.
7.2.51.1.1 uniform

- Keywords Area
- method
- polynomial_chaos
- p_refinement
- uniform

Refine an expansion uniformly in all dimensions.

Specification

Alias: none

Argument(s): none

Description

The quadrature_order or sparse_grid_level are ramped by one on each refinement iteration until either of the two convergence controls is satisfied. For the uniform refinement case with regression approaches, the expansion_order is ramped by one on each iteration while the oversampling ratio (either defined by collocation_ratio or inferred from collocation_points based on the initial expansion) is held fixed.

7.2.51.1.2 dimension_adaptive

- Keywords Area
- method
- polynomial_chaos
- p_refinement
- dimension_adaptive

Perform anisotropic expansion refinement by preferentially adapting in dimensions that are detected to have higher 'importance'.

Specification

Alias: none

Argument(s): none

Child Keywords:
### Description

Perform anisotropic expansion refinement by preferentially adapting in dimensions that are detected to hold higher 'importance' in resolving statistical quantities of interest.

Dimension importance must be estimated as part of the refinement process. Techniques include either sobol or generalized for stochastic collocation and either sobol, decay, or generalized for polynomial chaos. Each of these automated refinement approaches makes use of the max_iterations and convergence_tolerance iteration controls.

#### 7.2.51.2.1 sobol

- **Keywords Area**
- **method**
- **polynomial_chaos**
- **p_refinement**
- **dimension_adaptive**
- **sobol**

Estimate dimension preference for automated refinement of stochastic expansion using total Sobol' sensitivity indices.

### Specification

**Alias:** none  
**Argument(s):** none  
**Default:** generalized
Description

Determine dimension preference for refinement of a stochastic expansion from the total Sobol’ sensitivity indices
obtained from global sensitivity analysis. High indices indicate high importance for resolving statistical quantities of
interest and therefore result in high dimension preference.

Examples

```plaintext
method, polynomial_chaos
  sparse_grid_level = 3
  dimension_adaptive p_refinement sobol
  max_iterations = 20
  convergence_tol = 1.e-4
```

7.2.51.1.2.2 decay

- Keywords Area
- method
- polynomial_chaos
- p_refinement
- dimension_adaptive
- decay

Estimate spectral coefficient decay rates to guide dimension-adaptive refinement.

Specification

Alias: none
Argument(s): none

Example

```plaintext
method, polynomial_chaos
  sparse_grid_level = 3
  dimension_adaptive p_refinement decay
  max_iterations = 20
  convergence_tol = 1.e-4
```

7.2.51.1.2.3 generalized

- Keywords Area
- method
- polynomial_chaos

Estimate spectral coefficient decay rates from a rate estimation technique similar to Richardson extrapolation. These
decay rates are used to guide dimension-adaptive refinement, where slower decay rates result in higher dimension
preference.
7.2 method

- p_refinement
- dimension_adaptive
- generalized

Use the generalized sparse grid dimension adaptive algorithm to refine a sparse grid approximation of stochastic expansion.

Specification

Alias: none
Argument(s): none

Description

The generalized sparse grid algorithm is a greedy approach in which candidate index sets are evaluated for their impact on the statistical QOI, the most influential sets are selected and used to generate additional candidates, and the index set frontier of a sparse grid is evolved in an unstructured and goal-oriented manner (refer to User's Manual PCE descriptions for additional specifics).

Examples

```
method, polynomial_chaos
  sparse_grid_level = 3
dimension_adaptive p_refinement generalized
  max_iterations = 20
  convergence_tol = 1.e-4
```

7.2.51.2 max_refinement_iterations

- Keywords Area
- method
- polynomial_chaos
- max_refinement_iterations

Maximum number of expansion refinement iterations

Specification

Alias: none
Argument(s): INTEGER
Default: 100

Description

Limits the number of times the expansion can be refined under various refinement strategies.
7.2.51.3 convergence_tolerance

- Keywords Area
- method
- polynomial_chaos
- convergence_tolerance

Stopping criterion based on objective function or statistics convergence

Topics

This keyword is related to the topics:

- method_independent_controls

Specification

Alias: none
Argument(s): REAL
Default: 1.e-4

Description

The convergence_tolerance specification provides a real value for controlling the termination of iteration. For optimization, it is most commonly a relative convergence tolerance for the objective function; i.e., if the change in the objective function between successive iterations divided by the previous objective function is less than the amount specified by convergence_tolerance, then this convergence criterion is satisfied on the current iteration. Therefore, permissible values are between 0 and 1, non-inclusive.

Behavior Varies by Package/Library

This control is used with most optimization and least squares iterators (DOT, CONMIN, NLPQLP, NPSOL, NLSSOL, OPT++, and SCOLIB). Most other Dakota methods (such as DACE or parameter studies) do not use this control, but some adaptive methods, such as adaptive UQ, do.

Since no progress may be made on one iteration followed by significant progress on a subsequent iteration, some libraries require that the convergence tolerance be satisfied on two or more consecutive iterations prior to termination of iteration.

Notes on each library:

- DOT: relative tolerance that must be satisfied for two consecutive iterations
- NL2SOL: See nl2sol
• NLPQLP: used as Lagrangian gradient norm tolerance (ACC), not as a relative convergence tolerance
• NPSOL: used as a line search tolerance, not as a relative convergence tolerance

7.2.51.4 metric_scale

- Keywords Area
- method
- polynomial_chaos
- metric_scale

define scaling of statistical metrics when adapting UQ surrogates

Specification

**Alias**: none

**Argument(s)**: none

**Default**: relative

**Child Keywords**:

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group scale of refinement metric (Group 1)</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>

<td>relative</td>
<td>relative scaling of statistical metrics when adapting UQ surrogates</td>
</tr>
<tr>
<td></td>
<td>absolute</td>
<td>relative</td>
<td>use of absolute statistical metrics when adapting UQ surrogates</td>
</tr>
</tbody>
</table>

**Description**

When adapting a UQ surrogate model, e.g., by change in response covariance matrix or level mappings, this option controls the use of scaling. The `absolute` option indicates that there is no scaling such that the statistical change is compared directly to the convergence tolerance. The `relative` option indicates that the change is measured relative to the current reference value (which evolves during the refinement), such that the convergence tolerance controls the relative change.

**Default Behavior**

The default is `relative`.

**Expected Output**

**Usage Tips**

**Additional Discussion**

<td></td>
<td>non_nested</td>
<td>Enforce use of non-nested quadrature rules</td>
</tr>
</tbody>
</table>

**Description**

Multidimensional integration by a tensor-product of Gaussian quadrature rules (specified with quadrature_order, and, optionally, dimension_preference). The default rule selection is to employ non_nested Gauss rules including Gauss-Hermite (for normals or transformed normals), Gauss-Legendre (for uniforms or transformed uniforms), Gauss-Jacobi (for betas), Gauss-Laguerre (for exponentials), generalized Gauss-Laguerre (for gammas), and numerically-generated Gauss rules (for other distributions when using an Extended basis). For the case of p_refinement or the case of an explicit nested override, Gauss-Hermite rules are replaced with Genz-Keister nested rules and Gauss-Legendre rules are replaced with Gauss-Patterson nested rules, both of which exchange lower integrand precision for greater point reuse. By specifying a dimension_preference, where higher preference leads to higher order polynomial resolution, the tensor grid may be rendered anisotropic. The dimension specified to have highest preference will be set to the specified quadrature_order and all other dimensions will be reduced in proportion to their reduced preference; any non-integral portion is truncated. To synchronize with tensor-product integration, a tensor-product expansion is used, where the order $p_i$ of the expansion in each dimension is selected to be half of the integrand precision available from the rule in use, rounded down. In the case of non-nested Gauss rules with integrand precision $2m_i - 1$, $p_i$ is one less than the quadrature order $m_i$ in each dimension (a one-dimensional expansion contains the same number of terms, $p + 1$, as the number of Gauss points). The total number of terms, $N$, in a tensor-product expansion involving $n$ uncertain input variables is

$$N = 1 + P = \prod_{i=1}^{n} (p_i + 1)$$

In some advanced use cases (e.g., multifidelity UQ), multiple grid resolutions can be employed; for this reason, the quadrature_order specification supports an array input.
A corresponding sequence specification is documented at, e.g., `quadrature_order_sequence` and `quadrature_order_sequence`

- **Keywords Area**
- **method**
- **polynomial_ chaos**
- **sparse_grid_level**

Level to use in sparse grid integration or interpolation

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Child Keywords:**
Multi-dimensional integration by the Smolyak sparse grid method (specified with `sparse_grid_level` and, optionally, `dimension_preference`). The underlying one-dimensional integration rules are the same as for the tensor-product quadrature case; however, the default rule selection is nested for sparse grids (Genz-Keister for normals/transformed normals and Gauss-Patterson for uniforms/transformed uniforms). This default can be overridden with an explicit `non_nested` specification (resulting in Gauss-Hermite for normals/transformed normals and Gauss-Legendre for uniforms/transformed uniforms). As for tensor quadrature, the `dimension_preference` specification enables the use of anisotropic sparse grids (refer to the PCE description in the User’s Manual for the anisotropic index set constraint definition). Similar to anisotropic tensor grids, the dimension with greatest preference will have resolution at the full `sparse_grid_level` and all other dimension resolutions will be reduced in proportion to their reduced preference. For PCE with either isotropic or anisotropic sparse grids, a summation of tensor-product expansions is used, where each anisotropic tensor-product quadrature rule underlying the sparse grid construction results in its own anisotropic tensor-product expansion as described in case 1. These anisotropic tensor-product expansions are summed into a sparse PCE using the standard Smolyak summation (again, refer to the User’s Manual for additional details). As for quadrature_order, the `sparse_grid_level` specification admits an array input for enabling specification of multiple grid resolutions used by certain advanced solution methodologies.

A corresponding sequence specification is documented at, e.g., `sparse_grid_level_sequence` and `sparse_grid_level_sequence`.

7.2.51.6.2  restricted

- Keywords Area
- method
- polynomial_chaos
- sparse_grid_level
- restricted

Restrict the growth rates for nested and non-nested rules can be synchronized for consistency.

Specification

**Alias:** none

**Argument(s):** none

**Default:** restricted (except for generalized sparse grids)
Description

In the quadrature and sparse grid cases, growth rates for nested and non-nested rules can be synchronized for consistency. For a non-nested Gauss rule used within a sparse grid, linear one-dimensional growth rules of \( m = 2l + 1 \) are used to enforce odd quadrature orders, where \( l \) is the grid level and \( m \) is the number of points in the rule. The precision of this Gauss rule is then \( i = 2m - 1 = 4l + 1 \). For nested rules, order growth with level is typically exponential; however, the default behavior is to restrict the number of points to be the lowest order rule that is available that meets the one-dimensional precision requirement implied by either a level \( l \) for a sparse grid (\( i = 4l + 1 \)) or an order \( m \) for a tensor grid (\( i = 2m - 1 \)). This behavior is known as "restricted growth" or "delayed sequences." To override this default behavior in the case of sparse grids, the unrestricted keyword can be used; it cannot be overridden for tensor grids using nested rules since it also provides a mapping to the available nested rule quadrature orders. An exception to the default usage of restricted growth is the dimension_adaptive p_refinement generalized sparse grid case described previously, since the ability to evolve the index sets of a sparse grid in an unstructured manner eliminates the motivation for restricting the exponential growth of nested rules.

7.2.51.6.3 unrestricted

- Keywords Area
- method
- polynomial_chaos
- sparse_grid_level
- unrestricted

Override the default restriction of growth rates for nested and non-nested rules that are by default synchronized for consistency.

Specification

Alias: none

Argument(s): none

Description

7.2.51.7 cubature_integrand

- Keywords Area
- method
- polynomial_chaos
- cubature_integrand

Cubature using Stroud rules and their extensions

Specification

Alias: none

Argument(s): INTEGER
Description

Multi-dimensional integration by Stroud cubature rules [80] and extensions [94], as specified with `cubature_integrand`. A total-order expansion is used, where the isotropic order $p$ of the expansion is half of the integrand order, rounded down. The total number of terms $N$ for an isotropic total-order expansion of order $p$ over $n$ variables is given by

$$N = 1 + P = 1 + \sum_{s=1}^{p} \frac{1}{s!} \prod_{r=0}^{s-1} (n + r) = \frac{(n + p)!}{n! p!}$$

Since the maximum integrand order is currently five for normal and uniform and two for all other types, at most second- and first-order expansions, respectively, will be used. As a result, cubature is primarily useful for global sensitivity analysis, where the Sobol’ indices will provide main effects and, at most, two-way interactions. In addition, the random variable set must be independent and identically distributed (iid), so the use of `askey` or `wiener` transformations may be required to create iid variable sets in the transformed space (as well as to allow usage of the higher order cubature rules for normal and uniform). Note that global sensitivity analysis often assumes uniform bounded regions, rather than precise probability distributions, so the iid restriction would not be problematic in that case.

7.2.51.8 expansion_order

- **Keywords Area**
- **method**
- **polynomial_chaos**
- **expansion_order**

The (initial) order of a polynomial expansion

### Specification

**Alias:** none

**Argument(s):** INTEGER

### Description

When the expansion_order for a polynomial chaos expansion is specified, the coefficients may be computed by integration based on random samples or by regression using either random or sub-sampled tensor product quadrature points.

Multidimensional integration by Latin hypercube sampling (specified with `expansion_samples`). In this case, the expansion order \( p \) cannot be inferred from the numerical integration specification and it is necessary to provide an `expansion_order` to specify \( p \) for a total-order expansion.

Linear regression (specified with either `collocation_points` or `collocation_ratio`). A total-order expansion is used and must be specified using `expansion_order` as described in the previous option. To avoid requiring the user to calculate \( N \) from \( n \) and \( p \), the `collocation_ratio` allows for specification of a constant factor applied to \( N \) (e.g., `collocation_ratio = 2` produces samples = 2\( N \)). In addition, the default linear relationship with \( N \) can be overridden using a real-valued exponent specified using `ratio_order`. In this case, the number of samples becomes \( cN^o \) where \( c \) is the `collocation_ratio` and \( o \) is the `ratio_order`. The `use_derivatives` flag informs the regression approach to include derivative matching equations (limited to gradients at present) in the least squares solutions, enabling the use of fewer collocation points for a given expansion order and dimension (number of points required becomes \( cN^o + 1 \)). When admissible, a constrained least squares approach is employed in which response values are first reproduced exactly and error in reproducing response derivatives is minimized. Two collocation grid options are supported: the default is Latin hypercube sampling ("point collocation"), and an alternate approach of "probabilistic collocation" is also available through inclusion of the `tensor_grid` keyword. In this alternate case, the collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

If `collocation_points` or `collocation_ratio` is specified, the PCE coefficients will be determined by regression. If no regression specification is provided, appropriate defaults are defined. Specifically SVD-based least-squares will be used for solving over-determined systems and under-determined systems will be solved using LASSO. For the situation when the number of function values is smaller than the number of terms in a PCE, but the total number of samples including gradient values is greater than the number of terms, the resulting over-determined...
system will be solved using equality constrained least squares. Technical information on the various methods listed below can be found in the Linear regression section of the Theory Manual. Some of the regression methods (O-MP, LASSO, and LARS) are able to produce a set of possible PCE coefficient vectors (see the Linear regression section in the Theory Manual). If cross validation is inactive, then only one solution, consistent with the noise_tolerance, will be returned. If cross validation is active, Dakota will choose between possible coefficient vectors found internally by the regression method across the set of expansion orders (1,...,expansion_order) and the set of specified noise tolerances and return the one with the lowest cross validation error indicator.

7.2.51.8.1 dimension_preference

A set of weights specifying the relative importance of each uncertain variable (dimension)

Specification

Alias: none

Argument(s): REALLIST

Default: isotropic grids

Description

A set of weights specifying the relative importance of each uncertain variable (dimension). Using this specification leada to anisotropic integrations with differing refinement levels for different random dimensions.

<td>Calculate the coefficients of a polynomial chaos expansion using equality constrained least squares.</td>
</tr>
</tbody>
</table>

**Description**

Compute the coefficients of a polynomial expansion using least squares. Specifically SVD-based least-squares will be used for solving over-determined systems. For the situation when the number of function values is smaller than the number of terms in a PCE, but the total number of samples including gradient values is greater than the number of terms, the resulting over-determined system will be solved using equality constrained least squares.

- l2_penalty

The $l_2$ penalty used when performing compressed sensing with elastic net.

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 0. (reverts to standard LASSO formulation)

**Description**

The $l_2$ penalty used when performing compressed sensing with elastic net.
7.2.51.8.3.14 cross_validation

- Keywords Area
- method
- polynomial_chaos
- expansion_order
- collocation_points
- cross_validation

Use cross validation to choose the 'best' polynomial order of a polynomial chaos expansion.

**Specification**

**Alias:** none

**Argument(s):** none

**Child Keywords:**

<table>
<thead>
<tr>
<th>Required/Optional</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>noise_only</td>
<td></td>
<td>Restrict the cross validation process to estimating only the best noise tolerance.</td>
</tr>
<tr>
<td>Optional</td>
<td>max_cv_order_candidates</td>
<td></td>
<td>Limit the number of cross-validation candidates for basis order</td>
</tr>
</tbody>
</table>

**Description**

Use cross validation to choose the 'best' polynomial degree of a polynomial chaos expansion. 10 fold cross validation is used to estimate the cross validation error of a total-order polynomial expansion for orders 1 through to order. The order chosen is the one that produces the lowest cross validation error. If there are not enough points to perform 10 fold cross validation then one-at-a-time cross validation will be performed.

7.2.51.8.3.15 noise_only

- Keywords Area
- method
- polynomial_chaos
- expansion_order
- collocation_points
- cross_validation
- noise_only

Restrict the cross validation process to estimating only the best noise tolerance.
Specification

Alias: none
Argument(s): none
Default: false

Description

By default, cross validation estimates both the best noise tolerance and the best candidate basis order. For reasons of reducing computational cost by reducing the number of candidate solves, the user may wish to restrict this process to estimating only the best noise tolerance.

Generally speaking, computing the best noise tolerance through cross validation mitigates issues with over-fitting the data. Computing the best candidate basis order can also mitigate overfitting, while also controlling levels of mutual coherence resulting from high-order Vandermonde-like matrix systems.

7.2.51.8.3.16 max_cv_order_candidates

- Keywords Area
- method
- polynomial_chaos
- expansion_order
- collocation_points
- cross_validation
- max_cv_order_candidates

Limit the number of cross-validation candidates for basis order

Specification

Alias: none
Argument(s): INTEGER
Default: ushort max

Description

When generating refinement candidates by advancing the upper bound used for a cross-validation range, the number of cross-validation can eventually become excessive and hamper algorithm progress. This control limits the maximum number of candidates, which when active, will increase the lower bound for this range as the upper bound is advanced.

- multifidelity_function_train

7.2.51.8.3.17 ratio_order

- Keywords Area
- method
- polynomial_chaos
- expansion_order
- collocation_points
- ratio_order

Specify a non-linear relationship between the expansion order of a polynomial chaos expansion and the number of samples that will be used to compute the PCE coefficients.

Specification

Alias: none
Argument(s): REAL
Default: 1.

Description

When using regression type methods (specified with either collocation_points or collocation_ratio), a total-order expansion can be specified using expansion_order. To avoid requiring the user to calculate N from n and p), the collocation_ratio allows for specification of a constant factor applied to N (e.g., collocation_ratio = 2 produces samples = 2N). In addition, the default linear relationship with N can be overridden using a real-valued exponent specified using ratio_order. In this case, the number of samples becomes $cN^o$ where $c$ is the collocation_ratio and $o$ is the ratio_order.

7.2.51.8.3.18 response_scaling

- Keywords Area
- method
- polynomial_chaos
- expansion_order
- collocation_points
- response_scaling

Perform bounds-scaling on response values prior to surrogate emulation

Specification

Alias: none
Argument(s): none
Default: use original data
Description

Particularly in multifidelity methods based on regression solutions at each level of a model hierarchy, scaling can be an issue since the magnitude of discrepancy data may decay rapidly and regression solvers may employ absolute tolerances in places.

By activating `response_scaling`, the set of response data used for each recovery is scaled to $[0,1]$ based on the minimum value and range of the data set. This prevents loss of accuracy due to imbalances in scale across model levels.

See Also

These keywords may also be of interest:

- multifidelity_polynomial_chaos
- multifidelity_function_train

Specification

**Alias:** none

**Argument(s):** none

**Default:** use function values only

Description

The `use_derivatives` flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, its use with Surfpack Gaussian process is not recommended.

**Related Keywords**

- multifidelity_polynomial_chaos
- multifidelity_function_train

Use derivative data to construct surrogate models
7.2 method

- tensor_grid

Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.

Specification

Alias: none
Argument(s): none
Default: regression with LHS sample set (point collocation)

Description

The collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

7.2.51.8.3.21 reuse_points

- Keywords Area
- method
- polynomial_chaos
- expansion_order
- collocation_points
- reuse_points

This describes the behavior of reuse of points in constructing polynomial chaos expansion models.

Specification

Alias: reuse_samples
Argument(s): none
Default: no sample reuse in coefficient estimation

Description

The reuse_points option controls the reuse behavior of points for various types of polynomial chaos expansions, including: collocation_points, collocation_ratio, expansion_samples, or orthogonal_least_interpolation. If any of these approaches are specified to create a set of points for the polynomial chaos expansion, one can specify reuse_points so that any points that have been previously generated (for example, from the import_points file) can be reused.
Maximum iterations in determining polynomial coefficients

**Specification**

**Alias:** none

**Argument(s):** INTEGER

**Default:** 100

**Description**

When using an iterative polynomial coefficient estimation approach, e.g., cross-validation-based solvers, limits the maximum iterations in the coefficient solver.

**7.2.51.8.4 collocation_ratio**

- **Keywords Area**
- **method**
- **polynomial_chaos**
- **expansion_order**
- **collocation_ratio**

Set the number of points used to build a PCE via regression to be proportional to the number of terms in the expansion.

**Specification**

#### Description

Set the number of points used to build a PCE via regression to be proportional to the number of terms in the expansion. To avoid requiring the user to calculate $N$ from $n$ and $p$, the collocation_ratio allows for specification of a constant factor applied to $N$ (e.g., collocation_ratio = 2. produces samples = 2N). In addition, the default linear relationship with $N$ can be overridden using a real-valued exponent specified using ratio_order. In this case, the number of samples becomes $cN^o$ where $c$ is the collocation_ratio and $o$ is the ratio_order. The use_derivatives flag informs the regression approach to include derivative matching equations (limited to gradients at present) in the least squares solutions, enabling the use of fewer collocation points for a given expansion order and dimension (number of points required becomes $cN^o + 1$).

#### 7.2.51.8.4.1 least_squares

- Keywords Area
- method
- polynomial_chaos
- expansion_order
- collocation_ratio
- least_squares

Compute the coefficients of a polynomial expansion using least squares

#### Specification

**Alias:** none
**Argument(s):** none

**Default:** svd

**Description**

Compute the coefficients of a polynomial expansion using least squares. Specifically SVD-based least-squares will be used for solving over-determined systems. For the situation when the number of function values is smaller than the number of terms in a PCE, but the total number of samples including gradient values is greater than the number of terms, the resulting over-determined system will be solved using equality constrained least squares.

</tbody>
</table>

**Description**

Use cross validation to choose the 'best' polynomial degree of a polynomial chaos expansion. 10 fold cross validation is used to estimate the cross validation error of a total-order polynomial expansion for orders 1 through to order. The order chosen is the one that produces the lowest cross validation error. If there are not enough points to perform 10 fold cross validation then one-at-a-time cross validation will be performed.

7.2.51.8.4.15 noise_only

- Keywords Area
- method
- polynomial_chaos
- expansion_order
- collocation_ratio
- cross_validation
- noise_only

Restrict the cross validation process to estimating only the best noise tolerance.
7.2 method

Specification

**Alias**: none

**Argument(s)**: none

**Default**: false

Description

By default, cross validation estimates both the best noise tolerance and the best candidate basis order. For reasons of reducing computational cost by reducing the number of candidate solves, the user may wish to restrict this process to estimating only the best noise tolerance.

Generally speaking, computing the best noise tolerance through cross validation mitigates issues with over-fitting the data. Computing the best candidate basis order can also mitigate overfitting, while also controlling levels of mutual coherence resulting from high-order Vandermonde-like matrix systems.

7.2.51.8.4.16 max_cv_order_candidates

- **Keywords Area**
- **method**
- **polynomial_chaos**
- **expansion_order**
- **collocation_ratio**
- **cross_validation**
- **max_cv_order_candidates**

Limit the number of cross-validation candidates for basis order

Specification

**Alias**: none

**Argument(s)**: INTEGER

**Default**: ushort max

Description

When generating refinement candidates by advancing the upper bound used for a cross-validation range, the number of cross-validation can eventually become excessive and hamper algorithm progress. This control limits the maximum number of candidates, which when active, will increase the lower bound for this range as the upper bound is advanced.

See Also

These keywords may also be of interest:

- **increment_max_order**
- **increment_max_rank_order**
- **polynomial_chaos**
Specify a non-linear the relationship between the expansion order of a polynomial chaos expansion and the number of samples that will be used to compute the PCE coefficients.

**Specification**

**Alias:** none

**Argument(s):** REAL

**Default:** 1.

**Description**

When using regression type methods (specified with either collocation_points or collocation_ratio), a total-order expansion can be specified using expansion_order. To avoid requiring the user to calculate N from n and p), the collocation_ratio allows for specification of a constant factor applied to N (e.g., collocation_ratio = 2. produces samples = 2N). In addition, the default linear relationship with N can be overridden using a real-valued exponent specified using ratio_order. In this case, the number of samples becomes $cN^o$ where $c$ is the collocation_ratio and $o$ is the ratio_order.

**7.2.51.8.4.18 response_scaling**

Perform bounds-scaling on response values prior to surrogate emulation

**Specification**

**Alias:** none

**Argument(s):** none

**Default:** use original data
Description

Particularly in multifidelity methods based on regression solutions at each level of a model hierarchy, scaling can be an issue since the magnitude of discrepancy data may decay rapidly and regression solvers may employ absolute tolerances in places.

By activating `response_scaling`, the set of response data used for each recovery is scaled to \([0,1]\) based on the minimum value and range of the data set. This prevents loss of accuracy due to imbalances in scale across model levels.

7.2.51.8.4.19 use_derivatives

- Keywords Area
- method
- polynomial_chaos
- expansion_order
- collocation_ratio
- use_derivatives

Use derivative data to construct surrogate models

Specification

**Alias:** none

**Argument(s):** none

**Default:** use function values only

Description

The `use_derivatives` flag specifies that any available derivative information should be used in global approximation builds, for those global surrogate types that support it (currently, polynomial regression and the Surfpack Gaussian process).

However, it's use with Surfpack Gaussian process is not recommended.

7.2.51.8.4.20 tensor_grid

- Keywords Area
- method
- polynomial_chaos
- expansion_order
- collocation_ratio
- **tensor_grid**

Use sub-sampled tensor-product quadrature points to build a polynomial chaos expansion.

**Specification**

**Alias:** none  
**Argument(s):** none  
**Default:** regression with LHS sample set (point collocation)

**Description**

The collocation grid is defined using a subset of tensor-product quadrature points: the order of the tensor-product grid is selected as one more than the expansion order in each dimension (to avoid sampling at roots of the basis polynomials) and then the tensor multi-index is uniformly sampled to generate a non-repeated subset of tensor quadrature points.

7.2.51.8.4.21  **reuse_points**

- **Keywords Area**
- **method**
- **polynomial_chaos**
- **expansion_order**
- **collocation_ratio**
- **reuse_points**

This describes the behavior of reuse of points in constructing polynomial chaos expansion models.

**Specification**

**Alias:** reuse_samples  
**Argument(s):** none  
**Default:** no sample reuse in coefficient estimation

**Description**

The **reuse_points** option controls the reuse behavior of points for various types of polynomial chaos expansions, including: collocation_points, collocation_ratio, expansion_samples, or orthogonal_least_interpolation. If any of these approaches are specified to create a set of points for the polynomial chaos expansion, one can specify **reuse_points** so that any points that have been previously generated (for example, from the import_points file) can be reused.

7.2.51.8.4.22  **max_solver_iterations**

- **Keywords Area**
- **method**
- **polynomial_chaos**
- **expansion_order**
7.2 method

- collocation_ratio
- max_solver_iterations

Maximum iterations in determining polynomial coefficients

**Specification**

**Alias:** none  
**Argument(s):** INTEGER  
**Default:** 100

**Description**

When using an iterative polynomial coefficient estimation approach, e.g., cross-validation-based solvers, limits the maximum iterations in the coefficient solver.

7.2.51.8.5 expansion_samples

- **Keywords Area**
- method
- polynomial_chaos
- expansion_order
- expansion_samples

Number of simulation samples used to estimate the expected value of a set of PCE coefficients

**Specification**

**Alias:** none  
**Argument(s):** INTEGER

**Child Keywords:**

<table>

7.2.51.8.5.1 `reuse_points`

- `Keywords Area`
- `method`
- `polynomial_chaos`
- `expansion_order`
- `expansion_samples`
- `reuse_points`

This describes the behavior of reuse of points in constructing polynomial chaos expansion models.

Specification

**Alias:** reuse_samples

**Argument(s):** none

**Default:** no sample reuse in coefficient estimation

**Description**

The `reuse_points` option controls the reuse behavior of points for various types of polynomial chaos expansions, including: `collocation_points`, `collocation_ratio`, `expansion_samples`, or `orthogonal_least_interpolation`. If any of these approaches are specified to create a set of points for the polynomial chaos expansion, one can specify `reuse_points` so that any points that have been previously generated (for example, from the `import_points_file`) can be reused.

7.2.51.8.6 `import_build_points_file`

- `Keywords Area`
- `method`
- `polynomial_chaos`
- `expansion_order`
- `import_build_points_file`

File containing points you wish to use to build a surrogate

Specification

**Alias:** import_points_file

**Argument(s):** STRING

**Default:** no point import from a file

**Child Keywords:**
### Description

The `import_build_points_file` allows the user to specify a file that contains a list of points and truth model responses used to construct a surrogate model. These can be used by all methods that (explicitly, e.g. surrogate-based optimization, or implicitly, e.g. efficient global optimization) operate on a surrogate. In particular, these points and responses are used in place of truth model evaluations to construct the initial surrogate. When used to construct surrogate models or emulators these are often called build points or training data.

#### Default Behavior

By default, methods do not import points from a file.

#### Usage Tips

Dakota parses input files without regard to whitespace, but the `import_build_points_file` must be in one of three formats:

- annotated (default)
- custom_annotated
- freeform

#### Examples

```dakota
method
polynomial_chaos
    expansion_order = 4
    import_build_points_file = 'dakota_uq_rosenbrock_pce_import.annot.pts.dat'
```

### custom_annotated

- **Keywords Area**
  - method
  - polynomial_chaos
  - expansion_order
  - import_build_points_file
  - custom_annotated

Selects custom-annotated tabular file format
Topics
This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Default: annotated format

Child Keywords:

<table>
<thead>
<tr>
<th>Required/Optional Group</th>
<th>Description of Group</th>
<th>Dakota Keyword</th>
<th>Dakota Keyword Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td></td>
<td>header</td>
<td>Enable header row in custom-annotated tabular file</td>

<td>Enable evaluation ID column in custom-annotated tabular file</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
<td>interface_id</td>
<td>Enable interface ID column in custom-annotated tabular file</td>
</tr>
</tbody>
</table>

Description

A custom-annotated tabular file is a whitespace-separated text file typically containing row data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well. Custom-annotated allows user options for whether header row, eval_id column, and interface_id column appear in the tabular file, thus bridging freeform and (fully) annotated.

Default Behavior

The annotated format is the default for tabular export/import. To control which header row and columns are in the input/output, specify custom_annotated, followed by options, in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a custom-annotated tabular file in Dakota 6.0 format, which contained only header and eval_id (no interface_id), and data for variables and responses. Input file fragment:
environment
  tabular_data
tabular_data_file = 'dakota_summary.dat'
custom_annotated header eval_id

Resulting tabular file:

```
%eval_id x1   x2   obj_fn  nln_ineq_con_1  nln_ineq_con_2
1   0.9   1.1   0.0002   0.26   0.76
2   0.90009   1.1   0.0001996404857   0.2601620081   0.759955
3   0.89991   1.1   0.0002003604863   0.2598380081   0.760045
...```

7.2.51.8.6.2 header

7.2.51.8.6.5 annotated

• Keywords Area
• method
• polynomial_chaos
• expansion_order
• import_build_points_file
• annotated

Selects annotated tabular file format
This keyword is related to the topics:

- file_formats

### Specification

**Alias:** none  
**Argument(s):** none  
**Default:** annotated format

### Description

An annotated tabular file is a whitespace-separated text file with one leading header row of comments/column labels. Each subsequent row contains an evaluation ID and interface ID, followed by data for variables, or variables followed by responses, depending on context.

### Default Behavior

By default, Dakota imports and exports tabular files in annotated format. The annotated keyword can be used to explicitly specify this.

### Usage Tips

- To specify pre-Dakota 6.1 tabular format, which did not include interface_id, specify custom_annotated header eval_id

- Prior to October 2011, calibration and surrogate data files were in free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

### Examples

Export an annotated top-level tabular data file containing a header row, leading eval_id and interface_id columns, and data for variables and responses. Input file fragment:

```dakota
environment
  tabular_data
  tabular_data_file = 'dakota_summary.dat'
  annotated

%eval_id interface x1 x2 obj_fn nln_ineq_con_1 nln_ineq_con_2
1 NO_ID 0.9 1.1 0.0002 0.26 0.76
2 NO_ID 0.90009 1.1 0.0001996404857 0.2601620081 0.759955
3 NO_ID 0.89991 1.1 0.0002003604863 0.2598380081 0.760045
...```

Dakota Version 6.16 Reference Manual generated on May 12, 2022
7.2.51.8.6.6 freeform

- Keywords Area
- method
- polynomial_chaos
- expansion_order
- import_build_points_file
- freeform

Selects freeform file format

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none
Argument(s): none
Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

- Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

- When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

- In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

- Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.
Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```plaintext
environment
tabular_data
tabular_data_file = 'dakota_summary.dat'
freeform
```

Resulting tabular file:

```
0.9   1.1  0.0002  0.26   0.76
0.90009 1.1  0.0001996404857  0.2601620081  0.759955
0.89991 1.1  0.0002003604863  0.2598380081  0.760045
```

7.2.51.8.6.7 active_only

- Keywords Area
- method
- polynomial_chaos
- expansion_order
- import_build_points_file
- active_only

Import only active variables from tabular data file

Topics

This keyword is related to the topics:

- file_formats

Specification

**Alias:** none

**Argument(s):** none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

7.2.51.9 orthogonal_least_interpolation

- Keywords Area
- method
• polynomial_chaos
• orthogonal_least_interpolation

Build a polynomial chaos expansion from simulation samples using orthogonal least interpolation.

**Specification**

**Alias:** least_interpolation oli

**Argument(s):** none

This keyword is related to the topics:

- file_formats
Specification

Alias: none
Argument(s): none
Default: annotated format

Description

A freeform tabular file is whitespace-separated text file with no leading header row and no leading columns. Most commonly, each row contains data for variables, or variables followed by responses, though the format is used for other tabular exports/imports as well.

Default Behavior

The annotated format is the default for tabular export/import. To change this behavior, specify freeform in the relevant export/import context.

Usage Tips

• Prior to October 2011, calibration and surrogate data files were free-form format. They now default to annotated format, though freeform remains an option.

• When importing tabular data, a warning will be generated if a specific number of data are expected, but extra is found and an error generated when there is insufficient data.

• In freeform, the num_rows x num_cols total data entries may be separated with any whitespace including spaces, tabs, and newlines. In this format, vectors may therefore appear as a single row or single column (or mixture; entries will populate the vector in order).

• Some TPLs like SCOLIB and JEGA manage their own file I/O and only support the freeform option.

Examples

Export a freeform tabular file containing only data for variables and responses. Input file fragment:

```dakota
environment tabular_data
  tabular_data_file = 'dakota_summary.dat'
  freeform

Resulting tabular file:

<table>
<thead>
<tr>
<th>0.9</th>
<th>1.1</th>
<th>0.0002</th>
<th>0.26</th>
<th>0.76</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.90009</td>
<td>1.1</td>
<td>0.0001996404857</td>
<td>0.2601620081</td>
<td>0.759955</td>
</tr>
<tr>
<td>0.89991</td>
<td>1.1</td>
<td>0.0002003604863</td>
<td>0.2598380081</td>
<td>0.760045</td>
</tr>
</tbody>
</table>
...
```

7.2.51.9.4.7 active_only

• Keywords Area
  • method
  • polynomial_chaos
  • orthogonal_least_interpolation
  • import_build_points_file
  • active_only

Import only active variables from tabular data file
7.2 method

Topics

This keyword is related to the topics:

- file_formats

Specification

Alias: none

Argument(s): none

Description

By default, files for tabular data imports are expected to contain columns for all variables, active and inactive. The keyword `active_only` indicates that the file to import contains only the active variables.

This option should only be used in contexts where the inactive variables have no influence, for example, building a surrogate over active variables, with the state variables held at nominal. It should not be used in more complex nested contexts, where the values of inactive variables are relevant to the function evaluations used to build the surrogate.

7.2.51.10 import_expansion_file

- Keywords Area
- method
- polynomial_chaos
- import_expansion_file

Build a Polynomial Chaos Expansion (PCE) by import coefficients and a multi-index from a file

Specification

Alias: none

Argument(s): STRING

Description

The coefficients can be specified in an arbitrary order. The multi-index provided is used to generate a sparse expansion that consists only of the indices corresponding to the non-zero coefficients provided in the file.

7.2.51.11 askey

- Keywords Area
- method
- polynomial_chaos
- askey

Select the standardized random variables (and associated basis polynomials) from the Askey family that best match the user-specified random variables.
Specification

**Alias:** none  
**Argument(s):** none  
**Default:** extended (Askey + numerically-generated)

Description

The Askey option employs standard normal, standard uniform, standard exponential, standard beta, and standard gamma random variables in a transformed probability space. These selections correspond to Hermite, Legendre, Laguerre, Jacobi, and generalized Laguerre orthogonal polynomials, respectively.

Specific mappings for the basis polynomials are based on a closest match criterion, and include Hermite for normal (optimal) as well as bounded normal, lognormal, bounded lognormal, gumbel, frechet, and weibull (sub-optimal); Legendre for uniform (optimal) as well as loguniform, triangular, and bin-based histogram (sub-optimal); Laguerre for exponential (optimal); Jacobi for beta (optimal); and generalized Laguerre for gamma (optimal).

7.2.51.12 wiener

- **Keywords Area**
- **method**
- `polynomial_chaos`
- `wiener`

Use standard normal random variables (along with Hermite orthogonal basis polynomials) when transforming to a standardized probability space.

Specification

**Alias:** none  
**Argument(s):** none  
**Default:** extended (Askey + numerically-generated)

Description

The Wiener option employs standard normal random variables in a transformed probability space, corresponding to a Hermite orthogonal polynomial basis. This is the same nonlinear variable transformation used by local and global reliability methods (and therefore has the same variable support).

7.2.51.13 normalized

- Keywords Area
- method
- polynomial_chaos
- normalized

The normalized specification requests output of PCE coefficients that correspond to normalized orthogonal basis polynomials

Specification

Alias: none
Argument(s): none
Default: PCE coefficients correspond to unnormalized basis polynomials

Description

The normalized specification requests output of PCE coefficients that correspond to normalized orthogonal basis polynomials
